Poisoning. Ingestion of small quantities of hydrogen peroxide 3% generally results in only mild gastrointestinal effects. Ingestion of solutions of 10% or greater or large quantities of 3% solutions have been associated with severe morbidity and mortality. Irritation of the gastrointestinal tract with nausea, vomiting, foaming at the mouth, and haematemesis may occur. Blistering of the mucosa or oropharyngeal burns are common with solutions of 30% or greater. Large volumes of oxygen gas are produced in the stomach and this may result in painful gastric distension and belching. Apnoea, coma, convulsions, confusion, cyanosis, lethargy, stridor, and cardiorespiratory arrest have also been reported. Oxygen gas embolism is particularly dangerous. Immediate and permanent neurological damage has been reported after ingestion of hydrogen peroxide 35% and deaths have been reported in children and adults. Inhalation of high concentrations of hydrogen peroxide may cause irritation of the mucous membranes causing coughing and dyspnoea. Shock, convulsions, pulmonary oedema, and coma may follow. Exposure of the skin to concentrated solutions of hydrogen peroxide has resulted in blistering, erythema, focal epidermal necrosis, and purpura. Concentrations above 10% may result in ulceration or perforation of the cornea if they enter the eyes.[1]

Uses and Administration

Hydrogen peroxide is an oxidising agent used as an antiseptic, disinfectant, and deodorant. It has weak antibacterial activity and is also effective against viruses, including HIV. It also has a mild haemostatic action. It owes its antiseptic action to its ready release of oxygen when applied to tissues, but the effect lasts only as long as the oxygen is being released and is of short duration; in addition the antimicrobial effect of the liberated oxygen is reduced in the presence of organic matter. The mechanical effect of effervescence is probably more useful for wound cleansing (p.1624) than the antimicrobial action.

Hydrogen peroxide solutions are used to cleanse wounds and ulcers in concentrations of up to 6%; creams containing 1 or 1.5% stabilised hydrogen peroxide are also used. Although hydrogen peroxide alone is not considered effective on intact skin, it is used with other antiseptics for the disinfection of hands, skin, and mucous membranes. Injection into closed body cavities is dangerous (see above). Adhering and blood-soaked dressings may be released by the application of a solution of hydrogen peroxide.

A 1.5% solution of hydrogen peroxide has been used as a mouthwash in the treatment of acute stomatitis and as a deodorant gargle. A suitable solution can be prepared by diluting 15 mL of hydrogen peroxide 6% in half a tumblerful of warm water. An oral gel has also been used.

Hydrogen peroxide ear drops have been used for the removal of wax. Such ear drops were prepared by diluting a 6% solution of hydrogen peroxide with 3 parts of water preferably just before use.

Hydrogen peroxide 3% is used for disinfecting soft contact lenses.

Immersion for 30 minutes in hydrogen peroxide 6% has been suggested for disinfecting cleaned equipment.

For bleaching hair and delicate fabrics hydrogen peroxide 6% should be diluted with an equal volume of water.

Strong solutions (27 per cent and 30 per cent) of hydrogen peroxide are used for the preparation of weaker solutions and should not be applied to tissues undiluted.

Hydrogen peroxide and other peroxides have many industrial uses as bleaching and oxidising agents.

Disinfection. *CONTACT LENSES.* Hydrogen peroxide 3% is particularly useful for disinfecting soft contact lenses (p.1622) and lens storage cases since it is effective against *Acanthamoeba* spp. However, it is irritant to the cornea and requires inactivating with sodium pyruvate, catalase, or sodium thiosulfate, or with a platinum catalyst, before the lenses are used.

DIALYSIS EQUIPMENT. A disinfectant containing hydrogen peroxide and peracetic acid (*Renalin*) was not completely effective in killing *Mycobacterium chelonae* in high-flux dialysers. This possibly led to infection of 5 dialysis patients.[1] For a report of haemolysis and methaemoglobinaemia after inadvertent contamination of dialysis fluid with hydrogen peroxide, see Intravascular Administration under Adverse Effects and Precautions, above.

1. Lowry PW, *et al.* Mycobacterium chelonae infection among patients receiving high-flux dialysis in a hemodialysis clinic in California. *J Infect Dis* 1990; **161:** 85–90.

ENDOSCOPES. Peroxygen compounds have been suggested for disinfection of endoscopes as an alternative to glutaral (p.1623). In the USA, a product containing 7.5% hydrogen peroxide is available as a high level disinfectant for processing of reusable medical devices.[1] Products containing varying concentrations of hydrogen peroxide with peracetic acid have also been approved by the FDA.

Hydrogen peroxide damages external surfaces, particularly rubbers and plastics of the insertion tubes and can corrode aluminium, nickel-silver alloy, and chrome.[2,3] Other peroxygen-containing compounds have been assessed for disinfecting endoscopes, but they appear to be less active against enteroviruses[4] and mycobacteria.[5] The Working Party of the British Society of Gastroenterology does not recommend peroxygen disinfectants for gastrointestinal endoscopes.[3]

Residual hydrogen peroxide solution can cause mucosal damage (see Closed Body Cavities, under Adverse Effects, above) and endoscopes should be thoroughly rinsed before use.

Mouth ulceration and infection. The use of antiseptic mouthwashes may be helpful in the management of mouth ulcers (p.1700), although the use of high concentrations of hydrogen peroxide is not advisable (see Adverse Effects on the Mouth, above). Application of a 1.5% solution to individual ulcers with a topical corticosteroid may be useful. A randomised placebo-controlled study[1] to test the efficacy of a 1.5% hydrogen peroxide and 0.05% sodium fluoride-based mouthwash on gingivitis and tooth whitening, over a 6-month period found that it effectively whitened teeth and significantly reduced gingival redness. However, a review of the literature with practice guidelines pertaining to oral care of the critically ill[2] concluded that hydrogen peroxide could not be recommended as a mouthwash in this group, due to lack of evidence regarding its safety and efficacy in critically ill patients. A hydrogen peroxide denture cleaner was not effective in either preventing re-infection or in reducing mucosal inflammation in a study of 49 patients.[3] For oral candidal infections, specific antifungals are recommended (see p.518).

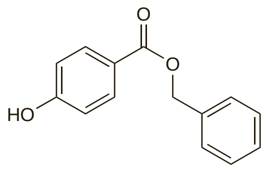
Hydroxybenzoates

Parabenos; Parabens.

Benzyl Hydroxybenzoate

Benzyl Parahydroxybenzoate; Benzylparaben; Parahidroxibenzoato de bencilo. Benzyl 4-hydroxybenzoate.

$C_{14}H_{12}O_3$ = 228.2.
CAS — 94-18-8.



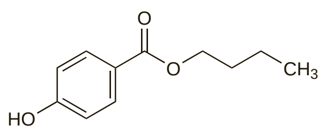
Pharmacopoeias. In *Br.* and *Int.*
BP 2008 (Benzyl Hydroxybenzoate). A white to creamy-white, odourless or almost odourless, crystalline powder. Practically insoluble in water; freely soluble in alcohol and in ether. It dissolves in solutions of alkali hydroxides. M.p. about 112°.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Butyl Hydroxybenzoate

Butilo parahidroksibenzoatas; Butilparabeno; Butil-parahidroxibenzoát; Butyl Parahydroxybenzoate; Butyle, parahydroxybenzoate de; Butylis parahydroxybenzoas; Butylis Paraoxybenzoas; Butylparaben; Butylparabenum; Butylparahydroxibensoat; Butylu parahydroksybenzoesan; Butyyliparahydroksibentsoaatti. Butyl 4-hydroxybenzoate.

$C_{11}H_{14}O_3$ = 194.2.
CAS — 94-26-8.



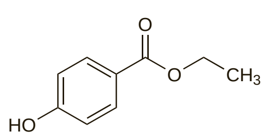
Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Butyl Parahydroxybenzoate; Butyl Hydroxybenzoate BP 2008). Colourless crystals or a white or almost white crystalline powder. Very slightly soluble in water; freely soluble in alcohol and in methyl alcohol. M.p. 68° to 71°.
USNF 26 (Butylparaben). Small colourless crystals or a white powder. Very slightly soluble in water and in glycerol; freely soluble in alcohol, in acetone, in ether, and in propylene glycol. M.p. 68° to 71°.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Ethyl Hydroxybenzoate

Aethylum Hydroxybenzoicum; E214; Ethyl Parahydroxybenzoate; Éthyle, parahydroxybenzoate d'; Ethylis parahydroxybenzoas; Ethylis Paraoxybenzoas; Ethylparaben; Ethylparabenum; Etilo parahidroksibenzoatas; Etilparabeno; Etil-parahidroxibenzoát; Etylparahydroxibensoat; Etylu parahydroksybenzoesan; Etyylipararahydroksibentsoaatti. Ethyl 4-hydroxybenzoate.

$C_9H_{10}O_3$ = 166.2.
CAS — 120-47-8.
ATC — D01AE10.
ATC Vet — QD01AE10.



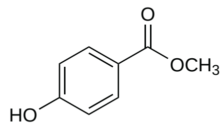
Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Ethyl Parahydroxybenzoate; Ethyl Hydroxybenzoate BP 2008). Colourless crystals or a white or almost white crystalline powder. Very slightly soluble in water; freely soluble in alcohol and in methyl alcohol.
USNF 26 (Ethylparaben). Small colourless crystals or a white powder. Slightly soluble in water and in glycerol; freely soluble in alcohol, in acetone, in ether, and in propylene glycol.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Methyl Hydroxybenzoate

E218; Metagin; Methyl Parahydroxybenzoate; Méthyle, parahydroxybenzoate de; Methylis Oxybenzoas; Methylis parahydroxybenzoas; Methylis Paraoxibenzoas; Methylparaben *(USAN)*; Methylparabenum; Metilo parahidroksibenzoatas; Metilparabeno; Metil-parahidroxibenzoát; Metylparahydroxibensoat; Metylu parahydroksybenzoesan; Metyyliparahydroksibentsoaatti. Methyl 4-hydroxybenzoate.

$C_8H_8O_3$ = 152.1.
CAS — 99-76-3.



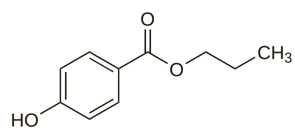
Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Methyl Parahydroxybenzoate; Methyl Hydroxybenzoate BP 2008). Colourless crystals or a white or almost white crystalline powder. Very slightly soluble in water; freely soluble in alcohol and in methyl alcohol. M.p. 125° to 128°.
USNF 26 (Methylparaben). Colourless crystals or a white crystalline powder. Soluble 1 in 400 of water, 1 in 50 of water at 80°, 1 in 3 of alcohol, and 1 in 10 of ether; freely soluble in methyl alcohol. M.p. 125° to 128°.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Propyl Hydroxybenzoate

E216; Propagin; Propilo parahidroksibenzoatas; Propilparabeno; Propil-parahidroxibenzoát; Propyl Parahydroxybenzoate; Propyle, parahydroxybenzoate de; Propylis Oxybenzoas; Propylis parahydroxybenzoas; Propylis Paraoxibenzoas; Propylparaben *(USAN)*; Propylparabenum; Propylparahydroxibensoat; Propylu parahydrobenzoesan; Propylu parahydroksybenzoesan; Propyyliparahydroksibentsoaatti. Propyl 4-hydroxybenzoate.

$C_{10}H_{12}O_3$ = 180.2.
CAS — 94-13-3.



Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Propyl Parahydroxybenzoate; Propyl Hydroxybenzoate BP 2008). A white or almost white, crystalline powder. Very slightly soluble in water; freely soluble in alcohol and in methyl alcohol. M.p. 96° to 99°.
USNF 26 (Propylparaben). Small colourless crystals or a white powder. Soluble 1 in 2500 of water, 1 in 400 of boiling water, 1 in 1.5 of alcohol, and 1 in 3 of ether. M.p. 96° to 99°.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Sodium Butyl Hydroxybenzoate

Butilparabeno sódico; Sodium Butyl Parahydroxybenzoate; Sodium Butylparaben.

$C_{11}H_{13}NaO_3$ = 216.2.
CAS — 36457-20-2.

Pharmacopoeias. In *Br.*
BP 2008 (Sodium Butyl Hydroxybenzoate). A white, odourless or almost odourless, hygroscopic powder. Freely soluble in water and in alcohol. A 0.1% solution in water has a pH of 9.5 to 10.5.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Sodium Ethyl Hydroxybenzoate

E215; Ethyl parahydroxybenzoate sodium; Éthyle (parahydroxybenzoate d') sodique; Ethylis Parahydroxybenzoas Natricum; Ethylis parahydroxybenzoas natricus; Ethylparaben sodná sůl; Etilo parahidroksibenzoato natrio druska; Etilparabeno sódico; Etylparahydroxibensoatnatrium; Etyyliparahydroksibentsoaattinatrium.

$C_9H_9NaO_3$ = 188.2.
CAS — 35285-68-8.

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Ethyl Parahydroxybenzoate Sodium; Ethyl Hydroxybenzoate Sodium BP 2008). A white or almost white, hygroscopic, crystalline powder. Freely soluble in water; soluble in dehydrated alcohol; practically insoluble in dichloromethane. A 0.1% solution in water has a pH of 9.5 to 10.5. Store in airtight containers.

The BP 2008 gives Ethylparaben Sodium as an approved synonym.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Sodium Methyl Hydroxybenzoate

E219; Méthyle (parahydroxybenzoate de) sodique; Methylis Parahydroxybenzoas Natricum; Methylis parahydroxybenzoas natricus; Methylparaben Sodium *(USAN)*; Methylparaben sodná sůl; Methylparabenum Natricum; Metilo parahidroksibenzoato natrio druska; Metilparabeno sódico; Metil-parahidroxibenzoátnátrium; Natriummetylparahydroxibensoat; Natriummetyyliparahydroksibentsoaatti; Sodium Methyl Parahydroxybenzoate; Sodium Methylparaben; Soluble Methyl Hydroxybenzoate.

$C_8H_7NaO_3$ = 174.1.
CAS — 5026-62-0.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Sodium Methyl Parahydroxybenzoate; Sodium Methyl Hydroxybenzoate BP 2008). A white or almost white, crystalline powder. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in dichloromethane. A 0.1% solution in water has a pH of 9.5 to 10.5.
USNF 26 (Methylparaben Sodium). A white, hygroscopic, powder. Freely soluble in water; sparingly soluble in alcohol; insoluble in fixed oils. A 0.1% solution in water has a pH of 9.5 to 10.5. Store in airtight containers.

Incompatibility and stability. The incompatibilities and stability of hydroxybenzoates are described under Sodium Propyl Hydroxybenzoate, below.

Sodium Propyl Hydroxybenzoate

E217; Natriumpropylparahydroxibensoat; Natriumpropyyliparahydroksibentsoaatti; Propilo parahidroksibenzoato natrio druska; Propilparabeno sódico; Propil-parahidroxibenzoátnátrium; Propyle (parahydroxybenzoate de) sodique; Propylis Parahydroxybenzoas Natricum; Propylis parahydroxybenzoas natricus; Propylparaben Sodium *(USAN)*; Propylparaben sodná sůl; Propylparabenum Natricum; Sodium Propyl Parahydroxybenzoate; Sodium Propylparaben; Soluble Propyl Hydroxybenzoate.

$C_{10}H_{11}NaO_3$ = 202.2.
CAS — 35285-69-9.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Sodium Propyl Parahydroxybenzoate; Sodium Propyl Hydroxybenzoate BP 2008). A white or almost white, crystalline powder. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in dichloromethane. A 0.1% solution in water has a pH of 9.5 to 10.5.
USNF 26 (Propylparaben Sodium). A white, hygroscopic, odourless powder. Freely soluble in water; sparingly soluble in alcohol; insoluble in fixed oils. A 0.1% solution in water has a pH of 9.5 to 10.5. Store in airtight containers.

Incompatibility and stability. The activity of hydroxybenzoates can be adversely affected by the presence of other excipients or active ingredients. There may be adsorption onto substances like magnesium trisilicate, aluminium magnesium silicate, talc, polysorbate 80,[1,2] carmellose sodium,[3] or plastics.[4] Nonionic surfactants can reduce hydroxybenzoate activity,[5] as may essential oils.[6] Other incompatibilities that have been reported include atropine,[7] iron,[4] sorbitol,[8] weak alkalis,[4] and strong acids.[4] Syrup preserved with hydroxybenzoates is incompatible with a range of compounds.[9,10] Methyl hydroxybenzoate 0.1% was reported[11] to be a poor preservative in insulin preparations, especially soluble insulin preparations. Increasing heat or pH can reduce stability and activity;[12] freeze-drying may also lead to a loss of activity.[13]

Adverse Effects and Precautions

Hypersensitivity reactions occur with the hydroxybenzoates. Generally these are of the delayed type, appearing as contact dermatitis. Immediate reactions with urticaria and bronchospasm have occurred rarely.

Breast cancer. Some researchers[1] have questioned whether *p*-hydroxybenzoic acid esters, the most common preservatives found in body care cosmetic products, could increase the incidence of breast cancer in women. The esters have been shown to be oestrogenic *in vitro* and *in vivo* and have been detected in human breast tumour tissue, although a causal association cannot be confirmed.

1. Harvey PW, Darbre P. Endocrine disrupters and human health: could oestrogenic chemicals in body care cosmetics adversely affect breast cancer incidence in women? *J Appl Toxicol* 2004; **24:** 167–76.

Hypersensitivity. Immediate hypersensitivity reactions such as urticaria and bronchospasm with generalised pruritus, have been reported rarely on injection of preparations containing hydroxybenzoates.[1,2] Delayed contact dermatitis occurs more frequently, usually after use of topical medications, but has also occurred after use of an ester or of *p*-hydroxybenzoic acid in oral preparations.[3] Hypersensitivity reactions have also been reported in patients given local anaesthetics containing hydroxybenzoates[1,4] and cross-reactions with other para-amino compounds including benzocaine, paraphenylenediamine, and sulfonamides have occurred rarely.[5]

The incidence of sensitisation to hydroxybenzoates ranges from 0 to 3.5% but has tended to stay relatively constant over time.[5] A report from the North American Contact Dermatitis Group[6] in 1972 provided an incidence of 3%, while another later review[7] of a large number of patients gave an incidence of 2.2%. The Swiss Contact Dermatitis Research Group reported[8] a sensitisation rate of 1.7% based on a one-year study from 1989 to 1990 in 2295 patients.

Subjects with healthy skin exposed to hydroxybenzoates, for example in cosmetics, are considered to have a much lower incidence of reactions than patients with eczema or skin trauma. Unusually, patients who have reacted to a hydroxybenzoate with a contact dermatitis appear to be able to apply that preservative to another unaffected site and yet not suffer a reaction; this has been termed the 'paraben paradox'.[9]

Neonates. An *in-vitro* study on serum from neonates with hyperbilirubinaemia indicated that methyl hydroxybenzoate at a concentration of 200 micrograms/mL of serum increased the concentration of free unconjugated bilirubin and interfered with the binding of bilirubin to serum proteins. Methyl hydroxybenzoate was present in an injection of gentamicin sulfate at a concentration of 1.3 to 1.8 mg/mL. Neither gentamicin nor propyl hydroxybenzoate had a significant effect on bilirubin.[1]

1. Loria CJ, *et al.* Effect of antibiotic formulations in serum protein: bilirubin interaction of newborn infants. *J Pediatr* 1976; **89:** 479–82.

Pharmacokinetics

Neonates. After intramuscular injection, methyl hydroxybenzoate present in a gentamicin preparation was excreted in the urine of preterm infants to a variable extent and mainly in the conjugated form.[1] *p*-Hydroxybenzoic acid was detected as a metabolite. The injection contained methyl hydroxybenzoate 3.6 mg, propyl hydroxybenzoate 400 micrograms, and gentamicin 80 mg. Propyl hydroxybenzoate was also detected in the urine samples.

1. Hindmarsh KW, *et al.* Urinary excretion of methylparaben and its metabolites in preterm infants. *J Pharm Sci* 1983; **72:** 1039–41.

Uses

The hydroxybenzoate preservatives are alkyl esters of *p*-hydroxybenzoic acid with antibacterial and antifungal properties. They are more active against Gram-positive than against Gram-negative bacteria. They are active over a broad pH range (4 to 8), though are generally more active in acidic solutions. Activity increases with increasing alkyl chain length but aqueous solubility decreases, although this may be overcome by employing the more soluble sodium salts as long as the pH of the preparation is not increased. Activity may also be increased by combining two hydroxybenzoates with short alkyl chains. Another way of increasing activity is to use a hydroxybenzoate with propylene glycol.

Hydroxybenzoates are used as preservatives in pharmaceutical preparations in usual concentrations of up to 0.25%. Methyl hydroxybenzoate and propyl hydroxybenzoate are used together in some preparations. There have been reports of the hydroxybenzoates not being satisfactory preservatives for ophthalmic preparations because of their relative lack of efficacy against some Gram-negative bacteria, particularly *Pseudomonas aeruginosa*. The hydroxybenzoate preservatives are widely used in cosmetics and are also used for food preservation.

Hydroxybenzoates have been used in preparations promoted for the management of skin infections or pruritus.

Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Nisapulvol; Nisaseptol; Nisasol; ***Malaysia:*** Nisapulvol.

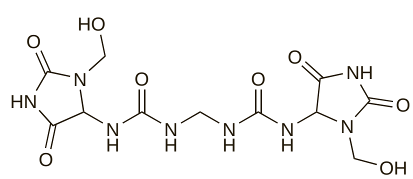
Imidurea

N,N″-Methylenebis{*N′*-[3-(hydroxymethyl)-2,5-dioxo-4-imidazolidinyl]urea}.

$C_{11}H_{16}N_8O_8$ = 388.3.

CAS — 39236-46-9.



Pharmacopoeias. In *USNF.*

USNF 26 (Imidurea). A white odourless powder. Soluble in water and in glycerol; sparingly soluble in propylene glycol; insoluble in most organic solvents. A 1% solution in water has a pH of 6.0 to 7.5. Store in airtight containers.

Profile

Imidurea is used as an antimicrobial preservative in topical pharmaceutical and cosmetic preparations.

Iodoform

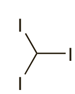
Iodoformo. Tri-iodomethane.

CHI_3 = 393.7.

CAS — 75-47-8.

ATC — D09AA13.

ATC Vet — QD09AA13.



Pharmacopoeias. In *Jpn* and *US.*

USP 31 (Iodoform). A lustrous greenish-yellow powder or lustrous crystals. It is slightly volatile at ordinary temperatures and distils slowly with steam. It decomposes at high temperatures emitting vapours of iodine. Practically insoluble in water; sparingly soluble in alcohol, in glycerol, and in olive oil; soluble in boiling alcohol; freely soluble in chloroform and in ether. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Profile

Iodoform slowly releases iodine (p.2169) when applied to the tissues and is used for its mild antiseptic action. Bismuth Subnitrate and Iodoform Paste (BPC 1954) (BIPP) has been applied to wounds and abscesses. Sterile gauze impregnated with the paste has also been used for packing cavities after oral and otorhinological surgery.

Adverse effects on the nervous system. Encephalopathy has been associated with the use of bismuth subnitrate and iodoform paste (BIPP) for the packing of wound cavities after ear, nose, and throat, oral, and maxillofacial surgery,[1,2] although there is some debate as to whether the bismuth or the iodoform component is responsible.[1-3] However, encephalopathy has been reported after application of iodoform gauze without bismuth.[4,5] CNS toxicity due to both iodine and bismuth has been reported[6] in an 86-year-old woman from an intra-oral plug of BIPP following partial maxillectomy. Five days after surgery the patient started to experience loss of appetite and lightheadedness, and by day 11 was suffering from fainting episodes, confusion, and paranoid ideation and was becoming increasingly aggressive. On day 14 the BIPP pack was removed; 7 days later the patient's condition improved and when discharged 5 days later she was alert and cooperative.

6. Harris RA, Poole A. Beware of bismuth: post maxillectomy delirium. *Aust N Z J Surg* 2002; **72:** 846–7.

Hypersensitivity. A retrospective analysis of 185 patients[1] who were treated with a bismuth-iodoform-paraffin paste (BIPP) impregnated ribbon gauze pack after ear surgery found the incidence of allergic reactions to be 5.9%. A fivefold increase risk of developing allergic reactions was also found in those with previous exposure to BIPP. Three cases of allergic contact otitis externa have been reported following the use of bismuth subnitrate and iodoform paste to pack the ear after surgery.[2]

1. Lim PVH, *et al.* Hypersensitive allergic reactions to bismuth-iodoform-paraffin paste following ear surgery. *J Laryngol Otol* 1998; **112:** 335–7.

Isopropyl Alcohol

Alcohol isopropílico; Alcohol isopropylicus; Alkohol izopropylowy; Dimethyl Carbinol; Isopropanol; Isopropylalkohol; Isopropylique, alcool; Isopropyylialkoholi; Izopropil Alkol; Izopropil-alkohol; Izopropilo alkoholis; 2-Propanol; Secondary Propyl Alcohol. Propan-2-ol.

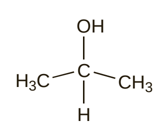
Изопропиловый Спирт

$(CH_3)_2CHOH$ = 60.10.

CAS — 67-63-0.

ATC — D08AX05.

ATC Vet — QD08AX05.



Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Isopropyl Alcohol). A clear colourless liquid. Miscible with water and with alcohol. Protect from light.

USP 31 (Isopropyl Alcohol). A transparent, colourless, mobile, volatile, flammable liquid with a characteristic odour. Miscible with water, with alcohol, with chloroform, and with ether. Store in airtight containers remote from heat.

Adverse Effects, Treatment, and Precautions

Isopropyl alcohol is considered to be more toxic than ethyl alcohol (p.1625), and the symptoms of intoxication appear to be similar, except that isopropyl alcohol has no initial euphoric action and gastritis, haemorrhage, pain, nausea, and vomiting are more prominent.

The lethal oral dose is reported to be about 120 to 240 mL in adults; however, toxic symptoms may be produced by as little as 20 mL. Ketoacidosis and ketonuria commonly occur due to the presence of the major metabolite, acetone, in the circulation. Inhalation of isopropyl alcohol vapour has been reported to produce coma.

Application of isopropyl alcohol to the skin may cause dryness and irritation; suitable precautions should be taken to prevent absorption through the skin, particularly in infants.

Treatment of adverse effects is as for Alcohol, p.1626.

Children. Reports of chemical skin burns caused by the topical application of isopropyl alcohol in premature infants.[1,2]

Haemorrhagic gastritis in a 2-year-old febrile child was attributed to topical absorption of isopropyl alcohol that had been used for sponge bathing and followed by wrapping the child tightly in a blanket.[3]

1. Schick JB, Milstein JM. Burn hazard of isopropyl alcohol in the neonate. *Pediatrics* 1981; **68:** 587–8.
2. Weintraub Z, Iancu TC. Isopropyl alcohol burns. *Pediatrics* 1982; **69:** 506.
3. Dyer S, *et al.* Hemorrhagic gastritis from topical isopropanol exposure. *Ann Pharmacother* 2002; **36:** 1733–5.

Rectal absorption. Intoxication and raised serum-creatinine concentrations due to absorption of isopropyl alcohol followed its use as a rectal douche.[1] An 85-year-old woman who accidentally received an isopropyl alcohol enema developed rapid CNS depression, renal failure, and metabolic acidosis. She became comatose within 15 minutes and died 12 hours later after a cardiac arrest. Post-mortem examination showed necrosis of the colon.[2]

2. Haviv YS, *et al.* Accidental isopropyl alcohol enema leading to coma and death. *Am J Gastroenterol* 1998; **93:** 850–1.

Pharmacokinetics

Isopropyl alcohol is readily absorbed from the gastrointestinal tract but there appears to be little absorption through intact skin. The vapour may be absorbed through the lungs. Isopropyl alcohol is metabolised more slowly than ethyl alcohol and about 15% of an ingested dose is metabolised to acetone.

◊ For reports of rectal absorption of isopropyl alcohol, see above.

Uses and Administration

Isopropyl alcohol is an antiseptic with bactericidal properties similar to those of alcohol (p.1627). It is used for pre-operative skin cleansing in concentrations of about 60 to 70%, and is an ingredient of preparations used for disinfection of hands and surfaces. Its marked degreasing properties may limit its usefulness in preparations used repeatedly. It is also used as a solvent, especially in cosmetics, perfumes and pharmaceutical preparations, and as a vehicle for other disinfectant compounds.

Propyl alcohol (p.1660) is also used as an antiseptic.

Preparations

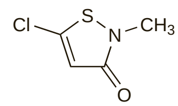
Isothiazolinones

Isotiazolinonas.

Methylchloroisothiazolinone

Metilcloroisotiazolinona. 5-Chloro-2-methyl-3(2*H*)-isothiazolone; 5-Chloro-2-methyl-4-isothiazolin-3-one.

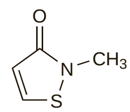
CAS — 26172-55-4.



Methylisothiazolinone

Metilisotiazolinona. 2-Methyl-3(2*H*)-isothiazolone; 2-Methyl-4-isothiazolin-3-one.

CAS — 2682-20-4.



Profile

A mixture of isothiazolinones consisting of methylchloroisothiazolinone and methylisothiazolinone (MCI/MI) in a ratio of about 3:1 is used as a preservative in industry and in cosmetic and household products. It is effective at very low concentrations against a wide spectrum of Gram-positive and -negative bacteria, yeasts, and fungi. The mixture is often referred to as Kathon CG, one of its proprietary names.

Isothiazolinones may cause contact dermatitis and local irritation.

Hypersensitivity. There have been reports of sensitisation and allergic contact dermatitis arising from the use of isothiazolinones in cosmetics, paints and from industrial exposure.[1-11] The incidence of allergy to methylchloroisothiazolinone and methylisothiazolinone (MCI/MI) is reported be dose-related and ranges from less than 1% to 8.4%.[4,8] A study[6] conducted in 4713 patients at 22 European contact dermatitis clinics over a 12 month period from 1988 to 1989 reported the frequency of positive reactions to 100 ppm MCI/MI to be 3%.

Most hypersensitivity reports are related to use in cosmetics, especially 'leave-on' products such as moisturising creams, while the risk attributed to their use in 'rinse-off' products such as shampoos is considered to be minimal.[4,7] A review[7] of such rinse-off products found that they were even well tolerated in MCI/MI sensitised people. Airborne contact dermatitis has been reported in people exposed to MCI/MI in paints.[9,10] Occupational contact allergy and dermatitis due to MCI/MI have also been reported,[11] and there has been a case report of occupational asthma developing in a worker 5 months after starting work in an isothiazolinone manufacturing plant.[5]

Preparations

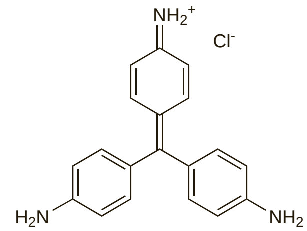
Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Switz.:*** Saltrates†.

Magenta

Aniline Red; Basic Fuchsin; Basic Magenta; CI Basic Violet 14; Colour Index No. 42510; Fuchsine; Fucsina.

CAS — 569-61-9 (pararosaniline hydrochloride); 632-99-5 (rosaniline hydrochloride).



(pararosaniline hydrochloride)

Description. Magenta is a mixture of the hydrochlorides of pararosaniline {4-[(4-aminophenyl)(4-iminocyclohexa-2,5-dien-1-ylidene)-methyl]aniline} and rosaniline {4-[(4-aminophenyl)-(4-iminocyclohexa-2,5-dien-1-ylidene)methyl]-2-methylaniline}.

Pharmacopoeias. In *US.*

USP 31 (Basic Fuchsin). A mixture of rosaniline and pararosaniline hydrochlorides. It contains the equivalent of not less than 88% of rosaniline hydrochloride ($C_{20}H_{20}ClN_3$ = 337.8), calculated on the dried basis. A dark green powder or greenish glistening crystalline fragments with a bronze-like lustre and not more than a faint odour. Soluble in water, in alcohol, and in amyl alcohol; insoluble in ether.

Profile

Magenta is a triphenylmethane antiseptic dye effective against Gram-positive bacteria and some fungi. Magenta Paint (BPC 1973) (Castellani's Paint) was formerly used in the treatment of superficial dermatophytoses.

Decolorised magenta solution (Schiff reagent) is used as a test for the presence of aldehydes.

Concerns about possible carcinogenicity have restricted the use of magenta.

Carcinogenicity. The handling of magenta was not thought to induce carcinogenesis but its actual manufacture may produce tumours. The International Agency for Research on Cancer has concluded that the manufacturing process of magenta involves exposure to substances that are considered to be definite human carcinogens. Pararosaniline hydrochloride (Basic Red 9), and magenta containing it, are considered possibly carcinogenic to humans.[1] Magenta was also considered to be unsafe for use in food.[2]

Multi-ingredient: ***Ital.:*** Fucsina Fenica; ***Pol.:*** Pigmentum Castellani.

Magnesium Peroxide

Magnesii peroxidum; Magnesium Perhydrolum; Magnésium, peroxyde de; Magnesiumperoksidi; Magnesiumperoxid; Magnézium-peroxid; Magnio peroksidas; Peroxid hořečnatý; Peróxido de magnesio.

CAS — 1335-26-8; 14452-57-4.

ATC — A02AA03; A06AD03.

ATC Vet — QA02AA03; QA06AD03.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Magnesium Peroxide). A mixture of magnesium peroxide and magnesium oxide. It contains not less than 22% and not more than 28% of MgO_2. A white or slightly yellow, amorphous, light powder. Practically insoluble in water and in alcohol; dissolves in mineral acids. Protect from light.

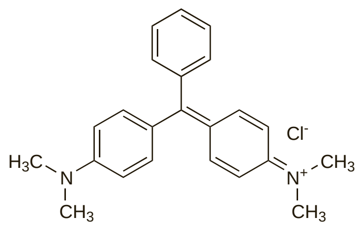
Profile
Magnesium peroxide is used as an antiseptic. It is also an ingredient of preparations for gastrointestinal disorders.

Preparations
Proprietary Preparations (details are given in Part 3)
Ger.: Ozovit†.
Multi-ingredient: ***Israel:*** Digestif-Ara†; ***Ital.:*** Carbonesia; Ektogan; ***Switz.:*** Desaquick extra fresh†; Desaquick fresh†; Magenpulver Hafter†.

Malachite Green
Aniline Green; China Green; CI Basic Green 4; Colour Index No. 42000; Diamond Green B; Verde de malaquita; Viride Malachitum; Zieleń malachitowa. [4-(4-Dimethylaminobenzhydrylidene)cyclohexa-2,5-dienylidene]dimethylammonium chloride.

CAS — 569-64-2.

ATC Vet — QP53AX16.



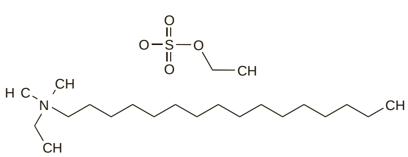
Profile
Malachite green is a triphenylmethane antiseptic dye with actions similar to those of brilliant green (p.1632). It has been used for skin disinfection.

Mecetronium Etilsulfate *(BAN, rINN)*
Etilsulfato de mecetronio; Mecetronii Etilsulfas; Mecetronium Ethylsulfate *(USAN)*; Mecetronium Ethylsulphate; Mécétronium, Étilsulfate de. Ethylhexadecyldimethylammonium ethyl sulphate.

Мецетрония Этилсульфат

$C_{22}H_{49}NO_4S$ = 423.7.

CAS — 3006-10-8.



Profile
Mecetronium etilsulfate is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is active against bacteria, including mycobacteria, fungi, and viruses, including hepatitis B virus. It is used in alcoholic solution for disinfection of the skin and hard surfaces.

Preparations
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Fr.:*** Sterillium†; ***Ger.:*** Bacillol; St-Tissues; Sterillium; ***Gr.:*** Sterillium; ***Neth.:*** Sterillium; ***Switz.:*** Sterillium†.

Merbromin *(rINN)*
Disodium 2,7-dibromo-4-hydroxymercurifluorescein; Merbromina; Merbromine; Merbrominum; Mercurescéine Sodique; Mercurochrome; Mercurodibromofluorescein; Merkürokrom. The disodium salt of [2,7-dibromo-9-(2-carboxyphenyl)-6-hydroxy-3-oxo-3*H*-xanthen-5-yl]hydroxymercury.

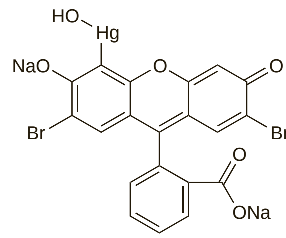
Мербромин

$C_{20}H_8Br_2HgNa_2O_6$ = 750.7.

CAS — 129-16-8.

ATC — D08AK04.

ATC Vet — QD08AK04.



NOTE. The use of the name Merbromin is limited; in some countries it is a trade-mark.

Pharmacopoeias. In *Fr., It., Jpn,* and *Viet.*

Incompatibility. Merbromin is incompatible with acids, most alkaloidal salts, many local anaesthetics, metals, and sulfides. Activity may be reduced in the presence of organic material.

Adverse Effects and Treatment
As for Mercury, p.2341.

◊ General references.

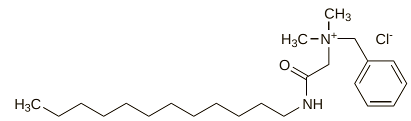
CAS — 100-95-8.



Profile
Metalkonium chloride is an antiseptic used for skin disinfection.

Preparations
Proprietary Preparations (details are given in Part 3)
Ital.: Theotex.

Methylated Spirits
Alcoholes desnaturalizados.

CAS — 8013-52-3 (ethyl alcohol-methyl alcohol mixture; industrial methylated spirit).

Description. Three classes of methylated spirits are listed under the Methylated Spirits Regulations, 1987 (SI 1987: No. 2009): industrial methylated spirits, mineralised methylated spirits, and denatured ethanol (denatured alcohol).
Industrial Methylated Spirits is defined as 95 parts by volume of spirits mixed with wood naphtha (mostly methyl alcohol—p.2024) 5 parts by volume. **Mineralised methylated spirits** is spirits mixed with wood naphtha 9.5 parts by volume and crude pyridine 0.5 parts by volume, and to every 2000 litres of this mixture is added 7.5 litres of mineral naphtha (petroleum oil) and 3 g of synthetic organic dyestuff (methyl violet). This is the only variety that may be sold in Great Britain for general use. **Denatured ethanol** is 999 parts by volume of spirits (of a strength not less than 85%) mixed with 1 part by volume of tertiary butyl alcohol, and to this mixture is added Bitrex (denatonium benzoate) 10 mg/litre.
As Industrial Methylated Spirit may contain small amounts of acetone it should not be used for the preparation of iodine solutions, since an irritating compound is formed by reaction between iodine and acetone; for such preparations Industrial Methylated Spirit (Ketone-free) should be used.

Pharmacopoeias. *Br.* includes Industrial Methylated Spirit and Industrial Methylated Spirit (Ketone-free).
BP 2008 (Industrial Methylated Spirit). A mixture of 19 volumes of ethyl alcohol of an appropriate strength with 1 volume of approved wood naphtha. Two strengths are available containing 99% and 95% v/v alcohol (also known as 74 OP and 66 OP respectively). It is a colourless, clear, mobile, volatile liquid with an odour which is spirituous and of wood naphtha. B.p. is about 78°.
The BP 2008 gives Industrial Methylated Spirits and IMS as approved synonyms.
BP 2008 (Industrial Methylated Spirit (Ketone-free)). A mixture of the same strength as Industrial Methylated Spirit, but it is substantially free from ketones, containing not more than the equivalent of 500 ppm of acetone.

Adverse Effects
As for Alcohol, p.1625, and Methyl Alcohol, p.2024. Adverse effects are due chiefly to consumption of methylated spirits rather than its topical use as a disinfectant.

Uses and Administration
Industrial methylated spirit, in a concentration of about 70%, is the usual form in which alcohol (p.1625) is used for disinfection. It is applied externally for its astringent action, but mucous membranes and excoriated skin surfaces must be protected. It may be used for skin preparation before injection.

Methylated spirits may be used in the form of Surgical Spirit (BP 2008), a mixture of methyl salicylate (0.5% v/v), diethyl phthalate (2% v/v), and castor oil (2.5% v/v) in industrial methylated spirit.

Preparations
BP 2008: Surgical Spirit.
Proprietary Preparations (details are given in Part 3)
Ital.: Esosan Gel.

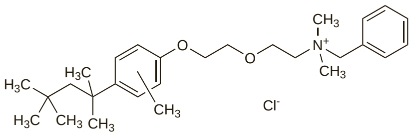
Methylbenzethonium Chloride *(BAN, rINN)*

Cloruro de metilbencetonio; Methylbenzethonii Chloridum; Méthylbenzéthonium, Chlorure de. Benzyldimethyl-2-{2-[4-(1,1,3,3-tetramethylbutyl)-*o*-tolyloxy]ethoxy}ethylammonium chloride monohydrate.

Метилбензетония Хлорид

$C_{28}H_{44}ClNO_2,H_2O$ = 480.1.

CAS — 25155-18-4 (anhydrous methylbenzethonium chloride); 1320-44-1 (methylbenzethonium chloride monohydrate).



Pharmacopoeias. In *US.*

USP 31 (Methylbenzethonium Chloride). White hygroscopic crystals with a mild odour. Soluble 1 in 0.8 of water, 1 in 0.9 of alcohol, 1 in more than 10 000 of chloroform, and 1 in 0.7 of ether. Solutions are neutral or slightly alkaline to litmus. Store in airtight containers.

Profile

Methylbenzethonium chloride is a quaternary ammonium disinfectant and antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used topically for minor infections or irritation of the skin.

Leishmaniasis. Topical treatment of cutaneous leishmaniasis (p.824) with methylbenzethonium chloride 5 or 12% and paromomycin sulfate has proved beneficial.

Preparations

USP 31: Methylbenzethonium Chloride Lotion; Methylbenzethonium Chloride Ointment; Methylbenzethonium Chloride Topical Powder.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Israel:*** Leshcutan; ***Ital.:*** Traumicid†; ***Mex.:*** Norforms†; ***USA:*** Acnotex; Dermasept Antifungal; Drytex; Finac; Orasept.

Methylrosanilinium Chloride *(BAN, rINN)*

CI Basic Violet 3; Cloruro de metilrosanilina; Colour Index No. 42555; Crystal Violet; Fiolet krystaliczny; Gentian Violet; Hexamethylpararosaniline Chloride; Jansiyen Moru; Kristal Viyole; Kristallviolett; Methylrosaniline Chloride; Methylrosanilinii chloridum; Méthylrosanilinium, chlorure de; Methylrosanilinium-chlorid; Metilrozanilinio chloridas; Metilrozanilinyum Klorür; Metylrosaniliniumklorid; Metyylirosaniliniumkloridi; Pyoctaninum Caeruleum; Viola Crystallina. 4-[4,4′Bis(dimethylamino)benzhydrylidene]cyclohexa-2,5-dien-1-ylidenedimethylammonium chloride.

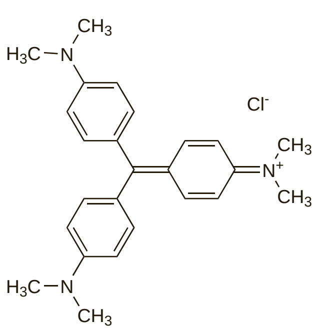
Метилрозанилиния Хлорид

$C_{25}H_{30}ClN_3$ = 408.0.

CAS — 548-62-9.

ATC — D01AE02; G01AX09.

ATC Vet — QD01AE02; QG01AX09.



NOTE. The name methyl violet—CI Basic Violet 1; Colour Index No. 42535—has been used as a synonym for methylrosanilinium chloride, but is applied to a mixture of the hydrochlorides of the higher methylated pararosanilines consisting principally of the tetramethyl-, pentamethyl-, and hexamethyl- compounds.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *US.*

Jpn includes a mixture of hexamethylpararosaniline hydrochloride with the tetramethyl- and pentamethyl- compounds.

Ph. Eur. 6.2 (Methylrosanilinium Chloride). A dark green, hygroscopic, shiny powder. It contains not more than 10% of pentamethyl-*p*-rosanilinium chloride. It is also known as crystal violet and gentian violet. Sparingly soluble in water; freely soluble in alcohol and in dichloromethane. Store in airtight containers.

USP 31 (Gentian Violet). A dark green powder or greenish, glistening pieces with a metallic lustre, and with not more than a faint odour. Sparingly soluble in water; soluble 1 in 10 of alcohol and 1 in 15 of glycerol; soluble in chloroform; insoluble in ether.

Incompatibility. The antimicrobial activity of methylrosanilinium chloride may be reduced through incompatibilities, decreasing pH, or through combination with organic matter.

The antibacterial activity of methylrosanilinium chloride was inhibited in suspensions of bentonite with which it formed a stable complex.[1]

1. Harris WA. The inactivation of cationic antiseptics by bentonite suspensions. *Australas J Pharm* 1961; **42:** 583–8.

Adverse Effects and Precautions

Topical application of methylrosanilinium chloride can produce irritation and ulceration of mucous membranes. Ingestion of methylrosanilinium chloride during prolonged or frequent treatment for oral candidiasis has resulted in oesophagitis, laryngitis, and tracheitis; ingestion may also cause nausea, vomiting, diarrhoea, and abdominal pain. In the UK it is recommended that methylrosanilinium chloride should not be applied to mucous membranes or open wounds. Contact with the eyes or broken skin should be avoided. Methylrosanilinium chloride may stain skin and clothing.

Animal carcinogenicity has restricted its use.

Carcinogenicity. Methylrosanilinium chloride has been shown *in vitro* to be capable of interacting with DNA of living cells,[1] and has demonstrable carcinogenicity in *mice*.[2]

1. Rosenkranz HS, Carr HS. Possible hazard in use of gentian violet. *BMJ* 1971; **3:** 702–3.
2. MAFF Food Advisory Committee. Final report on the review of the Colouring Matter in Food Regulations 1973: FdAC/REP/4. London: HMSO, 1987.

Effects on the skin and mucous membranes. Necrotic skin reactions have been reported after the use of topical 1% aqueous solutions of methylrosanilinium chloride;[1] areas affected include the submammary folds, gluteal fold, genitalia, and toe-webs. Similar reactions were observed in 2 patients after use of 1% methylrosanilinium chloride or brilliant green on stripped skin.[1] Oral ulceration developed in all of 6 neonates treated with aqueous methylrosanilinium chloride 0.5 or 1% for oral candidiasis.[2]

In the UK it is recommended that methylrosanilinium chloride should not be applied to mucous membranes or open wounds.

1. Björnberg A, Mobacken H. Necrotic skin reactions caused by 1% gentian violet and brilliant green. *Acta Derm Venereol (Stockh)* 1972; **52:** 55–60.
2. Horsfield P, *et al.* Oral irritation with gentian violet. *BMJ* 1976; **2:** 529.

Effects on the urinary tract. Severe haemorrhagic cystitis rapidly occurred in a 32-year-old woman after accidental injection through the urethra of a solution of methylrosanilinium chloride 1% and alcohol 2%.[1] Two cases of severe cystitis were also reported after instillation into the bladder of an undiluted solution containing methylrosanilinium chloride and brilliant green 1:1 (Bonney's blue).[2] Haemorrhagic cystitis has also been reported in a 16-month-old boy after a diluted solution of methylrosanilinium chloride 1% was instilled into his bladder during an inguinal herniorrhaphy.[3]

1. Walsh C, Walsh A. Haemorrhagic cystitis due to gentian violet. *BMJ* 1986; **293:** 732.
2. Christmas TJ, *et al.* Bonney's blue. *Lancet* 1988; **ii:** 459–60.
3. Kim SJ, *et al.* Hemorrhagic cystitis due to intravesical instillation of gentian violet completely recovered with conservative therapy. *Yonsei Med J* 2003; **44:** 163–5.

Porphyria. Methylrosanilinium chloride has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Uses and Administration

Methylrosanilinium chloride is a triphenylmethane antiseptic dye effective against some Gram-positive bacteria, particularly *Staphylococcus* spp., and some pathogenic fungi such as *Candida* spp. It is much less active against Gram-negative bacteria and ineffective against acid-fast bacteria and bacterial spores. Its activity increases as pH increases.

Methylrosanilinium chloride has been applied topically as a 0.25 to 2.0% aqueous solution or as a cream for the treatment of bacterial and fungal infections, but in the UK its use is now restricted to application to unbroken skin because of concern over *animal* carcinogenicity. It has also been used as a 0.5% solution with brilliant green 0.5% (Bonney's blue) for skin marking before surgery.

Preparations

USP 31: Gentian Violet Cream; Gentian Violet Topical Solution.

Proprietary Preparations (details are given in Part 3)

Pol.: Pioktanina; ***Spain:*** Vigencial; ***Turk.:*** Viojen.

Multi-ingredient: ***Chile:*** Calmante de Aftas†; Faxet; ***Hung.:*** Dermaforine†.

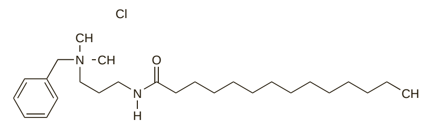
Miramistin

Myramistin. Alkylamidopropylmethylbenzylammonium chloride.

Мирамистин

$C_{26}H_{47}N_2OCl$ = 439.1.

CAS — 126338-77-0; 15809-19-5.



Profile

Miramistin is a quaternary ammonium antiseptic used for disinfection of the skin and mucous membranes. It is also included in topical preparations for skin disorders when prone to infection.

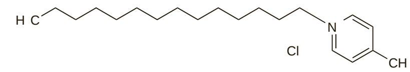
Miripirium Chloride *(rINN)*

Cloruro de miripirio; Miripirii Chloridum; Miripirium, Chlorure de; Myristyl-gamma-picolinium Chloride. 4-Methyl-1-tetradecylpyridinium chloride.

Мирипирия Хлорид

$C_{20}H_{36}ClN$ = 326.0.

CAS — 7631-49-4 (miripirium); 2748-88-1 (miripirium chloride).



Profile

Miripirium chloride is used as an antimicrobial preservative in some pharmaceutical products.

Hypersensitivity. Two patients who had a delayed hypersensitivity reaction to retrobulbar injection of methylprednisolone acetate suspension (*Depo-Medrol*)[1] were found on intradermal testing to be sensitive to methylprednisolone and to miripirium chloride, included as a preservative in the formulation. A similar case of contact allergy has been reported[2] in a 56-year-old woman who received an intra-articular injection of methylprednisolone acetate. Patch testing showed allergy to the preservative miripirium chloride.

1. Mathias CGT, Robertson DB. Delayed hypersensitivity to a corticosteroid suspension containing methylprednisolone. *Arch Dermatol* 1985; **121:** 258–61.
2. Färm G, Eriksson I. Contact allergy to miripirium chloride in Depo-Medrol. *Contact Dermatitis* 2001; **44:** 127.

Miristalkonium Chloride *(BAN, rINN)*

Cloruro de miristalconio; Miristalkonii Chloridum; Miristalkonium, Chlorure de; Myristylbenzalkonium Chloride. Benzyldimethyltetradecylammonium chloride.

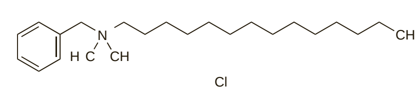
Миристалкония Хлорид

$C_{23}H_{42}ClN$ = 368.0.

CAS — 139-08-2.

ATC — R02AA10.

ATC Vet — QR02AA10.



Profile

Miristalkonium chloride is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It has been used in creams and lotions for disinfection of the skin and has been an ingredient of sprays used for the treatment of minor infections of the mouth and throat. It is also used as a vaginal spermicide.

Preparations

Proprietary Preparations (details are given in Part 3)

Fr.: Alpagelle.

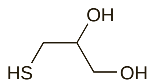
Multi-ingredient: ***Fr.:*** Sterlane; ***Ital.:*** Eburdent F.

Monothioglycerol

α-Monothioglycerol; Monotioglicerol; Thioglycerol. 3-Mercaptopropane-1,2-diol.

$C_3H_8O_2S$ = 108.2.

CAS — 96-27-5.



Pharmacopoeias. In *USNF.*

USNF 26 (Monothioglycerol). A colourless or pale yellow, viscous, hygroscopic liquid with a slight odour of sulfide. Freely soluble in water; miscible with alcohol; insoluble in ether. A 10% solution in water has a pH of 3.5 to 7.0. Store in airtight containers.

Profile

Monothioglycerol is used as an antoxidant preservative in pharmaceutical preparations. It has some antimicrobial activity.

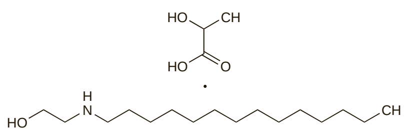
Myralact *(BAN, pINN)*

Miralacto; Myralactum. (2-Hydroxyethyl)tetradecylammonium lactate.

Миралакт

$C_{19}H_{41}NO_4$ = 347.5.

CAS — 15518-87-3.



Profile

Myralact is an antiseptic included in multi-ingredient preparations intended for the topical treatment of vaginal infections.

Preparations

Proprietary Preparations (details are given in Part 3)

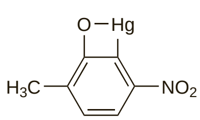
Multi-ingredient: ***Hong Kong:*** Ginetris†.

Nitromersol

5-Methyl-2-nitro-7-oxa-8-mercurabicyclo[4.2.0]octa-1,3,5-triene.

$C_7H_5HgNO_3$ = 351.7.

CAS — 133-58-4.



Pharmacopoeias. In *US.*

USP 31 (Nitromersol). A brownish-yellow to yellow odourless powder or granules. Very slightly soluble in water, in alcohol, in acetone, and in ether; soluble in solutions of alkalis and of ammonia with the formation of salts. Store in airtight containers. Protect from light.

Incompatibility. Nitromersol is incompatible with metals and sulfides. Its antimicrobial activity may be diminished in the presence of organic material.

Adverse Effects and Treatment

As for Mercury, p.2341.

Uses and Administration

Nitromersol is a mercurial antiseptic effective against some bacteria. It is not effective against spores or acid-fast bacteria. It has been used for superficial skin infections and for disinfection of the skin prior to surgical treatment.

Preparations

USP 31: Nitromersol Topical Solution.

Proprietary Preparations (details are given in Part 3)

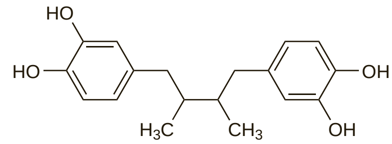
Multi-ingredient: ***Austral.:*** Butesin Picrate†; ***Chile:*** Butesin.

Nordihydroguaiaretic Acid

Acidum Nordihydroguaiareticum; NDGA; Nordihidroguayarético, ácido; Nordihydroguajareettiha ppo; Nordihydroguajaretsyra. 4,4′-(2,3-Dimethyltetramethylene)bis(benzene-1,2-diol).

$C_{18}H_{22}O_4$ = 302.4.

CAS — 500-38-9.



Profile

Nordihydroguaiaretic acid has been used as an antoxidant preservative. Allergic contact dermatitis has been reported.

Noxytiolin *(BAN, rINN)*

Noxitiolina; Noxythiolin; Noxytioline; Noxytiolinum. 1-Hydroxymethyl-3-methyl-2-thiourea.

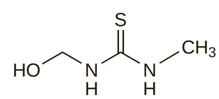
Нокситиолин

$C_3H_8N_2OS$ = 120.2.

CAS — 15599-39-0.

ATC — B05CA07.

ATC Vet — QB05CA07.



Adverse Effects and Treatment

When noxytiolin is given initially by irrigation for the treatment of the purulent infected bladder there may be an intense reaction with a burning sensation and the passage of large fibrin clumps. Giving it with a local anaesthetic such as tetracaine hydrochloride may control the pain.

Breath odour. A pervasive sweet breath odour characteristic of decaying vegetables has been noted in patients treated with peritoneal dialysis fluid containing noxytiolin.[1] The odour was attributed to unidentified sulfur metabolites.

1. Stewart WK, Fleming LW. Use your nose. *Lancet* 1983; **i:** 426.

Uses and Administration

Noxytiolin is an antiseptic with wide antibacterial and antifungal actions. It may act by slowly releasing formaldehyde in solution.

For instillation into, or irrigation of, the peritoneal cavity or other body cavities, a 1 or 2.5% solution is used. Solutions of noxytiolin should be warmed to 37° before instillation or irrigation. Treatment is usually for 3 to 7 days. The normal total daily amount used in adults should not exceed 5 g for instillation or 10 g for continuous irrigation.

Action. Although noxytiolin has generally been thought to act, at least in part, by slowly releasing formaldehyde into solution, it has been reported[1] that much smaller amounts are released than have previously been thought and that the antimicrobial effects of noxytiolin solutions cannot be attributed solely to the presence of formaldehyde. There is evidence *in vitro* that noxytiolin might reduce the adherence of micro-organisms to epithelial surfaces.[2]

1. Gorman SP, *et al.* Formaldehyde release from noxythiolin solutions. *Pharm J* 1984; **234:** 62–3.
2. Anderson L, *et al.* Clinical implications of the microbial antiadherence properties of noxythiolin. *J Pharm Pharmacol* 1985; **37** (suppl): 64P.

Infections of the pleural cavity. Three patients with pleural empyema or pneumonectomy space infection were treated by irrigation of the cavity with noxytiolin 1% in normal saline for 3 hours, followed by drainage for 1 hour, the cycle being repeated 4-hourly. Infection was eradicated within 21 days in all 3 patients.[1]

1. Rosenfeldt FL, *et al.* Comparison between irrigation and conventional treatment for empyema and pneumonectomy space infection. *Thorax* 1981; **36:** 272–7.

Preparations

Proprietary Preparations (details are given in Part 3)

Fr.: Noxyflex; ***Irl.:*** Noxyflex S; ***UK:*** Noxyflex S.

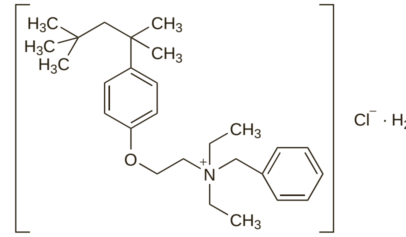
Octafonium Chloride *(BAN, rINN)*

Cloruro de octafonio; Octafonii Chloridum; Octafonium, Chlorure d'; Octaphonium Chloride; Phenoctide. Benzyldiethyl-2-[4-(1,1,3,3-tetramethylbutyl)phenoxy]ethylammonium chloride monohydrate.

Октафония Хлорид

$C_{27}H_{42}ClNO,H_2O$ = 450.1.

CAS — 15687-40-8 (anhydrous octafonium chloride); 78-05-7 (anhydrous octafonium chloride).



Profile

Octafonium chloride is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used in topical preparations for skin disinfection.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***S.Afr.:*** Germolene; ***UK:*** Germolene.

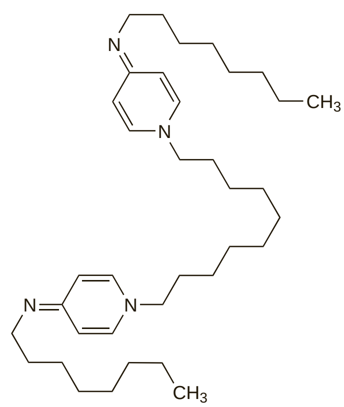
Octenidine Hydrochloride *(BANM, USAN, rINNM)*

Hidrocloruro de octenidina; Octénidine, Chlorhydrate d'; Octenidini Hydrochloridum; Win-41464 (octenidine); Win-41464-2 (octenidine hydrochloride); Win-41464-6 (octenidine saccharin). 1,1′,4,4′-Tetrahydro-*N,N*′-dioctyl-1,1′-decamethylenedi-(4-pyridylideneamine) dihydrochloride.

Октенидина Гидрохлорид

$C_{36}H_{62}N_4,2HCl$ = 623.8.

CAS — 71251-02-0 (octenidine); 70775-75-6 (octenidine hydrochloride).



(octenidine)

Profile

Octenidine is a bispyridine bactericidal antiseptic with some antiviral and antifungal activity. It has been used as the hydrochloride for skin and mucous membrane disinfection.

Preparations

Proprietary Preparations (details are given in Part 3)

Fr.: Phisomain.

Multi-ingredient: ***Austria:*** Octeniderm; Octenisept; ***Ger.:*** Neo Kodan†; Octenisept; ***Gr.:*** Octeniderm; Octenisept; ***Switz.:*** Octeniderm; Octenisept.

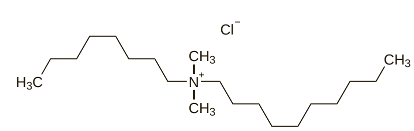
Octyldecyldimethylammonium Chloride

Decyldimethyloctylammonium Chloride; Decyloctyldimethylammonium Chloride; Octyl Decyl Dimethyl Ammonium Chloride. *N,N*-Dimethyl-*N*-octyl-1-decanaminium chloride.

Октилдецилдиметиламмоний Хлорид

$C_{20}H_{44}ClN$ = 334.0.

CAS — 32426-11-2.



Profile

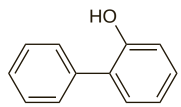
Octyldecyldimethylammonium chloride is a quaternary ammonium disinfectant used in preparations for disinfection of hard surfaces and the skin.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***USA:*** Vi Rid-Ready.

Orthophenylphenol

2-Biphenylol; E231; E232 (sodium-*o*-phenylphenol); 2-Hydroxybiphenyl; *o*-Hydroxydiphenyl; Ortofenilfenol. (1,1′-Biphenyl)-2-ol.
$C_{12}H_{10}O$ = 170.2.
CAS — 90-43-7.
ATC — D08AE06.
ATC Vet — QD08AE06.



Profile

Orthophenylphenol is a phenolic disinfectant with antimicrobial properties similar to those of chloroxylenol (p.1640). It is used for disinfection of skin, hands, instruments, and hard surfaces. It also has many industrial and agricultural uses as a preservative for a wide range of materials, particularly against moulds and rots. Sodium-*o*-phenylphenol has been used similarly.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Amocid; ***Ital.:*** Citromedics Disinfettante; Citrosteril Aspiratori; Crescom; Esofenol 60; Germozero Clean; Helix I; Higesan; Neo Esoformolo; Vcanalare†; ***Switz.:*** Manusept†.

Multi-ingredient: ***Austria:*** Dodesept; Dodesept Gefarbt; Kodan; ***Ger.:*** Bomix; Desderman N†; Freka-Derm; Freka-Sept 80; Helipur; Incidin Extra†; Kodan Tinktur Forte†; Primasept Med†; ***Ital.:*** Bergon†; Diaril†; Esofenol Ferri; Germozero Dermo; Germozero Plus; Helipur; Hygienist†; Norica; Sangen Casa; Sterosan; ***Switz.:*** Frekaderm†; Kodan Teinture forte; ***USA:*** BTK-Plus.

Oxychlorosene *(USAN)*

Monoxychlorosene; Oxicloroseno.
$C_{20}H_{34}O_3S,HOCl$ = 407.0.
CAS — 8031-14-9.

Oxychlorosene Sodium *(USAN)*

Oxicloroseno sódico; Sodium Oxychlorosene.
CAS — 52906-84-0.

Profile

Oxychlorosene is the hypochlorous acid complex of a mixture of the phenyl sulfonate derivatives of aliphatic hydrocarbons. It is a chlorine-releasing antiseptic with the general properties of chlorine, p.1638.

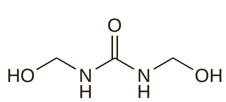
A 0.4% solution of oxychlorosene sodium has been used for cleansing wounds (although chlorine-releasing antiseptics are generally regarded as too irritant for this purpose—see Disinfection, Wounds, under Uses and Administration of Sodium Hypochlorite, p.1662) and for pre-operative skin preparation; a 0.1 or 0.2% solution has been used in urological and ophthalmological disinfection.

Preparations

Proprietary Preparations (details are given in Part 3)
USA: Clorpactin WCS-90.

Oxymethurea

Carbamol; *N,N′*-di(hydroksimetyyli)karbamidi; *N,N′*-di(hydroximetyl)-karbamid; Dihydroxymethyl Carbamide; *N,N′*-di(hydroxymethyl)carbamidum; Oximeturea. *N,N′*-Bis(hydroxymethyl)urea.
$C_3H_8N_2O_3$ = 120.1.
CAS — 140-95-4.



Profile

Oxymethurea is an antiseptic included in multi-ingredient preparations intended for the topical treatment of ear infections.

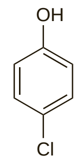
Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austria:*** Ciloprin cum Anaesthetico†; ***Fin.:*** Ciloprin cum Anaesthetico†; ***India:*** Otogesic; ***Switz.:*** Ciloprin ca†.

Parachlorophenol

Paraclorofenol. 4-Chlorophenol.
C_6H_5ClO = 128.6.
CAS — 106-48-9.



Pharmacopoeias. In *US.*
US also includes camphorated parachlorophenol.
USP 31 (Parachlorophenol). It consists of white or pink crystals with a characteristic phenolic odour. M.p. about 42°; congealing temperature between 42° and 44°. Sparingly soluble in water and in liquid paraffin; very soluble in alcohol, in chloroform, in ether, in glycerol, and in fixed and volatile oils; soluble in soft paraffin. A 1% solution in water is acid to litmus. Store in airtight containers. Protect from light.
USP 31 (Camphorated Parachlorophenol). It contains not less than 33% and not more than 37% of parachlorophenol and not less than 63% and not more than 67% of camphor, with the sum of the percentages of parachlorophenol and camphor not less than 97% and not more than 103%. Store in airtight containers. Protect from light.

Profile

Parachlorophenol is a chlorinated phenolic disinfectant and antiseptic with similar properties to phenol (p.1656). Camphorated parachlorophenol has been used in dentistry in the treatment of infected root canals.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ital.:*** Esofenol Ferri; Pasta Iodoformica Radiopaca; ***Spain:*** Cresophene; ***Switz.:*** Cresophene†.

Paraformaldehyde

Paraform; Paraformaldehído; Paraformic Aldehyde; Polymerised Formaldehyde; Polyoxymethylene; Trioxyméthylène.
$(CH_2O)_n$.
CAS — 30525-89-4.

Pharmacopoeias. In *Jpn.*

Adverse Effects, Treatment, and Precautions

As for Formaldehyde Solution, p.1644. There have been reports of allergic reactions and nerve damage associated with the dental use of paraformaldehyde as a root canal sealant; it should not extrude beyond the apex.

Uses and Administration

Paraformaldehyde is a disinfectant and antiseptic with the properties and uses of formaldehyde (p.1645) and is used as a source of formaldehyde. To disinfect rooms it has been vapourised by heating. Tablets prepared for this purpose should be coloured by the addition of a suitable blue dye.

Paraformaldehyde has been used in lozenges for the treatment of minor throat infections. In dentistry, it has been used as an obtundent for sensitive dentine and as an antiseptic in mummifying pastes and for root canals. Paraformaldehyde may also be used for the decontamination of equipment thought to be contaminated with the spores of *Bacillus anthracis.*

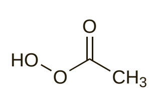
Preparations

Proprietary Preparations (details are given in Part 3)
Israel: Formalin.

Multi-ingredient: ***Ital.:*** Eso 70; Esoform 7 mc; Esoform 70 mc; Pasta Devitalizzante; ***Switz.:*** Asphaline†; Caustinerf forte†.

Peracetic Acid

Acetyl Hydroperoxide; Acidum Peraceticum; Kyselina peroctová; Peracético, ácido; Peroxyacetic Acid.
$C_2H_4O_3$ = 76.05.
CAS — 79-21-0.



Adverse Effects and Precautions

Concentrated peracetic acid is corrosive to the skin. Inhalation may produce respiratory symptoms, including pulmonary oedema, although commercial solutions are claimed to have low vapour activity.

Occupational exposure. Although corrosive and highly irritating to skin, eyes, mucous membranes and respiratory tract, solutions of peracetic acid (with hydrogen peroxide) were thought unlikely to cause sensitisation leading to hypersensitivity reactions in healthcare workers who were occupationally exposed. In contrast, *o*-phthaldialdehyde, although its sensitising potential was much lower than that of glutaral, might cause respiratory and dermal sensitisation.[1]

1. Rideout K, *et al.* Considering risks to healthcare workers from glutaraldehyde alternatives in high-level disinfection. *J Hosp Infect* 2005; **59:** 4–11.

Uses

Peracetic acid is a strong oxidising disinfectant. It is active against many micro-organisms including bacteria, spores, fungi, and viruses. It is used for disinfecting medical equipment including dialysers and endoscopes. It is used in the food industry and for disinfecting sewage sludge, and has been used as a spray for sterilisation of laboratories.

◊ Reviews.

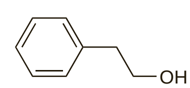
Phenethyl Alcohol *(BAN)*

Alcohol feniletílico; Alcohol Phenylethylicus; Alkohol fenyloetylowy; Benzyl Carbinol; Phenethanolum; Phenylethyl alcohol. 2-Phenylethanol.
$C_6H_5.CH_2.CH_2OH$ = 122.2.
CAS — 60-12-8.



Pharmacopoeias. In *Pol.* and *US.*
USP 31 (Phenylethyl Alcohol). A colourless liquid with a rose-like odour. Soluble 1 in 60 of water, 1 in less than 1 of alcohol, of chloroform, of ether, of benzyl benzoate, and of diethyl phthalate, and 1 in 2 of alcohol 50%; very soluble in glycerol, in propylene glycol, and in fixed oils; slightly soluble in liquid paraffin. Store in airtight containers in a cool, dry place. Protect from light.

Incompatibility. Phenethyl alcohol is incompatible with oxidising agents and proteins. Activity may be reduced by nonionic surfactants or by adsorption onto low density polyethylene containers.

Profile

Phenethyl alcohol is more active against Gram-negative than Gram-positive bacteria. It is used as a preservative in ophthalmic, nasal, and otic solutions at a concentration of 0.25 to 0.5%, with another bactericide, and up to 1% in topical preparations. It is also used as an antiseptic in topical products in concentrations of up to 7.5%. It is also used as a component of flavouring essences and perfumes.

Phenethyl alcohol may cause eye irritation.

Antimicrobial action. Antimicrobial activity may be enhanced by the addition of phenethyl alcohol to solutions preserved with benzalkonium chloride, chlorhexidine acetate, phenylmercuric nitrate, chlorocresol, or chlorobutanol.[1]

1. Richards RME, McBride RJ. The preservation of ophthalmic solutions with antibacterial combinations. *J Pharm Pharmacol* 1972; **24:** 145–8.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austral.:*** Resolve Tinea; Sebirinse; ***Canad.:*** Sclerodex; ***Ger.:*** Imazol; ***Irl.:*** Ceanel†; ***NZ:*** Sebirinse; ***UK:*** Ceanel.

Phenol

Carbolic Acid; Fenol; Fenoli; Fenolis; Phenic Acid; Phénol; Phenolum; Phenyl Hydrate; Phenylic Acid. Hydroxybenzene.

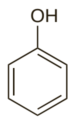
Оксибензол; Фенол

$C_6H_5.OH$ = 94.11.

CAS — 108-95-2.

ATC — C05BB05; D08AE03; N01BX03; R02AA19.

ATC Vet — QC05BB05; QD08AE03; QN01BX03; QR02AA19.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, *US*, and *Viet.*
Br., *Swiss*, and *US* also include a monograph for Liquefied Phenol.

Ph. Eur. 6.2 (Phenol). Colourless or faintly pink or faintly yellow deliquescent crystals or crystalline masses. F.p. not less than 39.5°. Soluble in water; very soluble in alcohol, in dichloromethane, and in glycerol. Store in airtight containers. Protect from light.

BP 2008 (Liquified Phenol). An aqueous mixture containing phenol 77.0 to 81.5% w/w in purified water. A colourless to faintly coloured, caustic liquid with a characteristic and not tarry odour. Soluble in water; miscible with alcohol, with ether, and with glycerol. Protect from light. It may congeal or deposit crystals if stored at a temperature below 4°. It should be completely melted before use.

When phenol is to be mixed with collodion, fixed oils, or paraffins, melted phenol should be used, and not Liquefied Phenol.

USP 31 (Phenol). Colourless to light pink, interlaced or separate, needle-shaped crystals, or a white to light pink crystalline mass, with a characteristic odour. It gradually darkens on exposure to light and air. Soluble 1 in 15 of water; very soluble in alcohol, in chloroform, in ether, in glycerol, and in fixed and volatile oils; soluble 1 in 70 of liquid paraffin. A solution of 1 g in 15 mL water is clear and is neutral or acid to litmus. Store in airtight containers. Protect from light.

USP 31 (Liquefied Phenol). Phenol maintained in a liquid condition by the presence of about 10% of water; it contains not less than 89% by weight of phenol. It may contain a suitable stabiliser. A colourless to pink liquid which may develop a red tint upon exposure to air or light, and with a characteristic, somewhat aromatic odour. Miscible with alcohol, with ether, and with glycerol. Store in airtight glass containers. Protect from light.

When phenol is to be mixed with a fixed oil, liquid paraffin, or white soft paraffin, crystalline Phenol and not Liquefied Phenol should be used.

Incompatibility. Phenol is incompatible with alkaline salts and nonionic surfactants. The antimicrobial activity of phenol may be diminished through increasing pH or through combination with blood and other organic matter.

Use for preservation. NOTE. Phenol should not be used to preserve preparations that are to be freeze-dried.

Adverse Effects

When ingested, phenol causes extensive local corrosion, with pain, nausea, vomiting, sweating, and diarrhoea. Excitation may occur initially but it is quickly followed by unconsciousness. There is depression of the CNS, with cardiac arrhythmias, and circulatory and respiratory failure, which may lead to death. Acidosis may develop and occasionally there is haemolysis and methaemoglobinaemia with cyanosis. The urine may become dark brown or green. Pulmonary oedema and myocardial damage may develop, and damage to the liver and kidneys may lead to organ failure.

Severe or fatal poisoning may occur from the absorption of phenol from unbroken skin or wounds and suitable precautions should be taken to prevent absorption. Applied to skin, phenol causes blanching and corrosion, sometimes with little pain. Aqueous solutions as dilute as 10% may be corrosive.

Toxic symptoms may also arise through absorption of phenol vapour by the skin or lungs. Phenol throat spray may cause local oedema.

Cresols and other phenolic substances have similar effects.

Effects on the heart. A 10-year-old boy developed life-threatening premature ventricular complexes during the application of a solution of phenol 40% and croton oil 0.8% in hexachlorophene soap and water for chemical peeling of a giant hairy naevus.[1] Cardiac arrhythmias have been reported after the use of phenol for chemical face peeling.[2] They were also seen in 3 of 16 children who received phenol 5% as a neurolytic.[3]

1. Warner MA, Harper JV. Cardiac dysrhythmias associated with chemical peeling with phenol. *Anesthesiology* 1985; **62:** 366–7.
2. Botta SA, *et al.* Cardiac arrhythmias in phenol face peeling: a suggested protocol for prevention. *Aesthetic Plast Surg* 1988; **12:** 115–17.
3. Morrison JE, *et al.* Phenol motor point blocks in children: plasma concentrations and cardiac dysrhythmias. *Anesthesiology* 1991; **75:** 359–62.

Effects on the kidneys. A 41-year-old man developed acute renal failure due to cutaneous absorption of phenol after falling into a shallow vat of industrial solvent containing 40% phenol in dichloromethane. No ingestion occurred. Other symptoms included 50% body-surface burns, cold extremities, nausea, vomiting, and respiratory distress. The patient required haemodialysis for 3 weeks; some abnormalities of renal function remained one year later.[1]

1. Foxall PJD, *et al.* Acute renal failure following accidental cutaneous absorption of phenol: application of NMR urinalysis to monitor the disease process. *Hum Toxicol* 1989; **9:** 491–6.

Effects on the liver. Phenol-induced hepatotoxicity has been reported[1] in a 43-year-old man after injection sclerotherapy for haemorrhoids with 5% phenol in arachis oil. During treatment the patient experienced pain radiating to the penis, then later developed backache and haematuria, and 6 days later was admitted to hospital with jaundice. He recovered well and his liver enzymes returned to normal levels after 6 months.

1. Suppiah A, Perry EP. Jaundice as a presentation of phenol induced hepatotoxocity [sic] following injection sclerotherapy for haemorrhoids. *Surgeon* 2005; **3:** 43–4.

Effects on sexual function. Three patients developed urinary symptoms and impotence which lasted up to one year after each receiving phenol 5% in arachis oil sclerotherapy for haemorrhoids.[1]

1. Bullock N. Impotence after sclerotherapy of haemorrhoids: case reports. *BMJ* 1997; **314:** 419.

Effects on the throat. Acute life-threatening epiglottitis occurred in a 49-year-old woman after the use of a throat spray containing the equivalent of 1.4% phenol. The reaction may have been anaphylactic or due to a direct toxic effect of the spray.[1] The UK CSM[2] reported in 1990 that it had received 4 reports of oedema of the epiglottis and/or larynx leading to respiratory difficulties. While the condition was rare, the effects were severe; 1 patient died and 2 survived only after emergency hospital treatment.

1. Ho S-L, Hollinrake K. Acute epiglottitis and Chloraseptic. *BMJ* 1989; **298:** 1584.
2. Committee on Safety of Medicines. Chloraseptic throat spray and oedema of the epiglottis and larynx. *Current Problems 28* 1990.

Treatment of Adverse Effects

If phenol has been swallowed, activated charcoal may be useful. Some sources suggest the cautious use of gastric lavage although this is generally inappropriate after ingestion of corrosive substances.

If phenol has been spilled on the skin removal of contaminated clothing and excess phenol should be followed by washing of the skin with glycerol or, alternatively, with copious amounts of water. Macrogol 300 and vegetable oils have also been used.

Contamination of the eyes should be treated by flooding with water or sodium chloride 0.9% only for at least 10 to 15 minutes.

The patient should be kept warm and given supportive treatment. Intravenous sodium bicarbonate should be given where there is metabolic acidosis.

Precautions

Solutions containing phenol should not be applied to large areas of skin or large wounds since sufficient phenol may be absorbed to give rise to toxic symptoms. Phenol should not be used as a throat spray in patients with epiglottitis, or in children aged under 6 years.

Pharmacokinetics

Phenol is absorbed from the gastrointestinal tract and through skin and mucous membranes. It is metabolised to phenylglucuronide and phenyl sulfate, and small amounts are oxidised to catechol and quinol which are mainly conjugated. The metabolites are excreted in the urine; on oxidation to quinones they may tint the urine dark brown or green.

Uses and Administration

Phenol is an antiseptic and disinfectant effective against vegetative Gram-positive and Gram-negative bacteria, mycobacteria, and some fungi, but only very slowly effective against spores. It is also active against certain viruses. Phenol is more active in acid solution.

Aqueous solutions up to 1% are bacteriostatic while stronger solutions are bactericidal.

A 0.5 to 1% solution has been used for its local anaesthetic effect to relieve itching.

A 1.4% solution is used for pain or irritation of the mouth and throat. Weak concentrations (up to 2%) have also been used topically for disinfection. A 5% solution has been used as a disinfectant for excreta.

Oily Phenol Injection (BP 2008), up to 10 mL, has been injected into the tissues around internal haemorrhoids as an analgesic sclerosing agent, but alternative procedures may be preferred. Aqueous phenol has also been used as a sclerosant in the treatment of hydroceles.

Solutions of phenol in glycerol have been given intrathecally for the alleviation of spasticity (p.1887) or injected intrathecally or into soft-tissue structures for the treatment of chronic low back pain. Other types of severe intractable pain may be relieved by injecting aqueous phenol close to motor nerves. Aqueous phenol has been used for chemical sympathectomy in peripheral vascular disorders and for the treatment of urinary incontinence.

Liquefied phenol has been used in the treatment of ingrowing toenails.

Dystonias. Phenol appears to produce a decrease in muscle tone without profound weakness and is considered to be an effective agent in treating focal dystonias.[1] Intramuscular phenol was reported[2] to have produced improvement in 2 adult patients with moderately severe spasmodic torticollis (p.1892) who had not responded adequately to intramuscular injections of botulinum A toxin. Response was maintained by re-injection every 6 months. Following this case report, an open trial[3] was conducted on 3 patients with spasmodic torticollis who had not responded to botulinum toxin A and other drug treatments. After 10 intramuscular injections of phenol, given weekly and then monthly, 2 of the patients showed improvement; one reached partial remission while the other had improvement that lasted for 3 months. The third patient did not respond to treatment with phenol. A study[4] to determine the effectiveness and adverse effects of a 2% phenol block in patients with spasmodic torticollis was conducted in 16 patients, all of whom were refractory to oral drug and rehabilitation therapies. Results showed significant improvement in neck movement and position. However, 4 patients developed reversible sensory disturbance of the transverse cutaneous nerve of the neck area. A patient who developed a focal dystonic contraction of the foot responded to single intramuscular injection of 5% aqueous phenol, after initial treatment with botulinum toxin A had shown no benefit.[5]

5. Kim J-S, *et al.* Idiopathic foot dystonia treated with intramuscular phenol injection. *Parkinsonism Relat Disord* 2003; **9:** 355–9.

Haemorrhoids. Sclerotherapy with oily phenol injection has been used[1] to treat haemorrhoids (p.1697). The technique for preventing mucosal prolapse is to inject small volumes (about 2 or 3 mL) of a 5% solution of phenol in arachis oil into the submucous space above each of the 3 principal haemorrhoids. Rather than causing the haemorrhoidal veins to thrombose, the injection works by producing submucosal fibrosis, fixing the mucosa to the underlying muscle. However, other techniques for mucosal fixation such as rubber band ligation or perhaps infra-red coagulation are more effective and associated with fewer complications.[2-5]

5. MacRae HM, McLeod RS. Comparison of hemorrhoidal treatment modalities: a meta-analysis. *Dis Colon Rectum* 1995; **38:** 687–94.

Ingrowing toenails. Liquefied phenol (88%) ablation has been performed as an alternative to surgical avulsion in the treatment of ingrowing toenails.[1,2] A systematic review[3] concluded that simple nail avulsion combined with treating the nail-bed with phenol was more effective at preventing symptomatic recurrence of ingrowing toenails than cutting out the nail-bed. However, there was a significant increase in postoperative infections when phenol was used.

3. Rounding C, Bloomfield S. Surgical treatments for ingrowing toenails. Available in The Cochrane Database of Systematic Reviews; Issue 1. Chichester: John Wiley; 2003 (accessed 15/03/06).

Pain. The neurolytic use of phenol to produce destructive nerve block (see under Pain, p.1852) has produced variable results, and some consider the risk of complications outweighs the benefits. However, it may have the advantage over alcohol that it is painless on injection, and smaller volumes can be used, potentially allowing greater precision (see p.1627).

Urinary incontinence. Although injection of phenol into the pelvic plexus to produce partial denervation has been used in the management of severe intractable urge incontinence, its use has been largely abandoned. Some patients, especially those with detrusor hyperreflexia, have derived benefit[1,2] but overall efficacy can be poor and benefits short-lived.[3]

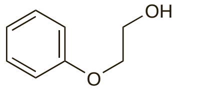
Phenoxyethanol

Ethylene Glycol 2-Monophenyl Ether; Ethyleneglycol Monophenylether; Fenoksietanoli; Fenoksietanolis; Fenoksyetanol; Fenoxietanol; Fenoxyethanol; Phenoxyaethanol; Phénoxyéthanol; Phenoxyethanolum; β-Phenoxyethyl Alcohol; 2-Phenoxyethyl Alcohol. 2-Phenoxyethanol.

$C_8H_{10}O_2$ = 138.2.
CAS — 122-99-6.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Phenoxyethanol). A colourless slightly viscous liquid. Slightly soluble in water, in arachis oil and in olive oil; miscible with alcohol, with acetone, and with glycerol.

USNF 26 (Phenoxyethanol). A colourless, slightly viscous liquid. Specific gravity 1.105 to 1.110 at 20°. Slightly soluble in water; miscible with alcohol, with acetone, and with glycerol; slightly soluble in arachis oil and in olive oil. Store in a dry place, in airtight containers at a temperature of 8° to 15°. Protect from light.

Incompatibility. The activity of phenoxyethanol may be reduced by interaction with nonionic surfactants and possibly by adsorption onto PVC.

Profile

Phenoxyethanol is effective against strains of *Pseudomonas aeruginosa* but less so against other Gram-negative and Gram-positive bacteria. It has been used as a preservative in cosmetics and topical pharmaceuticals at a concentration of 0.5 to 1%. It is often used with other preservatives, commonly hydroxybenzoates, to obtain a wider spectrum of antimicrobial activity.

Phenoxyethanol is used in concentrations of about 2% as an antiseptic for minor infections of skin, wounds, and mucous membranes. Aqueous solutions may be prepared by shaking the phenoxyethanol with hot water until dissolved, then adjusting to final volume when cool. Preparation of the solution can be aided by propylene glycol.

Phenoxypropanol and chlorophenoxyethanol are related compounds used in topical preparations.

Preparations

Proprietary Preparations (details are given in Part 3)
Singapore: Acnederm Wash; ***UK:*** Biactol Liquid.

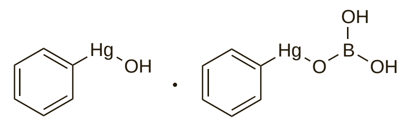
CAS — 8017-88-7 ($C_{12}H_{13}BHg_2O_4$); 6273-99-0 ($C_{12}H_{11}BHg_2O_3$); 102-98-7 ($C_6H_7BHgO_3$).
ATC — D08AK02.
ATC Vet — QD08AK02.



Pharmacopoeias. In *Eur.* (see p.vii).

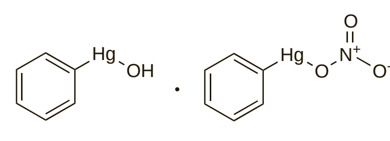
Ph. Eur. 6.2 (Phenylmercuric Borate). A compound consisting of equimolecular proportions of phenylmercuric orthoborate and phenylmercuric hydroxide ($C_{12}H_{13}BHg_2O_4$) or of the dehydrated form (metaborate, $C_{12}H_{11}BHg_2O_3$) or a mixture of the two compounds. Colourless shiny crystals or a white or slightly yellowish crystalline powder. Slightly soluble in water and in alcohol. Protect from light.

Incompatibility. The incompatibilities of phenylmercuric salts are described under Phenylmercuric Nitrate, below.

Phenylmercuric Nitrate

Basic Phenylmercury Nitrate; Fenilgyvsidabrio nitratas; Fenil-higany-nitrát; Fenilmercurio, nitrato de; Fenylhydrargyriumnitrát; Fenylkvicksilvernitrat; Fenylortęci(II) azotan; Fenyylimerkurinitraatti; Phenylhydrargyri nitras; Phénylmercure, nitrate de; PMN. Nitratophenylmercury.

$C_6H_5HgOH,C_6H_5HgNO_3$ = 634.4.
CAS — 8003-05-2 ($C_6H_5HgOH,C_6H_5HgNO_3$); 55-68-5 ($C_6H_5HgNO_3$).
ATC — D09AA04.
ATC Vet — QD09AA04.



($C_6H_5HgOH,C_6H_5HgNO_3$)

Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*

Ph. Eur. 6.2 (Phenylmercuric Nitrate). A mixture of phenylmercuric nitrate and phenylmercuric hydroxide. A white or pale yellow powder. Very slightly soluble in water and in alcohol; slightly soluble in hot water; dissolves in glycerol and in fatty oils. Protect from light.

USNF 26 (Phenylmercuric Nitrate). A mixture of phenylmercuric nitrate and phenylmercuric hydroxide. A white crystalline powder. Soluble 1 in 600 of water; slightly soluble in alcohol and in glycerol; more soluble in the presence of nitric acid or alkali hydroxides. A saturated solution in water is acid to litmus. Store in airtight containers. Protect from light.

Incompatibility. The activity of phenylmercuric salts may be reduced by interaction with compounds such as kaolin, magnesium trisilicate, starch, and talc.[1,2] Disodium edetate and sodium thiosulfate can also produce inactivation.[3] Sodium metabisulfite can lead to precipitation,[3] or chemical destruction,[4] but it can also produce increased activity.[3] Other incompatibilities include bromides, iodides (chlorides to a lesser extent), metals, and ammonia and its salts.[5] There can be adsorption onto rubber and some plastics[5,6] although sorption by low density polyethylene can be inhibited by phosphate ions.[7] Some filters, though not membrane filters, used for sterilisation removed considerable amounts of phenylmercuric nitrate from solution.[8] The pH may also affect activity.[9]

Adverse Effects and Precautions

While the adverse effects of inorganic mercury (p.2341) should be taken into account when considering the adverse effects of phenylmercuric compounds, there is little evidence of systemic toxicity arising from their use. They are irritant to the skin and may give rise to erythema and blistering. Hypersensitivity reactions have been reported. Topical application to eyes has been associated with mercurialentis and atypical band keratopathy; prolonged use of eye drops containing phenylmercuric preservatives is not recommended.

Effects on the eyes. References to primary atypical band keratopathy and pigmentation of the anterior capsule of the lens (mercurialentis) associated with the prolonged use of eye drops containing phenylmercuric preservative.

Uses

Phenylmercuric salts have antibacterial and antifungal properties. They are primarily bacteriostatic compounds although they also have a slow bactericidal action. Their activity has been reported to be pH dependent.

Phenylmercuric compounds are used as preservatives in cosmetic, ophthalmic, or pharmaceutical preparations and as antiseptics. They have also been used as spermicides.

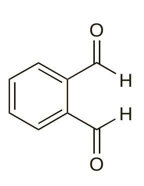
As a preservative in eye drops, a concentration of 0.002% is usually used; in injection solutions, the concentration is usually 0.001%.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austria:*** Panto Liquid; ***USA:*** Hem-Prep.

o-Phthaldialdehyde

o-Ftaldialdehído; *o*-Phthalaldehyde. 1,2-Benzenedicarboxaldehyde.
$C_8H_6O_2$ = 134.1.
CAS — 643-79-8.



Adverse Effects and Precautions

As for Formaldehyde Solution, p.1644.

The manufacturer warns that *o*-phthaldialdehyde should not be used to process equipment used to treat patients with a history of bladder cancer as there have been associated rare reports of anaphylactoid reactions in such patients.

Occupational exposure. For mention of the potential of *o*-phthaldialdehyde to cause sensitisation in those occupationally exposed, see under Peracetic Acid, p.1655.

Uses and Administration

o-Phthaldialdehyde is a bactericidal disinfectant with similar actions to those of glutaral (p.1645) but it is reported to be more active against mycobacteria and to be stable at a wider pH range of 3 to 9. Unlike glutaral it requires no activation before use.

A 0.55% aqueous solution of *o*-phthaldialdehyde is used for high-level disinfection of medical equipment that cannot be sterilised by heat. It is non-corrosive towards most materials. Complete immersion in the solution for a minimum of 12 minutes at 20° or 5 minutes at 25° or higher is recommended. For further details, see Disinfection of Endoscopes, p.1623.

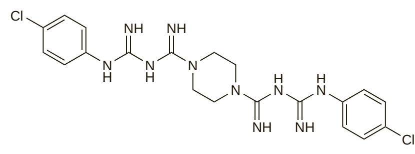
Picloxydine Dihydrochloride *(BANM, rINNM)*

Dihidrocloruro de picloxidina; Picloxydine, Dichlorhydrate de; Picloxydini Dihydrochloridum. 1,1′-[Piperazine-1,4-diylbis(formimidoyl)]bis[3-(4-chlorophenyl)guanidine] dihydrochloride.
Пиклоксидина Дигидрохлорид
$C_{20}H_{24}Cl_2N_{10}$,2HCl = 548.3.
CAS — 5636-92-0 (picloxydine); 19803-62-4 (picloxydine dihydrochloride).
ATC — S01AX16.
ATC Vet — QS01AX16.



(picloxydine)

Profile

Picloxydine is a biguanide disinfectant with properties similar to those of chlorhexidine (p.1635). It is used in eye drops containing 0.05% of the dihydrochloride for the treatment of superficial infections of the eye. It has also been used as a surface disinfectant with quaternary ammonium compounds.

Preparations

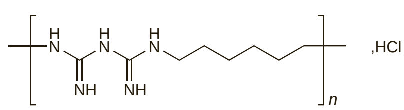
Polihexanide *(BAN, rINN)*

ICI-9073; Polihexanida; Polihexanidum; Polyhexamethylene Biguanide Hydrochloride; Polyhexanide. Poly(1-hexamethylenebiguanide hydrochloride).
Полигексанид
$(C_8H_{17}N_5,HCl)_n$.
CAS — 32289-58-0.
ATC — D08AC05.
ATC Vet — QD08AC05.



Profile

Polihexanide has antibacterial and antiamoebic activity. It is used as a surface disinfectant and for disinfecting soft contact lenses (p.1622). It is also used in the treatment of *Acanthamoeba* keratitis (p.822) and has also been tried as a mouthwash in dental care.

Bacterial vaginosis. A study[1] of the efficacy of a 2% polihexanide vaginal gel in the treatment of bacterial vaginosis found that a single application was comparable to that of a 2% clindamycin gel applied once daily for 7 consecutive days.

1. Gerli S, *et al.* A new approach for the treatment of bacterial vaginosis: use of polyhexamethylene biguanide: a prospective, randomized study. *Eur Rev Med Pharmacol Sci* 2003; **7:** 127–30.

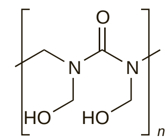
Polynoxylin *(BAN, rINN)*

Polinoxilina; Polynoksyliini; Polynoxyline; Polynoxylinum. Poly{[bis(hydroxymethyl)ureylene]methylene}.
Полиноксилин
$(C_4H_8N_2O_3)_n$.
CAS — 9011-05-6.
ATC — A01AB05; D01AE05.
ATC Vet — QA01AB05; QD01AE05.



Profile

Polynoxylin is a condensation product of formaldehyde and urea. It is an antiseptic with antibacterial and antifungal actions and, like noxytiolin (p.1654), may act by the release of formaldehyde. It is used topically for the local treatment of minor infections, usually at a concentration of 10%.

Potassium Nitrate ⊗

Dusičnan draselný; E252; Kalii nitras; Kalio nitratas; Kalium Nitricum; Kaliumnitraatti; Kaliumnitrat; Kálium-nitrát; Nitrato potásico; Nitre; Potassium, nitrate de; Potasu azotan; Saltpetre.
KNO_3 = 101.1.
CAS — 7757-79-1.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Potassium Nitrate). Colourless crystals or a white or almost white, crystalline powder. Freely soluble in water; very soluble in boiling water; practically insoluble in alcohol.

USP 31 (Potassium Nitrate). Colourless crystals or a white crystalline powder. Freely soluble in water; very soluble in boiling water; practically insoluble in alcohol; soluble in glycerol. Store in airtight containers.

Nomenclature. The name saltpetre has been used as a generic term for a number of potassium- and sodium-based preservatives used in food manufacture. For a report of poisoning when a mixture of sodium nitrate and sodium nitrite was supplied for saltpetre, see p.1662.

Adverse Effects and Precautions

After ingestion potassium nitrate may be reduced to nitrite in the gastrointestinal tract by the action of bacteria and ingestion of large amounts can therefore cause methaemoglobinaemia. Gastrointestinal disturbances, vertigo, headache, flushing of the skin, hypotension, irregular pulse, cyanosis, convulsions, and collapse may occur. The toxic dose varies greatly; 15 g may prove fatal but much larger doses have been taken without serious effects. Poisoning has frequently been reported in infants given water from wells contaminated with nitrates.

Nitrites are precursors of nitrosamines, which are *animal* carcinogens, but a relationship with human cancer has not been established.

Concern has been expressed regarding the concentrations of nitrates and nitrites in the public drinking water supply. National limits are often set for permissible concentrations in drinking water.

Handling. Potassium nitrate has been used for the illicit preparation of explosives or fireworks; care is required with its supply.

Uses and Administration

Potassium nitrate is used as a preservative in foods. It is also included in dentrifices to reduce the pain of hypersensitive teeth. When taken by mouth in dilute solution, it acts as a diuretic and was formerly used for this purpose.

Preparations

USP 31: Potassium Nitrate Solution.

Potassium Permanganate

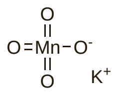
Kalii permanganas; Kalio permanganatas; Kalium Hypermanganicum; Kalium Permanganicum; Kaliumpermanganaatti; Kaliumpermanganat; Kálium-permanganát; Manganistan draselný; Permanganato potásico; Pot. Permang.; Potassium, permanganate de; Potasu nadmanganian; Potasyum Permanganat.

$KMnO_4$ = 158.0.

CAS — 7722-64-7.

ATC — D08AX06; V03AB18.

ATC Vet — QD08AX06; QV03AB18.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, *US*, and *Viet.*

Ph. Eur. 6.2 (Potassium Permanganate). Dark purple or almost black crystals or a dark purple or brownish-black granular powder, usually with a metallic lustre. It decomposes in contact with certain organic substances. Soluble in cold water and freely soluble in boiling water.

USP 31 (Potassium Permanganate). Dark purple crystals, almost opaque by transmitted light and with a blue metallic lustre by reflected light; its colour is sometimes modified by a dark bronze-like appearance. Soluble 1 in 15 of water and 1 in 3.5 of boiling water.

Incompatibility. Potassium permanganate is incompatible with iodides, reducing agents, and most organic substances.

Adverse Effects, Treatment, and Precautions

The dry crystals or concentrated solutions of potassium permanganate are highly corrosive to tissue, while dilute solutions are mildly irritant. Contact with the skin causes irritation, redness, pain and burns, and even dilute solutions cause hardening of the outer layer of the skin and leave a brown stain on the skin. Exposure of the eye to dry crystals (including crystal dust) or concentrated solutions causes irritation, blurred vision, redness, brown staining of the conjunctiva, swelling of the eyelids, and corneal and conjunctival burns. For the effects of ingestion, see below.

The insertion into the vagina of potassium permanganate for its supposed abortifacient action causes corrosive burns, severe vaginal haemorrhage, and perforation of the vaginal wall, leading to peritonitis. Vascular collapse may occur.

Handling and storage. Potassium permanganate may be explosive if it is brought into contact with organic or other readily oxidisable substances. It has been used for the illicit preparation of fireworks; care is required with its supply.

Poisoning. Ingestion of dilute solutions of potassium permanganate may result in the mouth and throat being stained brown, sore throat, dysphagia, abdominal pain, diarrhoea, and vomiting. Ingestion of dry crystals and concentrated solutions causes oedema and necrosis of the mouth, larynx, gastrointestinal tract, and upper respiratory tract. In severe cases, acute respiratory distress syndrome, coagulopathy, hypotension, methaemoglobinaemia, hepatic necrosis, pancreatitis, and acute renal failure may develop. Oesophageal strictures and pyloric stenosis are possible long-term consequences. The fatal dose is probably about 10 g and death is usually as a result of pharyngeal oedema and cardiovascular collapse, although multiple organ failure may occur. Inhalation of potassium permanganate causes sore throat, coughing, and shortness of breath. Chronic ingestion or inhalation of potassium permanganate has resulted in CNS symptoms such as sluggishness, sleepiness, weakness of the legs, tremor, spastic gait, and falling.

Symptoms of poisoning after ingestion of potassium permanganate should be treated symptomatically. Gut neutralisation and emesis are contra-indicated. Dilution with large quantities of water or milk is cautiously recommended, while the role of activated charcoal is unclear as it is not known whether it binds potassium permanganate. Similarly, the role of corticosteroids is controversial and the efficacy of *N*-acetylcysteine for potassium permanganate hepatotoxicity is unproven. Eyes and skin contaminated with potassium permanganate should be thoroughly washed.

Uses and Administration

Potassium permanganate possesses oxidising properties which in turn confer disinfectant and deodorising properties. It is also astringent. Though bactericidal *in vitro* its clinical value as a bactericide is minimised by its rapid reduction in the presence of body fluids.

Solutions are used as cleansing applications to wounds, ulcers, or abscesses and as wet dressings and in baths in eczematous conditions and acute dermatoses especially where there is secondary infection. It is often prepared as a concentrated 0.1% solution in water to be diluted 1 in 10 before use to provide a 0.01% (1 in 10 000) solution. Solutions have also been used in bromhidrosis, in mycotic infections such as athlete's foot, and in poison ivy dermatitis.

Potassium permanganate is added to formaldehyde solution to produce formaldehyde vapour for the disinfection of rooms and cabinets (see p.1645).

Povidone-Iodine *(BAN)*

Iodinated Povidone; Jodowany powidon; Polyvidone-Iodine; Polyvinylpyrrolidone-Iodine Complex; Povidon, joderad; Povidon jodovaný; Povidona yodada; Povidonas, joduotas; Povidone iodée; Povidoni, jodattu; Povidon-Iyot; Povidon-jód; Povidonum iodinatum; Propylèneglycol, monostéarate de; PVP-Iodine; PVP-Iodine.

Повидон-йод

CAS — 25655-41-8.

ATC — D08AG02; D09AA09; D11AC06; G01AX11; R02AA15; S01AX18.

ATC Vet — QD08AG02; QD09AA09; QD11AC06; QG01AX11; QG51AD01; QR02AA15; QS01AX18.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Povidone, Iodinated). A complex of iodine with povidone containing 9 to 12% of available iodine calculated with reference to the dried substance. Yellowish-brown or reddish-brown amorphous powder. It loses not more than 8% of its weight on drying. Soluble in water and in alcohol; practically insoluble in acetone. A 10% solution in water has a pH of 1.5 to 5.0. Protect from light.

USP 31 (Povidone-Iodine). A complex of iodine with povidone containing 9 to 12% of available iodine calculated on the dried basis. A yellowish-brown to reddish-brown amorphous powder with a slight characteristic odour. It loses not more than 8% of its weight on drying. Soluble in water and in alcohol; practically insoluble in acetone, in carbon tetrachloride, in chloroform, in ether, and in petroleum spirit. Its solutions are acid to litmus. Store in airtight containers.

Incompatibility. Antimicrobial activity may be reduced at high pH.

Dermatological reactions, described as second- and third-degree burns, were observed in 4 patients in whom wounds were covered with a povidone-iodine soaked bandage secured to the skin by compound benzoin tincture. It was suggested that an interaction had occurred resulting in a more acidic pH.[1]

A mixture of povidone-iodine solution and hydrogen peroxide [brown bubbly] has caused explosions.[2]

1. Schillaci LJ, *et al.* Reduced pH associated with mixture of povidone-iodine and compound tincture of benzoin. *Am J Hosp Pharm* 1983; **40:** 1694–5.
2. Dannenberg E, Peebles J. Betadine-hydrogen peroxide irrigation solution incompatibility. *Am J Hosp Pharm* 1978; **35:** 525.

Adverse Effects and Precautions

Povidone-iodine can cause hypersensitivity reactions and irritation of the skin and mucous membranes, although severe reactions are rare and povidone-iodine is considered to be less irritant than iodine.

The application of povidone-iodine to severe burns or to large areas otherwise denuded of skin may produce the systemic adverse effects associated with iodine (p.2169) and metabolic acidosis, hypernatraemia, and renal impairment. Hyperthyroidism or hypothyroidism may occur after ingestion or absorption of large quantities. Hypothyroidism has occurred in neonates both as a result of absorption of iodine from povidone-iodine applied to the neonate and also to the mother during pregnancy or breast feeding. Povidone-iodine application is contra-indicated in premature neonates or those weighing less than 1.5 kg.

Regular or prolonged use should be avoided in patients with thyroid disorders or those receiving lithium therapy.

Acidosis. There have been reports of acidosis in patients whose burns were treated topically with povidone-iodine.[1,2] Fatal metabolic acidosis[3] and seizures[4] have been reported after mediastinal irrigation with povidone-iodine.

1. Pietsch J, Meakins JL. Complications of povidone-iodine absorption in topically treated burn patients. *Lancet* 1976; **i:** 280–2.
2. Scoggin C, *et al.* Hypernatraemia and acidosis in association with topical treatment of burns. *Lancet* 1977; **i:** 959.
3. Glick PL, *et al.* Iodine toxicity in a patient treated by continuous povidone-iodine mediastinal irrigation. *Ann Thorac Surg* 1985; **39:** 478–80.
4. Zec N, *et al.* Seizures in a patient treated with continuous povidone-iodine mediastinal irrigation. *N Engl J Med* 1992; **326:** 1784.

Breast feeding. Use of povidone-iodine in a vaginal gel by a breast-feeding woman resulted in elevated iodine concentrations in the breast milk and an odour of iodine on the infant's skin.[1] The American Academy of Pediatrics considers however that the use of povidone-iodine is usually compatible with breast feeding.[2]

For more on precautions in breast feeding when treated with iodine compounds see p.2170.

1. Pastellon DC, Aranow R. Iodine in mother's milk. *JAMA* 1982; **247:** 463.

Hypersensitivity. Immediate type I hypersensitivity reactions have been reported after topical disinfection with povidone-iodine; anaphylaxis has been reported after vaginal application[1,2] and after wound disinfection during surgery.[3] In some cases[2,3] skin tests showed that the reactions were caused by the povidone component.

Contact dermatitis has been reported[4] in a 36-year-old man who received a compress with 10% povidone-iodine aqueous solution under an occlusive bandage. The patient experienced mild itching, erythema, exudation, and a bullous reaction, limited to the area of the compress, 48 hours after application. He responded to topical corticosteroids within 5 to 6 days, but an area of sharply demarcated brown hyperpigmentation persisted for a month. While this was considered to be suggestive of an irritant effect, a positive patch test supported an allergic mechanism. A study to evaluate the incidence of contact dermatitis associated with povidone-iodine[5] found that 14 of 500 patients (2.8%) had a positive patch test with 10% povidone-iodine aqueous solution. On retesting with the same solution using a repeated open application test only 2 of the 14 (0.4%) were found to have true contact dermatitis to povidone-iodine.

5. Lachapelle JM. Allergic contact dermatitis from povidone-iodine: a re-evaluation study. *Contact Dermatitis* 2005; **52:** 9–10.

Neonates. Hypothyroidism has been reported in premature and very low birth-weight infants after the use of povidone-iodine for routine antisepsis,[1,2] and hyperthyroidism in a full-term infant following mediastinal lavage.[3]

Perinatal vaginal use of povidone-iodine may also cause neonatal thyroid dysfunction.[4]

4. l'Allemand D, *et al.* Iodine-induced alterations of thyroid function in newborn infants after prenatal and perinatal exposure to povidone iodine. *J Pediatr* 1983; **102:** 935–8.

Uses and Administration

Povidone-iodine is an iodophore that is used as a disinfectant and antiseptic mainly for the treatment of contaminated wounds and pre-operative preparation of the skin and mucous membranes as well as for the disinfection of equipment.

Iodophores are loose complexes of iodine and carrier polymers. Solutions of povidone-iodine gradually release iodine to exert an effect against bacteria, fungi, viruses, protozoa, cysts, and spores; povidone-iodine is thus less potent than preparations containing free iodine but it is less toxic.

A wide variety of topical formulations is available, the majority containing about 4 to 10% of povidone-iodine; a 1% mouthwash has been used for oral infections including candidiasis and topical powders containing up to 2.5% povidone-iodine have been tried in the treatment and prevention of wound infection. For vaginal application povidone-iodine has also been used as pessaries containing 200 mg or as a 10% gel or solution.

Propamidine Isetionate *(BANM, rINNM)*

Isetionato de propamidina; M&B-782; Propamidine Isethionate; Propamidine, Isétionate de; Propamidini Isetionas. 4,4′-Trimethylenedioxydibenzamidine bis(2-hydroxyethanesulphonate).

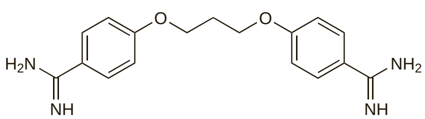
Пропамидина Изетионат

$C_{17}H_{20}N_4O_2,2C_2H_6O_4S$ = 564.6.

CAS — 104-32-5 (propamidine); 140-63-6 (propamidine isetionate).

ATC — D08AC03; S01AX15.

ATC Vet — QD08AC03; QS01AX15.



Profile

Propamidine isetionate is an aromatic diamidine antiseptic that is active against Gram-positive bacteria, but less active against Gram-negative bacteria and spore-forming organisms. It also has antifungal properties and is active against *Acanthamoeba*. Ophthalmic solutions containing 0.1% of propamidine isetionate are used for the treatment of conjunctivitis and blepharitis.

Acanthamoeba keratitis. The optimal regimen for the treatment of *Acanthamoeba* keratitis (p.822) has yet to be determined. Propamidine isetionate applied topically was the first drug used with some success.[1,2] It was used with an aminoglycoside such as neomycin or a neomycin-polymyxin-gramicidin preparation and a cure was achieved in about 50% of cases. Due to surface toxicity and poor *in-vitro* sensitivity of neomycin, propamidine was later used with chlorhexidine or polihexanide. However, poor cysticidal activity, chronic conjunctival infection, and resistance of some strains of *Acanthamoeba* to propamidine has prompted the suggestion that it should be replaced by another diamidine such as hexamidine.[3]

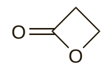
CAS — 57-57-8.



Profile

Propiolactone vapour is an irritant, mutagenic, possibly carcinogenic, disinfectant which is very active against most micro-organisms including viruses. It is rather less effective against bacterial spores.

Propiolactone vapour has been used for the gaseous sterilisation of pharmaceutical and surgical materials and for disinfecting large enclosed areas. It has low penetrating power. Propiolactone liquid has also been used.

Propyl Alcohol

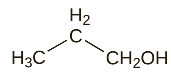
Alcohol propílico; Normal Propyl Alcohol; Primary Propyl Alcohol; Propanol; Propanoli; Propanolis; Propanolum. Propan-1-ol.

$CH_3.CH_2.CH_2OH$ = 60.10.

CAS — 71-23-8.

ATC — D08AX03.

ATC Vet — QD08AX03.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Propanol). A clear colourless liquid. Miscible with water and with dehydrated alcohol. Protect from light.

Adverse Effects and Treatment

As for Alcohol, p.1625; propyl alcohol is considered more toxic.

◊ References.

1. WHO. 1-Propanol. *Environmental Health Criteria 102.* Geneva: WHO, 1990. Available at: http://www.inchem.org/documents/ehc/ehc/ehc102.htm (accessed 15/03/06)

Uses and Administration

Propyl alcohol, an antiseptic with properties similar to those of alcohol (p.1627), is used in preparations for disinfection of the hands, skin, surfaces, and instruments.

Isopropyl alcohol (p.1651) is also used as an antiseptic.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Skinman Asept.

Multi-ingredient: *Austria:* Dodesept; Kodan; Marcocid; Octeniderm; ***Fr.:*** Anios DD; Sterillium†; ***Ger.:*** Aerodesin; Bacillol; Bacillol AF; Bacillol plus; Desmanol†; Freka-Steril; Hospisept; Incidin; Incidur Spray†; Kodan Tinktur Forte†; Meliseptol; Meliseptol Rapid; Neo Kodan†; Primasept Med†; Sagrosept†; Softa Man; St-Tissues; Sterillium; ***Gr.:*** Chiro Des; Octeniderm; Sterillium; ***Ital.:*** Softa Man; ***Neth.:*** Softa-Man; Sterillium; ***Singapore:*** Listerine Cool Mint; Listerine Fresh Burst; Listerine Tartar Control; ***Switz.:*** Kodan Teinture forte; Octeniderm; Softa-Man; Sterillium†.

Ritiometan *(rINN)*

Ritiométan; Ritiometán; Ritiometanum. (Methylidynetrithio)-triacetic acid.

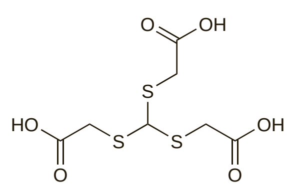
Ритиометан

$C_7H_{10}O_6S_3$ = 286.3.

CAS — 34914-39-1.

ATC — R01AX05.

ATC Vet — QR01AX05.



Profile

Ritiometan is used as the magnesium salt in an aerosol preparation for the treatment of infections of the nose and throat.

Preparations

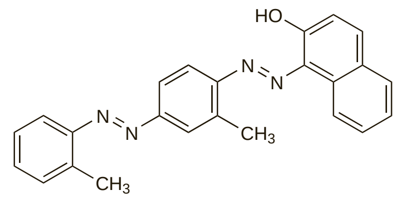
Proprietary Preparations (details are given in Part 3)
Fr.: Necyrane.

Scarlet Red

Biebrich Scarlet R Medicinal; CI Solvent Red 24; Colour Index No. 26105; Fat Ponceau R; Rojo escarlata; Rubrum Scarlatinum; Scharlachrot; Sudan IV. 1-[4-(*o*-Tolylazo)-*o*-tolylazo]naphth-2-ol.

$C_{24}H_{20}N_4O$ = 380.4.

CAS — 85-83-6.



Profile

Scarlet red is an antiseptic dye that has been used topically. It can be irritant. Scarlet red is not permitted as a food colour in the EU, as it is thought to be a genotoxic carcinogen.

Sodium Azide

Azida sódica; Sodu azydek.

N_3Na = 65.01.

CAS — 26628-22-8.

$$Na^+$$
$$^-N{=}N^+{=}N^-$$

Adverse Effects and Precautions

Sodium azide is a potent vasodilator and the most common adverse effect, regardless of the route of exposure, is hypotension. Hypotension developing more than an hour after exposure is associated with more severe toxicity and fatality. Other severe symptoms include seizure, coma, arrhythmia, tachypnoea, pulmonary oedema, metabolic acidosis, and cardiorespiratory arrest. Milder symptoms include nausea, vomiting, diarrhoea, headache, dizziness, temporary loss of vision, palpitations, dyspnoea, temporary loss of consciousness, or decreased mental status. There is no specific antidote for sodium azide intoxication.

Solutions containing sodium azide must not be disposed of into drain pipelines containing copper, lead, or brass since highly explosive heavy metal azides may be produced.

◊ References to acute poisoning with sodium azide.

Airbag deployment. Chemical and thermal burns have occurred after accidental perforation of airbags in motor vehicles and the release of sodium azide and other byproducts. Irritant contact dermatitis usually affecting the upper chest, arms, and face, and blunt trauma have also been reported.[1,2]

1. Corazza M, *et al.* Effects of airbag deployment: lesions, epidemiology, and management. *Am J Clin Dermatol* 2004; **5:** 295–300.
2. Suhr M, Kreusch T. Burn injuries resulting from (accidental) airbag inflation. *J Craniomaxillofac Surg* 2004; **32:** 35–7.

Effects on the nervous system. A study[1] to evaluate occupational neurotoxicity to sodium azide over a period of 3 years found that the only significant chronic symptom was trembling of the hands, occurring in 15 of 41 exposed workers compared with none of 42 controls. There was no difference between the 2 groups for other psychological or neuropsychological tests. Acute adverse effects most commonly reported by the exposed workers were heart palpitations, fatigue, nausea, vertigo, and irritated or red eyes.

1. Miljours S, Braun CMJ. A neuropsychotoxicological assessment of workers in a sodium azide production plant. *Int Arch Occup Environ Health* 2003; **76:** 225–32.

Haemodialysis. Of 10 investigations by the CDC[1] into outbreaks of disease caused by chemicals in haemodialysis facilities between 1979 and 1999, one was due to sodium azide. Inadequate rinsing of water filters resulted in the exposure of 9 patients to sodium azide in a dialysis centre. Patients experienced sudden hypotension, blurred vision, headache, nausea, vomiting, syncope, and 1 patient experienced cramps.

1. Arduino MJ. CDC investigations of noninfectious outbreaks of adverse events in hemodialysis facilities, 1979-1999. *Semin Dial* 2000; **13:** 86–91.

Uses

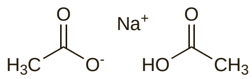
Sodium azide has been used as an antimicrobial preservative in laboratory reagents, serum samples, and dialysis equipment. It is also used in car airbags; sudden impact triggers an electrical charge causing the sodium azide to explode and nitrogen gas is released.

Sodium Diacetate

Diacetato de sodio; E262. Sodium hydrogen diacetate.

$CH_3COONa,CH_3COOH(+xH_2O)$.

CAS — 126-96-5 (anhydrous sodium diacetate).



Profile

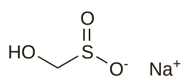
Sodium diacetate is used as a preservative in foods, particularly as an inhibitor of moulds and rope-forming micro-organisms in bread.

Sodium Formaldehyde Sulfoxylate

Formaldehído sulfoxilato sódico; Natrii Formaldehydosulfoxylas; Sodium Formaldehyde Sulphoxylate; Sodu formaldehydosulfoksylan. Sodium hydroxymethanesulphinate dihydrate.

$CH_3NaO_3S,2H_2O = 154.1$.

CAS — 149-44-0 (anhydrous sodium formaldehyde sulfoxylate); 6035-47-8 (sodium formaldehyde sulfoxylate, dihydrate).



Pharmacopoeias. In *Pol.* Also in *USNF.*

USNF 26 (Sodium Formaldehyde Sulfoxylate). White crystals or hard white masses with the characteristic odour of garlic. Soluble 1 in 3.4 of water, 1 in 510 of alcohol, 1 in 175 of chloroform, and 1 in 180 of ether; slightly soluble in benzene. A 2% solution in water has a pH of 9.5 to 10.5. Store at 15° to 30°. Protect from light.

Profile

Sodium formaldehyde sulfoxylate is an antoxidant used as a preservative in pharmaceuticals. It has been used in the treatment of acute mercury poisoning (p.2342).

Sodium Hypochlorite

Hipoclorito sódico.

Гипохлорит Натрия

$NaOCl,5H_2O = 164.5$.

CAS — 7681-52-9.

ATC — D08AX07.

ATC Vet — QD08AX07.

NOTE. The term ‘liquid chlorine’ has been used for solutions of sodium hypochlorite. These should not be confused with the pressurised form of chlorine gas (p.1638) which is also liquid and has been referred to similarly.

Pharmacopoeias. *Br., Fr.,* and *US* include sodium hypochlorite solutions.

BP 2008 (Dilute Sodium Hypochlorite Solution). It contains 1% of available chlorine. Store away from acids at a temperature not exceeding 20°. Protect from light.

BP 2008 (Strong Sodium Hypochlorite Solution). It contains not less than 8% of available chlorine. It should be diluted before use. Store away from acids at a temperature not exceeding 20°. Protect from light.

USP 31 (Sodium Hypochlorite Solution). It contains not less than 4% and not more than 6% w/w of anhydrous sodium hypochlorite. It is not suitable for application to wounds. Store in airtight containers. Protect from light.

USP 31 (Sodium Hypochlorite Topical Solution). It contains 0.025% sodium hypochlorite. Store in airtight containers. Protect from light.

Incompatibility. The antimicrobial activity of hypochlorites is rapidly reduced in the presence of organic material; it is also pH dependent being greater in acid pH although hypochlorites are more stable at alkaline pH.

Sodium hypochlorite solutions should not be mixed with solutions of strong acids or ammonia; the subsequent reactions release chlorine gas and tosylchloramide sodium gas, respectively.

Stability. The stability of sodium hypochlorite solutions increases with pH, solutions of pH 10 or more being most stable.[1] Stability studies have shown that solutions providing 0.04 to 0.12% ‘available chlorine’ stored in amber glass bottles at room temperature could carry a 23-month expiry date.[2]

1. Bloomfield SF, Sizer TJ. Eusol BPC and other hypochlorite formulations used in hospitals. *Pharm J* 1985; **235:** 153–5 and 157.
2. Fabian TM, Walker SE. Stability of sodium hypochlorite solutions. *Am J Hosp Pharm* 1982; **39:** 1016–17.

Adverse Effects

Hypochlorite solutions release hypochlorous acid upon contact with gastric juice and acids. Most patients ingesting hypochlorites will develop only mild gastrointestinal irritation. However, ingestion of small amounts of 3 to 5% hypochlorite solutions may result in irritation of the oropharynx, a burning sensation in the mouth and throat, and thirst. Nausea, vomiting, and haematemesis may occur. Ingestion of large amounts or more concentrated solutions causes irritation and corrosion of mucous membranes with chest and abdominal pain and tenderness, vomiting, haematemesis, watery diarrhoea and sometimes melaena. Ingestion of extremely large volumes may rarely cause hypernatraemia, hyperchloraemia, hypotension, and changes in mental status. In very severe cases ulceration or perforation of the oesophagus or stomach may occur leading to haemorrhage and shock.

Inhalation of the fumes is irritant to the eyes, nose, and respiratory tract. Sore throat, cough, bronchoconstriction, headache, ataxia, and confusion may develop. In severe cases dyspnoea and stridor due to laryngeal oedema may develop with breathlessness, wheeze, hypoxia, cyanosis, pneumonitis, and pulmonary oedema.

Hypochlorite solutions may be irritating to the skin and allergic contact dermatitis has been reported. Hypochlorite solutions may cause an alkali-type burn when splashed into the eye.

Effects on wound healing. For comment on the adverse effects of hypochlorite solutions on wound healing, see Disinfection: Wounds under Uses and Administration below.

Toxicity from mixing cleaning agents. Mixing the household cleaning agents bleach (5.25% sodium hypochlorite solution) and 4% phosphoric acid (p.2367) causes chlorine gas and water to be released. The chlorine in turn reacts with the water to form hydrochloric and hypochlorous acids. There have been case reports[1] of patients and hospital staff who have been accidentally exposed to chlorine gas as a result of mixing of these two cleaning agents. They had temporary illness and symptoms typical of chlorine toxicity; irritation of the eyes, nose and throat, headache, dizziness, nausea, cough, and chest pain or tightness. One patient had an acute exacerbation of asthma.

Tosylchloramide sodium gas is produced when common household cleaning agents containing sodium hypochlorite and ammonia (p.2256) are mixed together. On inhalation the water in the respiratory tract reacts with the tosylchloramide sodium gas to release ammonia, hydrochloric acid and oxygen free radicals. Numerous case reports have described the symptoms resulting from inhalation of these gases. A 12-month review[2] of 216 patients who reported to a regional poison information centre after exposure to tosylchloramide sodium gas as a result of mixing cleaning products found that only 1 patient, with a pre-existing respiratory-tract infection, required hospital admission for ongoing respiratory distress. The most frequent symptoms were cough and shortness of breath and other symptoms experienced were those commonly associated with exposure to chlorine gas (p.1638). Most (200) of the patients’ symptoms resolved within 6 hours and 145 patients were treated at home, while 71 were referred for further medical care. Oxygen was given to 62 patients, bronchodilators to 9 patients and 3 patients received corticosteroids. Similar symptoms and findings were reported[3] when 2 groups of 36 soldiers were exposed to tosylchloramide sodium gas as a result of mixing sodium hypochlorite and ammonia containing cleaning agents. Only 2 soldiers required hospital admission for persistent respiratory symptoms, with one of them requiring a few days of treatment in intensive care. Another case report[4] described a previously healthy 53-year-old woman who experienced shortness of breath progressing to pneumonitis and requiring emergency tracheostomy after a similar exposure to tosylchloramide sodium gas.

Toxicity during root canal irrigation. A review of case reports[1] where sodium hypochlorite had been inadvertently injected into the periapical tissues during root canal irrigation reported that most patients experienced immediate severe pain and swelling of the neighbouring soft tissue, which could possibly spread over the injured side of the face, upper lip and infra-orbital region. Other symptoms included bleeding from the root canal, interstitial bleeding with haemorrhage of the skin and mucosa, a chlorine taste, irritation of the throat, and reversible anaesthesia or paraesthesia.

1. Hülsmann M, Hahn W. Complications during root canal irrigation—literature review and case reports. *Int Endod J* 2000; **33:** 186–93.

Treatment of Adverse Effects

If sodium hypochlorite solution is ingested symptomatic care, including dilution with water, milk, or other demulcents should be given; opinion over the use of antacids is divided. Sodium thiosulfate 1 to 2.5% solution has been used but is of little or no value. If spilled on skin or eyes, washing with copious amounts of water is recommended.

Poisoning. A patient who accidentally received an intravenous infusion of 150 mL of a 1% solution of sodium hypochlorite experienced a slow heart rate, mild hypotension, and increased respiratory rate. The slow heart rate persisted for 3 days but other parameters returned to normal after symptomatic treatment.[1]

1. Marroni M, Menichetti F. Accidental intravenous infusion of sodium hypochlorite. *DICP Ann Pharmacother* 1991; **25:** 1008–9.

Precautions

Topically applied hypochlorites may dissolve blood clots and cause bleeding.

Uses and Administration

Sodium hypochlorite is a disinfectant and antiseptic with the brief and rapid actions of chlorine (see p.1638). Sodium hypochlorite pentahydrate contains about 43% of ‘available chlorine’ (see p.1638); anhydrous sodium hypochlorite contains about 95%. Powders and solutions are commonly used for the rapid disinfection of hard surfaces (see Disinfection in Creutzfeldt-Jakob Disease, p.1622 and in Hepatitis and HIV Infection, p.1623), food and dairy equipment, babies’ feeding bottles, excreta, and water (p.1623). Solutions for use as domestic bleaches contain up to 5.25% of hypochlorite. Only diluted solutions containing up to 0.5% of ‘available chlorine’ are suitable for use on the skin and in wounds (but see Wound Disinfection, p.1624). Sodium hypochlorite solutions ranging from 0.5 to 5.25% are used in dentistry for root canal irrigation.

Solutions of hypochlorites used as disinfectants have included Labarraque’s Solution containing sodium hypochlorite with an alkali, and Eau de Javel, containing sodium or potassium hypochlorite.

Disinfection. *INSTRUMENTS.* Needles and syringes should not usually be sterilised chemically. However, cleaning of injection equipment with hypochlorite has been suggested as a last resort in the absence of sterile equipment, to reduce the risk of HIV transmission associated with the enforced re-use of injection equipment by injection drug users.[1] Use of full-strength domestic bleach (about 5% sodium hypochlorite, about 2% of ‘available chlorine’) was reported to be effective for the cleaning of intravenous drug users’ equipment; a 30-second contact time was required.[1,2] A 1 in 10 dilution of bleach was not effective after exposure for 5 minutes.[2] Despite rinsing with water, a low residual concentration of hypochlorite and microaggregates of blood are likely to remain on the cleaned instruments. Free chlorine is a potent oxidant and low concentrations of oxidants have been shown to enhance tissue inflammation *in vivo* as well as HIV-1 replication *in vitro*. This has led some researchers to suggest that there may be an increased possibility of an injection drug user contracting HIV-1 through the sharing of a bleach-cleaned blood-contaminated syringe as a consequence of the concomitant transmission of residual bleach; however, there is no epidemiological evidence to confirm this.[3]

2. Watters JK, *et al.* Household bleach as disinfectant for use by injecting drug users. *Lancet* 1993; **342:** 742–3.
3. Contoreggi C, *et al.* Effects of varying concentrations of bleach on in vitro HIV-1 replication and the relevance to injection drug use. *Intervirology* 2000; **43:** 1–5.

WORMS. Sodium hypochlorite in aqueous solution at a concentration of 3.75% (or greater) is an effective ovicide for *Echinococcus* and may be used on hard surfaces, glassware, and sinks.[1]

1. Craig PS, Macpherson CNL. Sodium hypochlorite as an ovicide for Echinococcus. *Ann Trop Med Parasitol* 1988; **82:** 211–13.

WOUNDS. Hypochlorite solutions are now generally considered to be too irritant for use in the management of wounds (p.1585). Studies suggest that they may delay wound healing if repeatedly applied to open wounds.[1,2] It has been suggested that they may be of use in debriding burns (p.1578) or necrotic chronic wounds,[3] but also that any benefit that might be seen from the desloughing of necrotic tissue might be produced by damage of the superficial cell layer leading to separation[4] or from tissue hydration produced by wet dressing packs.[5] However, some burns units have found that hypochlorite as Dakin's solution (see Chlorinated Lime, p.1638) produces better healing than other antibacterials.[6]

Sodium Nitrate

E251; Natrii Nitras; Natrium Nitricum; Nitrato sódico; Sodu azotan.
$NaNO_3$ = 84.99.
CAS — 7631-99-4.

NOTE. Crude sodium nitrate is known as Chile Saltpetre.

Profile

Sodium nitrate has similar actions to potassium nitrate (p.1658) and is used as a preservative in foods, particularly in meat products.

Crude sodium nitrate is used as a fertiliser.

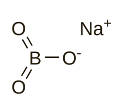
Handling. Sodium nitrate has been used for the illicit preparation of explosives or fireworks; care is required with its supply.

Poisoning. Cyanosis and methaemoglobinaemia has been reported[1] in 3 patients after eating sausages that had been preserved mistakenly with a mixture of sodium nitrate and sodium nitrite rather than with potassium nitrate (saltpetre). The name saltpetre is used as a generic term for a number of potassium- or sodium-based preservatives used in food manufacture.

1. Kennedy N, *et al.* Faulty sausage production causing methaemoglobinaemia. *Arch Dis Child* 1997; **76:** 367–8.

Sodium Perborate Monohydrate *(USAN)*

$NaBO_3,H_2O$ = 99.81.
CAS — 7632-04-4 (anhydrous sodium perborate); 10332-33-9 (sodium perborate monohydrate).
ATC — A01AB19.
ATC Vet — QA01AB19.



(anhydrous)

Sodium Perborate

Natrii perboras; Natrio perboratas; Natriumperboraatti; Natriumperborat; Nátrium-perborát; Perborato sódico; Perboritan sodný; Sod. Perbor.; Sodium, perborate de; Sodium Perborate Tetrahydrate.
$NaBO_3,4H_2O$ = 153.9.
CAS — 10042-94-1.
ATC — A01AB19.
ATC Vet — QA01AB19.

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Sodium Perborate, Hydrated; Sodium Perborate BP 2008). Colourless prismatic crystals or a white or almost white powder, stable in crystalline form. Sparingly soluble in water, with slow decomposition. It dissolves in dilute mineral acids. Store in airtight containers.

Adverse Effects

Frequent use of toothpowders containing sodium perborate may cause blistering and oedema. Hypertrophy of the papillae of the tongue has also been reported. The effects of swallowed sodium perborate are similar to those of boric acid (p.2268).

Uses and Administration

Sodium perborate is a mild disinfectant and deodorant. It readily releases oxygen in contact with oxidisable matter and has been used in aqueous solutions for purposes similar to weak solutions of hydrogen peroxide.

Sodium perborate is used for tooth whitening and has also been used, with calcium carbonate, as a toothpowder. A freshly prepared solution is used as a mouthwash.

The monohydrate is used similarly.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Hifamonil; ***Canad.:*** Amosan; ***India:*** Steradent; ***Ital.:*** Kavosan†; ***Neth.:*** Bocasan; ***USA:*** Amosan.

Multi-ingredient: ***Arg.:*** Oral-B Enjuague Bucal Amosan†; ***Austral.:*** Amosan; ***Belg.:*** Amosan; ***Braz.:*** Anginotricin; Malvatricin Branqueador; Oticerim; ***Fr.:*** Bactident; Hydralin; ***Hong Kong:*** Hydralin; ***Spain:*** Lema C; ***Switz.:*** Saltrates Rodell†; ***USA:*** Trichotine; ***Venez.:*** Novafix.

Sodium Percarbonate

Percarbonato sódico; Sodium Carbonate Peroxide.
$Na_2CO_3,1\frac{1}{2}H_2O_2$ = 157.0.
CAS — 15630-89-4.

Profile

Sodium percarbonate has similar uses to sodium perborate (above).

Preparations

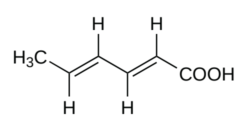
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Arg.:*** Ascoxal†; ***Austral.:*** Ascoxal; ***Fin.:*** Ascoxal†; ***Mex.:*** Ascoxal; ***Norw.:*** Ascoxal†; ***Swed.:*** Ascoxal†; ***Switz.:*** Desaquick forte†.

Sorbates

Sorbatos.

Sorbic Acid

Acide sorbique; Acidum sorbicum; E200; Kwas sorbowy; Kyselina sorbová; Sórbico, ácido; Sorbiinihappo; Sorbinsyra; Sorbo rūgštis; Szorbinsav. (*E,E*)-Hexa-2,4-dienoic acid.
$C_6H_8O_2$ = 112.1.
CAS — 22500-92-1.



Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Sorbic Acid). A white or almost white, crystalline powder. Slightly soluble in water; freely soluble in alcohol. Protect from light.
USNF 26 (Sorbic Acid). A free-flowing white crystalline powder with a characteristic odour. Soluble 1 in 1000 of water, 1 in 10 of alcohol, 1 in 8 of dehydrated alcohol, 1 in 15 of chloroform, 1 in 30 of ether, 1 in 8 of methyl alcohol, and 1 in 19 of propylene glycol. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Incompatibility. The incompatibility of sorbates is discussed under Potassium Sorbate, below.

Potassium Sorbate

E202; Kalii sorbas; Kalio sorbatas; Kaliumsorbaatti; Kaliumsorbat; Kalium-sorbát; Kálium-szorbát; Potassium, sorbate de; Sorbato potásico. Potassium (*E,E*)-hexa-2,4-dienoate.
$C_6H_7KO_2$ = 150.2.
CAS — 590-00-1; 24634-61-5.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Potassium Sorbate). White or almost white granules or powder. Very soluble in water; slightly soluble in alcohol. Protect from light.
USNF 26 (Potassium Sorbate). White crystals or powder with a characteristic odour. Soluble 1 in 4.5 of water, 1 in 35 of alcohol, and 1 in more than 1000 of chloroform and of ether. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Incompatibility. Sorbic acid can be inactivated by oxidation and to some extent by nonionic surfactants and plastics. Activity of the sorbates may be reduced by increases in pH.[1]

1. Cook W. Sorbic acid. In: Rowe RC, *et al.*, eds. *Handbook of pharmaceutical excipients.* 5th ed. London and Chicago: The Pharmaceutical Press and the American Pharmaceutical Association, 2006: 710–12.

Adverse Effects and Precautions

The sorbates can be irritant and have caused contact dermatitis.

Hypersensitivity. References to allergic-type skin reactions[1] and non-allergic irritant-type reactions[2,3] with potassium sorbate or sorbic acid.

1. Saihan EM, Harman RRM. Contact sensitivity to sorbic acid in 'Unguentum Merck'. *Br J Dermatol* 1978; **99:** 583–4.
2. Soschin D, Leyden JJ. Sorbic acid-induced erythema and edema. *J Am Acad Dermatol* 1986; **14:** 234–41.
3. Fisher AA. Erythema limited to the face due to sorbic acid. *Cutis* 1987; **40:** 395–7.

Uses

Potassium sorbate and sorbic acid possess antifungal, and to a lesser extent antibacterial, activity. They are relatively ineffective above a pH of about 6. They are used as preservatives in pharmaceutical preparations in concentrations of up to 0.2%, in enteral formulas, foods, and in cosmetic preparations.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austral.:*** Caprilate; ***Ger.:*** Klysma Sorbit; Saseem; ***Ital.:*** Evasen Dischetti; Evasen Liquido; ***Mex.:*** Adapettes; ***UK:*** Relaxit; ***USA:*** Clear Eyes Contact Lens Relief; ***Venez.:*** Saxacid.

Sulfites and Sulfur Dioxide

Sulfitos y dióxido de azufre.

Potassium Bisulfite

Bisulfito potásico; E228; Potassium Bisulphite; Potassium Hydrogen Sulphite.
$KHSO_3$ = 120.2.
CAS — 7773-03-7.

Potassium Metabisulfite

Dipotassium Pyrosulphite; Disiřičitan draselný; E224; Kalii Disulfis; Kalii metabisulfis; Kalio metabisulfitas; Kaliummetabisulfiitti; Kaliummetabisulfit; Metabisulfito potásico; Potassium, métabisulfite de; Potassium Metabisulphite; Potassium Pyrosulphite; Potasu pirosiarczyn.
$K_2S_2O_5$ = 222.3.
CAS — 16731-55-8.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Potassium Metabisulphite). A white or almost white powder or colourless crystals. Freely soluble in water; slightly soluble in alcohol. A 5% solution in water has a pH of 3.0 to 4.5. Store in airtight containers. Protect from light.
USNF 26 (Potassium Metabisulfite). White or colourless, free-flowing crystals, crystalline powder, or granules, usually with an odour of sulfur dioxide. Gradually oxidises in air to the sulfate. Soluble in water; insoluble in alcohol. Its solutions are acid to litmus. Store in well-filled airtight containers at a temperature not exceeding 40°.

Incompatibility and stability. The incompatibility and stability of sulfites are discussed under Sulfur Dioxide, below.

Sodium Bisulfite

Bisulfito sódico; E222; Sodium Bisulphite; Sodium Hydrogen Sulphite.
$NaHSO_3$ = 104.1.
CAS — 7631-90-5.

Pharmacopoeias. In *Chin.* and *Jpn*, described in both as consisting of a mixture of sodium bisulfite and sodium metabisulfite.

Sodium Metabisulfite

Disiřičitan sodný; Disodium Pyrosulphite; E223; Metabisulfito sódico; Natrii Disulfis; Natrii metabisulfis; Natrii Pyrosulfis; Natrio metabisulfitas; Nátrium-diszulfit; Natriummetabisulfiitti; Natriummetabisulfit; Sodium Disulphite; Sodium, métabisulfite de; Sodium Metabisulphite; Sodium Pyrosulphite; Sodu pirosiarczyn.
$Na_2S_2O_5$ = 190.1.
CAS — 7681-57-4.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Sodium Metabisulphite). Colourless crystals or a white or almost white crystalline powder. Freely soluble in water; slightly soluble in alcohol. A 5% solution in water has a pH of 3.5 to 5.0. Protect from light.
USNF 26 (Sodium Metabisulfite). White crystals or a white to yellowish crystalline powder with an odour of sulfur dioxide. Freely soluble in water and in glycerol; slightly soluble in alcohol. Store in well-filled airtight containers at a temperature not exceeding 40°.

Incompatibility and stability. The incompatibility and stability of sulfites are discussed under Sulfur Dioxide, below.

Sodium Sulfite

Anhydrous Sodium Sulphite; E221; Exsiccated Sodium Sulphite; Natrii Sulfis; Natrii sulfis anhydricus; Natrii Sulfis Siccatus; Natrii Sulphis; Natrio sulfitas, bevandenis; Natriumsulfiitti, vedetön; Natriumsulfit, vattenfritt; Siřičitan sodný; Sodium (sulfite de) anhydre; Sodium Sulphite; Sodu siarczyn; Sulfito sódico; Vízmentes nátrium-szulfit.

Na_2SO_3 = 126.0.
CAS — 7757-83-7.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn.* Also in *USNF.*
Eur. also includes the heptahydrate.

Ph. Eur. 6.2 (Sodium Sulphite, Anhydrous; Natrii Sulfis Anhydricus). A white or almost white powder. Freely soluble in water; very slightly soluble in alcohol. Store in airtight containers.

Ph. Eur. 6.2 (Sodium Sulphite Heptahydrate; Natrii Sulfis Heptahydricus). Colourless crystals. Freely soluble in water; very slightly soluble in alcohol.

USNF 26 (Sodium Sulfite). Colourless crystals. Freely soluble in water; very slightly soluble in alcohol. Store in airtight containers.

Incompatibility and stability. The incompatibility and stability of sulfites are discussed under Sulfur Dioxide, below.

Sulfur Dioxide

Dióxido de azufre; E220; Kükürt Dioksit; Siarki dwutlenek; Sulphur Dioxide.

SO_2 = 64.06.
CAS — 7446-09-5.

Pharmacopoeias. In *USNF.*

USNF 26 (Sulfur Dioxide). A colourless non-flammable gas with a strong suffocating odour characteristic of burning sulfur. It condenses readily under pressure to a colourless liquid that boils at –10° and has a wt per mL of about 1.5 g. Soluble 36 in 1 of water and 114 in 1 of alcohol by vol. at 20° and standard pressure. Soluble in chloroform and in ether. Store in cylinders. It is usually packaged under pressure in liquid form.

Incompatibility and stability. Sulfite antoxidants can react with and inactivate sympathomimetics such as adrenaline.[1] Measures need to be taken to prevent such a reaction if sulfites have to be used. Cisplatin is another compound that can be inactivated.[2] Phenylmercuric nitrate may be inactivated or its activity enhanced.[3,4] Sulfites are reported to react with chloramphenicol.[1] Hydrogen peroxide generation has been reported on exposure to light of amino acid solutions containing sulfites.[5] When used in foods there can be a noticeable taste and a reduction in thiamine content.[6] Stability is affected by air and moisture,[7] and there is decomposition at very low pH.[7] There can be adsorption on to rubber closures.[8]

Adverse Effects and Precautions

Gastric irritation due to liberation of sulfurous acid can follow ingestion of sodium metabisulfite and other sulfites. Large doses of sulfites may cause gastrointestinal upsets, respiratory or circulatory failure, and CNS disturbances.

Concentrated solutions of salts of sulfurous acid are irritant to skin and mucous membranes.

Sulfur dioxide is highly irritant to the eyes, skin, and mucous membranes. Inhalation results in irritation of the respiratory tract which may lead to bronchoconstriction and pulmonary oedema; very high concentrations may cause respiratory arrest and asphyxia. Contact with liquid sulfur dioxide results in acid burns.

Allergic reactions including anaphylaxis and deaths have been reported.

Hypersensitivity. Hypersensitivity reactions including bronchospasm, anaphylaxis, and some deaths have occurred in subjects, especially those with a history of asthma or atopic allergy, exposed to sulfites used as preservatives in foods.[1] These reactions have led to restrictions by the FDA on such use.[2] There have been case reports of reactions to sulfites in medicines;[3-9] such reports are considered to be few in number and the FDA has not extended the restriction on sulfites in foods to apply to their use in drugs since it was felt that in certain cases there was no suitable alternative to a sulfite.[2] It was even accepted that adrenaline recommended for use in treating allergic reactions could itself contain sulfite and that its presence should not preclude use of the adrenaline preparation even in sulfite-sensitive patients.[2]

Pharmacokinetics

Sulfites and metabisulfites are oxidised in the body to sulfate and excreted in the urine. Any sulfurous acid or sulfur dioxide is also converted to sulfate.

Uses

Sulfur dioxide and the sulfites that produce sulfur dioxide and sulfurous acid are strong reducing agents and are used as antoxidants. Concentrations of the sulfites in pharmaceutical preparations have ranged from 0.01 to 1.0%. At higher concentrations and preferably at an acid pH sulfur dioxide and the sulfites exhibit antimicrobial activity.

Sulfur dioxide and the sulfites are used in the food industry as antoxidants, antimicrobial preservatives, and anti-browning agents. They are used in wine making where tabletted sodium metabisulfite is commonly known as Campden Tablets. Concentrations of sulfites above 500 ppm impart a noticeable unpleasant taste to preparations. There is concern over the risk of severe allergic reactions arising from the use of sulfites in foods (see Hypersensitivity, above).

Tar Acids

Alquitrán, ácidos de.

Description. Tar acids are phenolic substances derived from the distillation of coal tar or petroleum fractions. The lowest boiling fraction of coal tar, distilling at 188° to 205°, consists of mixed cresol isomers. The middle fraction, known as 'cresylic acids', distils at 205° to 230° and consists of cresols and xylenols. The 'high-boiling tar acids', distilling at 230° to 290°, consist mainly of alkyl homologues of phenol, with naphthalenes and other hydrocarbons. Cresol is described on p.1641.

- **Black Fluids** are homogeneous solutions of coal-tar acids, or similar acids derived from petroleum, or any mixture of these, with or without hydrocarbons and with a suitable emulsifying agent.
- **White Fluids** are finely dispersed emulsions of coal-tar acids, or similar acids derived from petroleum, or any mixture of these, with or without hydrocarbons.
- **Modified Black Fluids** and **Modified White Fluids** may contain, as an addition, any other active ingredients, but if these are used, the type and amount must be disclosed, if required.

Adverse Effects and Treatment

As for Phenol, p.1656.

Tar acids are generally very irritant and corrosive to the skin, even when diluted to concentrations used for disinfection.

Poisoning. A report of fatal self-poisoning in a 59-year-old man after the ingestion of about 250 mL of a xylenol-containing disinfectant (*Stericol Hospital Disinfectant*).[1]

1. Watson ID, *et al.* Fatal xylenol self-poisoning. *Postgrad Med J* 1986; **62:** 411–12.

Uses

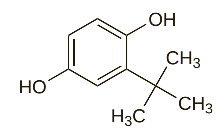
Tar acids are the phenolic components of coal tar and are used in the preparation of a range of fluids of varied activity used for household and general disinfection purposes.

Hydrocarbons are often used to enhance the activity of the tar acids in disinfectant fluids; they also help to reduce crystallisation of phenols.

Tertiary Butylhydroquinone

Butilhidroquinona terciaria; TBHQ. 2-*tert*-butylhydroquinone.

$C_{10}H_{14}O_2$ = 166.2.
CAS — 1948-33-0.



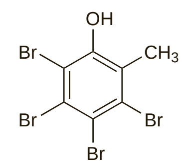
Profile

Tertiary butylhydroquinone is an antoxidant preservative used in foods. It has some antimicrobial activity.

Tetrabromocresol

3,4,5,6-Tetrabromo-*o*-cresol.

$C_7H_4Br_4O$ = 423.7.
CAS — 576-55-6.



Profile

Tetrabromocresol is a brominated phenolic antiseptic. It has been used for hand disinfection and is applied topically in preparations for the treatment of fungal infections of the skin and bromhidrosis.

Preparations

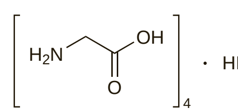
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austral.:*** Pedoz; ***Ger.:*** Gehwol Fungizid†.

Tetraglycine Hydroperiodide

Tetraglicina, hidroperioduro de.

Гидропериодид Тетраглицина

$C_{16}H_{42}I_7N_8O_{16}$ = 1490.9.
CAS — 7097-60-1.



Profile

Tetraglycine hydroperiodide is an iodine-based disinfectant that is used in the emergency treatment of drinking water (p.1623).

Preparations

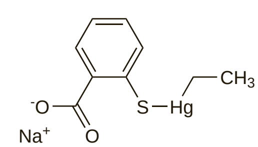
Proprietary Preparations (details are given in Part 3)
UK: Potable Aqua; ***USA:*** Potable Aqua.

Thiomersal *(BAN, rINN)*

Mercurothiolate; Mercurothiolate Sodique; Sodium Ethyl Mercurithiosalicylate; Thimerosal; Thiomersalate; Thiomersalum; Tiomersaali; Tiomersal; Tiomersalis; Tiomerzál. Sodium (2-carboxyphenylthio)ethylmercury.

Тиомерсал

$C_9H_9HgNaO_2S$ = 404.8.
CAS — 54-64-8.
ATC — D08AK06.
ATC Vet — QD08AK06.



The symbol † denotes a preparation no longer actively marketed

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Thiomersal). A white or almost white crystalline powder. Freely soluble in water; sparingly soluble or soluble in alcohol; practically insoluble in dichloromethane. A 0.8% solution in water has a pH of 6.0 to 8.0. Protect from light.

USP 31 (Thimerosal). A light cream-coloured crystalline powder with a slight characteristic odour. Soluble 1 in 1 of water and 1 in 12 of alcohol; practically insoluble in ether. A 1% solution in water has a pH of about 6.7. Store in airtight containers. Protect from light.

Incompatibility. Thiomersal is incompatible with acids, metal ions, and iodine. It forms precipitates with many alkaloids. The rate of oxidation of thiomersal in solution is greatly increased by traces of copper ions. In slightly acid solution thiomersal may be precipitated as the corresponding acid which undergoes slow decomposition with the formation of insoluble products. The activity of thiomersal may also be reduced by boric acid, edetic acid, or sodium thiosulfate or by the presence of blood or organic matter. Thiomersal may be adsorbed by plastic or rubber packaging materials.

Hypersensitivity. Both delayed (allergic contact) and immediate (including anaphylaxis and immune complex mediated disorders) hypersensitivity reactions have been associated with thiomersal.[1] The frequency of positive patch tests varies, with a Canadian centre reporting[2] an average incidence of 4.53% and a centre in the USA an incidence of 8.7%.[3] Most reactions are local and mild, involving application sites or blepharoconjunctivitis from ocular preparations,[1,4] although there has been a report of acute laryngeal obstruction in a patient previously sensitised to the substance who used a throat spray preserved with thiomersal.[5] A case of occupational allergic contact dermatitis has been reported in a nurse as a result of contact with thiomersal as a preservative in childhood vaccines.[6] A generalised maculopapular eruption from an influenza vaccine containing thiomersal has also been reported.[7] The main source of sensitisation is thought to be thiomersal-preserved vaccines. Most people with patch tests positive to thiomersal are able to tolerate thiomersal-containing vaccines, although some individuals may experience reactions ranging from mild to serious.[1] If there is a definite history of anaphylaxis to thiomersal in any product, vaccines containing thiomersal should not be given. However, while anaphylaxis has not been shown to occur as a result of thiomersal in vaccines, it remains a theoretical risk.[1]

Poisoning. Serious adverse effects have followed parenteral and topical use of thiomersal.

Six poisonings (5 fatal) resulted from the use of 1000 times the normal concentration of thiomersal in a preparation of chloramphenicol for intramuscular injection.[1] There has also been a case report[2] of mercury poisoning associated with the intravenous use of high-dose hepatitis B immunoglobulin, preserved with thiomersal, after liver transplantation. Initial symptoms were paranoia, which rapidly progressed to severe dysarthria, static tremor, chorea, and decreased motor strength, as well as haemorrhagic gastritis. The patient responded well to chelation therapy.

Thiomersal used in topical antiseptic preparations was found to be toxic to epidermal cells.[3] After the death of 10 of 13 children as a result of treatment of omphaloceles (umbilical hernia) with a tincture of thiomersal, it was recommended that organic mercurial disinfectants be heavily restricted or withdrawn from hospital use as absorption occurred readily through intact membranes.[4]

A 44 year-old man who drank 83 mg/kg of a thiomersal-containing solution in an attempted suicide, spontaneously vomited after 15 minutes.[5] On admission to hospital a gastric lavage was performed and chelating drugs given. Despite this he developed gastritis, renal failure, dermatitis, gingivitis, delirium, polyneuropathy, respiratory failure, and coma. The patient was treated symptomatically, and 148 days after ingestion had recovered fully, except for sensory defects in two toes.

Vaccines. The use of thiomersal as a preservative in vaccines and its role as a possible cause of autism and neurodevelopmental disorders has been a controversial topic since 1999[1] when the regulatory authorities in both Europe[2] and the USA[3] issued statements recommending that the use of thiomersal in vaccines be phased out. This was based on the fact that the cumulative amount of mercury in the infant immunisation schedule potentially exceeds the recommended maximum level set by the US government for methyl mercury. More recently, however, a number of studies[4] have indicated a lack of association between thiomersal-containing vaccines and neurodevelopmental disorders such as autism and speech disorders. These findings were supported by the fact that thiomersal is metabolised to ethylmercury, which has substantially different pharmacokinetics to methylmercury. Ethylmercury is more rapidly excreted and does not accumulate in the body. The EMEA has issued a further statement[5] in which it confirmed that thiomersal could be used as a preservative when no alternative was available, subject to certain labelling requirements regarding hypersensitivity. The UK CSM[6] and the US FDA[7] have similarly concluded that there is no evidence of neurological adverse effects caused by the small amounts of thiomersal present in some vaccines; despite this, both endorse the view that the use of vaccines without thiomersal would be a prudent precautionary measure. WHO states[8,9] that there is no compelling scientific evidence of safety problems and advises that thiomersal-containing vaccines may continue to be used for global immunisation programmes because the benefit outweighs any theoretical risk of toxicity.

Interactions

Tetracyclines. Nine patients using a contact lens solution containing 0.004% thiomersal developed varying degrees of ocular irritation after taking oral *tetracyclines* concurrently. Exposure to either the tetracyclines or thiomersal alone did not cause the response.[1]

1. Crook TG, Freeman JJ. Reactions induced by the concurrent use of thimerosal and tetracycline. *Am J Optom Physiol Opt* 1983; **60:** 759–61.

Uses and Administration

Thiomersal is a bacteriostatic and fungistatic mercurial antiseptic that has been applied topically usually in a concentration of 0.1%. Its antibacterial action results from the release of ethylmercury after breakdown to thiosalicylate and ethylmercury.

Thiomersal, 0.001 to 0.01%, is used as a preservative in biological and pharmaceutical products. It has also been used to preserve solutions used in the care of contact lenses (p.1622).

Preparations

USP 31: Thimerosal Tincture; Thimerosal Topical Aerosol; Thimerosal Topical Solution.

Proprietary Preparations (details are given in Part 3)
Arg.: Lithiorsan; Merthiolate; ***Chile:*** Intrasept; ***Mon.:*** Vitaseptol; ***S.Afr.:*** Merthiolate; Thiomersalate; ***Thai.:*** Merthiolate†; ***USA:*** Aeroaid; Mersol; ***Venez.:*** Merthiolate.

Multi-ingredient: ***Spain:*** Proskin; ***Venez.:*** Thimerfesa†.

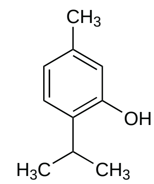
Thymol

Acido Timico; Isopropylmetacresol; Thymolum; Timol; Timolis; Tymol; Tymoli. 2-Isopropyl-5-methylphenol.

$C_{10}H_{14}O = 150.2.$

CAS — 89-83-8.

ATC Vet — QP53AX22.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Thymol). Colourless crystals. The melting range is 48° to 52°. Very slightly soluble in water; very soluble in alcohol; freely soluble in volatile and in fixed oils; sparingly soluble in glycerol; dissolves in dilute solutions of alkali hydroxides. Protect from light.

USNF 26 (Thymol). Colourless, often large, crystals or a white crystalline powder with an aromatic thyme-like odour. The melting range is 48° to 51°; when melted it remains liquid at a considerably lower temperature. Soluble 1 in 1000 of water, 1 in 1 of alcohol and of chloroform, 1 in 1.5 of ether, and 1 in 2 of olive oil; soluble in glacial acetic acid and in fixed and volatile oils. Store in airtight containers. Protect from light.

Incompatibility. The antimicrobial activity of thymol is reduced by combination with protein.

Adverse Effects, Treatment, and Precautions

As for Phenol, p.1656.

When ingested, thymol is less toxic than phenol. It is irritant to the gastric mucosa. Fats and alcohol increase absorption and aggravate the toxic symptoms.

Hypersensitivity. Contact allergy to a heparinoid cream was due to an allergen formed by the reaction between thymol and the degradation products of a triazine derivative, both present as preservatives.[1]

1. Smeenk G, *et al.* Contact allergy to a reaction product in Hirudoid cream: an example of compound allergy. *Br J Dermatol* 1987; **116:** 223–31.

Uses and Administration

Thymol is a phenolic antiseptic with antibacterial and antifungal activity. It is more powerful than phenol but its use is limited by its low solubility in water, irritancy, and susceptibility to protein.

Thymol is used chiefly as a deodorant in mouthwashes and gargles such as Compound Thymol Glycerin (BP 1988), an aqueous mixture of thymol 0.05% and glycerol 10% with colouring and flavouring, which may be used diluted with about 3 times its volume of warm water before use. Thymol has been used topically in the treatment of skin disorders and is also inhaled, with other volatile substances, for colds, coughs, and associated respiratory disorders.

Thymol 0.01% is added as an antoxidant to halothane, trichloroethylene, and tetrachloroethylene.

Thymol iodide is used in preparations for dental hygiene.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Medophyll†; ***S.Afr.:*** Cool Mint Listerine; Freshburst Listerine.

Tosylchloramide Sodium *(BAN, rINN)*

Chloramidum; Chloramina; Chloramine; Chloramine T; Chloraminum; Cloramina; Klóramin; Mianin; Natrium Sulfaminochloratum; Tosilchloramido natrio druska; Tosilcloramida sódica; Tosylchloramid sodná sůl trihydrát; Tosylchloramide sodique; Tosylchloramidum natricum; Tosylchloramidum Natricum Trihydricum; Tosylkloramidnatrium; Tosyylikloramidinatrium. Sodium *N*-chlorotoluene-*p*-sulphonimidate trihydrate.

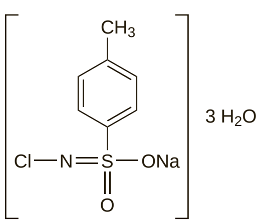
Тозилхлорамид Натрий

$C_7H_7ClNNaO_2S,3H_2O$ = 281.7.

CAS — 144-86-5 (tosylchloramide); 127-65-1 (tosylchloramide sodium).

ATC — D08AX04.

ATC Vet — QD08AX04.



NOTE. The name Chloramin has also been formerly used for a preparation of chlorphenamine maleate (p.571).

Pharmacopoeias. In *Eur.* (see p.vii) and *Viet.*

Ph. Eur. 6.2 (Tosylchloramide Sodium). A white or slightly yellow, crystalline powder. Freely soluble in water; soluble in alcohol. A 5% solution in water has a pH of 8.0 to 10.0. Store in airtight containers. Protect from light.

Adverse Effects and Treatment

Vomiting, cyanosis, circulatory collapse, frothing at the mouth, and respiratory failure can occur within a few minutes of tosylchloramide sodium ingestion. Fatalities have occurred. Tosylchloramide sodium in tap water has caused methaemoglobinaemia and haemolysis in patients undergoing dialysis. Bronchospasm has occurred after inhalation.

Treatment of adverse effects is similar to that for Sodium Hypochlorite, p.1661.

Effects on the lungs. A study in Finland in dental staff who had reported occupational respiratory hypersensitivity between 1990 and 1998 found that 1 of 28 cases of rhinitis and 3 of 28 cases of asthma could be attributed to tosylchloramide sodium.[1] For further reference to respiratory effects associated with tosylchloramide sodium gas, see under Sodium Hypochlorite: Toxicity from mixing cleaning agents, p.1661.

1. Piirilä P, *et al.* Occupational respiratory hypersensitivity in dental personnel. *Int Arch Occup Environ Health* 2002; **75:** 209–16.

Uses and Administration

Tosylchloramide sodium is an organic chlorine-releasing compound. It has general properties similar to those of chlorine (p.1638) but is more stable. It contains about 25% w/w of 'available chlorine' (see p.1638). It is stable at an alkaline pH although it is much more active in acid media. It is more slowly active than hypochlorite solutions.

Tosylchloramide sodium is used for the treatment of minor wound infections and as a skin and hard surface disinfectant. It is also used for the treatment of drinking water (p.1623). It was formerly used as a spermicide.

Tosylchloramide sodium B (chlorogenium; sodium *N*-chlorobenzenesulphonimidate sesquihydrate) has been used similarly to tosylchloramide sodium.

Preparations

Proprietary Preparations (details are given in Part 3)

Belg.: Chloraseptine; Chlorazol; Chloronguent; Clonazone; ***Fr.:*** Hydroclonazone; ***Ger.:*** Chloramin T; Clorina; Trichlorol; ***Hung.:*** Neomagnol; ***Ital.:*** Amuclor Med; Citromed Chlor; Dermedal; Euclorina; Minachlor; Ottoclor†; Steridrolo; ***Spain:*** Clorina.

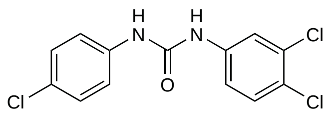
Triclocarban *(USAN, rINN)*

NSC-72005; TCC; 3,4,4′-Trichlorocarbanilide; Triclocarbán; Triclocarbanum. 1-(4-Chlorophenyl)-3-(3,4-dichlorophenyl)urea.

Триклокарбан

$C_{13}H_9Cl_3N_2O$ = 315.6.

CAS — 101-20-2.



Adverse Effects and Precautions

When subjected to prolonged high temperatures triclocarban can decompose to form toxic chloroanilines, which can be absorbed through the skin and cause methaemoglobinaemia. Mild photosensitivity has been seen in patch testing.

Uses and Administration

Triclocarban is an anilide antiseptic. It is bacteriostatic against Gram-positive organisms but is not effective against Gram-negative organisms. It inhibits growth of some fungi. It is used in antiperspirants and soaps for disinfection of skin and mucous membranes.

Preparations

Proprietary Preparations (details are given in Part 3)

Arg.: Jabobip†; Sodorant; Ungel; ***Braz.:*** Derso TCC†; ***Fr.:*** Cutisan; Nobacter; Solubacter; ***Gr.:*** Antibacter Forte; ***Ital.:*** Citrosil Sapone; Sangen Sapone Disinfettante; ***Mex.:*** Nutegen A†; ***UK:*** Valderma; ***USA:*** Cuticura†.

Multi-ingredient: ***Arg.:*** Bacteroskin†; LB Jabon con Purcelin†; Sodorant; ***Braz.:*** Soapex; ***Fr.:*** Septosan; Spray du Marcheur; ***Ger.:*** Ansudor†; ***Mex.:*** Septosan; ***Switz.:*** Septivon N.

Triclosan *(BAN, USAN, rINN)*

CH-3565; Cloxifenol; Triclosán; Triclosanum. 5-Chloro-2-(2,4-dichlorophenoxy)phenol; 2,4,4′-Trichloro-2′-hydroxydiphenyl ether.

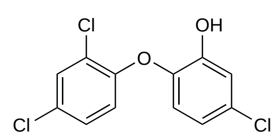
Триклозан

$C_{12}H_7Cl_3O_2$ = 289.5.

CAS — 3380-34-5.

ATC — D08AE04; D09AA06.

ATC Vet — QD08AE04; QD09AA06.



Pharmacopoeias. In *US.*

USP 31 (Triclosan). A fine whitish crystalline powder. M.p. about 57°. Practically insoluble in water; soluble in alcohol, in acetone, and in methyl alcohol; slightly soluble in petroleum spirit. Store in airtight containers. Protect from light.

Profile

Triclosan is a chlorinated bisphenol antiseptic, effective against Gram-positive and most Gram-negative bacteria but with variable or poor activity against *Pseudomonas* spp. It is also active against fungi. It is used in soaps, creams, and solutions in concentrations of up to 2% for disinfection of the hands and wounds and for disinfection of the skin prior to surgery, injections, or venepuncture. It is also used in oral hygiene products and in preparations for acne. There have been isolated reports of contact dermatitis.

MRSA control. Control of meticillin-resistant *Staphylococcus aureus* (MRSA) infection in surgical units has been achieved by procedures including handwashing and bathing with triclosan.[1-3] In the UK, guidelines on the control of MRSA recommend it as one of several alternatives for such purposes,[4] although alcohol hand rubs (also mentioned in the guidelines) are currently preferred for general hand hygiene (see p.1624). However, triclosan resistance has been reported.[5-7]

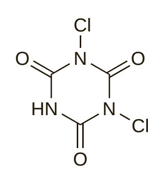
Troclosene *(rINNM)*

Dichloroisocyanuric Acid; Troclosène; Trocloseno; Troclosenum. 1,3-Dichloro-1,3,5-triazine-2,4,6(1*H*,3*H*,5*H*)-trione.

Троклозен

$C_3HCl_2N_3O_3$ = 198.0.

CAS — 2782-57-2.



Troclosene Potassium *(USAN, rINN)*

Potassium Dichloroisocyanurate; Potassium Troclosene; Troclosène Potassique; Trocloseno de potasio; Troclosenum Kalicum.

Троклозен Калий

$C_3Cl_2KN_3O_3$ = 236.1.

CAS — 2244-21-5.

Troclosene Sodium *(rINNM)*

Sodium Dichloroisocyanurate; Sodium Dichloro-s-triazinetrione; Sodium Troclosene; Troclosène Sodique; Trocloseno sódico; Troclosenum Natricum.

Троклозен Натрий

$C_3Cl_2N_3NaO_3$ = 219.9.

CAS — 2893-78-9.

Profile

Troclosene sodium is a disinfectant with the general properties of chlorine (p.1638) and sodium hypochlorite (above) but it remains active as pH increases from 6 to 10 and is reported to be less susceptible to inactivation by organic material. It contains about 56 to 65% of 'available chlorine' (see p.1638).

Troclosene sodium is used for disinfecting hard surfaces (see Disinfection in Hepatitis and HIV Infection, p.1623), babies' feeding bottles, and food and dairy equipment, for treating water (p.1623), for rapid disinfection of swimming pools, for soft contact lens care (p.1622), and in various commercial bleach detergents and scouring powders as a relatively stable source of chlorine.

Troclosene, troclosene potassium, and symclosene (trichloroisocyanuric acid $C_3Cl_3N_3O_3$ = 232.4) are similarly used.

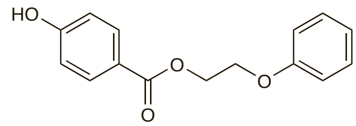
Preparations

Proprietary Preparations (details are given in Part 3)
Austral.: Aquatabs (Puritabs); Milton; ***Fr.:*** Aquatabs; ***Hong Kong:*** Actichlor; ***Israel:*** Klor-De; Klorsept; Taharmayim; Taharsept; Tahartaf; ***Ital.:*** Dialster; Dicloraster; ***NZ:*** Puritabs; ***S.Afr.:*** Softab; ***Singapore:*** Milton Anti-Bacterial; ***UK:*** Milton; Presept.

Multi-ingredient: ***Fr.:*** Micropur Forte DCCNa.

Undebenzophene

Parahydroxybenzoate Phenoxyethanol; Undebenzofeno. 2-Phenoxyethyl *p*-hydroxybenzoate.
$C_{15}H_{14}O_4$ = 258.3.
CAS — 55468-88-7.



Profile

Undebenzophene is an antiseptic that has been included in preparations intended for wound and burn disinfection.

Urea Hydrogen Peroxide

Carbamide Peroxide; Hydroperite; Peróxido de hidrógeno y urea; Urea Peroxide.
$NH_2.CO.NH_2,H_2O_2$ = 94.07.
CAS — 124-43-6.

Pharmacopoeias. In *US.*

USP 31 (Carbamide Peroxide). Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Profile

Urea hydrogen peroxide consists of hydrogen peroxide and urea in equimolecular proportions. It is used for the extemporaneous preparation of hydrogen peroxide. It is used for tooth whitening, and has been used for infections of the ear, mouth, skin, and mucous membranes and for softening ear wax.

Preparations

USP 31: Carbamide Peroxide Topical Solution.

Proprietary Preparations (details are given in Part 3)
Arg.: Blanc Dient; Yadid; ***Austral.:*** Ear Clear; ***Braz.:*** Aceratun; ***Canad.:*** Murine; ***Ger.:*** Elawox; ***Hung.:*** Hyperol; ***Irl.:*** Exterol; ***Israel:*** Exterol; ***Ital.:*** Debrox; Dermoxyl; Ginoxil; ***NZ:*** Earclear; ***UK:*** Exterol; Otex; ***USA:*** Auraphene-B; Auro; Debrox; ERO; Gly-Oxide; Mollifene; Murine; Orajel Perioseptic.

Multi-ingredient: ***Arg.:*** Hexiben Plus†.

Zinc Peroxide

Peróxido de zinc; Zinc Dioxide; Zinc Superoxide; ZPO.
ZnO_2 = 97.38.
CAS — 1314-22-3.

Profile

The action of zinc peroxide is similar to that of hydrogen peroxide (p.1647). Applied locally it has been used for disinfecting and deodorising burns, wounds, and various ulcers and lesions.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Braz.:*** Anaseptil; ***Fr.:*** Bioxyol; ***Ital.:*** Ektogan.

Electrolytes are used to correct disturbances in fluid and electrolyte homoeostasis or acid–base balance and to re-establish osmotic equilibrium of specific ions. The osmotic effects of solutions may be expressed in terms of

- osmolality, which is defined as the 'molal' concentration in moles (or osmoles) per kg of solvent

or

- osmolarity, which is the 'molar' concentration in moles (or osmoles) per litre of solution

In clinical practice, solute concentrations are measured per litre of solution and are expressed as millimoles (mmol) per litre or sometimes as milliequivalents (mEq) per litre. Milliequivalents are converted to millimoles by dividing by the valency of the ion.

Positively charged ions are known as *cations* and include calcium, magnesium, potassium, and sodium ions. Negatively charged ions are known as *anions* and include bicarbonate, chloride, and phosphate ions. The ions principally involved in fluid and electrolyte homoeostasis and acid–base balance are sodium, chloride, bicarbonate, and potassium. Calcium, phosphate, and magnesium have a central role in the formation of bone mineral.

Acid–base Balance

Within the body, acid is mostly produced during cellular respiration in the form of carbon dioxide. Small amounts of various non-volatile acids are generated via metabolism, including lactic acid, uric acid, keto acids, and some inorganic acids such as sulfuric and phosphoric acids. For normal tissue function, the pH of the body needs to be held within a narrow range. The pH of arterial blood is normally maintained between about 7.38 and 7.42 by means of compensatory respiratory, renal, and buffering mechanisms.

The most important buffer system in the extracellular fluid is the bicarbonate-carbonic acid system. Bicarbonate and hydrogen ions are in equilibrium with carbonic acid which is in turn in equilibrium with carbon dioxide in the body fluid, as expressed by:

$$H^+ + HCO_3^- \leftrightarrow H_2CO_3 \leftrightarrow CO_2 + H_2O$$

A normal plasma-bicarbonate concentration in adults is in the range of 20 to 30 mmol/litre and arterial partial pressure of carbon dioxide (P_aCO_2) is normally 4.7 to 5.7 kPa (35 to 43 mmHg).

Ultimately, excess acid must be removed from the body and base regenerated. P_aCO_2 is under respiratory control with carbon dioxide being excreted by the lungs. Plasma-bicarbonate concentrations are regulated by the kidneys, where bicarbonate is actively regenerated or reabsorbed. Organic acids such as lactic acid may be eliminated by metabolism; and other non-volatile acids, such as the inorganic acids of phosphate and sulfate, are excreted via the kidneys with simultaneous regeneration of bicarbonate.

The relationship between plasma pH, P_aCO_2, and bicarbonate is defined by the Henderson-Hasselbalch equation which is used to assess acid–base balance.

For clinical purposes, this equation becomes

$$\mathrm{pH} = \mathrm{pK}_{CO_2} + \log\left(\frac{C_{HCO_3}}{\alpha \times P_aCO_2}\right)$$

where pH is the plasma pH, pK_{CO_2} is the carbonic acid dissociation constant (6.1), C_{HCO_3} is the plasma-bicarbonate concentration, α is a value representing carbon dioxide solubility, and P_aCO_2 is the arterial partial pressure of carbon dioxide. Disorders of acid–base balance may be due to a change in plasma-bicarbonate concentrations (metabolic) or to a change in P_aCO_2 (respiratory), although mixed disorders do occur.

The 4 major acid–base disturbances are:

- metabolic acidosis—a decrease in the plasma-bicarbonate concentration
- metabolic alkalosis—an increase in the plasma-bicarbonate concentration
- respiratory acidosis—hypoventilation and a raised P_aCO_2
- respiratory alkalosis—hyperventilation and a reduced P_aCO_2

A further measure that may provide useful information in the assessment of metabolic acidosis is the plasma anion gap. This is the difference in ionic charge between the principal plasma cation (sodium) and anions (chloride and bicarbonate), and provides an estimation of unmeasured serum anions, which include inorganic and organic acids.

Metabolic acidosis. Metabolic acidosis, characterised by a low plasma-bicarbonate concentration and a tendency towards a fall in arterial pH, is the most frequent acid–base abnormality.

Metabolic acidosis with a *normal anion gap* is usually caused by excessive losses of bicarbonate from the gastrointestinal tract (as in severe diarrhoeas) or failure of the kidneys to reabsorb or regenerate adequate bicarbonate (as in the renal tubular acidoses). Ingestion of acidifying salts such as ammonium chloride, which generate hydrochloric acid, can also result in this type of acidosis. Metabolic acidosis characterised by an *increased anion gap* is often due to a reduction in the renal excretion of inorganic acids such as phosphates and sulfates as in renal failure (uraemic acidosis), or to the net accumulation of organic acids as, for example, in lactic acidosis or diabetic ketoacidosis.

Metabolic acidosis is diagnosed and monitored by measurement of serum electrolytes, arterial pH, and P_aCO_2. There is often hyperventilation with reduced cardiac function, constriction of peripheral veins, inhibition of the hepatic metabolism of lactate, and impairment of consciousness.

The main aim of **treatment** is to manage any underlying disorder,[1,2] and in some cases this will be sufficient to enable the body's homoeostatic mechanisms to correct the acid–base imbalance. The advantages of more active treatment of the acidosis must be balanced against the risks, including over-alkalinisation, and in consequence such therapy tends to be reserved for more persistent or severe cases.

The usual alkalinising agent is sodium bicarbonate. It may be given orally to replace bicarbonate losses in various chronic metabolic acidoses such as uraemic acidosis or renal tubular acidosis. Potassium bicarbonate may be preferred if the acidosis is associated with potassium deficiency. Potassium citrate and sodium citrate have also been used. More severe and acute cases (particularly where arterial pH is below 7.1) may require intravenous sodium bicarbonate therapy. Intravenous sodium bicarbonate has a role in acute metabolic acidoses attributable to severe renal failure, severe secretory diarrhoeas, and renal tubular acidosis. Although hypertonic solutions have been used, for example, in patients with circulatory overload, roughly isotonic bicarbonate solutions are otherwise preferred; arterial pH and plasma bicarbonate should be raised a little at a time and the patient's response monitored.

Although the role of bicarbonate is accepted in the forms of metabolic acidosis mentioned, its use in the treatment of metabolic acidosis with concomitant tissue hypoxia, particularly lactic acidosis, is controversial.[1-4] The administration of bicarbonate generates carbon dioxide which, if not appropriately eliminated, due to poor tissue perfusion or impaired ventilation or both, diffuses rapidly into the cells exacerbating intracellular acidosis. In addition, in metabolic acidosis associated with organic acids such as lactic acid, there is a risk of over-alkalinisation due to the metabolism of the acid after correction of the arterial pH. For similar reasons, the use of sodium bicarbonate in advanced cardiac life support (p.1156) is no longer routine, although current guidelines permit consideration of its use to correct acidosis if the resuscitation effort is prolonged.

The role of bicarbonate in the management of diabetic ketoacidosis is also limited, although it may be appropriate in certain situations—see Diabetic Emergencies, p.435.

Because of concerns about the effects of bicarbonate, other agents have been investigated for the treatment of metabolic acidosis, including trometamol (THAM) and sodium dichloroacetate.[1-4] Alkalinising agents that have to be metabolised to bicarbonate before they have an effect, such as sodium lactate, are not generally used as many patients with acute acidosis have impaired metabolic activity, particularly of lactate.

Peritoneal dialysis, haemodialysis, or haemofiltration is required for refractory metabolic acidosis associated with acute renal failure (p.1672).

Metabolic alkalosis. Metabolic alkalosis with an increased plasma-bicarbonate concentration and a sustained elevation in arterial pH results from excessive renal reabsorption and/or regeneration of bicarbonate. It is commonly seen with volume contraction (chloride depletion), potassium depletion, or mineralocorticoid excess, and may occur with excessive alkali intake as in the milk-alkali syndrome. If the metabolic alkalosis is severe, cardiac arrhythmias and hypoventilation may develop and there can be symptoms of concomitant hypokalaemia such as muscle weakness.

Treatment is generally aimed at the underlying disturbances.[1-3] Correcting volume depletion by giving a chloride salt often obviates the need for other treatment; sodium chloride is normally used. However, potassium chloride may also be required if there is potassium depletion, particularly if this is severe. Rarely, direct acidification with ammonium chloride, dilute hydrochloric acid, or acidifying salts such as lysine hydrochloride or arginine hydrochloride may be required if the alkalosis is severe.

Calcium Homoeostasis

The adult body contains about 1.2 kg of calcium, of which about 99% is incorporated into the skeleton where its primary role is structural. The remaining 1% is found in body tissues and fluids and is essential for normal nerve conduction, muscle activity, and blood coagulation.

The concentration of calcium in plasma is normally kept within a narrow range (total calcium about 2.15 to 2.60 mmol/litre) by homoeostatic mechanisms involving parathyroid hormone, calcitonin, and vitamin D. Normally about 50% of calcium in plasma is in the ionised physiologically active form (giving a usual range of about 1.1 to 1.3 mmol/litre), about 10% is complexed with anions such as phosphate or citrate, and the remainder is bound to proteins, principally albumin. If the plasma-albumin concentration is raised (as in dehydration) or reduced (as is common in malignancy) it will affect the proportion of ionised calcium. Thus, the total plasma-calcium concentration is commonly adjusted for plasma albumin.

Hypercalcaemia. Hypercalcaemia, an increase in plasma-calcium concentration above the normal range, is most commonly due to primary hyperparathyroidism (p.1087) or malignant disease.[1-4] Less common causes of hypercalcaemia include vitamin D intoxication, granulomatous diseases such as sarcoidosis, familial benign hypercalcaemia, renal failure, thyrotoxicosis, and excess calcium carbonate ingestion (milk-alkali or calcium-alkali syndrome).[1-4]

Mild asymptomatic hypercalcaemia is often associated with a plasma-concentration elevated above the normal but below 3.00 mmol/litre. Severe symptomatic hypercalcaemia is broadly correlated with a plasma-calcium concentration of more than 3.50 mmol/litre.

Symptoms of hypercalcaemia include thirst, polyuria, anorexia, constipation, muscle weakness, fatigue, and confusion. In severe cases, there may be nausea and vomiting; cardiac arrhythmias may develop but are rare. Extreme hypercalcaemia may result in coma and death. Chronic hypercalcaemia can lead to interstitial nephritis and calcium renal calculi.[3]

Mild asymptomatic hypercalcaemia is best corrected by increasing oral fluid intake and treating any identified underlying disease. Patients with more severe hypercalcaemia, and/or significant symptoms, need prompt **treatment** to reduce plasma-calcium concentrations independent of the cause.[2,3]

The first step is rehydration with intravenous sodium chloride 0.9% to restore the intravascular volume and to promote renal excretion of calcium. Loop diuretics will enhance calcium excretion, but are usually only given to prevent fluid overload or heart failure.[1-4] Thiazide diuretics should be avoided[2] as they increase the renal tubular reabsorption of calcium. Peritoneal dialysis or haemodialysis with calcium-free dialysate should be considered[2,4,5] in patients with renal failure for whom urinary excretion of calcium is inadequate.

In life-threatening hypercalcaemia, more specific immediate therapy is generally required in addition to saline.[2,3] Most experience has been gained in the treatment of hypercalcaemia of malignancy (p.1083) using drugs that inhibit bone resorption, notably bisphosphonates.[1-5] Calcitonins have a rapid onset of action, but their effect is moderate and generally short-lived. Thus, they are seldom used alone, or as first-line agents; they may be given with bisphosphonates to rapidly lower serum calcium.[2,4] Plicamycin lowers serum calcium quickly but toxicity has limited its use.[2,3] Gallium nitrate is also effective when given continuously over several days; adverse effects such as nephrotoxicity are frequent and severe.[2,4] Corticosteroids are particularly effective for hypercalcaemia secondary to haematological malignancy, or associated with vitamin D toxicity, such as sarcoidosis.[1-5] They have been used to prolong the efficacy of calcitonin. Intravenous phosphates rapidly lower plasma-calcium concentrations but can cause soft tissue calcification (resulting in serious adverse effects such as irreversible renal damage and hypotension), and are best avoided.[2,3] Where intestinal calcium absorption is increased, dietary calcium and vitamin D intake should be restricted,[4,5] although some consider this unnecessary and ineffective.[1]

Choice of subsequent therapy is likely to depend on the specific cause.

HYPERCALCAEMIA OF MALIGNANCY. About 10% of patients with cancer develop hypercalcaemia of malignancy, which is typically severe and progressive. Bisphosphonates are the preferred drugs for treating hypercalcaemia once the patient has been adequately rehydrated (see Hypercalcaemia of Malignancy, p.1083).

HYPERPARATHYROIDISM. Excess secretion of parathyroid hormone in primary hyperparathyroidism (p.1087) is characterised by hypercalcaemia, which is most frequently asymptomatic, and by hypophosphataemia. Oral phosphates and bisphosphonates have been used to control hypercalcaemia. However, in the long term, hypercalcaemia associated with primary hyperparathyroidism appears to be best managed by parathyroidectomy. Symptomatic hypocalcaemia may occur after surgery, requiring short-term treatment with calcium supplements and vitamin D.

VITAMIN D-MEDIATED HYPERCALCAEMIA. Hypercalcaemia can occur because of increased gastrointestinal absorption of calcium mediated by the active metabolite of vitamin D, 1,25-dihydroxycholecalciferol (calcitriol). This may be a feature of diseases associated with increased vitamin D sensitivity or increased vitamin D production, or may occur due to overdose of vitamin D. For example, granulomatous diseases such as sarcoidosis (p.1512) are associated with unregulated production of 1,25-dihydroxycholecalciferol. Hypercalcaemia due to vitamin D is most commonly seen in patients with renal failure receiving vitamin D analogues such as ergocalciferol.

Treatment of severe hypercalcaemia requires prompt rehydration regardless of the cause (see Hypercalcaemia, above). Where hypercalcaemia is due to excessive doses of a vitamin D analogue, it should be discontinued until normocalcaemia is achieved. Corticosteroids effectively reduce gastrointestinal absorption of calcium, and these may be used intravenously as adjuncts to rehydration in severe hypercalcaemia, and orally for milder hypercalcaemia or longer term therapy. Oral sodium cellulose phosphate, which binds calcium in the gastrointestinal tract, and a low-calcium diet may also be considered. Oral chloroquine or hydroxychloroquine have been used in hypercalcaemia associated with sarcoidosis. Ketoconazole may be useful as an alternative to corticosteroids.

Hypocalcaemia. Hypocalcaemia, a decrease in plasma-calcium concentration below the normal range, may be due to impaired or reduced absorption of calcium from the gastrointestinal tract, as with vitamin D deficiency disorders (see Osteomalacia and Rickets, p.1084) and chronic renal failure (see Renal Osteodystrophy, p.1086). Alternatively, it may be due to deficient parathyroid hormone secretion and/or action as in hypoparathyroidism (p.1087) and hypomagnesaemia (see below). Excessive phosphate administration is also a cause of hypocalcaemia (see Hyperphosphataemia, below). Rarely, hypocalcaemia may follow repeated infusions of citrate ions, for example, during transfusions utilising citrated blood, as the citrate complexes with the calcium ion. Respiratory alkalosis due to hyperventilation can also lead to depression of ionised plasma-calcium concentrations.

Where symptoms of hypocalcaemia occur, they are typically associated with increased neuromuscular excitability; paraesthesias can occur and in more severe cases, carpopedal spasm, muscle cramps, tetany, and convulsions may develop.[1-3] Other symptoms include ECG changes and mental disturbances such as irritability and depression. Prolonged hypocalcaemia can lead to dental defects, cataract formation, and in children can result in mental retardation.

In patients with hypocalcaemia due to an underlying disease, long-term management should be aimed at **treating** this disease. Vitamin D supplements are widely used to enhance calcium absorption and correct vitamin D deficiency disorders and hypoparathyroidism. Oral supplements of calcium salts are often also given. Acute hypocalcaemia or hypocalcaemic tetany require emergency treatment with intravenous calcium salts.

Magnesium Homoeostasis

Magnesium is an essential body cation that is involved in numerous enzymatic reactions and physiological processes including energy transfer and storage, skeletal development, nerve conduction, and muscle contraction. Over half of the magnesium in the body is found in bone, about 40% is present in muscle and soft tissue, and only about 1% is present in the extracellular fluid. A normal concentration for magnesium in plasma is from about 0.7 to 1.0 mmol/litre.

Magnesium homoeostasis appears to be primarily regulated by the kidney where magnesium is extensively reabsorbed. Bone may act as a magnesium reservoir to reduce plasma-magnesium fluctuations. Magnesium is actively absorbed from the gastrointestinal tract and this is enhanced to some extent by 1,25-dihydroxycholecalciferol (calcitriol).

Hypermagnesaemia. Hypermagnesaemia is an increase in the plasma concentration of magnesium above the normal range, as may follow excessive parenteral doses of salts such as magnesium sulfate. Hypermagnesaemia due to oral intake is uncommon as the kidneys are able to excrete a relatively large magnesium load. However, it may occur in patients with impaired renal function taking large amounts of magnesium, for example, in antacids or laxatives.

Symptoms of hypermagnesaemia include nausea, vomiting, CNS and respiratory depression, hyporeflexia, muscle weakness, and cardiovascular effects including peripheral vasodilatation, hypotension, bradycardia, and cardiac arrest.

Treatment of mild hypermagnesaemia is usually limited to restricting magnesium intake. In severe hypermagnesaemia, ventilatory and circulatory support may be required. Slow intravenous injection of 10 to 20 mL of calcium gluconate 10% is recommended to reverse the effects on cardiovascular and respiratory systems. If renal function is normal, adequate fluids should be given to promote renal magnesium clearance. This may be increased by the use of furosemide. Haemodialysis using a magnesium-free dialysis solution effectively removes magnesium, and this may be necessary in patients with renal impairment, or for whom other methods prove ineffective.

Hypomagnesaemia. Hypomagnesaemia, a plasma-magnesium concentration below the normal range, may result from a reduced magnesium intake as in dietary deficiency or malabsorption syndromes. Alternatively, it may be due to excessive magnesium loss, either via the kidney because of inadequate reabsorption, or more often from the gut, for example during chronic diarrhoea. Drugs that may cause renal magnesium wasting include aminoglycosides, amphotericin B, ciclosporin, cisplatin (see Effects on Electrolytes, p.699), and diuretics.[1]

Hypomagnesaemia is closely associated with other electrolyte disturbances, especially hypocalcaemia (see above) and hypokalaemia (see below), and rarely occurs alone. Specific symptoms are therefore difficult to determine but may include anorexia, nausea, weakness, neuromuscular dysfunction such as tetany, tremor, and muscle fasciculations, and rarely seizures. Cardiac arrhythmias may occur, but the relative contribution of hypomagnesaemia and hypokalaemia to these is uncertain.

Magnesium salts can be given by mouth for the **treatment** of chronic or asymptomatic magnesium deficiency.[2,3] Parenteral therapy may be preferred in patients with poor gastrointestinal absorption of magnesium or who are unable to tolerate oral supplements (usually because they cause diarrhoea); magnesium sulfate can be given by intravenous or intramuscular injection. In acute symptomatic hypomagnesaemia, rapid replacement therapy with intravenous magnesium salts may be necessary. Renal function and plasma-magnesium concentrations should be monitored.

Phosphate Homoeostasis

Phosphate is an essential bone mineral; about 80% of phosphorus in an adult body is incorporated into the skeleton as a calcium salt where it is required to give rigidity. The remainder is present in the soft tissues and is involved in several metabolic and enzymatic reactions including energy storage and transfer.

Phosphate exists in body fluids mainly as the divalent HPO_4^{2-} ion (about 80%) or monovalent $H_2PO_4^-$ ion (about 20%). Phosphate measurements are usually expressed as inorganic phosphorus to avoid confusion with the anion content. A normal range for phosphorus in plasma in adults is about 0.85 to 1.45 mmol/litre, but as only a small proportion of body phosphate is found in the extracellular fluid, plasma-phosphorus levels may not always reflect total body stores or predict replacement needs.

Phosphate concentrations in plasma are primarily regulated by renal excretion; parathyroid hormone reduces the renal tubular reabsorption of phosphate. Intestinal absorption of phosphate is enhanced by the vitamin D metabolite, 1,25-dihydroxycholecalciferol.

Hyperphosphataemia. Hyperphosphataemia, an abnormally raised plasma-phosphorus concentration, is usually associated with renal failure and may lead to renal osteodystrophy (p.1086). Hyperphosphataemia may also be a consequence of release of phosphate from cells; this can occur in conditions of cell breakdown such as haemolysis or rhabdomyolysis, during chemotherapy (when it may be part of the tumour lysis syndrome), or as a result of acidoses. Hypoparathyroidism may also lead to hyperphosphataemia due to decreased levels of parathyroid hormone (see Hypoparathyroidism, p.1087). Other causes include excessive phosphate doses during treatment of hypophosphataemia, overuse of phosphate enemas or oral phosphate bowel preparations, and excessive vitamin D intake.

Hyperphosphataemic symptoms include those of associated hypocalcaemia (see above). Complexation with calcium may lead to metastatic calcification.

The **treatment** of hyperphosphataemia[1,2] usually involves control of the relevant underlying condition, and the use of low-phosphate diets, and if necessary oral phosphate-binding agents, such as calcium acetate or carbonate or aluminium hydroxide. Sevelamer, a polymer capable of binding phosphate, may also be given.[2,3] Lanthanum carbonate has also been used.[2-4] Haemodialysis has been used to correct hyperphosphataemia in renal failure.[4]

4. Albaaj F, Hutchison AJ. Hyperphosphataemia in renal failure: causes, consequences and current management. *Drugs* 2003; **63:** 577–96.

Hypophosphataemia. Hypophosphataemia, a reduction in plasma-phosphorus concentrations below the normal range, may be due to insufficient absorption of phosphate or increased renal clearance as in primary hyperparathyroidism, vitamin D deficiency, or X-linked familial hypophosphataemia. An increased cell uptake of phosphate can also result in hypophosphataemia, for example in chronic respiratory alkalosis and related disorders including alcoholism, hepatic failure, and septicaemia. As phosphate is widely available in foods, dietary deficiency is rare though it may occur in infants of low birth-weight fed exclusively on human breast milk (see Rickets of Prematurity, p.1684). The absorption of phosphate from the gastrointestinal tract can be reduced if phosphate-binding antacids are taken in large amounts.

Hypophosphataemia is usually asymptomatic but clinical symptoms become apparent when plasma-phosphorus concentrations fall below 0.3 mmol/litre.[1-4] Symptoms include neuromuscular dysfunction such as muscle weakness and paraesthesias, convulsions, cardiomyopathy, respiratory failure, and haematological abnormalities. Prolonged hypophosphataemia can result in rickets or osteomalacia (p.1084).

Treatment of hypophosphataemia primarily involves correction of any underlying disease.[4] Milk or oral phosphate supplements may be appropriate if a phosphate deficiency is identified or in certain disorders such as X-linked hypophosphataemic rickets. Intravenous phosphate may be required for severe hypophosphataemia (see p.1683), but this should be used cautiously to avoid hypocalcaemia and metastatic calcification.[2,3] Consideration should be given to correcting concomitant electrolyte disturbances such as hypomagnesaemia.

Potassium Homoeostasis

Potassium is mainly an intracellular cation, primarily found in muscle; only about 2% is present in the extracellular fluid. It is essential for numerous metabolic and physiological processes including nerve conduction, muscle contraction, and acid–base regulation. A normal concentration of potassium in plasma is about 3.5 to 5.0 mmol/litre, but factors influencing transfer between intracellular and extracellular fluids such as acid–base disturbances can distort the relationship between plasma concentrations and total body stores. The body content of potassium is primarily regulated by renal glomerular filtration and tubular secretion. Aldosterone enhances the renal secretion of potassium and other factors such as sodium excretion, dietary potassium intake, and plasma pH can modulate the excretion of potassium by the kidney. Insulin, $beta_2$ agonists, and aldosterone, and increases in plasma pH, can promote the cellular uptake of potassium. The passage of potassium into the cells and retention against the concentration gradient requires active transport via the Na^+/K^+ ATPase enzyme.

Hyperkalaemia. Hyperkalaemia, an abnormally raised plasma-potassium concentration, can occur if the potassium intake is increased, if the renal excretion decreases (as in renal failure or adrenocortical insufficiency), or if there is a sudden efflux of potassium from intracellular stores, (as in acidosis, or cell destruction due to tissue trauma, burns, haemolysis, or rhabdomyolysis). Renal failure is the commonest cause of severe hyperkalaemia.[1] Hyperkalaemia may also be induced by drugs such as the potassium-sparing diuretics, ciclosporin, tacrolimus, NSAIDs, or ACE inhibitors.[2,3] Usually the renal mechanisms for potassium excretion adapt readily to an increased potassium load, and hyperkalaemia due to increased dietary intake is rare unless renal function is also impaired.

Hyperkalaemia mainly affects the heart, but skeletal muscle function may also be affected. Symptoms include ECG abnormalities, ventricular arrhythmias, cardiac arrest, and also neuromuscular dysfunction such as muscle weakness and paralysis.[3,4]

Treatment involves giving calcium to counteract the negative effects of hyperkalaemia on cardiac excitability, drugs such as insulin or sodium bicarbonate to promote the transfer of potassium from the extracellular to the intracellular fluid compartment, and enhancing potassium excretion with exchange resins or dialysis.[3,4] The methods used depend largely on the severity of the hyperkalaemia and critically, any associated ECG changes. Hyperkalaemia associated with a plasma concentration of potassium above 6.0 to 7.0 mmol/litre or with ECG changes is usually considered a medical emergency.

If effects on the heart are present, then first-line therapy should be with a calcium salt given intravenously; typically 10 to 20 mL of calcium gluconate 10% is given by slow intravenous injection, the dosage being titrated and adjusted based on ECG improvement.

Calcium will not, however, reduce the plasma-potassium concentration. In moderate to severe hyperkalaemia, insulin, together with glucose to prevent hypoglycaemia, is given intravenously in order to reduce the potassium concentration by stimulating the uptake of potassium by cells.[1,5] Insulin is given as a rapid-acting soluble insulin and typical doses are 5 to 10 units with 50 mL of glucose 50% given slowly over 5 to 15 minutes. Doses may need to be repeated as necessary. Alternatively or additionally, intravenous sodium bicarbonate may be used to correct acidosis and promote cellular uptake of potassium (but see Metabolic Acidosis above). Opinions vary on its value[5] and on the appropriate dose and concentration, but it may be indicated where there is severe associated acidosis (pH less than 7.2).[1]

The $beta_2$ agonist, salbutamol, given intravenously or by a nebuliser, has also been found to enhance the cellular uptake of potassium and reduce plasma-potassium concentrations.[3-6] However, its effect may be inconsistent,[6] and some clinicians prefer to avoid $beta_2$ agonists because of fears that large doses may induce cardiac arrhythmias.[7] Some consider that it should only ever be used in conjunction with insulin, as up to 40% of patients may not respond.[1]

After the plasma-potassium concentration has been reduced in the immediate term by enhancing cellular potassium uptake, treatments are often required that will remove excess potassium from the body over the longer term. Cation exchange resins such as calcium or sodium polystyrene sulfonate can be given orally or rectally and, after about 1 to 2 hours, will begin to remove potassium from the body, although the evidence to support their use is lacking.[5] Haemodialysis removes potassium from the body very effectively[5] and is particularly useful in patients with acute renal failure, hypervolaemia, hypernatraemia, or severe hyperkalaemia. Peritoneal dialysis is effective in some patients.

HYPERKALAEMIC PERIODIC PARALYSIS. Hyperkalaemic periodic paralysis is an inherited disorder in which sudden increases in plasma-potassium concentrations cause muscle paralysis, sometimes followed by myotonia. An acute attack may require intravenous calcium gluconate and insulin with glucose (see above). Inhalation of a $beta_2$ agonist such as salbutamol has been used to treat or abort attacks.[1,2] Diuretics such as acetazolamide or the thiazides are used prophylactically to reduce the frequency of attacks.[2,3]

Hypokalaemia. Chronic hypokalaemia, a prolonged reduction of the plasma concentration of potassium, usually indicates a reduction in total body potassium. It may result from an inadequate intake, or gastrointestinal losses, for example in patients with secretory diarrhoeas, or from excessive renal losses as in hyperaldosteronism, Cushing's syndrome, or chronic metabolic alkalosis. Thiazides or loop diuretics increase urinary-potassium losses. Other drugs, notably corticosteroids and some antibacterials such as gentamicin, also have this effect. Hypokalaemia can also be caused by an increased cellular uptake of potassium rather than excess body losses. This may occur with drugs such as $beta_2$ agonists or xanthines, during insulin therapy, acute alkalosis, or possibly be induced by catecholamines after myocardial infarction. Hypokalaemia secondary to hypomagnesaemia (see above) can occur.

Hypokalaemia results in neuromuscular disturbances ranging from muscle weakness to paralysis and respiratory insufficiency and can also cause rhabdomyolysis, ECG abnormalities, and ileus. Chronic hypokalaemia may lead to renal tubular damage (hypokalaemic nephropathy). Hypokalaemia increases the risk of digoxin toxicity.

Treatment involves correcting any underlying disorder and replacement therapy with potassium salts. Oral potassium supplements are generally preferred but in severe hypokalaemia associated with cardiac arrhythmias, paralysis or diabetic ketoacidosis, parenteral therapy may be necessary. Potassium salts, usually potassium chloride, may be given by intravenous infusion but must be administered slowly to avoid causing hyperkalaemia and associated cardiac toxicity; plasma-potassium concentrations should be closely monitored and ECG monitoring may be required. The choice of salt for oral potassium replacement depends on co-existing acid–base and electrolyte disturbances. Potassium chloride is generally the drug of choice for the treatment of hypokalaemia in patients with metabolic alkalosis with hypochloraemia, whereas a salt such as the bicarbonate may be preferred in patients with hyperchloraemic acidosis as in some renal tubular acidoses. Hypokalaemia secondary to hypomagnesaemia requires magnesium replacement therapy.

BARTTER'S SYNDROME. Bartter's syndrome is a set of closely related disorders thought to result from inherited defects in ion transport in various sections of the renal tubule.[1,2] Patients exhibit hyperplasia of the juxtaglomerular cells, hypokalaemia and metabolic alkalosis, and excess aldosterone, prostaglandin, and renin production. Symptoms are primarily those of the hypokalaemia, including muscle weakness; polyuria and enuresis, and growth retardation in children, can occur. In contrast to other hyperreninaemic states, patients do not have hypertension or oedema.

Treatment rarely completely corrects hypokalaemia. Potassium supplementation may be given, while a cyclo-oxygenase inhibitor such as indometacin, or an ACE inhibitor such as captopril, can produce benefit.[2] Spironolactone and propranolol have also been tried and magnesium salts may be given if there is hypomagnesaemia.[2]

2. Amirlak I, Dawson KP. Bartter syndrome: an overview. *Q J Med* 2000; **93:** 207–15.

DIURETIC-INDUCED HYPOKALAEMIA. Reduced potassium concentrations may result from the use of potassium-losing diuretics, particularly thiazides and loop diuretics. Clinically significant hypokalaemia is unlikely at the doses used in hypertension and the routine use of potassium supplements is no longer recommended. However, the concomitant use of a potassium-sparing diuretic such as amiloride or, less usually, a potassium supplement, may be necessary in patients at risk of hypokalaemia (see also Hydrochlorothiazide, Effects on Electrolyte Balance, p.1308).

HYPOKALAEMIC PERIODIC PARALYSIS. Hypokalaemic periodic paralysis is an inherited disorder in which episodes of hypokalaemia with muscle weakness or paralysis appear to be associated with a shift in potassium from the extracellular to the intracellular fluid. Acute attacks are treated with potassium, given orally or intravenously. Prophylaxis with acetazolamide has been found to reduce the frequency and severity of attacks.[1,2]

Sodium Homoeostasis

Sodium is the principal cation in the extracellular fluid and is responsible for the maintenance of the extracellular fluid volume and osmolality. In addition, sodium is also involved in nerve conduction, muscle contraction, acid–base balance, and cell nutrient uptake. A usual plasma concentration of sodium would be expected to be within 135 to 145 mmol/litre.

Sodium homoeostasis is complex and closely associated with fluid balance. The osmolality and volume of the extracellular fluid are tightly regulated. Small changes in osmolality (plasma-sodium concentrations) are corrected by alteration of extracellular volume. This balance of plasma osmolality is achieved by the secretion or suppression of antidiuretic hormone (ADH; vasopressin), which primarily controls water excretion by the kidney. A tendency towards hyponatraemia suppresses ADH secretion and promotes renal loss of water; an increase in ADH secretion increases water reabsorption by the renal distal tubules. Changes in extracellular volume will also affect ADH release independently of osmolality. In addition, changes in extracellular volume result in modulation of the renal excretion of sodium.

Total body sodium content is regulated by renal sodium excretion, which can vary widely depending on dietary intake. Various mechanisms are involved in controlling renal sodium excretion including the renin-angiotensin system, glomerular filtration rate, and natriuretic factors. A reduction in extracellular fluid volume leads to the production of angiotensin II which stimulates the secretion of aldosterone. Aldosterone promotes the reabsorption of sodium ions by the distal tubules. There may be significant effects on sodium homoeostasis if adrenal insufficiency or mineralocorticoid excess disturb this mechanism.

Hypernatraemia. Hypernatraemia is an abnormal rise in the plasma-sodium concentration with a simultaneous rise in plasma osmolality. It is generally associated with volume depletion when water intake is less than water losses through renal or extrarenal routes. The causes include impaired thirst, as in coma or essential hypernatraemia, osmotic diuresis (solute diuresis), as in diabetic ketoacidosis (see Diabetic Emergencies, p.435) or after drugs such as mannitol, and excessive water losses, either from the kidney, as in diabetes insipidus (p.2179), or extrarenally, for example because of excessive sweating or diarrhoea.

Hypernatraemia can also occur after excessive oral sodium intake (but this is uncommon) and after inappropriate use of intravenous sodium chloride.

The clinical manifestations of hypernatraemia are caused by the effect of increased plasma osmolality on the brain and include somnolence, confusion, respiratory paralysis, and coma. CNS symptoms are more severe when hypernatraemia develops rapidly. If there is volume depletion, other symptoms such as hypotension, tachycardia, and symptoms of circulatory insufficiency may occur as well. A high volume of dilute urine is seen in patients with abnormal renal water conservation, whereas a low volume of concentrated urine is expected in patients with impaired thirst or excessive extrarenal water loss.

Treatment of hypernatraemia usually requires water replacement, and drinking water may be sufficient for some patients. In more severe conditions, glucose 5% may be given by slow intravenous infusion. Alternatively, some recommend the use of sodium chloride 0.9% if volume depletion is severe. Care is required, as too rapid correction can induce cerebral oedema, particularly in chronic conditions.

If the total body sodium is too high, loop diuretics may be used to increase sodium excretion, with fluid losses being replaced by an infusion of glucose 5% and potassium chloride. It has also been suggested that dialysis may be necessary if there is significant renal impairment, if the patient is moribund, or if the serum-sodium concentration is greater than 200 mmol/litre.

Hyponatraemia. Hyponatraemia, an abnormal fall in the plasma-sodium concentration, usually with a simultaneous fall in the plasma osmolality, is not uncommon, and may occur in diseases as diverse as heart failure, cirrhosis, adrenocortical insufficiency, hyperglycaemia, and AIDS.

The kidney is able to conserve sodium, and sodium depletion due to low salt intake is rare. Sodium depletion may occur if there are abnormal losses, either from the gut as a consequence of repeated diarrhoea and/or vomiting or from the kidney, for example, due to various renal disorders or the overuse of diuretics (see under Hydrochlorothiazide, Effects on Electrolyte Balance, p.1308).

The most common cause of hyponatraemia is dilution. This may result from excessive fluid intake, for example the ingestion of large volumes of water in patients with primary polydipsia (psychogenic polydipsia). More often, however, it is a result of reduced water excretion, as in renal impairment or the syndrome of inappropriate secretion of antidiuretic hormone (SIADH—p.2182). Postoperative hyponatraemia is a frequent complication which can be exacerbated by the inappropriate intravenous use of hypotonic,[1] or even isotonic,[2] fluids.

Hyponatraemia due to sodium depletion in the presence of volume contraction may cause orthostatic hypotension and circulatory insufficiency. Dilutional hyponatraemia can be asymptomatic but headache, confusion, nausea, vomiting, somnolence, and weakness may occur. If severe, cerebral oedema may lead to respiratory arrest, convulsions, and coma. CNS symptoms are more common when the condition is acute.

Therapy is guided by the rate of development and degree of hyponatraemia, accompanying symptoms, and the state of water balance, and should also take into account the underlying cause. Mild asymptomatic hyponatraemia does not usually require specific therapy. Chronic mild to moderate sodium depletion, such as occurs in salt-losing bowel or renal disease, may be treated with oral sodium chloride supplements while ensuring adequate fluid intake.

When there is substantial volume depletion, volume replacement is necessary and intravenous sodium chloride 0.9% is often used.[3-5]

Chronic dilutional hyponatraemia, which is often asymptomatic, can generally be managed by correcting the underlying disease; water restriction may also be necessary and drugs that interfere with the action of ADH such as demeclocycline or lithium carbonate may be useful in SIADH.[3-6] Furosemide plus oral sodium chloride supplements have also been used.[7]

Acute symptomatic hyponatraemia (water intoxication) is generally associated with plasma-sodium concentrations below 120 mmol/litre and requires more aggressive therapy. This involves giving hypertonic or isotonic sodium chloride intravenously, often with a loop diuretic such as furosemide, especially if fluid overload is likely to be a problem.[4,6,7] The aim is to render the patient asymptomatic, with a plasma-sodium concentration of 120 to 130 mmol/litre; the plasma-sodium concentration should not be corrected to normal values nor should hypernatraemia be allowed to develop.[1,6,7] Plasma-sodium concentrations and the total body-water volume should be monitored throughout.

A rare neurological syndrome known as central pontine myelinolysis (osmotic demyelination) has been associated with the over-rapid correction of symptomatic hyponatraemia, particularly if the condition is well established. However, there is no consensus about the optimal administration of intravenous sodium chloride, and a number of regimens have been suggested. Generally, it has been recommended that the rate of correction of plasma-sodium should be 0.5 to 1 mmol/litre per hour, and not exceeding 2 mmol/litre per hour; maximum corrections have included 8 mmol/litre per 24 hours,[7] 12 mmol/litre per 24 hours or 18 mmol/litre over the first 48 hours,[6] and 20 mmol/litre in the first 48 hours.[1] Some[1,5] have given more specific recommendations depending on the severity of symptoms, suggesting that patients with severe symptoms, such as seizures, respiratory arrest, or neurogenic pulmonary oedema, require rapid correction in the first few hours, aiming for an initial increase in plasma-sodium of 2 to 4 mmol/litre, followed by a continuous infusion.

More recently, the vasopressin receptor antagonist conivaptan has become available for the management of euvolaemic and hypervolaemic hyponatraemia. It must be given intravenously, and other vasopressin receptor antagonists that are orally active are under investigation.[5,6]

Dialysis Solutions

Soluciones para diálisis.

Pharmacopoeias. In *Eur.* (see p.vii), which includes separate monographs for solutions for haemodialysis, haemofiltration and haemodiafiltration, and peritoneal dialysis.

Dialysis and Haemofiltration

Dialysis and filtration solutions are solutions of electrolytes formulated in concentrations similar to those of extracellular fluid or plasma. They always contain sodium and chloride and bicarbonate or a bicarbonate precursor. In addition, they often contain calcium and magnesium, and rarely potassium. Glucose may be added as an osmotic agent. These solutions allow the removal of water and metabolites and the replacement of electrolytes.

In *haemodialysis*, the exchange of ions between the solution and the patient's blood is made across a semi-permeable membrane, primarily by diffusion. Excess fluid is removed by ultrafiltration achieved by a pressure gradient. Membranes are either derived from cellulose (e.g. cuprophane) or are synthetic. Bicarbonate rather than a bicarbonate precursor is increasingly preferred as the bicarbonate source in haemodialysis since the problems of precipitation of calcium and magnesium have been overcome by changes in dialysis technique. Acetate is still used in some dialysers, but is thought to have vasodilator and cardiodepressant actions, and may not be converted to bicarbonate fast enough for high-flux haemodialysis or in patients with liver disease. Haemodialysis solutions are provided in a sterile concentrated form for dilution with water before use; this water need not be sterile.

In *peritoneal dialysis*, the exchange is made across the membranes of the peritoneal cavity primarily by diffusion. Excess fluid is removed by ultrafiltration achieved by the use of osmotic agents such as glucose. The problems of calcium bicarbonate precipitation have not yet been overcome, and lactate is generally used as the bicarbonate precursor. Peritoneal dialysis solutions must be sterile and apyrogenic.

In *haemofiltration*, blood is filtered rather than dialysed. Metabolites are removed by convective transport, and excess water by hydrostatic ultrafiltration. Fluid and electrolytes are replaced by direct intravenous infusion. Most haemofiltration solutions use acetate or lactate as the bicarbonate source. Haemofiltration solutions must be sterile and apyrogenic.

Adverse Effects

Adverse effects occurring during *haemodialysis* include nausea, vomiting, hypotension, muscle cramps, and air embolus. Effects related to vascular access include infection, thrombosis, and haemorrhage. Adverse effects occurring during *haemofiltration* are similar to those for haemodialysis.

The most common adverse effects associated with *peritoneal dialysis* include peritonitis, hernias, hyperglycaemia, protein malnutrition, and catheter complications.

Long-term complications in dialysed patients, some of which may relate to renal failure itself, include haemodialysis-related amyloidosis, acquired cystic kidney disease, and accelerated atherosclerosis. Dialysis dementia is a special hazard of aluminium overload. Long-term peritoneal dialysis results in progressive structural changes to the peritoneal membrane ultimately resulting in dialysis failure.

Aluminium overload. Accumulation of aluminium in patients on dialysis may result in dialysis dementia, anaemia, and aluminium-related bone disease (see also p.2254). Sources of aluminium include the water used for preparation of dialysis fluids and aluminium-containing phosphate binders used in treating renal osteodystrophy (p.1086). It is therefore important that water used for the preparation of dialysis fluids has a low aluminium concentration; Ph. Eur. 6.2 specifies a limit for aluminium of 10 micrograms/litre. Non-aluminium-containing phosphate binders such as calcium acetate or calcium carbonate may be preferred for long-term therapy. Aluminium overload in patients on dialysis has been treated with desferrioxamine (p.1441).

Copper toxicity. Liver and haematological toxicity has occurred as a result of absorption of copper from dialysis fluids (see Adverse Effects of Copper, p.1935).

Haemodialysis-induced cramp. Muscle cramps (see Muscle Spasms, p.1887) commonly occur during haemodialysis procedures and between sessions. Cramping usually affects the lower extremities, causing severe pain, and is a common reason for avoiding or stopping haemodialysis. The aetiology is not clear but possibly related to hypovolaemia, hypotension, changes in plasma osmolality, and hyponatraemia.[1]

Non-pharmacological measures to treat cramp during haemodialysis include the local application of moist heat and massage, and stretching the affected muscle. Hypotension should be corrected, by slowing or stopping ultrafiltration, and possibly giving isotonic or hypertonic sodium chloride infusion.[1] Adjustment of the dialysate sodium concentration during dialysis, or the use of a dialysate containing bicarbonate instead of one containing acetate, are other measures that may be used to reduce hypotension and cramp. Midodrine has also been recommended for the management of hypotension.[2] Hypertonic solutions of sodium chloride or glucose may be used to raise plasma osmolality; mannitol has also been used but may accumulate in the extracellular space.[1]

Quinine has been widely used for the prevention of haemodialysis-induced cramp, but it can cause serious adverse effects and such use has been discouraged.[1] Other treatments that have been tried as prophylaxis include carnitine, creatine, and vitamins C and E. However, information on these is limited and data on long-term efficacy and safety are lacking.[1] There is also limited evidence that a traditional herbal medicine, shao-yao-gan-cao-tang (shakuyaku-kanzo-to), comprising extracts of peony and liquorice roots, may be of benefit for both prevention and treatment of haemodialysis-induced cramp.[1]

Hypersensitivity. For anaphylactic reactions associated with the use of ethylene oxide for the disinfection of dialysis equipment, see p.1643.

Infections. Patients undergoing haemodialysis are at risk of infections from microbial contamination of dialysis fluid, and from inadequate care of vascular access sites. Maximum microbial counts and limits for endotoxins have been specified for water used in dialysis fluids. Bicarbonate-based dialysis solutions are more susceptible to microbial growth than acetate-based solutions.

Peritonitis is common in patients receiving peritoneal dialysis. The risk of infection may be minimised by using disconnect systems, good aseptic technique, and by good care of catheters. Treatment of bacterial peritonitis requires intraperitoneal antibacterials, which are usually added to the dialysis fluid (see p.184).

Dialysis equipment should be regularly disinfected with agents such as formaldehyde (p.1645) or ethylene oxide (p.1643), but for mention of ethylene oxide anaphylactoid reactions, see p.1643.

Metabolic complications. The high concentrations of glucose in peritoneal dialysis solutions required to form an osmotic gradient can lead to weight gain, hyperglycaemia, hyperlipidaemia, and increased protein loss. Alternative osmotic agents such as icodextrin (p.1937) can be used, and amino acid-based solutions are also available.

Precautions

Peritoneal dialysis is not appropriate for patients with abdominal sepsis, previous abdominal surgery, or severe inflammatory bowel disease.

Haemodialysis should be used with caution in patients with unstable cardiovascular disease or active bleeding. During haemodialysis and haemofiltration, heparin (see Extracorporeal Circulation, p.1304) or epoprostenol (Uses, p.1280) are required to prevent clotting of the blood in the extracorporeal circuit.

Dialysis solutions should be warmed to body temperature with dry heat because wet heat carries a risk of microbial contamination.

Interactions

The effects of dialysis and filtration procedures on drug concentrations in the body can be complex. More drug may be removed by one dialysis technique than another. In general, drugs of low molecular weight, high water solubility, low volume of distribution, low protein binding, and high renal clearance are most extensively removed by dialysis. For example, aminoglycosides are extensively removed by dialysis procedures, and extra doses may be needed to replace losses. Specific drug dosage adjustments for dialysis procedures may be used where these are known. For drugs where the effect of dialysis is unknown, it is usual to give maintenance doses after dialysis. Dialysis has been used to remove some drugs in the treatment of overdosage and poisoning (see below).

Dialysis-induced changes in fluids and electrolytes have the potential to alter the effects of some drugs. For example, hypokalaemia predisposes to digoxin toxicity.

In patients undergoing peritoneal dialysis, drugs such as insulin and antibacterials may be added to the dialysis fluid. Consideration should be given to the possibility of adsorption of drugs onto the PVC bags.

Uses and Administration

Dialysis and filtration procedures are used in renal failure to correct electrolyte imbalance, correct fluid overload, and remove metabolites. They also have a limited role in the treatment of overdosage and poisoning. The two main techniques are haemodialysis and peritoneal dialysis; haemofiltration is used less frequently. The choice of technique will depend on the condition to be treated, the clinical state of the patient, patient preference, and availability.

Haemodialysis is more efficient than peritoneal dialysis at clearing small molecules such as urea, whereas peritoneal dialysis may be better at clearing larger molecules. Haemodialysis is considered to be less physiological as it alternates periods of high clearance with periods of no clearance.

Haemodialysis is usually performed intermittently (often 3 times a week); a typical session takes 3 to 5 hours. More recently high-flux dialysers have been developed which have reduced the time required for dialysis sessions.

Peritoneal dialysis may be performed continuously or intermittently. Continuous ambulatory peritoneal dialysis (CAPD) is the most commonly used technique. Patients remain mobile, except during exchanges, and can carry out the procedure themselves. There is always dialysis solution in the peritoneal cavity, and this is drained and replaced 3 to 5 times daily. Continuous cycle peritoneal dialysis (CCPD) is similar, except that exchanges are carried out automatically overnight, and patients do not have to carry out any exchanges during the day. Intermittent peritoneal dialysis (IPD) requires the patient to be connected to a dialysis machine for 12 to 24 hours 2 to 4 times a week. During this time, dialysis solution is pumped into and out of the peritoneal cavity, with a dwell time of about 10 to 20 minutes.

Haemofiltration is usually performed as a continuous technique and, as it is not portable, its principal use is in intensive care units. It may also be used intermittently as an adjunct to haemodialysis in patients with excess fluid weight gain. Continuous arteriovenous or venovenous haemodiafiltration (CAVHD or CVVHD) combines dialysis and filtration.

Assessing serum concentrations of urea or creatinine before the next dialysis session is not a good measure of the adequacy of the dialysis, so various other measures have been developed including the urea reduction ratio and urea kinetic modelling. The use of such measures is more established for haemodialysis than for peritoneal dialysis.

Acute renal failure. Acute renal failure is characterised by a rapid decline in kidney function, and has a variety of causes.[1-7] It is often classified by origin as *prerenal* (e.g. due to hypovolaemia such as that associated with shock, burns, or dehydration; congestive heart failure; or renal artery obstruction), *renal* (such as acute tubular necrosis or interstitial nephritis of various causes, including nephrotoxic drugs and infections), or *postrenal* (acute urinary tract obstruction). The prognosis depends on the underlying disease, which should be identified and treated if possible, but the mortality may still be as high as 60%, particularly after surgery or trauma and in patients who become oliguric. Management is essentially supportive in the hope that renal function will recover. Complications of acute renal failure include extracellular volume overload and hyponatraemia, hyperkalaemia, metabolic acidosis, hyperphosphataemia and hypocalcaemia. Those complications requiring urgent treatment, often including the use of dialysis, are severe hyperkalaemia (p.1669), pulmonary oedema, pericarditis, and severe metabolic acidosis (p.1667). The use of dialysis before clinical signs of uraemia is a matter of debate since it does not appear to hasten recovery *per se*,[1] but all save the shortest episodes of acute renal failure will require some form of renal replacement therapy with dialysis or filtration. Intermittent haemodialysis and peritoneal dialysis are both used, but the newer haemofiltration techniques have theoretical advantages in terms of volume control and cardiovascular stability, and are increasingly preferred.[2,8,9]

Numerous drugs have been tried in attempts to attenuate renal injury or hasten recovery in patients with acute tubular necrosis due to ischaemia or nephrotoxins.[1,5,10,11] These include drugs to increase renal blood flow (e.g. low-dose dopamine, atrial natriuretic peptide, or prostaglandins), drugs to increase urine flow and protect the epithelial cells (mannitol and loop diuretics, calcium-channel blockers), or the use of chelating agents or antidotes against specific nephrotoxins. Consistent clinical benefit has not, however, been shown.

Acute renal failure is reversible in about 95% of patients who survive the complications. A few patients who survive acute renal failure will require long-term dialysis or kidney transplantation (p.1813).

Chronic renal failure. Chronic renal failure is the irreversible, usually progressive, loss of renal function that eventually results in end-stage renal disease (ESRD) and the need for renal replacement therapy (dialysis or renal transplantation). The rate of decline in renal function is generally constant for each patient and is usually monitored by measuring serum-creatinine concentrations as an indirect index of the glomerular filtration rate (GFR). In its early stages when the patient is asymptomatic, progressive loss of renal function is described as diminished renal reserve or chronic renal insufficiency. When the limits of renal reserve have been exceeded and symptoms become apparent, it is termed chronic renal failure or overt renal failure. When renal function is diminished to such an extent that life is no longer sustainable (GFR less than 5 mL/minute), the condition is termed ESRD or uraemia. Many diseases can lead to ESRD, the most common being diabetes (p.433), glomerulonephritis (p.1504), and hypertension (p.1171).

The management of patients with chronic renal failure prior to ESRD involves measures to conserve renal function and compensate for renal insufficiency. Methods to slow the progression of renal failure include the treatment of hypertension (p.1171), reduction of proteinuria, and the reduction of hyperlipidaemia (p.1169). ACE inhibitors (p.1199) or angiotensin II receptor antagonists (see Losartan, p.1328) are used for the reduction of proteinuria and the control of hypertension. Dietary protein restriction (see Renal Failure, p.1923) has also been used for control of proteinuria, but conclusive evidence for a renal protective effect is lacking. Anaemia (p.1063), hyperphosphataemia (p.1669), secondary hyperparathyroidism (p.1087), and renal osteodystrophy (p.1086) often require active treatment. Nephrotoxic drugs, including NSAIDs, should be avoided.

The choice between haemodialysis, peritoneal dialysis, and organ transplantation is considered, and the patient prepared, before it is actually required. In patients for whom transplantation is the preferred option, dialysis may still be required while waiting for a kidney. Kidney transplantation is discussed on p.1813. There are differences between countries in the choice of dialysis technique for patients with ESRD. For example, in-centre haemodialysis is used in about 80% of patients in the USA, whereas CAPD is used in over 50% of patients in the UK. Overall survival appears to be similar between the 2 techniques, but more patients on CAPD will eventually require a change to another dialysis method because of treatment failure.

Unlike renal transplant patients, dialysis patients still require replacement therapy with hormones that are usually produced by the kidney. Thus, recombinant erythropoietin and hydroxylated vitamin D analogues are commonly given.

Electrolyte disturbances. Haemodialysis with magnesium-free dialysis solution has been used to remove magnesium from the body in severe hypermagnesaemia (p.1668). Similarly, haemodialysis, and sometimes peritoneal dialysis, has been used in treating hypercalcaemia (p.1668), hyperkalaemia (p.1669), hypernatraemia (p.1670), and hyperphosphataemia (p.1669).

Overdosage and poisoning. Haemodialysis, or less often peritoneal dialysis, can be used to remove some substances from the body after overdosage or poisoning. Substances most readily removed have a low molecular weight, low volume of distribution, low protein binding, high water solubility, and high renal clearance. Examples of agents for which haemodialysis may have a role in the treatment of severe overdosage include alcohol (p.1626), ethylene glycol (p.2300), methyl alcohol (p.2024), lithium (p.403), and salicylates such as aspirin (p.20). Dialysis may be particularly important when poisoning with these agents is complicated by renal failure.

Preparations

Ph. Eur.: Solutions for Haemodialysis; Solutions for Haemofiltration and for Haemodiafiltration; Solutions for Peritoneal Dialysis.

Proprietary Preparations: some preparations are listed in Part 3.

Oral Rehydration Solutions

Soluciones de rehidratación oral.

Oral rehydration solutions have 4 main constituents:

- electrolytes—typically sodium chloride and potassium chloride
- a bicarbonate source to correct or prevent metabolic acidosis, such as sodium bicarbonate or sodium citrate
- water to replace fluid losses
- a carbohydrate source to maximise absorption of fluid and electrolytes—typically glucose, although cereal-based formulations may also be used.

They are most commonly available as oral powders (oral rehydration salts) that are reconstituted with water before use, but effervescent tablets and ready-to-use oral solutions are also available.

Adverse Effects

Vomiting can occur after taking oral rehydration solution, and may be an indication that it was given too quickly. If vomiting occurs, administration should be halted for 10 minutes then resumed in smaller, more frequent, amounts.

The risk of hypernatraemia or overhydration with oral rehydration solutions is low in patients with normal renal function. Overdosage of oral rehydration solutions in patients with renal impairment may lead to hypernatraemia and hyperkalaemia.

Precautions

Oral rehydration salts or effervescent tablets should be reconstituted only with water and at the volume stated. Fresh drinking water is generally appropriate, but freshly boiled and cooled water is preferred when the solution is for infants or when drinking water is not available. The solution should not be boiled after it is prepared. Other ingredients such as sugar should not be added. Unused solution should be stored in a refrigerator and discarded within 24 hours of preparation.

Oral rehydration solutions are not appropriate for patients with gastrointestinal obstruction, oliguric or anuric renal failure, or when parenteral rehydration therapy is indicated as in severe dehydration or intractable vomiting.

Uses and Administration

Oral rehydration solutions are used for oral replacement of electrolytes and fluids in patients with dehydration, particularly that associated with acute diarrhoea of various aetiologies (p.1694).

The dosage of oral rehydration solutions should be tailored to the individual based on body-weight and the stage and severity of the condition. The initial aim of treatment is to rehydrate the patient, and, subsequently, to maintain hydration by replacing any further losses due to continuing diarrhoea and vomiting and normal losses from respiration, sweating, and urination. Initial rehydration should be rapid, over 3 to 4 hours, unless the patient is hypernatraemic, in which case rehydration over 12 hours is appropriate.

For adults, a usual dose of 200 to 400 mL of oral rehydration solution for every loose motion has been suggested. The dosage for children is 200 mL for every loose motion, and for infants is 1 to 1.5 times their usual feed volume. Normal feeding can continue after the initial fluid deficit has been corrected. Breast feeding should continue between administrations of oral rehydration solution.

Sodium content and osmolarity. The original standard WHO oral rehydration solution contained 90 mmol/litre of sodium and 111 mmol/litre of glucose.[1-3] While it has been used safely and effectively,[4] it does not reduce the volume or duration of diarrhoea,[3] and solutions with reduced sodium content and osmolarity have been suggested to be more effective.[1,2] WHO and UNICEF now recommend a solution containing 75 mmol/litre of sodium and 75 mmol/litre of glucose, with a reduced osmolarity.[4] However, there have been concerns that the reduced sodium content of this formulation may increase the risk of hyponatraemia in patients with cholera,[3,5,6] and especially in adults.[4] WHO and UNICEF have stated that hyponatraemia may also occur with the standard WHO formulation, and that there is no evidence to suggest that this transient hyponatraemia has had significant adverse clinical consequences for cholera patients.[4] Solutions containing less sodium have been recommended in more developed countries: 60 mmol/litre in Europe,[7] and 45 to 90 mmol/litre in the USA.[8]

For discussion of modified formulations of oral rehydration solutions in the treatment of diarrhoea, including the use of cereal-based and low osmolarity preparations, see oral rehydration therapy under Diarrhoea, p.1694.

Oral versus intravenous rehydration. Although intravenous rehydration is advised for patients with the most severe dehydration (see Diarrhoea, p.1694) it is also widely used in some countries in the management of less severe degrees of fluid loss.[1,2] However, a meta-analysis of 16 randomised controlled studies in children with gastroenteritis (5 of which included children with severe dehydration) found that oral or nasogastric rehydration with an appropriate rehydration solution was at least as effective as intravenous rehydration in terms of weight gain and intestinal losses, and was associated with a lower incidence of adverse effects and a reduced length of hospital stay.[3] The authors concluded that there was no evidence to support the ongoing use of intravenous rehydration in most cases of childhood gastroenteritis.

Preparations

BP 2008: Oral Rehydration Salts;
USP 31: Oral Rehydration Salts;
WHO/UNICEF: Oral Rehydration Salts.

Proprietary Preparations: some preparations are listed in Part 3.

Bicarbonate

Bicarbonato.

Description. Bicarbonate is an alkalinising agent given as bicarbonate-containing salts (sodium or potassium bicarbonate) or bicarbonate-producing salts (acetate, citrate, or lactate salts). Allowance should be made for the effect of the cation.

Incompatibility. Bicarbonate-producing or bicarbonate-containing solutions have been reported to be incompatible with a wide range of drugs. In many cases this incompatibility is a function of the alkaline nature of the bicarbonate solution. Precipitation of insoluble carbonates may occur, as may production of gaseous carbon dioxide when the bicarbonate ion is reduced by acidic solutions.

Potassium Bicarbonate

E501; Hydrogenuhličitan draselný; Kalii Hydrocarbonas; Kalii Hydrogenocarbobnas; Kalii hydrogenocarbonas; Kalio-vandenilio karbonatas; Kálium-hidrogén-karbonát; Kaliumvätekarbonat; Kaliumvetykarbonaatti; Monopotassium Carbonate; Potasio, bicarbonato de; Potassium, bicarbonate de; Potassium Hydrogen Carbonate; Potasu wodorowęglan; Potasyum Bikarbonat.

$KHCO_3$ = 100.1.
CAS — 298-14-6.
ATC — A12BA04.
ATC Vet — QA12BA04.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Potassium Hydrogen Carbonate; Potassium Bicarbonate BP 2008). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; practically insoluble in alcohol. When heated in the dry state or in solution, it is gradually converted to potassium carbonate. A freshly prepared 5% solution in water has a pH of not more than 8.6.

USP 31 (Potassium Bicarbonate). Colourless, odourless, transparent monoclinic prisms or white granular powder. Freely soluble in water; practically insoluble in alcohol. Its solutions are neutral or alkaline to phenolphthalein.

Equivalence. Each g of potassium bicarbonate represents about 10 mmol of potassium and of bicarbonate. Potassium bicarbonate 2.56 g is equivalent to about 1 g of potassium.

Potassium Citrate

Citronan draselný monohydrát; E332; Kalii citras; Kalii Citras Monohydricus; Kalio citratas; Kaliumcitrat; Kaliumsitraatti; Potasio, citrato de; Potassium, citrate de; Potasu cytrynian; Potasyum Sitrat; Trikálium-citrát; Tripotassium Citrate. Tripotassium 2-hydroxypropane-1,2,3-tricarboxylate monohydrate.

$C_6H_5K_3O_7,H_2O$ = 324.4.
CAS — 866-84-2 (anhydrous potassium citrate); 6100-05-6 (potassium citrate monohydrate).
ATC — A12BA02.
ATC Vet — QA12BA02.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.,* and *US.*

Ph. Eur. 6.2 (Potassium Citrate). Transparent, hygroscopic crystals or a white or almost white granular powder. Very soluble in water; practically insoluble in alcohol. Store in airtight containers.

USP 31 (Potassium Citrate). Transparent crystals or a white granular powder. It is odourless and is deliquescent in moist air. Soluble 1 in 1 of water and 1 in 2.5 of glycerol; almost insoluble in alcohol. Store in airtight containers.

Equivalence. Each g of potassium citrate (anhydrous) represents about 9.8 mmol of potassium and 3.26 mmol of citrate. Each g of potassium citrate (monohydrate) represents about 9.3 mmol of potassium and 3.08 mmol of citrate. Potassium citrate (monohydrate) 2.77 g is equivalent to about 1 g of potassium.

Sodium Acetate

E262; Natrii Acetas; Natrii acetas trihydricus; Natrio acetatas trihidratas; Natrium Aceticum; Nátrium-acetát; Natriumacetat trihydrat; Natriumasetaattitrihydraatti; Octan sodný trihydrát; Sodio, acetato de; Sodium (acétate de) trihydraté; Sodu octan.

$CH_3.CO_2Na,3H_2O$ = 136.1.
CAS — 127-09-3 (anhydrous sodium acetate); 6131-90-4 (sodium acetate trihydrate).
ATC — B05XA08.
ATC Vet — QB05XA08.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn,* and *US.*
US also allows the anhydrous form.

Ph. Eur. 6.2 (Sodium Acetate Trihydrate). Colourless crystals. Very soluble in water; soluble in alcohol. A 5% solution in water has a pH of 7.5 to 9.0. Store in airtight containers.

USP 31 (Sodium Acetate). It contains three molecules of water of hydration or is anhydrous. Colourless, transparent crystals, or a white, granular crystalline powder, or white flakes. It is odourless or has a faint acetous odour. It is efflorescent in warm dry air. Soluble 1 in 0.8 of water, 1 in 0.6 of boiling water, and 1 in 19 of alcohol. pH of a solution in water containing the equivalent of 3% of anhydrous sodium acetate is between 7.5 and 9.2. Store in airtight containers.

Equivalence. Each g of sodium acetate (anhydrous) represents about 12.2 mmol of sodium and of acetate. Each g of sodium acetate (trihydrate) represents about 7.3 mmol of sodium and of acetate. Sodium acetate (anhydrous) 3.57 g is equivalent to about 1 g of sodium. Sodium acetate (trihydrate) 5.92 g is equivalent to about 1 g of sodium.

Sodium Acid Citrate

Disodium Hydrogen Citrate; Disodu wodorocytrynian; E331; Natrium Citricum Acidum; Sodio, citrato ácido de.

$C_6H_6Na_2O_7,1\frac{1}{2}H_2O$ = 263.1.
CAS — 144-33-2.

Pharmacopoeias. In *Br.*

BP 2008 (Sodium Acid Citrate). A white, odourless or almost odourless, powder. Freely soluble in water; practically insoluble in alcohol. A 3% solution in water has a pH of 4.9 to 5.2.
The BP gives Disodium Hydrogen Citrate as an approved synonym.

Equivalence. Each g of sodium acid citrate (sesquihydrate) represents about 7.6 mmol of sodium and 3.8 mmol of citrate. Sodium acid citrate (sesquihydrate) 5.72 g is equivalent to about 1 g of sodium.

Sodium Bicarbonate

Baking Soda; E500; Hydrogenuhličitan sodný; Monosodium Carbonate; Natrii Bicarbonas; Natrii hydrogenocarbonas; Natrio-vandenilio karbonatas; Nátrium-hidrogén-karbonát; Natriumvätekarbonat; Natriumvetykarbonaatti; Sal de Vichy; Sodio, hidrogenocarbonato de; Sodium Acid Carbonate; Sodium, bicarbonate de; Sodium Hydrogen Carbonate; Sodu wodorowęglan; Sodyum Bikarbonat.

$NaHCO_3$ = 84.01.
CAS — 144-55-8.
ATC — B05CB04; B05XA02.
ATC Vet — QB05CB04; QB05XA02; QG04BQ01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Sodium Hydrogen Carbonate; Sodium Bicarbonate BP 2008). A white or almost white, crystalline powder. Soluble in water; practically insoluble in alcohol. The pH of a freshly prepared 5% solution in water is not more than 8.6. When heated in the dry state or in solution, it gradually changes into sodium carbonate.

USP 31 (Sodium Bicarbonate). A white crystalline powder that slowly decomposes in moist air. Soluble 1 in 12 of water; insoluble in alcohol. Its solutions, when freshly prepared with cold water, without shaking, are alkaline to litmus; alkalinity increases on standing, agitation, or heating.

Equivalence. Each g of sodium bicarbonate (anhydrous) represents about 11.9 mmol of sodium and of bicarbonate. Sodium bicarbonate 3.65 g is equivalent to about 1 g of sodium.

Sodium Citrate

Citronan sodný dihydrát; E331; Natrii citras; Natrii Citras Dihydricus; Natrio citratas; Natriumcitrat; Natriumsitraatti; Sodio, citrato de; Sodium, citrate de; Sodu cytrynian; Sodyum Sitrat; Trinátrium-citrát; Trisodium Citrate. Trisodium 2-hydroxypropane-1,2,3-tricarboxylate dihydrate.

$C_6H_5Na_3O_7,2H_2O$ = 294.1.
CAS — 68-04-2 (anhydrous sodium citrate); 6132-04-3 (sodium citrate dihydrate).
ATC — B05CB02.
ATC Vet — QB05CB02.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *Viet.*
Int. and *US* specify anhydrous or dihydrate.

Ph. Eur. 6.2 (Sodium Citrate). A white or almost white, crystalline powder or white or almost white, granular crystals; slightly deliquescent in moist air. Freely soluble in water; practically insoluble in alcohol. Store in airtight containers.

USP 31 (Sodium Citrate). It is anhydrous or contains two molecules of water of hydration. Colourless crystals, or a white crystalline powder. The hydrous form is soluble 1 in 1.5 of water and 1 in 0.6 of boiling water; insoluble in alcohol. Store in airtight containers.

Equivalence. Each g of sodium citrate (anhydrous) represents about 11.6 mmol of sodium and 3.9 mmol of citrate. Each g of sodium citrate (dihydrate) represents about 10.2 mmol of sodium and 3.4 mmol of citrate. Sodium citrate (anhydrous) 3.74 g is equivalent to about 1 g of sodium. Sodium citrate (dihydrate) 4.26 g is equivalent to about 1 g of sodium.

Storage. Sterilised solutions when stored may cause separation of particles from glass containers and solutions containing such particles must not be used.

Sodium Lactate

E325; Lactato de sodio; Natrii lactatis; Natriumlaktaatti; Natriumlaktat; Sodium, lactate de. Sodium 2-hydroxypropionate.

$C_3H_5NaO_3$ = 112.1.
CAS — 72-17-3.

Pharmacopoeias. *Chin., Eur.* (see p.vii), and *US* include preparations of sodium lactate.

Ph. Eur. 6.2 (Sodium Lactate Solution). It contains a minimum of 50% w/w of sodium lactate and is a mixture of the two enantiomers in about equal proportions. Sodium (*S*)-Lactate Solution contains a minimum of 50% w/w of sodium lactate, not less than 95% of which is the (*S*)-enantiomer. The solutions are clear, colourless, slightly syrupy liquids. Miscible with water and with alcohol. pH 6.5 to 9.0.

USP 31 (Sodium Lactate Solution). It is an aqueous solution containing at least 50% sodium lactate. A clear, colourless or practically colourless, slightly viscous liquid, odourless or having a slight, not unpleasant, odour. Miscible with water. pH between 5.0 and 9.0. Store in airtight containers.

Equivalence. Each g of sodium lactate (anhydrous) represents about 8.9 mmol of sodium and of lactate. Sodium lactate (anhydrous) 4.88 g is equivalent to about 1 g of sodium.

Adverse Effects and Treatment

Excessive use of bicarbonate or bicarbonate-forming compounds may lead to hypokalaemia and metabolic alkalosis, especially in patients with impaired renal function. Symptoms include mood changes, tiredness, slow breathing, muscle weakness, and irregular heartbeat. Muscle hypertonicity, twitching, and tetany may develop, especially in hypocalcaemic patients. Treatment of metabolic alkalosis associated with bicarbonate overdose consists mainly of appropriate correction of fluid and electrolyte balance. Replacement of calcium, chloride, and potassium ions may be of particular importance.

Excessive doses of *sodium salts* may also lead to sodium overloading and hyperosmolality (see Adverse Effects of Sodium, p.1686). Sodium bicarbonate given orally can cause stomach cramps, belching, and flatulence. Extravasation of irritant hypertonic sodium bicarbonate solutions resulting in local tissue necrosis has been reported after intravenous dosage.

Excessive doses of *potassium salts* may lead to hyperkalaemia (see Adverse Effects of Potassium, p.1684). Ingestion of potassium salts can cause gastrointestinal adverse effects, and tablet formulations may cause contact irritation due to high local concentrations of potassium.

Excessive oral doses of *citrate salts* may have a laxative effect.

Effects on the gastrointestinal tract. In addition to minor gastrointestinal effects (see above), spontaneous rupture of the stomach, although an exceedingly rare event, has been reported on several occasions after ingestion of sodium bicarbonate. The bicarbonate was believed to have resulted in the rapid production of enough carbon dioxide to rupture a stomach already distended with food, liquid, or air.[1,2]

1. Mastrangelo MR, Moore EW. Spontaneous rupture of the stomach in a healthy adult man after sodium bicarbonate ingestion. *Ann Intern Med* 1984; **101:** 649.
2. Lazebnik N, *et al.* Spontaneous rupture of the normal stomach after sodium bicarbonate ingestion. *J Clin Gastroenterol* 1986; **8:** 454–6.

Effects on mental state. Sodium lactate infusions have been reported to induce panic attacks, especially in patients with anxiety states, and have been used as a pharmacological model in the evaluation of mechanisms involved in panic disorder.[1] However, the mechanism that underlies panic attacks induced by lactate remains unknown,[1] and it has been suggested[2] that rapid administration of the large sodium load may be involved. There has also been a report[3] of a patient receiving oral lactate (as calcium lactate) who was suffering from panic disorder associated with agoraphobia; when lactate was discontinued, the patient reported a reduction in panic intensity without a decrease in the frequency of attacks.

1. Bourin M, *et al.* Provocative agents in panic disorder. *Therapie* 1995; **50:** 301–6.
2. Peskind ER, *et al.* Sodium lactate and hypertonic sodium chloride induce equivalent panic incidence, panic symptoms, and hypernatremia in panic disorder. *Biol Psychiatry* 1998; **44:** 1007–16.
3. Robinson D, *et al.* Possible oral lactate exacerbation of panic disorder. *Ann Pharmacother* 1995; **29:** 539–40.

Epileptogenic effect. Alkalosis may precipitate seizures; however, absence seizures have also been reported to be associated with sodium bicarbonate administration in a child in whom the serum pH was normal.[1]

1. Reif S, *et al*. Absence seizures associated with bicarbonate therapy and normal serum pH. *JAMA* 1989; **262:** 1328–9.

Precautions

Bicarbonate or bicarbonate-forming compounds should not generally be given to patients with metabolic or respiratory alkalosis, hypocalcaemia, or hypochlorhydria. During treatment of acidosis, frequent monitoring of serum-electrolyte concentrations and acid–base status is essential.

Sodium-containing salts should be given extremely cautiously to patients with heart failure, oedema, renal impairment, hypertension, eclampsia, or aldosteronism (see Sodium, p.1686).

Potassium-containing salts should be given with considerable care to patients with renal or adrenocortical insufficiency, cardiac disease, or other conditions that may predispose to hyperkalaemia (see Potassium, p.1685).

Abuse. High doses of bicarbonate have been taken by athletes to enhance performance in endurance sports by buffering hydrogen ions produced in conjunction with lactic acid.[1] Bicarbonates have also been used to alkalinise the urine and prolong the half-life of basic drugs, notably sympathomimetics and stimulants, thereby avoiding detection; however, such a practice may enhance toxicity.

1. Kennedy M. Drugs and athletes—an update. *Adverse Drug React Bull* 1994; (Dec): 639–42.

Interactions

The effect of oral bicarbonate or bicarbonate-forming compounds in raising intra-gastric pH may reduce or increase the rate and/or extent of absorption of a number of drugs (see also Antacids, p.1692). Alkalinisation of the urine leads to increased renal clearance of acidic drugs such as salicylates, tetracyclines, and barbiturates. Conversely, it prolongs the half-life of basic drugs and may result in toxicity (see also under Abuse, above).

Sodium bicarbonate enhances lithium excretion. The use of *potassium-containing salts* with drugs that increase serum-potassium concentrations such as ACE inhibitors and potassium-sparing diuretics should generally be avoided (p.1685). *Citrate salts* taken orally can enhance the absorption of aluminium from the gastrointestinal tract (see Toxicity, p.1706 under Adverse Effects of Aluminium Hydroxide). Patients with impaired renal function are particularly susceptible to aluminium accumulation and citrate-containing oral preparations, including many effervescent or dispersible tablets, are best avoided by patients with renal failure taking aluminium-containing compounds.

Pharmacokinetics

Oral bicarbonate, such as sodium bicarbonate, neutralises gastric acid with the production of carbon dioxide. Bicarbonate not involved in that reaction is absorbed and in the absence of a deficit of bicarbonate in the plasma, bicarbonate ions are excreted in the urine, which is rendered alkaline, and there is an accompanying diuresis.

Acetates such as potassium acetate and sodium acetate, citrates such as potassium citrate, sodium acid citrate, and sodium citrate, and lactates such as sodium lactate are metabolised, after absorption, to bicarbonate.

Uses and Administration

Bicarbonate-providing salts are alkalinising agents used for a variety of purposes including the correction of metabolic acidosis, alkalinisation of the urine, and as antacids.

When an alkalinising agent is indicated for treating acute or chronic **metabolic acidosis** (p.1667), sodium bicarbonate is usually used. In conditions when acute metabolic acidosis is associated with tissue hypoxia, such as *cardiac arrest* and *lactic acidosis*, the role of such alkalinising agents is controversial (see p.1667, and for guidelines on advanced cardiac life support, p.1156). Sodium lactate has been given as an alternative to sodium bicarbonate in acute metabolic acidosis, but is no longer recommended because of the risk of precipitating lactic acidosis. In *chronic hyperchloraemic acidosis* associated with potassium deficiency, potassium bicarbonate may be preferred to sodium bicarbonate. The citrate salts of potassium or sodium have also been used as alternatives to sodium bicarbonate in treating chronic metabolic acidosis resulting from *renal disorders*. Sodium bicarbonate, lactate and acetate, and potassium acetate are used as bicarbonate sources in *dialysis fluids* (p.1670).

The dose of bicarbonate required for the treatment of acidotic states must be calculated on an individual basis, and is dependent on the acid–base balance and electrolyte status of the patient. In the treatment of chronic acidosis bicarbonate has been given orally and doses providing 57 mmol (4.8 g sodium bicarbonate) or more daily may be required. In severe acidosis, sodium bicarbonate has been given intravenously by continuous infusion usually as a 1.26% (150 mmol/litre) solution or by slow intravenous injection of a stronger (hypertonic) solution of up to 8.4% (1000 mmol/litre) sodium bicarbonate (but see the discussion on metabolic acidosis, p.1667). For the correction of acidosis during advanced cardiac life support procedures, doses of 50 mmol of sodium bicarbonate (50 mL of an 8.4% solution) may be given intravenously to adults. Frequent monitoring of serum-electrolyte concentrations and acid–base status is essential during treatment of acidosis.

Sodium bicarbonate may be used in the management of **hyperkalaemia** (p.1669) to promote the intracellular uptake of potassium and correct associated acidosis, although there is some debate as to its value. Some sources suggest that 50 to 100 mL of an 8.4% solution may be given in severe hyperkalaemia accompanied by acidosis, although more dilute solutions have been used, and care is required, particularly if there is accompanying renal impairment.

Sodium bicarbonate, sodium citrate, and potassium citrate cause **alkalinisation of the urine**. They may therefore be given to relieve discomfort in mild *urinary-tract infections* (p.199) and to prevent the development of uric-acid renal calculi in the initial stages of *uricosuric* therapy for hyperuricaemia in chronic gout (for example, see Precautions for Probenecid, p.558). In both cases, they are given with a liberal fluid intake, usually by mouth, in divided doses of up to about 10 g daily. Sodium bicarbonate may also be used to alkalinise the urine in *acute poisoning* with weakly acidic drugs such as salicylates and phenoxyacetate pesticides; use with a diuretic for ‘forced alkaline diuresis’ is no longer recommended.

When given orally, sodium bicarbonate and potassium bicarbonate neutralise acid secretions in the gastrointestinal tract and sodium bicarbonate in particular is therefore frequently included in **antacid** preparations (p.1692). To relieve *dyspepsia* doses of about 1 to 5 g of sodium bicarbonate in water have been taken when required. Sodium citrate has been widely used as a ‘clear’ (non-particulate) antacid, usually with an H_2-antagonist, for the *prophylaxis of acid aspiration* associated with anaesthesia (p.1693). Sodium bicarbonate is also used in various preparations for *double-contrast radiography* where production of gas (carbon dioxide) in the gastrointestinal tract is necessary. Similarly, solutions containing sodium bicarbonate or citrate have been used to treat acute *oesophageal impaction*.

Sodium bicarbonate and sodium or potassium citrate are used as buffering or alkalinising agents in *pharmaceutical formulation*. Sodium or potassium bicarbonate and anhydrous sodium citrate are used in effervescent tablet formulations.

Individual salts also have **other specific uses**. A 5% solution of sodium bicarbonate can be administered as ear drops to soften and remove *ear wax* (see under Docusates, p.1725). Sodium bicarbonate injection has been used to treat *extravasation of anthracycline antineoplastics* (p.640) although as mentioned in Adverse Effects, above, hypertonic solutions may themselves cause necrosis.

Sodium citrate has anti-clotting properties and is used, as sodium acid citrate, with other agents in solutions for the anticoagulation and preservation of blood for *transfusion* purposes. Similarly, sodium citrate 3% irrigation may be useful for the dissolution of *blood clots in the bladder* as an alternative to sodium chloride 0.9%. Enemas containing sodium citrate are given rectally as *osmotic laxatives*. Sodium citrate is also a common ingredient in *cough* mixtures. Eye drops containing sodium citrate 10% have been used in the treatment of chemical *eye burns* (below); they may be used with potassium ascorbate eye drops (see Uses of Vitamin C Substances, p.1984).

Eye disorders. Sodium bicarbonate is used in the management of blepharitis, an inflammation of the margin of the eyelids with various causes. It may be allergic in nature or associated with seborrhoea of the scalp. Infection of the eyelids can produce ulcerative blepharitis, a condition characterised by the formation of yellow crusts which may glue the eyelashes together. Parasites occasionally cause blepharitis. The condition is first treated by cleaning the eyes and eyelids with sodium bicarbonate solution or a suitable bland eye lotion; simple eye ointment or diluted baby shampoo can also be used to soften crusts to aid removal. If an infection is present, antibacterials may be required (p.171). Long-term management consists of daily cleansing of the lid margins with a bland eye lotion.

EYE BURNS. Both heat and chemicals can burn the eye, causing damage to the conjunctiva, cornea, and underlying structures. Burn severity may be influenced by the amount of burning substance that enters the eye and the duration of contact, its temperature and impact force, whether it is a liquid or solid, its pH, and osmolarity.[1,2] Hydrofluoric acid, sulfurous acid, and alkalis readily penetrate the corneal stroma.[2] Immediate irrigation is essential, and a duration of at least 15 to 30 minutes is recommended; it may need to be repeated periodically.

Water or sodium chloride 0.9% solution may be used initially, but because they are hypotonic to the eye there can be an increased uptake of the fluid and diffusion of the burning substance into the deeper layers of the cornea, resulting in oedema. To reduce this risk solutions with higher osmolarities have been suggested, if available, and include balanced salt solution, buffered solutions such as lactated Ringer's solution, and commercial decontamination preparations with amphoteric and chelating properties.[1,2]

For acid and alkali burns ascorbate and citrate eye drops have been tried, and ascorbate given orally, based on suggestions that ascorbate may scavenge free radicals and citrate may reduce the release of free radicals and proteolytic enzymes in burn tissue.[1] However, a retrospective analysis of 121 patients with alkali burns to the eye suggested those with less severe burns (grades 1 and 2) did not benefit from an intensive topical therapy regimen including 10% ascorbate drops and 10% citrate drops;[3] a trend to more rapid healing and better visual outcome were seen in patients with grade 3 burns but in those with the most severe damage (grade 4) the regimen made no difference. In the management of hydrofluoric acid burns of the eye, calcium gluconate has also been used after initial irrigation (see p.2322). Other general treatments that may be required include topical application of anaesthesia, corticosteroids, and antibacterials, treatment for glaucoma, and surgery.[1,2]

Osteoporosis. Potassium bicarbonate in an oral dose of 1 to 2 mmol/kg daily improved mineral balance and bone metabolism in a short-term study.[1] However, the authors cautioned against the use of bicarbonate to treat or prevent osteoporosis (p.1084) without further study.[2]

Renal calculi. Citrate forms soluble complexes with calcium, thereby reducing urinary saturation of stone-forming calcium salts. Potassium citrate has a hypocalciuric effect when given orally, probably due to enhanced renal calcium absorption. Urinary calcium excretion is unaffected by sodium citrate, since the alkali-mediated hypocalciuric effect is offset by a sodium-linked calciuresis.[1] Potassium citrate may be beneficial in reducing the rate of stone formation in patients with hypocitraturia[2,3] or hypercalciuria.[4] As mentioned in Uses above, sodium bicarbonate or sodium or potassium citrate may also be used for their alkalinising action, as an adjunct to a liberal fluid intake, to prevent development of uric-acid renal calculi during uricosuric therapy.

Other causes of renal calculi and their treatment are discussed on p.2181.

Urinary alkalinisation with sodium bicarbonate, sodium citrate, or potassium citrate may be useful in the management of cystine stone formation in patients with cystinuria (see under Penicillamine, p.1459).

Multi-ingredient: numerous preparations are listed in Part 3.

Calcium

Calcio; Kalsiyum; Kalzium.
Ca = 40.078.

Description. Calcium is a cation given as various calcium-containing salts.

Incompatibility. Calcium salts have been reported to be incompatible with a wide range of drugs. Complexes may form resulting in the formation of a precipitate.

Calcium Acetate

Acetate of Lime; Calcii acetas; Calcio, acetato de; Calcium, acétate de; E263; Kalcio acetatas; Kalciumacetat; Kalcium-acetát; Kalsiumasetaatti; Kalsiyum Asetat; Lime Acetate.
$C_4H_6CaO_4$ = 158.2.
CAS — 62-54-4.
ATC — A12AA12.
ATC Vet — QA12AA12.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Calcium Acetate). A white or almost white, hygroscopic powder. Freely soluble in water; slightly soluble in alcohol. A 5% solution in water has a pH of 7.2 to 8.2. Store in airtight containers.
USP 31 (Calcium Acetate). A white, odourless or almost odourless, hygroscopic, crystalline powder. It decomposes to calcium carbonate and acetone when heated to above 160°. Freely soluble in water; slightly soluble in methyl alcohol; practically insoluble in dehydrated alcohol, in acetone, and in benzene. A 5% solution in water has a pH of 6.3 to 9.6. Store in airtight containers.

Equivalence. Each g of calcium acetate (anhydrous) represents about 6.3 mmol of calcium. Calcium acetate (anhydrous) 3.95 g is equivalent to about 1 g of calcium.

Calcium Chloride

Calcii Chloridum; Calcii chloridum dihydricum; Calcio, cloruro de; Calcium Chloratum; Calcium, chlorure de; Chlorid vápenatý; Cloreto de Cálcio; Cloruro de Calcio; E509; Kalcio chloridas; Kalciumklorid; Kalcium-klorid; Kalsiumkloridi; Kalsiyum Klorür; Wapnia chlorek.
$CaCl_2,xH_2O$ = 110.0 (anhydrous); 147.0 (dihydrate).
CAS — 10043-52-4 (anhydrous calcium chloride); 7774-34-7 (calcium chloride hexahydrate); 10035-04-8 (calcium chloride dihydrate).
ATC — A12AA07; B05XA07; G04BA03.
ATC Vet — QA12AA07; QB05XA07; QG04BA03.

Pharmacopoeias. *Chin., Eur.* (see p.vii), *Jpn, US,* and *Viet.* include the dihydrate.
Eur. also specifies the hexahydrate.
Ph. Eur. 6.2 (Calcium Chloride Dihydrate; Calcii Chloridum Dihydricum). A white or almost white, hygroscopic, crystalline powder. Freely soluble in water; soluble in alcohol. Store in airtight containers.
Ph. Eur. 6.2 (Calcium Chloride Hexahydrate; Calcii Chloridum Hexahydricum). A white or almost white, crystalline mass or colourless crystals. Very soluble in water; freely soluble in alcohol. F.p. about 29°.
USP 31 (Calcium Chloride). White, hard, odourless fragments or granules. Is deliquescent. Soluble 1 in 0.7 of water, 1 in 0.2 of boiling water, 1 in 4 of alcohol, and 1 in 2 of boiling alcohol. pH of a 5% solution in water is between 4.5 and 9.2. Store in airtight containers.

Equivalence. Each g of calcium chloride (dihydrate) represents about 6.8 mmol of calcium and 13.6 mmol of chloride. Calcium chloride (dihydrate) 3.67 g is equivalent to about 1 g of calcium.

Each g of calcium chloride (hexahydrate) represents about 4.56 mmol of calcium and 9.13 mmol of chloride. Calcium chloride (hexahydrate) 5.47 g is equivalent to about 1 g of calcium.

Calcium Citrate

Calcio, citrato de; Tricalcium Citrate. Tricalcium 2-hydroxypropane-1,2,3-tricarboxylate tetrahydrate.
$C_{12}H_{10}Ca_3O_{14},4H_2O$ = 570.5.
CAS — 5785-44-4.

Pharmacopoeias. In *US.*
USP 31 (Calcium Citrate). A white, odourless, crystalline powder. Slightly soluble in water; insoluble in alcohol; freely soluble in diluted 3N hydrochloric acid and in diluted 2N nitric acid.

Equivalence. Each g of calcium citrate (tetrahydrate) represents about 5.3 mmol of calcium and 3.5 mmol of citrate. Calcium citrate (tetrahydrate) 4.74 g is equivalent to about 1 g of calcium.

Calcium Glubionate *(USAN, rINN)*

Calcii Glubionas; Calcium Gluconate Lactobionate Monohydrate; Calcium Gluconogalactogluconate Monohydrate; Glubionate de Calcium; Glubionato de calcio. Calcium D-gluconate lactobionate monohydrate.
Кальция Глубионат
$(C_{12}H_{21}O_{12},C_6H_{11}O_7)Ca,H_2O$ = 610.5.
CAS — 31959-85-0 (anhydrous calcium glubionate); 12569-38-9 (calcium glubionate monohydrate).
ATC — A12AA02.
ATC Vet — QA12AA02.

Pharmacopoeias. *US* includes Calcium Glubionate Syrup.

Equivalence. Each g of calcium glubionate (monohydrate) represents about 1.6 mmol of calcium. Calcium glubionate (monohydrate) 15.2 g is equivalent to about 1 g of calcium.

Calcium Gluceptate

Calcium Glucoheptonate *(pINN)*; Calcii glucoheptonas; Calcium, glucoheptonate de; Glucoheptonate de Calcium; Glucoheptonato de calcio; Kalcio gliukoheptonatas; Kalciumglukoheptonat; Kalcium-glükoheptonát; Kalcium-glukoheptonát; Kalsiumglukoheptonaatti.
Кальция Глюкогептонат
$C_{14}H_{26}CaO_{16}$ = 490.4.
CAS — 17140-60-2 (anhydrous calcium gluceptate); 29039-00-7 (anhydrous calcium gluceptate).
ATC — A12AA10.
ATC Vet — QA12AA10.

Pharmacopoeias. In *Eur.* (see p.vii). *US* allows anhydrous or with varying amounts of water of hydration.
Ph. Eur. 6.2 (Calcium Glucoheptonate). A mixture in variable proportions of calcium di(D-*glycero*-D-*gulo*-heptonate) and calcium di(D-*glycero*-D-*ido*-heptonate). A white or very slightly yellow, hygroscopic, amorphous powder. Very soluble in water; practically insoluble in alcohol and in acetone. A 10% solution in water has a pH of 6.0 to 8.0. Store in airtight containers.
USP 31 (Calcium Gluceptate). It is anhydrous or contains varying amounts of water of hydration. It consists of the calcium salt of the alpha-epimer of glucoheptonic acid or of a mixture of the alpha and beta epimers of glucoheptonic acid. A white to faintly yellow amorphous powder. It is stable in air, but the hydrous forms may lose part of their water of hydration on standing. Freely soluble in water; insoluble in alcohol and in many other organic solvents. pH of a 10% solution in water is between 6.0 and 8.0.

Equivalence. Each g of calcium gluceptate (anhydrous) represents about 2 mmol of calcium. Calcium gluceptate (anhydrous) 12.2 g is equivalent to about 1 g of calcium.

Calcium Gluconate

Calcii gluconas; Calcii Gluconas Monohydricus; Calcio, gluconato de; Calcium, gluconate de; Calcium Glyconate; E578; Glukonan vápenatý monohydrát; Kalcio gliukonatas; Kalciumglukonat; Kalcium-glükonát; Kalsiumglukonaatti; Wapnia glukonian. Calcium D-gluconate monohydrate.
$C_{12}H_{22}CaO_{14},H_2O$ = 448.4.
CAS — 299-28-5 (anhydrous calcium gluconate); 18016-24-5 (calcium gluconate monohydrate).
ATC — A12AA03; D11AX03.
ATC Vet — QA12AA03; QD11AX03.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *Viet.* Also in *US* as the anhydrous or the monohydrate form.
Calcium borogluconate is included as an injection in *BP(Vet).*
Ph. Eur. 6.2 (Calcium Gluconate). A white or almost white, crystalline or granular, powder. Sparingly soluble in water; freely soluble in boiling water.
USP 31 (Calcium Gluconate). It is anhydrous or contains one molecule of water of hydration. White, odourless, crystalline granules or powder. Slowly soluble 1 in 30 of water; soluble 1 in 5 of boiling water; insoluble in alcohol. Its solutions are neutral to litmus.

Equivalence. Each g of calcium gluconate (monohydrate) represents about 2.2 mmol of calcium. Calcium gluconate (monohydrate) 11.2 g is equivalent to about 1 g of calcium.

Calcium Glycerophosphate

Calcii glycerophosphas; Calcio, glicerofosfato de; Calcium Glycerinophosphate; Calcium, glycérophosphate de; Calcium Glycerylphosphate; Glycerofosforečnan vápenatý; Kalcio glicerofosfatas; Kalcium-glicerofoszfát; Kalciumglycerofosfat; Kalsiumglyserofosfaatti.

$C_3H_7CaO_6P(+xH_2O)$ = 210.1 (anhydrous).
CAS — 27214-00-2 (anhydrous calcium glycerophosphate).
ATC — A12AA08.
ATC Vet — QA12AA08.

Pharmacopoeias. In *Eur.* (see p.vii), *US.*, and *Viet.*
Ph. Eur. 6.2 (Calcium Glycerophosphate). A mixture in variable proportions of calcium (*RS*)-2,3-dihydroxypropyl phosphate and of calcium 2-hydroxy-1-(hydroxymethyl)ethyl phosphate, which may be hydrated. It contains not less than 18.6% and not more than 19.4% of calcium, calculated with reference to the dried substance. A white or almost white, hygroscopic powder. Sparingly soluble in water; practically insoluble in alcohol. It loses not more than 12% of its weight on drying.
USP 31 (Calcium Glycerophosphate). A mixture, in variable proportions, of calcium *(RS)*-2,3-dihydroxypropyl phosphate and calcium 2-hydroxy-1-(hydroxymethyl)ethyl phosphate, which may be hydrated. It contains not less than 18.6% and not more than 19.4% of calcium, calculated with reference to the dried substance. Store at a temperature between 20° and 25°, excursions permitted between 15° and 30°.

Equivalence. Each g of calcium glycerophosphate (anhydrous) represents about 4.8 mmol of calcium. Calcium glycerophosphate (anhydrous) 5.24 g is equivalent to about 1 g of calcium.

Calcium Hydrogen Phosphate

Calcii et Hydrogenii Phosphas; Calcii hydrogenophosphas; Calcio, hidrogenofosfato de; Calcium, hydrogénophosphate de; Calcium Hydrophosphoricum; Calcium Monohydrogen Phosphate; Dicalcium Orthophosphate; Dicalcium Phosphate; E341; Hydrogenfosforečnan vápenatý; Kalcio-vandenilio fosfatas; Kalcium-hidrogén-foszfát; Kalciumvätefosfat; Kalsiumvetyfosfaatti; Wapna wodorofosforan. Calcium hydrogen orthophosphate.

$CaHPO_4$ = 136.1 (anhydrous); 172.1 (dihydrate).
CAS — 7757-93-9 (anhydrous calcium hydrogen phosphate); 7789-77-7 (calcium hydrogen phosphate dihydrate).

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, and *US*, which includes monographs for the anhydrous substance and the dihydrate form.
Ph. Eur. 6.2 (Calcium Hydrogen Phosphate, Anhydrous; Calcii Hydrogenophosphas Anhydricus). A white or almost white, crystalline powder, or colourless crystals. Practically insoluble in water and in alcohol; dissolves in dilute hydrochloric acid and in dilute nitric acid.
Ph. Eur. 6.2 (Calcium Hydrogen Phosphate Dihydrate; Calcii Hydrogenophosphas Dihydricus; Calcium Hydrogen Phosphate BP 2008). A white or almost white, crystalline powder. Practically insoluble in cold water and in alcohol; dissolves in dilute hydrochloric acid and in dilute nitric acid.
The BP 2008 gives Dibasic Calcium Phosphate as an approved synonym.
USP 31 (Anhydrous Dibasic Calcium Phosphate).
USP 31 (Dibasic Calcium Phosphate Dihydrate).

Equivalence. Each g of calcium hydrogen phosphate (dihydrate) represents about 5.8 mmol of calcium and of phosphate. Calcium hydrogen phosphate (dihydrate) 4.29 g is equivalent to about 1 g of calcium.

Calcium Lactate

Calcii lactas; Calcio, lactato de; Calcium, lactate de; E327; Kalcio laktatas; Kalciumlaktat; Kalcium-laktát; Kalsiumlaktaatti; Kalsiyum Laktat; Mléčnan vápenatý; Wapnia mleczan. Calcium 2-hydroxypropionate.

$C_6H_{10}CaO_6,xH_2O$ = 218.2 (anhydrous); 308.3 (pentahydrate); 272.3 (trihydrate).
CAS — 814-80-2 (anhydrous calcium lactate); 41372-22-9 (hydrated calcium lactate); 5743-47-5 (calcium lactate pentahydrate); 63690-56-2 (calcium lactate pentahydrate).
ATC — A12AA05.
ATC Vet — QA12AA05.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.
Eur. has separate monographs for the anhydrous substance, the monohydrate, the pentahydrate, and the trihydrate. *US* allows anhydrous or hydrous forms. *Viet.* has monographs for the pentahydrate and the trihydrate.
Ph. Eur. 6.2 (Calcium Lactate, Anhydrous; Calcii Lactas Anhydricus). A white or almost white, crystalline or granular powder. Soluble in water; freely soluble in boiling water; very slightly soluble in alcohol.
Ph. Eur. 6.2 (Calcium Lactate Monohydrate; Calcii Lactas Monohydricus). A white or almost white, crystalline or granular powder. Soluble in water; freely soluble in boiling water; very slightly soluble in alcohol.
Ph. Eur. 6.2 (Calcium Lactate Pentahydrate; Calcii Lactas Pentahydricus). A white or almost white, slightly efflorescent, crystalline or granular powder. Soluble in water; freely soluble in boiling water; very slightly soluble in alcohol.
The BP 2008 gives Calcium Lactate as an approved synonym.
Ph. Eur. 6.2 (Calcium Lactate Trihydrate; Calcii Lactas Trihydricus). A white or almost white, crystalline or granular powder. Soluble in water; freely soluble in boiling water; very slightly soluble in alcohol.
USP 31 (Calcium Lactate). White, practically odourless, granules or powder. The pentahydrate is somewhat efflorescent and at 120° becomes anhydrous. The pentahydrate is soluble 1 in 20 of water and practically insoluble in alcohol. Store in airtight containers.

Equivalence. Each g of calcium lactate (trihydrate) represents about 3.7 mmol of calcium. Each g of calcium lactate (pentahydrate) represents about 3.2 mmol of calcium. Calcium lactate (pentahydrate) 7.7 g and calcium lactate (trihydrate) 6.8 g are each equivalent to about 1 g of calcium.

Calcium Lactate Gluconate

Calcio, gluconato lactato de.

$Ca_5(C_3H_5O_3)_6,(C_6H_{11}O_7)_4,2H_2O$ = 1551.4.
ATC — A12AA06.
ATC Vet — QA12AA06.

Equivalence. Each g of calcium lactate gluconate (dihydrate) represents about 3.2 mmol of calcium. Calcium lactate gluconate (dihydrate) 7.74 g is equivalent to about 1 g of calcium.

Calcium Lactobionate

Calcii Lactobionas; Calcio, lactobionato de; Calcium Lactobionate Dihydrate; Kalciumlaktobionat; Kalsiumlaktobionaatti. Calcium 4-*O*-β-D-galactopyranosyl-D-gluconate dihydrate.

$C_{24}H_{42}CaO_{24},2H_2O$ = 790.7.
CAS — 110638-68-1.

Pharmacopoeias. In *US.*
USP 31 (Calcium Lactobionate). pH of a 5% solution in water is between 5.4 and 7.4.

Equivalence. Each g of calcium lactobionate (dihydrate) represents about 1.3 mmol of calcium. Calcium lactobionate (dihydrate) 19.7 g is equivalent to about 1 g of calcium.

Calcium Levulinate *(BAN)*

Calcii Laevulas; Calcii laevulinas; Calcii Laevulinas Dihydricus; Calcii Levulinas Dihydricum; Calcio, levulinato de; Calcium Laevulate; Calcium Laevulinate; Calcium, lévulinate de; Kalcio levulinatas; Kalciumlevulat; Kalcium-levulát dihydrát; Kalciumlevulinat; Kalcium-levulinát; Kalsiumlevulaatti; Kalsiumlevulinaatti; Lévulinate Calcique. Calcium 4-oxovalerate dihydrate.

$C_{10}H_{14}CaO_6,2H_2O$ = 306.3.
CAS — 591-64-0 (anhydrous calcium levulinate); 5743-49-7 (calcium levulinate dihydrate).
ATC — A12AA30.
ATC Vet — QA12AA30.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Calcium Levulinate Dihydrate). A white or almost white, crystalline powder. Freely soluble in water; very slightly soluble in alcohol; practically insoluble in dichloromethane. A 10% solution in water has a pH of 6.8 to 7.8. Protect from light.
USP 31 (Calcium Levulinate). A white crystalline or amorphous powder, having a faint odour suggestive of burnt sugar. Freely soluble in water; slightly soluble in alcohol; insoluble in chloroform and in ether. pH of a 10% solution in water is between 7.0 and 8.5.

Equivalence. Each g of calcium levulinate (dihydrate) represents about 3.3 mmol of calcium. Calcium levulinate (dihydrate) 7.64 g is equivalent to about 1 g of calcium.

Calcium Phosphate

Calcii Phosphas; Calcio, fosfato de; Calcium Orthophosphate; E341; Fosfato Tricalcico; Fosforečnan vápenatý; Kalcio fosfatas; Kalcium-foszfát; Phosphate Tertiaire de Calcium; Phosphate tricalcique; Precipitated Calcium Phosphate; Tricalcii phosphas; Tricalcium Phosphate; Trikalciumfosfat; Trikalsiumfosfaatti; Wapnia fosforan.

CAS — 7758-87-4 (tricalcium diorthophosphate); 12167-74-7 (calcium hydroxide phosphate).
ATC — A12AA01.
ATC Vet — QA12AA01.

Description. Calcium phosphate is not a clearly defined chemical entity but is a mixture of calcium phosphates that has been most frequently described as either tricalcium diorthophosphate, $Ca_3(PO_4)_2$ = 310.2, or calcium hydroxide phosphate, $Ca_5OH(PO_4)_3$ = 502.3.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *Viet.* Also in *USNF.*
Ph. Eur. 6.2 (Calcium Phosphate). It consists of a mixture of calcium phosphates and contains 35 to 40% of Ca. A white or almost white powder. Practically insoluble in water; dissolves in dilute hydrochloric acid and in dilute nitric acid.
The BP 2008 gives Tribasic Calcium Phosphate as an approved synonym.
USNF 26 (Tribasic Calcium Phosphate). It consists of a variable mixture of calcium phosphates having the approximate composition $10CaO.3P_2O_5.H_2O$. It contains not less than 34% and not more than 40% of calcium. A white, odourless, powder. Practically insoluble in water; insoluble in alcohol; readily soluble in 3N hydrochloric acid and in 2N nitric acid.

Calcium Pidolate *(pINNM)*

Calcii Pidolas; Calcium Pyroglutamate; Pidolate de Calcium; Pidolato de calcio. Calcium 5-oxopyrrolidine-2-carboxylate.

Кальций Пидолат

$Ca(C_5H_6NO_3)_2$ = 296.3.
CAS — 31377-05-6.

Equivalence. Each g of calcium pidolate (anhydrous) represents about 3.4 mmol of calcium. Calcium pidolate (anhydrous) 7.39 g is equivalent to about 1 g of calcium.

Calcium Silicate

Calcio, silicato de; E552.

CAS — 1344-95-2; 10101-39-0 (calcium metasilicate); 10034-77-2 (calcium diorthosilicate); 12168-85-3 (calcium trisilicate).
ATC — A02AC02.
ATC Vet — QA02AC02.

Description. A naturally occurring mineral, the most common forms being calcium metasilicate ($CaSiO_3$ = 116.2), calcium diorthosilicate (Ca_2SiO_4 = 172.2), and calcium trisilicate (Ca_3SiO_5 = 228.3). It is usually found in hydrated forms containing various amounts of water of crystallisation. Commercial calcium silicate is prepared synthetically.

Pharmacopoeias. In *USNF.*
USNF 26 (Calcium Silicate). Crystalline or amorphous calcium silicate is a compound of calcium oxide and silicon dioxide containing not less than 4% of CaO and not less than 35% of SiO_2. A white to off-white free-flowing powder. Insoluble in water; with mineral acids it forms a gel. A 5% aqueous suspension has a pH of 8.4 to 11.2.

Calcium Sodium Lactate

Calcio, lactato sódico de.

$2C_3H_5NaO_3,(C_3H_5O_3)_2Ca,4H_2O$ = 514.4.

Equivalence. Each g of calcium sodium lactate (tetrahydrate) represents about 1.9 mmol of calcium and 3.9 mmol of sodium and of lactate. Calcium sodium lactate (tetrahydrate) 12.8 g is equivalent to about 1 g of calcium.

Adverse Effects and Treatment

Oral calcium salts can cause gastrointestinal irritation; calcium chloride is generally considered to be the most irritant of the commonly used calcium salts.

Injection of calcium salts can also produce irritation, and intramuscular or subcutaneous injection in particular can cause local reactions including sloughing or necrosis of the skin; solutions of calcium chloride are extremely irritant and should not be injected intramuscularly or subcutaneously. Soft-tissue calcification has followed the use of calcium salts parenterally.

Excessive amounts of calcium salts may lead to hypercalcaemia. This complication is usually associated with parenteral use, but can occur after oral dosage, usually in patients with renal failure or who are also taking vitamin D. Symptoms of hypercalcaemia include anorexia, nausea, vomiting, constipation, abdominal pain, muscle weakness, mental disturbances, polydipsia, polyuria, nephrocalcinosis, renal calculi, and, in severe cases, cardiac arrhythmias and coma. Too rapid intravenous injection of calcium salts may also lead to symptoms of hypercalcaemia, as well as a chalky taste, hot flushes, and peripheral vasodilatation. Mild asymptomatic hypercalcaemia will usually resolve if calcium and other contributory drugs such as vitamin D are stopped (see also Vitamin D-mediated Hypercalcaemia, p.1668). If hypercalcaemia is severe, urgent treatment is required as outlined on p.1668.

Precautions

Solutions of calcium salts, particularly calcium chloride, are irritant, and care should be taken to prevent extravasation during intravenous injection. Calcium salts should be given cautiously to patients with renal impairment, or diseases associated with hypercalcaemia such as sarcoidosis and some malignancies. In addition, they should generally be avoided in patients with calcium renal calculi, or a history of renal calculi. Calcium chloride, because of its acidifying nature, is unsuitable for the treatment of hypocalcaemia caused by renal insufficiency or in patients with respiratory acidosis or failure.

Plasma-calcium concentrations should be monitored closely in patients with renal impairment and during parenteral dosage and if large doses of vitamin D are used concurrently.

Interactions

Hypercalcaemia has occurred when calcium salts are given with thiazide diuretics or vitamin D. Vitamin D increases the gastrointestinal absorption of calcium and thiazide diuretics decrease its urinary excretion. Plasma-calcium concentrations should be monitored in patients receiving the drugs together.

Bran decreases the gastrointestinal absorption of calcium, and may therefore decrease the efficacy of calcium supplements. Corticosteroids also reduce calcium absorption.

Calcium enhances the effects of digitalis glycosides on the heart and may precipitate digitalis intoxication; parenteral calcium therapy is best avoided in patients receiving cardiac glycosides. Citrate salts increase the absorption of aluminium from the gastrointestinal tract (see Toxicity, under Adverse Effects of Aluminium Hydroxide, p.1706), therefore patients with renal failure taking aluminium compounds should avoid taking calcium citrate. Calcium salts reduce the absorption of a number of other drugs such as bisphosphonates, fluoride, some fluoroquinolones, and tetracyclines; doses should be separated by at least 3 hours.

Pharmacokinetics

Calcium is absorbed mainly from the small intestine by active transport and passive diffusion. About one-third of ingested calcium is absorbed although this can vary depending upon dietary factors and the state of the small intestine; also absorption is increased in calcium deficiency and during periods of high physiological requirement such as during childhood or pregnancy and lactation. 1,25-Dihydroxycholecalciferol (calcitriol), a metabolite of vitamin D, enhances the active phase of absorption.

Excess calcium is mainly excreted renally. Unabsorbed calcium is eliminated in the faeces, together with that secreted in the bile and pancreatic juice. Minor amounts are lost in the sweat, skin, hair, and nails. Calcium crosses the placenta and is distributed into breast milk.

Human Requirements

Calcium is the most abundant mineral in the body and is an essential body electrolyte. However, defining individual calcium requirements has proved difficult and guidelines vary widely by country and culture. Some authorities have adopted a factorial approach. For example, in the UK the dietary reference value (DRV) represents the apparent calcium requirements of healthy people under the prevailing dietary circumstances. The amount of calcium absorbed varies according to several factors including the requirements of the body, but is normally only about 30 to 40% of the dietary intake.

The richest dietary sources of calcium are milk and milk products. Significant amounts can also be consumed in green leafy vegetables, fortified flour, the soft bones of fish, and hard water.

UK and US recommended dietary intake. In the UK dietary reference values (DRV—see Human Requirements, p.1925) have been published for calcium.[1] In the USA recommended dietary allowances (RDA) had been set,[2] but have been replaced by dietary reference intakes (see p.1925).[3] In the UK the estimated average requirement (EAR) for adults is 525 mg (13.1 mmol) daily and the reference nutrient intake (RNI) for adults is 700 mg (17.5 mmol) daily; these figures are based on a mean absorption of calcium of 30% from mixed diets. In the USA the traditional RDA was 800 mg daily for adults aged over 25 years; this figure was based on an absorption rate of 40%. Under the new dietary reference intakes, adequate intakes (AI) for calcium have been set, which are higher in some age groups than the previous RDAs.[3] For adults aged up to 50 years the AI is 1 g daily, and for those 51 years or older, it is 1.2 g daily.[3] The tolerable upper intake is considered to be 2.5 g daily.[3]

Table 1. Some calcium salts and their calcium content.

Calcium salt	Calcium content per g mg	mmol	mEq
Calcium acetate (anhydrous)	253	6.3	12.6
Calcium carbonate	400	10.0	20.0
Calcium chloride (dihydrate)	273	6.8	13.6
Calcium chloride (hexahydrate)	183	4.6	9.1
Calcium citrate (tetrahydrate)	211	5.3	10.5
Calcium glubionate (monohydrate)	66	1.6	3.3
Calcium glucoheptonate (anhydrous)	82	2.0	4.1
Calcium gluconate (monohydrate)	89	2.2	4.5
Calcium glycerophosphate (anhydrous)	191	4.8	9.5
Calcium hydrogen phosphate (dihydrate)	233	5.8	11.6
Calcium lactate (anhydrous)	184	4.6	9.2
Calcium lactate (trihydrate)	147	3.7	7.3
Calcium lactate (pentahydrate)	130	3.2	6.5
Calcium lactate gluconate (dihydrate)	129	3.2	6.4
Calcium lactobionate (dihydrate)	51	1.3	2.5
Calcium levulinate (dihydrate)	131	3.3	6.5
Calcium phosphate [$10CaO.3P_2O_5.H_2O$]	399	10.0	19.9
Calcium pidolate (anhydrous)	135	3.4	6.7
Calcium silicate [$CaSiO_3$]	345	8.6	17.2
Calcium sodium lactate (tetrahydrate)	78	1.9	3.9

Uses and Administration

Calcium salts are used in the management of **hypocalcaemia** (p.1668) and **calcium deficiency states** resulting from dietary deficiency or ageing (see also Osteoporosis, p.1084). Doses may be expressed in terms of mmol or mEq of calcium, mass (mg) of calcium, or mass of calcium salt (for comparative purposes, see Table 1, above).

In simple deficiency states calcium salts may be given orally, usually in doses of 10 to 50 mmol (400 mg to 2 g) of calcium daily adjusted to the individual patient's requirements.

In severe acute hypocalcaemia or hypocalcaemic tetany parenteral dosage is necessary, generally by slow intravenous injection or continuous infusion of calcium chloride or calcium gluconate (see also Administration, below). A typical dose is 2.25 to 4.5 mmol of calcium by slow intravenous injection, either repeated as required, or followed by continuous intravenous infusion of about 9 mmol daily. 2.25 mmol of calcium is provided by 10 mL of calcium gluconate 10%. Calcium gluceptate and calcium glycerophosphate with calcium lactate have been given by the intramuscular route; the chloride and gluconate are unsuitable for this route because of their irritancy. The intravenous route is used in children.

Intravenous calcium salts are also used to reverse the toxic cardiac effects of potassium in the emergency treatment of severe **hyperkalaemia** (p.1669), and as an antidote to magnesium in severe **hypermagnesaemia** (p.1668). For these indications, 2.25 to 4.5 mmol of calcium (10 to 20 mL of calcium gluconate 10%) is commonly used.

Individual calcium salts have specific uses. Calcium carbonate (p.1714) or acetate are effective phosphate binders and are given orally to reduce phosphate absorption from the gut in patients with **hyperphosphataemia**; this is particularly relevant to patients with chronic renal failure in order to prevent the development of renal osteodystrophy (p.1086). The initial dose of calcium carbonate is 2.5 g daily titrated to a maximum of 17 g daily. A typical initial dose of calcium acetate is 3 or 4 g daily; most patients require 6 to 12 g daily.

Calcium carbonate and calcium silicate, given orally, are used for their **antacid** properties (p.1692).

Some of the calcium salts discussed here also have *pharmaceutical uses* as diluents in capsules and tablets, buffers and dissolution aids in dispersible tablets, disintegrant and anticaking agents, and as a basis or abrasive in dental preparations. Calcium phosphate is also used as a bone graft substitute.

Homoeopathy. Various calcium salts have been used in homoeopathic medicines under the following names:

- Calcium acetate: Calcarea acetica; Calc. ace.
- Calcium arsenite: Calcium arsenicosum; Calcarea arsenicosa; Cal. ars.
- Calcium chloride: Calcarea muriatica; Cal. mur.
- Calcium hydrogen phosphate: Calcium phosphoricum
- Calcium hypophosphite: Calcarea hypophosphorosa; Calc. hyp.
- Calcium oxalate: Calcarea oxalica; Cal. oxal.
- Calcium phosphate: Calcarea phosphorica; Calc. phos.; Cal. phos.
- Calcium picrate: Calcarea picrata; Cal. pic.
- Calcium silicate: Calcarea silicata; Calc. sil.

Other calcium salts used in homoeopathy and described elsewhere include: calcium bromide (p.2269), calcium carbonate (p.1714), calcium fluoride (p.1932), calcium hydroxide (p.2272), calcium iodide (p.1553), and calcium sulfate (p.2273).

Administration. Some prefer calcium chloride to calcium gluconate for parenteral preparations,[1,2] because retention of the chloride is greater and more predictable than of the gluconate, and results in a more predictable increase in extracellular ionised calcium concentration. However, calcium chloride is considered to be the most irritant of the calcium salts in general use (see Adverse Effects, above).

Calcium gluconate has been given by the intraperitoneal route[3] for the treatment of chronic hypocalcaemia after parathyroidectomy in a patient undergoing continuous ambulatory peritoneal dialysis, resulting in improved systemic bioavailability compared with oral and intravenous use.

3. Stamatakis MK, Seth SK. Treatment of chronic hypocalcemia with intraperitoneal calcium. *Am J Health-Syst Pharm* 1995; **52:** 201–3.

Bites and stings. Calcium gluconate 10% solution has been given intravenously as an alternative to the use of conventional muscle relaxants for the management of pain and muscle spasm associated with neurotoxic spider envenomation (p.2239) by species such as *Latrodectus mactans* (black widow spider).[1,2] Although the precise mechanism of action of calcium in the alleviation of neuromuscular symptoms is unknown it is believed to be due to the replenishment of calcium stores in the sarcoplasmic reticulum of muscle depleted by stimulation.

2. Woestman R, *et al.* The black widow: is she deadly to children? *Pediatr Emerg Care* 1996; **12:** 360–4.

Bone disease. Calcium is essential for the development and maintenance of normal bone, and calcium salts may be indicated in the treatment of some bone disorders associated with calcium deficiency, such as certain types of osteomalacia and rickets (p.1084). Oral doses of 1 to 3 g of calcium daily are used in osteomalacia.

Oral calcium supplements can also be used as an adjunct in the management of osteoporosis (p.1084) and corticosteroid-induced osteoporosis (see Effects on Bones and Joints, under Corticosteroids, p.1491).

Cramps. Calcium salts are one of a number of interventions that have been tried in the management of cramps (see Muscle Spasm, p.1887). However, evidence for these interventions is mostly lacking and a small systematic review concluded that oral calcium was not of benefit for leg cramps during pregnancy.[1]

1. Young GL, Jewell D. Interventions for leg cramps in pregnancy. Available in The Cochrane Database of Systematic Reviews; Issue 1. Chichester: John Wiley; 2002 (accessed 21/06/05).

Diagnosis of insulinoma. Calcium stimulates the release of insulin from insulinomas. Intra-arterial calcium gluconate, followed by hepatic venous sampling, has been found to be accurate and sensitive in the diagnosis and localisation of insulinomas,[1-4] even when other investigations have been negative.[5,6]

Fluoride toxicity. Inorganic fluoride is corrosive to skin and mucous membranes and acute intoxication disrupts many physiological systems; severe burns and profound hypocalcaemia may ensue. Absorption of the fluoride can be prevented by conversion to an insoluble form such as calcium fluoride and thus irrigation of skin (or gastric lavage as appropriate) with lime water, milk, or a 1% solution of calcium gluconate is recommended. Immediate treatment should also consist of 10 mL of calcium gluconate 10% intravenously, repeated after one hour; 30 mL should be given if tetany is present. In the short term affected skin and tissue should be injected with a 10% solution of calcium gluconate at a dose of 0.5 mL/cm^2 and burnt skin treated with a calcium gluconate 2.5% gel.[1]

Hypertension. Meta-analysis suggests that calcium supplementation results in a small reduction in systolic and diastolic blood pressure.[1] Although the effect was too small to support the use of calcium supplementation for preventing or treating hypertension (p.1171), it is possible that calcium supplementation might have beneficial effects on blood pressure in those with an inadequate intake. In a controlled trial, calcium with vitamin D supplementation reduced systolic blood pressure more effectively than calcium alone.[2]

PREGNANCY. Despite an earlier meta-analysis[1] which concluded that calcium supplementation during pregnancy reduced systolic and diastolic blood pressure and the incidence of pre-eclampsia and hypertension, results from a double-blind, placebo-controlled trial in a total of 4589 women indicated that calcium supplementation during normal pregnancy did not prevent pre-eclampsia, pregnancy-associated hypertension without pre-eclampsia, or a number of other related disorders.[2] A subsequent review[3] found that calcium supplementation was beneficial, but it was noted that there was a wide variation in results between different studies; most of the effect was in studies including women identified as being at high risk for pre-eclampsia, and results from studies including lower-risk women found that calcium had no effect. The high-risk studies were carried out in areas with a low dietary calcium intake, suggesting that benefit might be greatest in such populations. However, a further study[4] in 8325 women living in areas with a low calcium intake but not specifically at high risk found that calcium supplementation had no significant effect on the incidence of pre-eclampsia, although it did reduce the risk of severe pre-eclamptic complications. An updated meta-analysis,[5] which included this study, concluded that calcium supplementation during pregnancy was safe and that it did reduce the incidence of pre-eclampsia and serious complications, particularly in high-risk women.

For discussions of hypertension in pregnancy and eclampsia and pre-eclampsia, see p.1171 and p.470, respectively.

Malignant neoplasms. There is some evidence that calcium supplementation may modestly reduce the risk[1-3] of colorectal cancer and its recurrence.[4-6] This protective effect appears to be more pronounced for advanced colorectal lesions,[7] and when serum concentrations of vitamin D are in the higher range.[8]

Premenstrual syndrome. Calcium supplementation was effective in relieving the luteal phase symptoms of premenstrual syndrome (p.2099) in 1 study.[1] A review of this and other studies suggested that calcium supplementation at a dose of 1.2 to 1.6 g daily should be considered in patients with premenstrual syndrome.[2]

Magnesium

Magnesio; Magnésium; Magnez.

Mg = 24.305.

Description. Magnesium is a cation given as various magnesium-containing salts.

Incompatibility. Magnesium salts have been reported to be incompatible with a wide range of drugs.

Magnesium Acetate

Magnesii acetas tetrahydricus; Magnesio, acetato de; Magnésium (acétate de) tétrahydraté; Magnesiumacetattetrahydrat; Magnesiumasetaattitetrahydraatti; Magnézium acetáttetrahidrát; Magnezu octan; Magnio acetatas tetrahidratas; Octan hořečnatý tetrahydrát.

$C_4H_6MgO_4,4H_2O$ = 214.5.

CAS — 142-72-3 (anhydrous magnesium acetate); 16674-78-5 (magnesium acetate tetrahydrate).

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Magnesium Acetate Tetrahydrate). Colourless crystals or a white or almost white, crystalline powder. Freely soluble in water and in alcohol. A 5% solution in water has a pH of 7.5 to 8.5.

Equivalence. Each g of magnesium acetate (tetrahydrate) represents about 4.7 mmol of magnesium and the equivalent of bicarbonate. Magnesium acetate (tetrahydrate) 8.83 g is equivalent to about 1 g of magnesium.

Magnesium Ascorbate

Magnesio, ascorbato de.

$(C_6H_7O_6)_2Mg$ = 374.5.
CAS — 15431-40-0.

Equivalence. Each g of magnesium ascorbate (anhydrous) represents about 2.7 mmol of magnesium. Magnesium ascorbate (anhydrous) 15.4 g is equivalent to about 1 g of magnesium.

Magnesium Aspartate

Bázisos magnézium-aszpartát-dihidrát; Magnesii aspartas dihydricus; Magnesii Hydrogenoaspartas Dihydricus; Magnesio, aspartato de; Magnésium (aspartate de) dihydraté; Magnesium Aspartate Dihydrate; Magnesiumaspartaattidihydraatti; Magnesiumaspartatdihydrat; Magnesium-hydrogen-aspartát dihydrát; Magnio aspartatas dihidratas. Magnesium aminosuccinate dihydrate; Magnesium di[(*S*)-2-aminohydrogenobutane-1,4-dioate].

$C_8H_{12}MgN_2O_8,2H_2O$ = 324.5.
CAS — 18962-61-3 (anhydrous magnesium aspartate); 2068-80-6 (anhydrous magnesium aspartate or magnesium aspartate dihydrate); 7018-07-7 (magnesium aspartate tetrahydrate);.
ATC — A12CC05.
ATC Vet — QA12CC05.

Pharmacopoeias. *Eur.* (see p.vii) includes the dihydrate form of the (*S*)-aspartate. *Ger.* includes the tetrahydrate form of the racemic aspartate.
Ph. Eur. 6.2 (Magnesium Aspartate Dihydrate; Magnesium Aspartate BP 2008). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water. A 2.5% solution in water has a pH of 6.0 to 8.0.

Equivalence. Each g of magnesium aspartate (dihydrate) represents about 3.1 mmol of magnesium. Magnesium aspartate (dihydrate) 13.4 g is equivalent to about 1 g of magnesium.

Each g of magnesium aspartate (tetrahydrate) represents about 2.8 mmol of magnesium. Magnesium aspartate (tetrahydrate) 14.8 g is equivalent to about 1 g of magnesium.

Magnesium Chloride

Chlorid hořečnatý; Chlorure de Magnésium Cristallisé; Cloreto de Magnésio; E511; Magnesii chloridum; Magnesio, cloruro de; Magnesium Chloratum; Magnésium, chlorure de; Magnesiumklorid; Magnesiumkloridi; Magnézium-klorid; Magnezu chlorek; Magnio chloridas.

$MgCl_2,xH_2O$ = 95.21 (anhydrous); 203.3 (hexahydrate).
CAS — 7786-30-3 (anhydrous magnesium chloride); 7791-18-6 (magnesium chloride hexahydrate).
ATC — A12CC01; B05XA11.
ATC Vet — QA12CC01; QB05XA11.

Pharmacopoeias. *Eur.* (see p.vii), *US*, and *Viet.* include the hexahydrate.
Eur. also includes magnesium chloride 4.5-hydrate.
Ph. Eur. 6.2 (Magnesium Chloride Hexahydrate; Magnesii Chloridum Hexahydricum). Colourless, hygroscopic crystals. Very soluble in water; freely soluble in alcohol. Store in airtight containers.
Ph. Eur. 6.2 (Magnesium Chloride 4.5-Hydrate; Magnesii Chloridum 4.5-Hydricum; Partially Hydrated Magnesium Chloride BP 2008). A white or almost white, hygroscopic, granular powder. Very soluble in water; freely soluble in alcohol. Store in airtight containers.
USP 31 (Magnesium Chloride). Colourless, odourless, deliquescent flakes or crystals, which lose water when heated to 100° and lose hydrochloric acid when heated to 110°. Very soluble in water; freely soluble in alcohol. pH of a 5% solution in water is between 4.5 and 7.0. Store in airtight containers.

Equivalence. Each g of magnesium chloride (hexahydrate) represents about 4.9 mmol of magnesium and 9.8 mmol of chloride. Magnesium chloride (hexahydrate) 8.36 g is equivalent to about 1 g of magnesium.

Magnesium Gluceptate

Magnesio, glucoheptonato de; Magnesium Glucoheptonate.

$C_{14}H_{26}MgO_{16}$ = 474.7.

Equivalence. Each g of magnesium gluceptate (anhydrous) represents about 2.1 mmol of magnesium. Magnesium gluceptate (anhydrous) 19.5 g is equivalent to about 1 g of magnesium.

Magnesium Gluconate

Magnesii gluconas; Magnesio, gluconato de; Magnésium, gluconate de. Magnesium D-gluconate hydrate.

$C_{12}H_{22}MgO_{14}(+xH_2O)$ = 414.6 (anhydrous).
CAS — 3632-91-5 (anhydrous magnesium gluconate); 59625-89-7 (magnesium gluconate dihydrate).
ATC — A12CC03.
ATC Vet — QA12CC03.

Pharmacopoeias. In *Eur.* (see p.vii), which allows either anhydrous or hydrated forms, and in *US*, which allows either anhydrous or the dihydrate.
Ph. Eur. 6.2 (Magnesium Gluconate). A white or almost white, amorphous, hygroscopic, crystalline or granular powder. Freely soluble in water; slightly soluble in alcohol; very slightly soluble in dichloromethane. Store in airtight containers.
USP 31 (Magnesium Gluconate). Colourless crystals or a white powder or granules. Is odourless. Freely soluble in water; very slightly soluble in alcohol; insoluble in ether. pH of a 5% solution in water is between 6.0 and 7.8.

Equivalence. Each g of magnesium gluconate (anhydrous) represents about 2.4 mmol of magnesium. Magnesium gluconate (anhydrous) 17.1 g is equivalent to about 1 g of magnesium.

Magnesium Glycerophosphate

Glycerofosforečnan hořečnatý; Magnesii glycerophosphas; Magnesio, glicerofosfato de; Magnesium Glycerinophosphate; Magnésium, glycérophosphate de; Magnesiumglycerofosfat; Magnesiumglyserofosfaatti; Magnézium-glicerofoszfát; Magnio glicerofosfatas.

$C_3H_7MgO_6P(+xH_2O)$ = 194.4 (anhydrous).
CAS — 927-20-8 (anhydrous magnesium glycerophosphate).

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Magnesium Glycerophosphate). A mixture, in variable proportions, of magnesium (*R,S*)-2,3-dihydroxypropyl phosphate and magnesium 2-hydroxy-1-(hydroxymethyl)ethyl phosphate. It may be hydrated. A white or almost white, hygroscopic powder. Practically insoluble in alcohol; dissolves in dilute solutions of acids. Store in airtight containers.

Equivalence. Each g of magnesium glycerophosphate (anhydrous) represents about 5.1 mmol of magnesium. Magnesium glycerophosphate (anhydrous) 8 g is equivalent to about 1 g of magnesium.

Magnesium Lactate

Magnesii lactas; Magnesio, lactato de; Magnésium, lactate de; Magnesiumlaktaatti; Magnesiumlaktat; Magnesium-laktát; Magnezu mleczan. Magnesium 2-hydroxypropionate.

$C_6H_{10}MgO_6$ = 202.4.
CAS — 18917-93-6.
ATC — A12CC06.
ATC Vet — QA12CC06.

Pharmacopoeias. *Eur.* (see p.vii) includes the dihydrate.
Ph. Eur. 6.2 (Magnesium Lactate Dihydrate; Magnesii Lactas Dihydricus). A white or almost white, crystalline or granular powder. Slightly soluble in water; soluble in boiling water; practically insoluble in alcohol. A 5% solution in water has a pH of 6.5 to 8.5.

Equivalence. Each g of magnesium lactate (anhydrous) represents about 4.9 mmol of magnesium. Magnesium lactate (anhydrous) 8.33 g is equivalent to about 1 g of magnesium.

Magnesium Phosphate

Magnesio, fosfato de; Tribasic Magnesium Phosphate; Trimagnesium Phosphate.

$Mg_3(PO_4)_2,5H_2O$ = 352.9.
CAS — 7757-87-1 (anhydrous magnesium phosphate); 10233-87-1 (magnesium phosphate pentahydrate).
ATC — B05XA10.
ATC Vet — QB05XA10.

Pharmacopoeias. In *US*.
Ger. includes Magnesium Hydrogen Phosphate Trihydrate ($MgHPO_4,3H_2O$ = 174.3).
USP 31 (Magnesium Phosphate). A white, odourless, powder. Almost insoluble in water; readily soluble in dilute mineral acids.

Equivalence. Each g of magnesium phosphate (pentahydrate) represents about 8.5 mmol of magnesium and 5.7 mmol of phosphate. Magnesium phosphate (pentahydrate) 4.84 g is equivalent to about 1 g of magnesium.

Magnesium Pidolate *(pINNM)*

Magnesii pidolas; Magnésium, pidolate de; Magnesium Pyroglutamate; Magnesiumpidolaatti; Magnesiumpidolat; Magnesium-pidolát; Magnézium-pidolát; Magnio pidolatas; Pidolate de Magnesium; Pidolato de magnesio. Magnesium 5-oxopyrrolidine-2-carboxylate.

Магния Пидолат

$(C_5H_6NO_3)_2Mg$ = 280.5.
CAS — 62003-27-4.
ATC — A12CC08.
ATC Vet — QA12CC08.

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Magnesium Pidolate). An amorphous, white or almost white, hygroscopic powder. Very soluble in water; practically insoluble in dichloromethane; soluble in methyl alcohol. A 10% solution in water has a pH of 5.5 to 7.0. Store in airtight containers.

Equivalence. Each g of magnesium pidolate (anhydrous) represents about 3.6 mmol of magnesium. Magnesium pidolate (anhydrous) 11.5 g is equivalent to about 1 g of magnesium.

Magnesium Sulfate

518; Epsom Salts; Magnesii sulfas; Magnesio, sulfato de; Magnésium, sulfate de; Magnesium Sulphate; Magnesiumsulfaatti; Magnesiumsulfat; Magnézium-szulfát; Magnezu siarczan; Magnio sulfatas; Sal Amarum; Sel Anglais; Sel de Sedlitz; Síran hořečnatý.

$MgSO_4,xH_2O$ = 120.4 (anhydrous); 246.5 (heptahydrate).
CAS — 7487-88-9 (anhydrous magnesium sulfate); 10034-99-8 (magnesium sulfate heptahydrate).
ATC — A06AD04; A12CC02; B05XA05; D11AX05; V04CC02.
ATC Vet — QA06AD04; QA12CC02; QB05XA05; QD11AX05; QV04CC02.

Pharmacopoeias. *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, and *Viet.* include the heptahydrate.
US allows the dried form, the monohydrate, or the heptahydrate form.
The dried form is included in *Br.*
Ph. Eur. 6.2 (Magnesium Sulphate Heptahydrate; Magnesii Sulfas Heptahydricus). A white or almost white, crystalline powder or brilliant, colourless crystals. Freely soluble in water; very soluble in boiling water; practically insoluble in alcohol.
The BP 2008 gives Epsom Salts as an approved synonym.
BP 2008 (Dried Magnesium Sulphate). A white odourless or almost odourless powder, prepared by drying magnesium sulfate (heptahydrate) at 100° until it has lost about 25% of its weight; it contains 62 to 70% of $MgSO_4$. Freely soluble in water; more rapidly soluble in hot water.
The BP gives Dried Epsom Salts as an approved synonym.
USP 31 (Magnesium Sulfate). It is the dried form, monohydrate, or the heptahydrate. Small, colourless crystals, usually needle-like. It effloresces in warm dry air. Soluble 1 in 0.8 of water and 1 in 0.5 of boiling water; freely but slowly soluble 1 in 1 of glycerol; sparingly soluble in alcohol. pH of a 5% solution in water is between 5.0 and 9.2.

Equivalence. Each g of magnesium sulfate (heptahydrate) represents about 4.1 mmol of magnesium. Magnesium sulfate (heptahydrate) 10.1 g is equivalent to about 1 g of magnesium.

Adverse Effects

Excessive parenteral doses of magnesium salts lead to the development of hypermagnesaemia, important signs of which are respiratory depression and loss of deep tendon reflexes, both due to neuromuscular blockade. Other symptoms of hypermagnesaemia may include nausea, vomiting, flushing of the skin, thirst, hypotension due to peripheral vasodilatation, drowsiness, confusion, slurred speech, double vision, muscle weakness, bradycardia, coma, and cardiac arrest.

Hypermagnesaemia is uncommon after oral magnesium salts except in the presence of renal impairment. Ingestion of magnesium salts may cause gastrointestinal irritation and watery diarrhoea.

Effects on the gastrointestinal tract. There are isolated reports of paralytic ileus in patients receiving magnesium salts.[1,2] Delayed intestinal transit has also been reported in a neonate who received an intramuscular overdose of magnesium.[3] See also Pregnancy, under Precautions, below.

1. Hill WC, *et al.* Maternal paralytic ileus as a complication of magnesium sulfate tocolysis. *Am J Perinatol* 1985; **2:** 47–8.
2. Golzarian J, *et al.* Hypermagnesemia-induced paralytic ileus. *Dig Dis Sci* 1994; **39:** 1138–42.
3. Narchi H. Neonatal hypermagnesemia: more causes and more symptoms. *Arch Pediatr Adolesc Med* 2001; **155:** 1074.

Hypersensitivity. Hypersensitivity reactions characterised by urticaria were described in 2 women after receiving magnesium sulfate intravenously.[1]

1. Thorp JM, *et al.* Hypersensitivity to magnesium sulfate. *Am J Obstet Gynecol* 1989; **161:** 889–90.

Treatment of Adverse Effects

The management of hypermagnesaemia is reviewed on p.1668.

Hypermagnesaemia. A patient with hypermagnesaemia of a degree that is normally fatal was successfully treated using assisted ventilation, calcium chloride administered intravenously, and forced diuresis with mannitol infusions.[1] In another report, a 7-year-old boy given an Epsom salt (magnesium sulfate) enema for abdominal cramping, developed asystole and died, despite aggressive attempts at resuscitation. Such enemas should be avoided because of the risk of significant, unpredictable rectal absorption, leading to toxic hypermagnesaemia.[2]

1. Bohman VR, Cotton DB. Supralethal magnesemia with patient survival. *Obstet Gynecol* 1990; **76:** 984–6.
2. Tofil NM, *et al.* Fatal hypermagnesemia caused by an Epsom salt enema: a case illustration. *South Med J* 2005; **98:** 253–6.

Precautions

Parenteral magnesium salts should generally be avoided in patients with heart block or severe renal impairment. They should be used with caution in less severe degrees of renal impairment and in patients with myasthenia gravis. Patients should be monitored for clinical signs of excess magnesium (see Adverse Effects, above), particularly when being treated for conditions not associated with hypomagnesaemia such as eclampsia. An intravenous preparation of a calcium salt should be available in case of toxicity. When used for hypomagnesaemia, serum-magnesium concentrations should be monitored.

Magnesium crosses the placenta. When used in pregnant women, fetal heart rate should be monitored and use within 2 hours of delivery should be avoided (see also Pregnancy, below).

Oral magnesium salts should be used cautiously in patients with renal impairment. Taking with food may decrease the incidence of diarrhoea. Chronic diarrhoea from long-term use may result in electrolyte imbalance.

Breast feeding. In breast milk samples from 10 pre-eclamptic women given magnesium sulfate, mean magnesium concentrations 24 hours after delivery were about 6.4 mg per 100 mL, and significantly higher than those in control subjects. However, by 48 and 72 hours after delivery, values were not significantly different. In both treated and control subjects, milk-magnesium concentrations were about twice those of maternal plasma concentrations. Although total doses of magnesium given to mothers may differ, the authors considered any increased magnesium load to a breast-fed infant to be quite small, about 1.5 mg of additional magnesium daily, and unlikely to significantly alter magnesium clearance from the neonate.[1] Based on this, the American Academy of Pediatrics considers that use of magnesium sulfate is therefore usually compatible with breast feeding.[2]

1. Cruikshank DP, *et al.* Breast milk magnesium and calcium concentrations following magnesium sulfate treatment. *Am J Obstet Gynecol* 1982; **143:** 685–8.
2. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 18/05/04)

Hepatic disorders. Severe hypermagnesaemia and hypercalcaemia developed in 2 patients with hepatic encephalopathy given magnesium sulfate enemas; both patients died, one during and one after asystole. It was recommended that patients with liver disease who might develop renal impairment, or in whom renal failure is established, should not be prescribed enemas containing magnesium for treatment of hepatic encephalopathy as serious magnesium toxicity can occur, which may contribute to death.[1]

1. Collinson PO, Burroughs AK. Severe hypermagnesaemia due to magnesium sulphate enemas in patients with hepatic coma. *BMJ* 1986; **293:** 1013–14. Correction. *ibid.*; 1222.

Pregnancy. The meconium-plug syndrome (abdominal distention and failure to pass meconium) has been described in 2 neonates who were hypermagnesaemic after their mothers had received magnesium sulfate for eclampsia.[1] It was believed that the hypermagnesaemia may have depressed the function of intestinal smooth muscle. See also Effects on the Gastrointestinal Tract, above. In 36 hypermagnesaemic infants born to pre-eclamptic mothers treated with magnesium sulfate, significant neurobehavioural impairment persisted for over 24 hours after birth. Impairment was manifest by prolonged weakness in activities such as head lag, ventral suspension, suck reflex, and cry response; improvement corresponded to the decrease in plasma-magnesium concentrations.[2]

In studies in women with[3] and without[4] pre-eclampsia there were decreases in short-term fetal heart rate variability when women were given intravenous magnesium sulfate; however, although variability is considered a sign of fetal well-being the decrease was considered clinically insignificant.

2. Rasch DK, *et al.* Neurobehavioral effects of neonatal hypermagnesemia. *J Pediatr* 1982; **100:** 272–6.
3. Atkinson MW, *et al.* The relation between magnesium sulfate therapy and fetal heart rate variability. *Obstet Gynecol* 1994; **83:** 967–70.
4. Hallak M, *et al.* The effect of magnesium sulfate on fetal heart rate parameters: a randomized, placebo-controlled trial. *Am J Obstet Gynecol* 1999; **181:** 1122–7.

Interactions

Parenteral magnesium sulfate potentiates the effects of competitive and depolarising neuromuscular blockers (p.1904). The neuromuscular blocking effects of parenteral magnesium and aminoglycoside antibacterials may be additive. Similarly, parenteral magnesium sulfate and nifedipine have been reported to have additive effects (p.1353).

Oral magnesium salts decrease the absorption of tetracyclines and bisphosphonates, and doses should be separated by a number of hours.

Pharmacokinetics

About one-third of magnesium is absorbed from the small intestine after oral doses and even soluble magnesium salts are generally very slowly absorbed. The fraction of magnesium absorbed increases if magnesium intake decreases. In plasma, about 25 to 30% of magnesium is protein bound. Parenteral magnesium salts are excreted mainly in the urine, and oral doses are eliminated in the urine (absorbed fraction) and the faeces (unabsorbed fraction). Small amounts are distributed into breast milk. Magnesium crosses the placenta.

Human Requirements

Magnesium is the second most abundant cation in intracellular fluid and is an essential body electrolyte which is a cofactor in numerous enzyme systems.

The body is very efficient at maintaining magnesium concentrations by regulating absorption and renal excretion, and symptoms of deficiency are rare. It is therefore difficult to establish a daily requirement.

Foods rich in magnesium include nuts, unmilled grains, and green vegetables.

UK and US recommended dietary intake. In the United Kingdom dietary reference values (DRV—see Human Requirements, p.1925)[1] and in the United States recommended daily allowances (RDA)[2] have been published for magnesium. In the UK the estimated average requirement (EAR) is 200 mg (or 8.2 mmol) daily for adult females and 250 mg (or 10.3 mmol) daily for adult males; the reference nutrient intake (RNI) is 270 mg (or 10.9 mmol) daily for adult females and 300 mg (or 12.3 mmol) daily for adult males; no increment is recommended during pregnancy but an increment of 50 mg (or 2.1 mmol) daily in the RNI is advised during lactation. In the USA under the new dietary reference intakes an EAR of 330 to 350 mg daily has been set in adult males and 255 to 265 mg daily in adult females; the corresponding RDAs are 400 to 420 mg and 310 to 320 mg daily.[2] An increase in RDA to 350 to 360 mg is recommended during pregnancy but the standard RDA is considered adequate during lactation. A tolerable upper intake level of 350 mg daily has been set for adults.[2]

Uses and Administration

Some magnesium salts are given as a source of magnesium ions in the treatment of **magnesium deficiency and hypomagnesaemia** (p.1668). Doses may be expressed in terms of mmol or mEq of magnesium, mass (mg) of magnesium, or mass of magnesium salt (for comparative purposes, see Table 2, above). In acute or severe hypomagnesaemia, magnesium may be given parenterally, usually as the chloride or sulfate. One suggested regimen is 20 mmol of magnesium in 1 litre of infusion solution (glucose 5% or sodium chloride 0.9%) given *intravenously* over 3 hours. Alternatively, 35 to 50 mmol of magnesium in 1 litre of infusion solution may be given over a period of 12 to 24 hours. Up to a total of 160 mmol may be required over 5 days. In those receiving parenteral nutrition, doses of about 12 mmol magnesium daily may be given to prevent recurrence of the deficit. Magnesium sulfate can also be given *intramuscularly* for severe magnesium deficiency. A recommended dose is 1 mmol/kg of magnesium, given over a period of 4 hours; this route is stated to be painful. Careful monitoring of plasma-magnesium and other electrolyte concentrations is essential. Doses should be reduced in renal impairment. Other salts which are, or have been, used parenterally include magnesium ascorbate, magnesium aspartate hydrochloride, and magnesium pidolate.

Table 2. Some magnesium salts and their magnesium content.

Magnesium salt	Magnesium content per g		
	mg	mmol	mEq
Magnesium acetate (tetrahydrate)	113	4.7	9.3
Magnesium ascorbate (anhydrous)	65	2.7	5.3
Magnesium aspartate (dihydrate)	75	3.1	6.2
Magnesium aspartate (tetrahydrate)	67	2.8	5.5
Magnesium chloride (hexahydrate)	120	4.9	9.8
Magnesium gluceptate (anhydrous)	51	2.1	4.2
Magnesium gluconate (anhydrous)	59	2.4	4.8
Magnesium glycerophosphate (anhydrous)	125	5.1	10.3
Magnesium lactate (anhydrous)	120	4.9	9.9
Magnesium phosphate (pentahydrate)	207	8.5	17.0
Magnesium pidolate (anhydrous)	87	3.6	7.1
Magnesium sulfate (heptahydrate)	99	4.1	8.1

In simple deficiency states magnesium salts may be given *orally* in doses adjusted according to individual requirements. For preventing recurrence of hypomagnesaemia, doses of 24 mmol daily in divided doses have been recommended. Salts that are, or have been, used orally include magnesium aspartate, magnesium chloride, magnesium citrate, magnesium fluoride, magnesium gluceptate, magnesium gluconate, magnesium glycerophosphate, magnesium lactate, magnesium levulinate, magnesium orotate, and magnesium pidolate.

Magnesium salts such as the carbonate, hydroxide, oxide, and trisilicate are widely used for their **antacid** properties (p.1692). Magnesium salts also act as **osmotic laxatives** (see Constipation, p.1693); the salts generally used for this purpose are magnesium sulfate (an oral dose of 5 to 10 g in 250 mL of water being given for rapid bowel evacuation) and magnesium hydroxide (p.1743).

Parenteral magnesium sulfate has some specific uses. It is used for the emergency treatment of some **arrhythmias** such as torsade de pointes (see below) and those associated with hypokalaemia (p.1669). The usual dose is 2 g of magnesium sulfate (8 mmol of magnesium) given intravenously over 10 to 15 minutes and repeated once if necessary.

Parenteral magnesium sulfate is also used for the prevention of recurrent seizures in pregnant women with **eclampsia** (see below). Debate continues as to which dosage regimen is most appropriate. Typically an intravenous loading dose of 4 g of magnesium sulfate (16 mmol of magnesium) is given over 10 to 15 minutes. This is then followed by either an infusion of 1 g (4 mmol magnesium) per hour (for at least 24 hours after the last seizure) or by deep intramuscular injection of 5 g (20 mmol magnesium) into each buttock then

5 g intramuscularly every 4 hours (for at least 24 hours after the last seizure). Should seizures recur under either regimen, then an additional intravenous dose of 2 to 4 g can be given. It is essential to monitor for signs of hypermagnesaemia, and to stop magnesium dosage should this occur. Doses should be reduced in renal impairment.

The use of magnesium sulfate in **acute myocardial infarction** and **premature labour** is discussed below.

Dried magnesium sulfate has been used in the form of Magnesium Sulphate Paste (BP 2008) as an application to inflammatory skin conditions such as boils and carbuncles, but prolonged or repeated use may damage the surrounding skin.

Anaesthesia. Magnesium sulfate has been used to prevent the undesirable haemodynamic response sometimes associated with intubation (p.1900). It has also been tried in the treatment of postanaesthetic shivering (p.1779).

Arrhythmias. Cardiac function is strongly influenced by electrolyte concentrations and some cardiac arrhythmias (p.1160) may be associated with magnesium deficiency. Parenteral magnesium has a role in the management of torsade de pointes and some other arrhythmias, and has also been used to prevent postoperative atrial fibrillation. However, for the suggestion that it did not have an antiarrhythmic effect in patients with myocardial infarction see Myocardial Infarction, below.

Eclampsia and pre-eclampsia. Parenteral magnesium sulfate has become the preferred treatment for seizures associated with **eclampsia** (p.470). Studies and systematic reviews have shown it to be more effective than phenytoin,[1,2] diazepam,[1,3] or lytic cocktail,[4] as well as causing fewer adverse effects. Its advantages included a rapid effect and lack of sedation in the mother or the infant.[5] It was also considered to have a wide safety margin with the added security of calcium gluconate being an easily available antidote should overdose occur. Subsequent meta-analysis[6] and systematic review[2-4] reinforced this favourable view.

Magnesium sulfate may also be used to prevent eclampsia in **pre-eclamptic** patients; trials have shown it to be more effective than phenytoin,[7] or nimodipine.[8] A randomised placebo-controlled study[9] involving over 10 000 women in 33 countries found that treatment with magnesium sulfate approximately halved the risk of developing eclampsia; the number of maternal deaths was also less in the treatment group although the differences in risk between this group and the placebo group were not significant.

Despite some concerns about the effects on the fetus of magnesium sulfate use in premature labour, (see below), many,[10,11] including WHO, consider magnesium sulfate the drug of choice for both treatment and prevention of eclampsia. Moreover, follow-up studies of the international study mentioned above found that it was not associated with an increased risk of death or disability in the children at 18 months[12] and in the mothers at 2 years.[13]

Hypokalaemia. Potassium and magnesium homoeostasis are linked, and hypokalaemia with increased urine potassium excretion may occur in patients with hypomagnesaemia. In this situation, correction of potassium deficit usually requires magnesium to be given as well. Magnesium sulfate at doses greater than those required to correct hypomagnesaemia has been associated with greater improvements in potassium balance than doses just sufficient to correct hypomagnesaemia.[1]

Migraine. Low magnesium concentrations are thought to be important in the pathogenesis of migraine (p.616), but the precise role of magnesium supplementation in the disorder remains to be determined.[1] In a double-blind study,[2] 24 mmol magnesium daily (in the form of magnesium citrate) reduced the incidence of migraine headache by 42% compared with a reduction of 16% with placebo. However, in another similar study,[3] 20 mmol magnesium daily (in the form of magnesium aspartate hydrochloride) was no more effective than placebo in producing a 50% reduction in migraine frequency or intensity. Intravenous magnesium sulfate has shown benefit in the treatment of migraine attacks,[4] especially in those with aura,[5,6] or in patients with low serum-magnesium levels.[7]

Myocardial infarction. Magnesium has an important physiological role in maintaining the ion balance in muscle including the myocardium. Magnesium might have an antiarrhythmic effect (see also Arrhythmias, above) and protect the myocardium against reperfusion injury including myocardial stunning (delayed recovery of myocardial contractility function). Intravenous magnesium salts have been used for cardiac arrhythmias and in an overview of studies in patients with suspected myocardial infarction their use, generally within 12 hours of the onset of chest pain, reduced mortality.[1] The beneficial effect on mortality appeared to be confirmed by the LIMIT-2 study[2] in which 8 mmol of magnesium was given by intravenous injection before thrombolysis and followed by a maintenance infusion of 65 mmol over the next 24 hours. Benefit was confirmed at follow-up an average of 2.7 years later;[3] however, there was no evidence of an antiarrhythmic effect. These beneficial effects were not borne out by the larger ISIS-4 study,[4] although there were slight differences in the magnesium regimen and its timing which might have played a part in these contradictory results. In an attempt to resolve the controversy, the MAGIC trial[5] was designed to test the hypothesis that early use of magnesium in a similar dose to that used in the LIMIT-2 study would reduce short-term mortality in patients with ST elevation myocardial infarction. No benefit or harm of magnesium was observed, and at present the routine use of magnesium in myocardial infarction (p.1175) cannot be recommended.

Patients with acute myocardial infarction may have magnesium deficiency and long-term treatment with oral magnesium has been tried, but in one study was associated with an increased risk of adverse cardiac events and could not be recommended for secondary prevention.[6]

Porphyria. Magnesium sulfate is one of the drugs that has been used for seizure prophylaxis in patients with porphyria (p.471) who continue to experience convulsions while in remission.

Premature labour. Magnesium sulfate has been given intravenously to suppress initial uterine contractions in the management of premature labour[1-3] (p.2003). Although it has been found to possess similar efficacy to beta$_2$ agonists,[4,5] and is widely used, in particular in the USA, a systematic review[6] concluded it was ineffective at delaying birth or preventing preterm birth. Other magnesium salts have also sometimes been given orally.[7,8] Retrospective observational studies found a lower incidence of cerebral palsy in children with birth-weights of less than 1500 g when mothers were treated with magnesium sulfate for pre-eclampsia, eclampsia or premature labour.[9,10] However, increased total paediatric mortality was noted in an interim analysis of a trial of antenatal magnesium sulfate in preterm labour,[11] and the trial was subsequently stopped. Although they considered the safety of magnesium sulfate well established in gestation at term, the authors cautioned against the use of magnesium sulfate in very preterm labour. Subsequent studies found that magnesium sulfate was associated with increased perinatal mortality in low birth-weight offspring, particularly when doses of more than 48 g were used,[12] and that neonates with intraventricular haemorrhage (p.1050) had mothers with higher serum-magnesium concentrations at delivery.[13] Some studies have commented[14,15] on other results, including trials of magnesium for treatment and prevention of eclampsia (see above), and have concluded, along with a systematic review[6] that its use as a tocolytic increases the risk of infant mortality.

Although magnesium sulfate is widely used, the American College of Obstetricians and Gynecologists does not promote it (or any drug) for first-line tocolysis.[16] It is not recommended in Europe,[17] and some in the USA have called for such use to be stopped.[18,19]

Pulmonary hypertension of the newborn. Preliminary studies have suggested that intravenous magnesium sulfate may be effective in treating persistent pulmonary hypertension of the newborn, as mentioned on p.1179.

Respiratory disorders. Magnesium sulfate, given intravenously over 20 minutes in doses of 1.2 g to patients with acute exacerbations of chronic obstructive pulmonary disease (p.1112) who had received inhaled salbutamol, appeared to have moderate efficacy.[1]

Infusion of magnesium has been reported to be of benefit in some patients with acute asthma (p.1108), but results have been conflicting;[2-5] meta-analyses of these and other studies concluded that its routine use was not justified, but that it may benefit some patients with severe exacerbations.[6,7] A meta-analysis of 5 studies in children concluded that intravenous magnesium sulfate is likely to be an effective adjunct to standard therapy in the symptomatic treatment of moderate to severe acute childhood asthma.[8] Inhalation of magnesium has also been investigated, either alone or with salbutamol; another meta-analysis considered that it improved pulmonary function, particularly in combination with a $beta_2$ agonist, with the best results seen in more severe cases.[9]

Phosphate

Fosfato.

Description. Phosphate is an anion given as various potassium or sodium salts.

Incompatibility. Phosphates are incompatible with calcium salts; the mixing of calcium and phosphate salts can lead to the formation of insoluble calcium-phosphate precipitates. Incompatibility has also been reported with magnesium salts.

Monobasic Potassium Phosphate

Dihydrogenfosforečnan draselný; E340; Kalii dihydrogenophosphas; Kalio-divandenilio fosfatas; Kálium-dihidrogén-foszfát; Kaliumdivätefosfat; Kaliumdivetyfosfaatti; Monopotassium Phosphate; Phosphate monopotassique; Potasio, dihidrogenofosfato de; Potassium Acid Phosphate; Potassium Biphosphate; Potassium Dihydrogen Phosphate; Potasu diwodorofosforan. Potassium dihydrogen orthophosphate.

KH_2PO_4 = 136.1.
CAS — 7778-77-0.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Potassium Dihydrogen Phosphate). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; practically insoluble in alcohol. A 5% solution in water has a pH of 4.2 to 4.5.
USNF 26 (Monobasic Potassium Phosphate). Colourless crystals or a white granular or crystalline powder. Is odourless. Freely soluble in water; practically insoluble in alcohol. pH of a 1% solution in water is about 4.5. Store in airtight containers.

Equivalence. Each g of monobasic potassium phosphate represents about 7.3 mmol of potassium and of phosphate.

Dibasic Potassium Phosphate

Dikalii phosphas; Dikalio fosfatas; Dikaliumfosfaatti; Dikaliumfosfat; Dikálium-hidrogén-foszfát; Dipotasio, hidrogenofosfato de; Dipotassium Hydrogen Phosphate; Dipotassium Phosphate; Dipotasu wodorofosforan; E340; Hydrogenfosforečnan draselný; Kalii Hydrogenophosphas; Phosphate dipotassique; Potassium Phosphate. Dipotassium hydrogen orthophosphate.

K_2HPO_4 = 174.2.
CAS — 7758-11-4.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Dipotassium Phosphate; Dipotassium Hydrogen Phosphate BP 2008). A very hygroscopic, white or almost white powder or colourless crystals. Very soluble in water; very slightly soluble in alcohol. Store in airtight containers.
USP 31 (Dibasic Potassium Phosphate). Colourless or white, somewhat hygroscopic, granular powder. Freely soluble in water; very slightly soluble in alcohol. pH of a 5% solution in water is between 8.5 and 9.6.

Equivalence. Each g of dibasic potassium phosphate represents about 11.5 mmol of potassium and 5.7 mmol of phosphate.

Monobasic Sodium Phosphate

Dihydrogenfosforečnan sodný; E339; Monobazik Sodyum Fosfat; Natrii dihydrogenophosphas; Natrio-divandenilio fosfatas; Natrium Phosphoricum Monobasicum; Nátrium-dihidrogén-foszfát; Natriumdivätefosfat; Natriumdivetyfosfaatti; Phosphate monosodique; Sodio, dihidrogenofosfato de; Sodium Acid Phosphate; Sodium Biphosphate; Sodium Dihydrogen Phosphate; Sodu diwodorofosforan; Sodyum Dihidrojen Fosfat. Sodium dihydrogen orthophosphate.

NaH_2PO_4,xH_2O.
CAS — 7558-80-7 (anhydrous monobasic sodium phosphate); 10049-21-5 (monobasic sodium phosphate monohydrate); 13472-35-0 (monobasic sodium phosphate dihydrate).
ATC — A06AD17; A06AG01.
ATC Vet — QA06AD17; QA06AG01.

Pharmacopoeias. In *Eur.* (see p.vii) (with $2H_2O$); in *Chin.* (with $1H_2O$). *Br.* also includes monographs for the anhydrous and monohydrate forms. *US* permits the anhydrous, monohydrate, and dihydrate forms.
Ph. Eur. 6.2 (Sodium Dihydrogen Phosphate Dihydrate; Natrii Dihydrogenophosphas Dihydricus). A white or almost white powder or colourless crystals. Very soluble in water; very slightly soluble in alcohol. A 5% solution in water has a pH of 4.2 to 4.5.
The BP 2008 gives Sodium Acid Phosphate as an approved synonym.
BP 2008 (Anhydrous Sodium Dihydrogen Phosphate). A white, slightly deliquescent, crystals or granules. Very soluble in water; very slightly soluble in alcohol. A 5% solution in water has a pH of 4.2 to 4.5.
BP 2008 (Sodium Dihydrogen Phosphate Monohydrate). A white powder or colourless crystals. Very soluble in water; very slightly soluble in alcohol. A 5% solution in water has a pH of 4.2 to 4.5.
USP 31 (Monobasic Sodium Phosphate). It contains one or two molecules of water of hydration, or is anhydrous. Colourless crystals or white crystalline powder. Is odourless and is slightly deliquescent. Freely soluble in water; practically insoluble in alcohol. Its solutions are acid to litmus and effervesce with sodium carbonate. pH of a 5% solution in water of the monohydrate form is between 4.1 and 4.5.

Equivalence. Each g of monobasic sodium phosphate (anhydrous) represents about 8.3 mmol of sodium and of phosphate. Each g of monobasic sodium phosphate (monohydrate) represents about 7.2 mmol of sodium and of phosphate. Each g of monobasic sodium phosphate (dihydrate) represents about 6.4 mmol of sodium and of phosphate.

Dibasic Sodium Phosphate

Dibazik Sodyum Hidrojen Fosfat; Dinatrii phosphas; Dinatrio fosfatas; Dinatriumfosfaatti; Dinatriumfosfat; Dinátrium-hidrogén-foszfát; Disodio, hidrogenofosfato de; Disodium Hydrogen Phosphate; Disodium Phosphate; Disodu fosforan; Disodu wodorofosforan; Disodyum Hidrojen Fosfat; E339; Hydrogenfosforečnan sodný; Natrii Hydrogenophosphas; Natrii Phosphas; Natrii Phosphatis; Natriumfosfaatti; Natriumfosfat; Phosphate disodique; Sodium Phosphate. Disodium hydrogen orthophosphate.

Na_2HPO_4,xH_2O.
CAS — 7558-79-4 (anhydrous dibasic sodium phosphate); 10028-24-7 (dibasic sodium phosphate dihydrate); 7782-85-6 (dibasic sodium phosphate heptahydrate); 10039-32-4 (dibasic sodium phosphate dodecahydrate).
ATC — A06AD17; A06AG01; B05XA09.
ATC Vet — QA06AD17; QA06AG01; QB05XA09.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.* The pharmacopoeias may specify one or more states of hydration; monographs and specifications can be found for the anhydrous form (Na_2HPO_4 = 142.0), the dihydrate ($Na_2HPO_4,2H_2O$ = 178.0), the heptahydrate ($Na_2HPO_4,7H_2O$ = 268.1), and the dodecahydrate ($Na_2HPO_4,12H_2O$ = 358.1), although not necessarily all will be found in any one pharmacopoeia.
Ph. Eur. 6.2 (Disodium Phosphate, Anhydrous; Dinatrii Phosphas Anhydricus; Anhydrous Disodium Hydrogen Phosphate BP 2008). A white or almost white, hygroscopic powder. Soluble in water; practically insoluble in alcohol. A 5% solution in water is slightly alkaline. Store in airtight containers.
Ph. Eur. 6.2 (Disodium Phosphate Dihydrate; Dinatrii Phosphas Dihydricus; Disodium Hydrogen Phosphate Dihydrate BP 2008). A white or almost white powder or colourless crystals. Soluble in water; practically insoluble in alcohol. A 5% solution in water is slightly alkaline.
The BP 2008 gives Sodium Phosphate Dihydrate as an approved synonym.
Ph. Eur. 6.2 (Disodium Phosphate Dodecahydrate; Dinatrii Phosphas Dodecahydricus; Disodium Hydrogen Phosphate Dodecahydrate BP 2008). Colourless, transparent, very efflorescent crystals. Very soluble in water; practically insoluble in alcohol. A 10% solution in water is slightly alkaline.

USP 31 (Dibasic Sodium Phosphate). It is dried, or contains one, two, seven, or twelve molecules of water of hydration.
The dried substance is a white powder that readily absorbs moisture. It is soluble 1 in 8 of water; insoluble in alcohol.
The heptahydrate is a colourless or white, granular or caked salt that effloresces in warm, dry air. It is freely soluble in water; very slightly soluble in alcohol. Its solutions are alkaline to phenolphthalein, a 0.1M solution having a pH of about 9.
Store all forms in airtight containers.

Equivalence. Each g of dibasic sodium phosphate (anhydrous) represents about 14.1 mmol of sodium and 7.0 mmol of phosphate. Each g of dibasic sodium phosphate (dihydrate) represents about 11.2 mmol of sodium and 5.6 mmol of phosphate. Each g of dibasic sodium phosphate (heptahydrate) represents about 7.5 mmol of sodium and 3.7 mmol of phosphate. Each g of dibasic sodium phosphate (dodecahydrate) represents about 5.6 mmol of sodium and 2.8 mmol of phosphate.

Tribasic Sodium Phosphate

E339; Sodio, fosfato de; Trisodium Orthophosphate; Trisodium Phosphate.

Na_3PO_4 = 163.9.
CAS — 7601-54-9.
ATC — A06AD17; A06AG01.
ATC Vet — QA06AD17; QA06AG01.

Pharmacopoeias. In *USNF.*

USNF 26 (Tribasic Sodium Phosphate). It is anhydrous or contains 1 to 12 molecules of water of hydration. White, odourless crystals or granules, or a crystalline powder. Freely soluble in water; insoluble in alcohol. pH of a 1% solution in water is between 11.5 and 12.0. Store in airtight containers.

Equivalence. Each g of tribasic sodium phosphate (anhydrous) represents about 18.3 mmol of sodium and 6.1 mmol of phosphate.

Adverse Effects and Treatment

Excessive doses of intravenous phosphate cause hyperphosphataemia, particularly in patients with renal failure. Hyperphosphataemia leads in turn to hypocalcaemia, which may be severe, and to ectopic calcification, particularly in patients with initial hypercalcaemia. Tissue calcification may cause hypotension and organ damage and result in acute renal failure. Hyperphosphataemia, hypocalcaemia, and tissue calcification are rare after oral or rectal doses (but see Effects on Electrolytes, and Effects on the Kidneys, below).

Adverse effects of oral phosphates may include nausea, vomiting, diarrhoea, and abdominal pain. When they are being used for indications other than their laxative effects, diarrhoea may necessitate a reduction in dosage. Sodium phosphates given rectally for bowel evacuation may cause local irritation.

Phosphates are given as the potassium or sodium salts or both, and may thus be associated with hyperkalaemia, and hypernatraemia and dehydration. Sodium phosphate may cause hypokalaemia.

Treatment of adverse effects involves withdrawal of phosphate, general supportive measures, and correction of serum-electrolyte concentrations, especially calcium. Measures to remove excess phosphate such as oral phosphate binders and haemodialysis may be required (see also Hyperphosphataemia, p.1669).

Effects on electrolytes. Although less common than after intravenous therapy, hyperphosphataemia, accompanied by hypocalcaemia or other severe electrolyte disturbances and resulting in tetany[1,2] and even death,[2] has been reported after the use of phosphate enemas. Similar effects have also been reported with the use of oral phosphate laxatives,[3-7] and in the USA, the FDA has issued warnings of the risk of electrolyte disturbances after the use of high oral doses of sodium phosphate, particularly in vulnerable patients.[8] Infants or children,[2,9,10] the elderly,[4,11] and those with renal impairment,[1,4,11] or congestive heart failure[4] have often had these adverse effects. Licensed product information for one oral sodium phosphate bowel cleanser (*Visicol; Salix, USA*) states that there have been reports of generalised tonic-clonic seizures and/or loss of consciousness in patients with no history of seizures; these cases were associated with electrolyte abnormalities, and low serum osmolality.

Hyperphosphataemia may precipitate nephrocalcinosis, causing an acute phosphate nephropathy, see Effects on the Kidneys, below.

Effects on the kidneys. Acute renal failure and nephrocalcinosis have been reported after the use of oral phosphate-based cathartics for bowel cleansing.[1,2] Although relatively rare with oral preparations, this acute phosphate nephropathy is a serious adverse effect; most patients were left with chronic renal insufficiency, and some developed end-stage renal disease. Potential contributing factors include inadequate hydration, increased age, a history of hypertension and arteriosclerosis, and concurrent use of ACE inhibitors, angiotensin receptor antagonists, diuretics, or NSAIDs.[2] The FDA has issued warnings[3] about the use of oral sodium phosphate products, especially in patients with impaired renal function, dehydration, or uncorrected electrolyte abnormalities, or in those taking drugs likely to contribute to the risk of nephropathy. The patient should be advised to take the correct dose of oral sodium phosphate, to drink sufficient liquid during bowel cleansing, and to avoid other phosphate-containing laxatives. Patients at increased risk should have their electrolytes and renal function monitored.

Nephrocalcinosis has also been reported in children with hypophosphataemic rickets treated with calcitriol and phosphate supplements; this was found to be associated with the phosphate dose.[4]

4. Verge CF, *et al.* Effects of therapy in X-linked hypophosphatemic rickets. *N Engl J Med* 1991; **325:** 1843–8.

Local toxicity. Rectal gangrene has been associated with the use of phosphate enemas in elderly patients and was believed to be due to a direct necrotising effect of the phosphate on the rectum.[1]

1. Sweeney JL, *et al.* Rectal gangrene: a complication of phosphate enema. *Med J Aust* 1986; **144:** 374–5.

Precautions

Phosphates should not generally be given to patients with severe renal impairment. They should be avoided in patients who may have low serum-calcium concentrations, as these may decrease further, and in patients with infected phosphate renal calculi. Potassium phosphates should be avoided in patients with hyperkalaemia and sodium phosphates should generally be avoided in patients with congestive heart failure, hypertension, and oedema. Serum electrolytes and renal function should be monitored during therapy, particularly if phosphates are given parenterally.

Oral or rectal sodium phosphate preparations for bowel evacuation should not be used in patients with gastrointestinal obstruction, inflammatory bowel disease, and conditions where there is likely to be increased colonic absorption. They should be used cautiously in elderly and debilitated patients, and in those with pre-existing electrolyte disturbances (see Effects on Electrolytes, above).

Interactions

Oral phosphate supplements should not be used with aluminium, calcium, or magnesium salts as these will bind phosphate and reduce its absorption. Vitamin D increases the gastrointestinal absorption of phosphates and therefore increases the potential for hyperphosphataemia.

Hyperphosphataemia, hypocalcaemia, and hypernatraemia are more likely to occur with phosphate enemas or oral laxatives if these are given to patients receiving diuretics or other drugs that may affect serum electrolytes. The risk of ectopic calcification may be increased by concurrent use of calcium supplements or calcium-containing antacids.

The risk of hyperkalaemia is increased if potassium phosphates are given with drugs that can increase serum-potassium concentrations.

Pharmacokinetics

About two-thirds of ingested phosphate is absorbed from the gastrointestinal tract. Excess phosphate is mainly excreted in the urine, the remainder being excreted in the faeces.

Human Requirements

Phosphorus requirements are usually regarded as equal to those of calcium.

Most foods contain adequate amounts of phosphate, particularly meat and dairy products, hence deficiency is virtually unknown except in certain disease states, in patients receiving total parenteral nutrition, or in those who have received phosphate-binding drugs for prolonged periods; for further details see under Hypophosphataemia, p.1669.

UK and US recommended dietary intake. In the UK dietary reference values (DRV—see Human Requirements, p.1925)[1] and in the USA dietary reference intakes including recommended dietary allowances (RDA)[2] have been published for phosphorus. In the UK the reference nutrient intake (RNI) for adults is about 550 mg (17.5 mmol) daily; no additional amount is recommended for pregnancy although an additional amount of about 440 mg (14.3 mmol) daily is advised during lactation. In the USA the RDA is 1250 mg daily for those aged 9 to 18 years and 700 mg daily in adults; no increase in RDA is recommended during pregnancy and lactation. A tolerable upper intake level of 4 g daily has been set in adults aged up to 70 years; in those older than 70 a maximum of 3 g daily is recommended.[2]

Uses and Administration

Phosphates are used in the management of **hypophosphataemia** caused by phosphate deficiency or hypophosphataemic states (p.1669). Doses of up to 100 mmol of phosphate daily may be given orally. The intravenous route is seldom necessary, but a dose of up to 9 mmol of phosphate as monobasic potassium phosphate may be given over 12 hours and repeated every 12 hours as necessary for severe hypophosphataemia. Alternatively, 0.2 to 0.5 mmol/kg phosphate, up to a maximum of 50 mmol, may be given over 6 to 12 hours (see also below). Plasma-electrolyte concentrations, especially phosphate and calcium, and renal function should be carefully monitored. Reduced doses may be necessary in patients with renal impairment. Phosphate supplements are used in total parenteral nutrition regimens; typical daily requirements are 20 to 30 mmol of phosphate.

Phosphates act as mild osmotic **laxatives** (p.1693) when given orally as dilute solutions or by the rectal route. Phosphate enemas or concentrated oral solutions are used for bowel cleansing before surgery or endoscopy procedures. Preparations typically combine monobasic and dibasic sodium phosphates but the composition and dosage do vary slightly. Phosphate enemas act within 2 to 5 minutes, whereas the oral solutions act within 30 minutes to 6 hours.

Phosphates also have **other uses**. They lower the pH of urine and have been given as adjuncts to urinary antibacterials that depend on an acid urine for their activity. Phosphates have also been used for the prophylaxis of calcium renal calculi; the phosphates reduce urinary excretion of calcium thus preventing calcium deposition. A suggested oral dose for both uses is 7.4 mmol of phosphate four times daily.

Butafosfan (1-butylamino-1-methylethylphosphinic acid) and the sodium salt of toldimfos (4-dimethylamino-*O*-tolylphosphinic acid) are used as phosphorus sources in veterinary medicine.

Bowel evacuation. A review concluded that the efficacy and tolerability of oral sodium phosphate solution was generally similar to, or significantly better than, that of polyethylene glycol-based or other colorectal cleansers in patients preparing for colorectal-related procedures.[1]

1. Curran MP, Plosker GL. Oral sodium phosphate solution: a review of its use as a colorectal cleanser. *Drugs* 2004; **64:** 1697–1714.

Hypercalcaemia. Intravenous phosphates have been used to lower plasma-calcium concentrations in hypercalcaemic emergencies (p.1668), but because of their potential to cause serious adverse effects other drugs are now preferred. Oral phosphates may be used to prevent gastrointestinal absorption of calcium in the treatment of hypercalcaemia. The dose in adults is up to 100 mmol phosphate daily adjusted according to response.

Hypophosphataemia. Phosphate salts are given in the management of hypophosphataemia when a phosphate deficiency is identified, as discussed in Uses and Administration, above. Intravenous phosphates are associated with serious adverse effects if hypophosphataemia is over-corrected, and the rise in serum-phosphorus concentration cannot be predicted from a given dose. Consequently, it has been recommended[1-4] that intravenous phosphate be used cautiously in the treatment of severe hypophosphataemia (for the standard rate and dose see Uses and Administration, above). However, some advocate a more aggressive fixed-dose regimen in critically ill patients.[5-7]

Osteomalacia. Vitamin D deficiency, or its abnormal metabolism, is the most usual cause of osteomalacia and rickets (p.1084); however, phosphate depletion may also contribute, and phosphate supplementation may be given as appropriate. A suggested oral dose for vitamin-D-resistant hypophosphataemic osteomalacia in adults is 65 to 100 mmol phosphate daily, and for vitamin D-resistant rickets in children is 32 to 48 mmol phosphate daily.

RICKETS OF PREMATURITY. Dietary deficiency of phosphorus is unusual, but can occur in small premature infants fed exclusively on human breast milk. The phosphate intake in these infants appears to be inadequate to meet the needs of bone mineralisation, and hypophosphataemic rickets can develop. It has been proposed that this condition, variably called metabolic bone disease of prematurity, or rickets of prematurity, could be prevented by giving phosphorus supplements to very low-birth-weight babies (less than about 1000 g) fed on breast milk alone.[1] A suggested regimen is to add 10 to 15 mg of phosphorus per 100 mL of feed (as buffered sodium phosphate) until the infant reached 2000 g. Concomitant calcium and vitamin D supplementation are also recommended.[1] A placebo-controlled study[2] in infants weighing less than 1250 g at birth confirmed that phosphate supplements (50 mg daily) could prevent the development of the bone defects of rickets of prematurity.

Potassium

Kalium; Potasio.
K = 39.0983.

Description. Potassium salts covered in this section are those principally given as a source of potassium ions, but consideration should also be given to the effect of the anion. Phosphate salts of potassium are covered under Phosphate, p.1682, and the bicarbonate and citrate salts under Bicarbonate, p.1673.

Potassium Acetate

E261; Kalii acetas; Kalio acetatas; Kaliumacetat; Kálium-acetát; Kaliumasetaatti; Octan draselný; Potasio, acetato de; Potassium, acétate de; Potasu octan.
$CH_3.CO_2K$ = 98.14.
CAS — 127-08-2.

Pharmacopoeias. In *Eur.* (see p.vii) and *US*.
Ph. Eur. 6.2 (Potassium Acetate). Deliquescent white or almost white, crystalline powder or colourless crystals. Very soluble in water; freely soluble in alcohol. A 5% solution in water has a pH of 7.5 to 9.0. Protect from moisture.
USP 31 (Potassium Acetate). Colourless, monoclinic crystals, or a white crystalline powder. It is odourless or has a faint acetous odour. Deliquesces on exposure to moist air. Soluble 1 in 0.5 of water, 1 in 0.2 of boiling water, and 1 in 3 of alcohol. pH of a 5% solution in water is between 7.5 and 8.5. Store in airtight containers.

Equivalence. Each g of potassium acetate (anhydrous) represents about 10.2 mmol of potassium. Potassium acetate (anhydrous) 2.51 g is equivalent to about 1 g of potassium.

Potassium Aspartate

Aspartate monopotassique hémihydraté; Kalii hydrogenoaspartas hemihydricus; Kalio-divandenilio aspartatas hemihidratas; Kalium-hydrogen-aspartát hemihydrát; Kaliumväteaspartathemihydrat; Kaliumvetyaspartaattihemihydraatti; Potassium Hydrogen Aspartate Hemihydrate. Potassium aminosuccinate hemihydrate.
$C_4H_6KNO_4,\frac{1}{2}H_2O$ = 180.2.
CAS — 7259-25-8 (hemihydrate).

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Potassium Hydrogen Aspartate Hemihydrate). A white or almost white, powder or crystalline powder, or colourless crystals. Very soluble in water; practically insoluble in alcohol and in dichloromethane. pH of a 2.5% solution in water is between 6.0 and 7.5.

Equivalence. Each g of potassium aspartate represents about 5.5 mmol of potassium. Potassium aspartate 4.61 g is equivalent to about 1 g of potassium.

Potassium Chloride

Chlorid draselný; Cloreto de Potássio; E508; Kalii chloridum; Kalio chloridas; Kalium Chloratum; Kaliumklorid; Kálium-klorid; Kaliumkloridi; Potasio, cloruro de; Potassium, chlorure de; Potasu chlorek.
KCl = 74.55.
CAS — 7447-40-7.
ATC — A12BA01; B05XA01.
ATC Vet — QA12BA01; QB05XA01.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, *US*, and *Viet.*
Ph. Eur. 6.2 (Potassium Chloride). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; practically insoluble in dehydrated alcohol.
USP 31 (Potassium Chloride). Colourless, elongated, prismatic, or cubical crystals, or a white, granular powder. Is odourless. Soluble 1 in 2.8 of water, and 1 in 2 of boiling water; insoluble in alcohol. Its solutions are neutral to litmus.

Equivalence. Each g of potassium chloride represents about 13.4 mmol of potassium. Potassium chloride 1.91 g is equivalent to about 1 g of potassium.

Potassium Gluconate

E577; Potasio, gluconato de. Potassium D-gluconate.
$CH_2OH.[CH(OH)]_4.CO_2K$ = 234.2.
CAS — 299-27-4 (anhydrous potassium gluconate); 35398-15-3 (potassium gluconate monohydrate).
ATC — A12BA05.
ATC Vet — QA12BA05.

Pharmacopoeias. In *Fr.*
US permits anhydrous or the monohydrate.
USP 31 (Potassium Gluconate). It is anhydrous or contains one molecule of water of hydration. A white or yellowish-white, odourless, crystalline powder or granules. Soluble 1 in 3 of water; practically insoluble in dehydrated alcohol, in chloroform, in ether, and in benzene. Its solutions are slightly alkaline to litmus. Store in airtight containers.

Equivalence. Each g of potassium gluconate (anhydrous) represents about 4.3 mmol of potassium. Each g of potassium gluconate (monohydrate) represents about 4 mmol of potassium. Potassium gluconate (anhydrous) 5.99 g and potassium gluconate (monohydrate) 6.45 g are each equivalent to about 1 g of potassium.

Potassium Sulfate

E515; Kalii sulfas; Kalio sulfatas; Kalium Sulfuricum; Kaliumsulfaatti; Kaliumsulfat; Potasio, sulfato de; Potassii Sulphas; Potassium, sulfate de; Potassium Sulphate; Síran draselný; Tartarus Vitriolatus.
K_2SO_4 = 174.3.
CAS — 7778-80-5.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.*
Ph. Eur. 6.2 (Potassium Sulphate). A white or almost white, crystalline powder or colourless crystals. Soluble in water; practically insoluble in dehydrated alcohol.

Equivalence. Each g of potassium sulfate represents about 11.5 mmol of potassium. Potassium sulfate 2.23 g is equivalent to about 1 g of potassium.

Potassium Tartrate

E336; Potasio, tartrato de; Potasu winian.
$C_4H_4K_2O_6,\frac{1}{2}H_2O$ = 235.3.
CAS — 921-53-9 (anhydrous potassium tartrate).

Equivalence. Each g of potassium tartrate (hemihydrate) represents about 8.5 mmol of potassium. Potassium tartrate (hemihydrate) 3.00 g is equivalent to about 1 g of potassium.

Adverse Effects

Excessive doses of potassium may lead to the development of hyperkalaemia (p.1669), especially in patients with renal impairment. Symptoms include paraesthesia of the extremities, muscle weakness, paralysis, cardiac arrhythmias, heart block, cardiac arrest, and confusion. Cardiac toxicity is of particular concern after intravenous dosage.

Pain or phlebitis may occur when given intravenously via peripheral veins, particularly at higher concentrations.

Nausea, vomiting, diarrhoea, and abdominal cramps may occur with oral potassium salts. There have been numerous reports of gastrointestinal ulceration, sometimes with haemorrhage and perforation or with the late formation of strictures, after the use of enteric-coated tablets of potassium chloride. Ulceration has also occurred after the use of sustained-release tablets.

Treatment of Adverse Effects

The treatment of hyperkalaemia discussed on p.1669 also applies when hyperkalaemia occurs during potassium therapy. However, in mild hyperkalaemia that has developed on long-term treatment, stopping the potassium supplement and other drugs that may increase plasma-potassium concentrations, and avoidance of foods with a high potassium content may be sufficient to correct the hyperkalaemia.

In cases of acute oral overdosage of potassium supplements, the stomach should be emptied by gastric lavage in addition to the measures described on p.1669.

Precautions

Potassium salts should be given with considerable care to patients with cardiac disease or conditions predisposing to hyperkalaemia such as renal or adrenocortical insufficiency, acute dehydration, or extensive tissue destruction as occurs with severe burns. Excessive use of potassium-containing salt substitutes or potassium supplements may lead to accumulation of potassium especially in patients with renal insufficiency. Regular monitoring of clinical status, serum electrolytes, and the ECG is advisable in patients receiving potassium therapy, particularly those with cardiac or renal impairment.

Liquid or effervescent preparations are preferred to solid dosage forms for oral use; use of the former, with or after food, may reduce gastric irritation. Solid oral dosage forms of potassium salts should not be given to patients with gastrointestinal ulceration or obstruction. They should be given with care to patients in whom passage through the gastrointestinal tract may be delayed, as in pregnant patients. Treatment should be stopped if severe nausea, vomiting, or abdominal distress develops.

Potassium chloride should not be used in patients with hyperchloraemia.

Direct injection of potassium chloride concentrates without appropriate dilution may cause instant death. For the view that glucose-containing solutions should not be used for the initial intravenous administration of potassium in hypokalaemia see Administration, below.

Interactions

Potassium supplements should be used with caution, if at all, in patients receiving drugs that increase serum-potassium concentrations. These include potassium-sparing diuretics, ACE inhibitors, ciclosporin, and drugs that contain potassium such as the potassium salts of penicillin. Similarly, the concomitant use of potassium-containing salt substitutes for flavouring food should be avoided. Antimuscarinics delay gastric emptying and consequently may increase the risk of gastrointestinal adverse effects in patients receiving solid oral dosage forms of potassium.

Table 3. Some potassium salts and their potassium content.

Potassium salt	Potassium content per g		
	mg	mmol	mEq
Potassium acetate (anhydrous)	398	10.2	10.2
Potassium aspartate	217	5.5	5.5
Potassium bicarbonate	391	10.0	10.0
Potassium chloride	524	13.4	13.4
Potassium citrate (anhydrous)	383	9.8	9.8
Potassium citrate (monohydrate)	361	9.3	9.3
Potassium gluconate (anhydrous)	167	4.3	4.3
Potassium gluconate (monohydrate)	155	4.0	4.0
Potassium sulfate (anhydrous)	449	11.5	11.5
Potassium tartrate (hemihydrate)	332	8.5	8.5

Pharmacokinetics

Potassium salts other than the phosphate, sulfate, and tartrate are generally readily absorbed from the gastrointestinal tract. Potassium is excreted mainly by the kidneys; it is secreted in the distal tubules in exchange for sodium or hydrogen ions. Some potassium is excreted in the faeces and small amounts may also be excreted in sweat.

Human Requirements

Potassium is an essential body electrolyte. However, requirements are difficult to determine and have been estimated from the amount accumulated during growth and reported urinary and faecal excretion.

Over 90% of dietary potassium is absorbed from the gastrointestinal tract. Potassium is particularly abundant in vegetables, potatoes, and fruit.

UK and US recommended dietary intake. In the UK dietary reference values (DRV—see Human Requirements, p.1925)[1] have been estimated for potassium. The reference nutrient intake (RNI) for adults is 3.5 g (90 mmol) daily. In the USA, no recommended dietary allowance (RDA) has been established for potassium. However a daily intake of 1.6 to 2 g (40 to 50 mmol) is considered adequate for adults.

1. DoH. Dietary reference values for food energy and nutrients for the United Kingdom: report of the panel on dietary reference values of the committee on medical aspects of food policy. *Report on health and social subjects 41.* London: HMSO, 1991.

Uses and Administration

Potassium salts in this section are used for the prevention and treatment of potassium depletion and/or **hypokalaemia** (p.1669) and have been used in the prevention of **diuretic-induced hypokalaemia** (see Hydrochlorothiazide, Effects on Electrolyte Balance, p.1308). Doses may be expressed in terms of mmol or mEq of potassium, mass (mg) of potassium, or mass of potassium salt (for comparative purposes see Table 3, below). Treatment should be monitored by plasma-potassium estimations because of the risk of inducing hyperkalaemia, especially where there is renal impairment.

Potassium chloride is probably the most commonly used potassium salt; this is because hypochloraemic alkalosis, which is often associated with hypokalaemia, can be corrected by the chloride ions. An alkalinising salt such as potassium acetate, potassium bicarbonate, or potassium citrate may be preferable if a metabolic acidosis, such as occurs in renal tubular acidosis, accompanies the hypokalaemia (see p.1667). Other salts that are or have been used in the management of potassium deficiency include potassium ascorbate, potassium aspartate, potassium benzoate, potassium gluceptate, potassium gluconate, potassium phosphate, and potassium tartrate. Typical doses for the prevention of hypokalaemia may be up to 50 mmol daily and similar doses may be adequate in mild potassium deficiency. However, higher doses may be needed in more severe deficiency. Patients with renal impairment should receive correspondingly lower doses. *Oral* treatment is used for prophylaxis and is also suitable for treating most cases of hypokalaemia. Oral potassium salts are more irritating than the corresponding sodium salts; they should be taken with or after meals with plenty of fluid; liquid preparations are preferable.

An *intravenous* potassium salt may be required in severe acute hypokalaemia. This normally entails infusing a solution containing 20 mmol of potassium in 500 mL over 2 to 3 hours under ECG control. A recommended maximum dose is 2 to 3 mmol/kg of potassium in 24 hours. Higher concentrations have been given when an infusion pump has been used (see Administration below). Adequate urine flow must be ensured and careful monitoring of plasma-potassium and other electrolyte concentrations is essential. Potassium chloride is the salt most commonly used and solutions intended for intravenous use that are in a concentrated form (such as 1.5 or 2 mmol/mL) *must* be diluted to the appropriate concentration before use. There should be careful and thorough mixing when adding concentrated potassium chloride solutions to infusion fluids. Potassium chloride is also available as premixed infusions with sodium chloride and/or glucose containing 10 to 40 mmol/litre of potassium (but see also Administration, below). Potassium acetate is also given intravenously.

Amongst **other uses**, the sulfate, and tartrate salts of potassium have been given orally as osmotic laxatives (p.1693).

Some potassium salts are used as sodium-free condiments when sodium intake must be restricted.

Potassium chloride is sometimes used as an excipient in pharmaceutical formulations.

Administration. The standard concentration and rate of administration of potassium chloride for infusion is discussed in Uses and Administration, above. However, higher concentrations (200 or 300 mmol/litre) and faster infusion rates have been used, via an infusion pump, for cases of severe symptomatic hypokalaemia, especially with fluid overload.[1,2]

There has been controversy regarding the preferred route of administration of these higher concentrations of potassium chloride.[1] The central route avoids the problems of pain and phlebitis when potassium is given peripherally. However, it has been suggested that high concentrations of potassium given centrally may carry a greater risk of cardiac toxicity if the infusion is carried directly to the heart. Use of lidocaine has improved tolerability of peripheral administration of potassium chloride.[2]

Intravenous potassium is usually given in sodium chloride and/or glucose infusion. However, it has been pointed out that glucose can reduce serum-potassium concentrations, and that glucose-free solutions should be used for the initial intravenous administration of potassium in hypokalaemia.[3]

3. Agarwal A, Wingo CS. Treatment of hypokalaemia. *N Engl J Med* 1999; **340:** 154–5.

Diabetic ketoacidosis. As discussed under Diabetic Emergencies on p.435, potassium replacement is given in diabetic ketoacidosis to restore total body stores of potassium and thereby prevent the hypokalaemia induced by insulin.

Hypertension. A meta-analysis[1] has reported that potassium supplementation results in reductions of both systolic and diastolic blood pressure. The size of the effect in hypertensive patients was sufficiently great to suggest a possible role in the treatment of hypertension (p.1171); effects in normotensive subjects were less marked but consistent with a role for potassium supplementation in preventing hypertension. Most studies have used potassium chloride, but an effect has also been demonstrated with the aspartate[2] and the citrate.[3]

3. He FJ, *et al.* Effect of short-term supplementation of potassium chloride and potassium citrate on blood pressure in hypertensives. *Hypertension* 2005; **45:** 571–4.

Myocardial infarction. A glucose, insulin, and potassium infusion has been investigated in acute myocardial infarction (see p.452).

Termination of pregnancy. Solutions of potassium chloride are used to reduce fetal numbers in multifetal pregnancies[1-3] or for severe fetal malformation by abolishing the fetal cardiac activity. The solution is injected into the thorax of the fetus without affecting the others which are allowed to continue to term. Alternatively, potassium chloride may be injected into the umbilical vein when access to the fetal heart is difficult. A retrospective comparison[4] found both techniques to be effective. Significantly smaller doses were required for the umbilical route, possibly because a sustained dose is delivered directly to the fetal heart and myocardium, compared with intraventricular injection.

Sodium

Natrium; Sód; Sodio.

Na = 22.98976928.

Description. Sodium chloride is the principal sodium salt used as a source of sodium ions. Sodium salts used chiefly as sources of bicarbonate ions, such as the acetate, bicarbonate, citrate, and lactate, are covered under Bicarbonate, p.1673. Phosphate salts of sodium are covered under Phosphate, p.1682.

Sodium Chloride

Chlorid sodný; Chlorure de Sodium; Cloreto de Sódio; Natrii chloridum; Natrio chloridas; Natriumklorid; Nátrium-klorid; Natriumkloridi; Salt; Sodio, cloruro de; Sodium, chlorure de; Sodu chlorek; Sodyum Klorür.

NaCl = 58.44.

CAS — 7647-14-5.

ATC — A12CA01; B05CB01; B05XA03.

ATC Vet — QA12CA01; QB05CB01; QB05XA03.

NOTE. An aqueous solution of sodium chloride 0.9% is often known as physiological saline.

SALINE is a code approved by the BP 2008 for use on single unit doses of eye drops containing sodium chloride 0.9% where the individual container may be too small to bear all the appropriate labelling information. HECL is a similar code approved for hyetellose and sodium chloride eye drops.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, *US*, and *Viet.*

Ph. Eur. 6.2 (Sodium Chloride). A white or almost white, crystalline powder or colourless crystals or white or almost white pearls. Freely soluble in water; practically insoluble in dehydrated alcohol.

USP 31 (Sodium Chloride). Colourless cubic crystals or white crystalline powder. Soluble 1 in 2.8 of water, 1 in 2.7 of boiling water, and 1 in 10 of glycerol; slightly soluble in alcohol.

Equivalence. Each g of sodium chloride represents about 17.1 mmol of sodium and of chloride. Sodium chloride 2.54 g is equivalent to about 1 g of sodium.

Storage. Solutions of some sodium salts, including sodium chloride, when stored, may cause separation of solid particles from glass containers and solutions containing such particles must not be used.

Adverse Effects

Adverse effects of sodium salts are attributable to electrolyte imbalances from excess sodium; there may also be effects due to the specific anion.

Retention of excess sodium in the body usually occurs when there is defective renal sodium excretion. This leads to the accumulation of extracellular fluid to maintain normal plasma osmolality, which may result in pulmonary and peripheral oedema and their consequent effects.

Hypernatraemia (a rise in plasma osmolality) is usually associated with inadequate water intake, or excessive water losses (see p.1670). It rarely occurs after therapeutic doses of sodium chloride, but has occurred with the use of hypertonic saline for induction of emesis or for gastric lavage and after errors in the formulation of infant feeds. Hypernatraemia may also occur after inappropriate intravenous use of hypertonic saline.

The most serious effect of hypernatraemia is dehydration of the brain which causes somnolence and confusion progressing to convulsions, coma, respiratory failure, and death. Other symptoms include thirst, reduced salivation and lachrymation, fever, sweating, tachycardia, hypertension or hypotension, headache, dizziness, restlessness, irritability, weakness, and muscular twitching and rigidity.

Gastrointestinal effects associated with acute oral ingestion of hypertonic solutions or excessive amounts of sodium chloride include nausea, vomiting, diarrhoea, and abdominal cramps.

Excessive use of chloride salts may cause a loss of bicarbonate with an acidifying effect.

Intra-amniotic injection of hypertonic solutions of sodium chloride, which has been used for termination of pregnancy, has been associated with serious adverse effects including disseminated intravascular coagulation, renal necrosis, cervical and uterine lesions, haemorrhage, pulmonary embolism, pneumonia, and death.

Treatment of Adverse Effects

In patients with mild sodium excess, drinking water and restricting sodium intake is sufficient. However, in the event of recent acute oral overdose of sodium chloride, gastric lavage should be carried out along with general symptomatic and supportive treatment. Serum-sodium concentrations should be measured, and if severe hypernatraemia is present this should be treated (see p.1670).

Precautions

Sodium salts should be used with caution in patients with hypertension, heart failure, peripheral or pulmonary oedema, renal impairment, pre-eclampsia, or other conditions associated with sodium retention.

When sodium supplements are given orally, adequate water intake should be maintained. Sustained-release tablets should not be given to patients with gastrointestinal disorders associated with strictures or diverticula because of the risk of obstruction.

Sodium chloride solutions should *not* be used to induce emesis; this practice is dangerous and deaths from resulting hypernatraemia have been reported.

Pharmacokinetics

Sodium chloride is well absorbed from the gastrointestinal tract. Excess sodium is mainly excreted by the kidney, and small amounts are lost in the faeces and sweat.

Human Requirements

The body contains about 4 mol (92 g) of sodium of which about one-third is found in the skeleton and about half is present in the extracellular fluid.

The body can adapt to a wide range of intakes by adjustment of renal excretion through physical and hormonal factors. Loss through the skin is significant only if excessive sweating occurs. Sodium requirements may be increased with exercise or exposure to high ambient temperatures in the short term, until the body adjusts.

Sodium is widely available in foods and is also added as salt during processing, cooking, and at the table. Dietary deficiency of sodium is therefore extremely rare and more concern has been expressed that current intakes are excessive. Restriction of sodium intake, by limiting the amount of culinary salt consumed, may be a useful aid in the management of some patients with hypertension (p.1171).

UK and US recommended dietary intake. In the UK dietary reference values (DRV—see Human Requirements, p.1925)[1] have been published for sodium. The reference nutrient intake (RNI) for adults is 1.6 g of sodium (70 mmol) daily, which is about 4 g of sodium chloride. In the USA, it has been recommended that daily intakes of sodium be limited to 2.4 g (6 g of sodium chloride) or less.[2] Dietary intake is often in excess of these recommendations, and may be a factor in essential hypertension,[3] and osteoporosis.[4]

Uses and Administration

Sodium chloride is used in the management of deficiencies of sodium and chloride ions in salt-losing conditions (see Hyponatraemia, p.1670). Sodium chloride solutions are used as a source of sodium chloride and water for hydration.

A 0.9% solution in water is iso-osmotic, and thus in most cases isotonic with serum and lachrymal secretions. Doses may be expressed in terms of mEq or mmol of sodium, mass (mg) of sodium, or mass of sodium salt. For comparative purposes, see Table 4, below.

A typical oral replacement dose of sodium chloride in **chronic salt-losing conditions** is about 2.4 to 4.8 g (about 40 to 80 mmol of sodium) daily as a modified-release preparation, accompanied by a suitable fluid intake; doses of up to 12 g daily may be necessary in

Table 4. Some sodium salts and their sodium content.

	Sodium content per g		
Sodium salt	mg	mmol	mEq
Sodium acetate (anhydrous)	280	12.2	12.2
Sodium acetate (trihydrate)	169	7.3	7.3
Sodium acid citrate	175	7.6	7.6
Sodium bicarbonate	274	11.9	11.9
Sodium chloride	394	17.1	17.1
Sodium citrate (anhydrous)	267	11.6	11.6
Sodium citrate (dihydrate)	235	10.2	10.2
Sodium lactate	205	8.9	8.9

severe cases. Oral supplements are also used for the prevention of muscle cramps during routine haemodialysis (p.1671); a suggested dose is about 6 to 10 g of a modified-release preparation per dialysis session.

Glucose facilitates the absorption of sodium from the gastrointestinal tract, and solutions containing sodium chloride and glucose usually with additional electrolytes (see p.1672) are used for oral rehydration in acute diarrhoea (p.1694).

The concentration and dosage of sodium chloride solutions for intravenous use is determined by several factors including the age, weight, and clinical condition of the patient and in particular the patients' hydration state. Serum-electrolyte concentrations should be carefully monitored. In severe sodium depletion, 2 to 3 litres of sodium chloride 0.9% may be given over 2 to 3 hours and thereafter at a slower rate. If there is combined water and sodium depletion a 1 to 1 mixture of sodium chloride 0.9% and glucose 5% may be appropriate. Although hypertonic sodium chloride solutions may be used in certain patients with severe acute dilutional hyponatraemia, over-rapid correction may have severe neurological adverse effects (see Hyponatraemia, p.1670). Solutions containing 1.8 to 5% are available.

In **hypernatraemia** with volume depletion (p.1670), sodium chloride 0.9% may be used to maintain plasma-sodium concentrations with expanding fluid volume. Sodium chloride 0.9% (or rarely, in marked hypernatraemia, 0.45%) is used for fluid replacement in diabetic ketoacidosis (see Diabetic Emergencies, p.435).

Among its **other uses**, sodium chloride solution 0.9%, being isotonic, is a useful fluid for sterile irrigations, for example, of the eye or bladder, and general skin or wound cleansing. The 0.9% concentration is also widely used as a vehicle or diluent for the parenteral administration of other drugs. Nasal drops of sodium chloride 0.9% are used to relieve nasal congestion. A mouthwash containing sodium chloride is also available for oral hygiene.

Sodium chloride solutions should *not* be used to induce emesis; this practice is dangerous and deaths from resulting hypernatraemia have been reported.

Sodium chloride is sometimes used as an excipient in capsules and tablets.

Homoeopathy. Sodium chloride has been used in homoeopathic medicines under the following names: Natrium muriaticum; Nat. Mur.; Natrii chloridum; Natricum chloratum; Natrum muriaticum.

NOTE. Do not confuse Natricum chloratum with sodium chlorate (p.2389).

Catheters and cannulas. For reference to sodium chloride 0.9% being used to maintain the patency of catheters and cannulas, and to its equivalent efficacy to heparin, see Catheters and Cannulas under Uses and Administration of Heparin, p.1304.

Cystic fibrosis. Inhalation of 4 mL of a hypertonic solution of sodium chloride (7%) twice daily for 48 weeks in 82 patients with stable cystic fibrosis (p.166) was associated with a moderate but sustained improvement in lung function and a marked reduction in the number of exacerbations and need for antibiotics, when compared with 80 placebo-treated patients.[1] There was, however, no difference in the rate of change of lung function. Each inhalation was preceded by a bronchodilator to minimise airway narrowing; adverse reactions to the active treatment were nonetheless reported in 14 patients and included cough, chest tightness or pharyngitis, sinusitis, haemoptysis, sneezing, and vomiting. As a result, 6 patients withdrew from the study, but the effects resolved in the remainder without the need for dose reduction or interruption. Hypertonic saline was considered to be an inexpensive and safe adjunctive therapy in patients with cystic fibrosis.

Termination of pregnancy. Trans-abdominal intra-amniotic instillation of sodium chloride 20% (maximum volume 200 to 250 mL) has been used for the termination of second-trimester pregnancy. However, serious adverse effects have occurred (see above), and other methods are generally preferred (p.2004).

Gases

This chapter includes monographs on gases with medical or pharmaceutical uses and applications (such as oxygen, carbon dioxide, helium, and nitrogen) as well as those where the medical interest lies primarily in management of their toxicity or adverse effects (such as carbon monoxide or hydrogen sulfide). Also included are some compressed and liquefied gases used as refrigerants and aerosol propellants. Nitric oxide gas is used in bronchopulmonary disorders and is discussed in Cardiovascular Drugs (p.1358). Other gases with medical uses can be found in Disinfectants and Preservatives (p.1622) and General Anaesthetics (p.1779).

Refrigerants and Aerosol Propellants

A number of compressed and liquefied gases are used as refrigerants and as aerosol propellants; these include nitrogen, nitrous oxide, carbon dioxide, propane, and the butanes. Chlorofluorocarbons (CFCs) were widely used but because of environmental hazards their general use has been severely restricted and they are being phased out in medicine and pharmacy. Hydrogenated chlorofluorocarbons (hydrochlorofluorocarbons) and nonchlorinated fluorocarbons (hydrofluorocarbons) are being developed as alternatives, although neither are devoid of environmental effects.

The evaporation of halogenated hydrocarbon propellants produces an intense cold that numbs the tissues, and they have been used as topical analgesics (see Rubefacients and Topical Analgesia, p.5).

Refrigerants and aerosol propellants have been subject to deliberate abuse. Inhalation of high concentrations of halogenated hydrocarbons for their euphoriant effect may result in CNS depression, cardiac arrhythmias, respiratory depression, and death. Propane and butane can act as simple asphyxiants. Heat can cause the decomposition of halogenated hydrocarbons into irritant and toxic gases such as hydrogen chloride and phosgene.

Toxicity. Reviews have covered the toxicity and adverse effects that may occur as a consequence of the deliberate abuse of aerosol propellants[1-4] as well as the hazards associated with occupational exposure.[5] Further references relevant to the toxicity of individual agents are given in the monographs.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Batistol†; Frionex; ***Fr.:*** Cliptol Sport†.

Carbon Dioxide

Anglies dioksidas; Carbone, dioxyde de; Carbonei dioxidum; Carbonei Dioxydum; Carbonic Acid Gas; Carbonic Anhydride; Dióxido de carbono; E290; Hiilidioksidi; Koldioxid; Oxid uhličitý; Szén-dioxid; Węgla dwutlenek.

CO_2 = 44.01.

CAS — 124-38-9.

ATC — V03AN02.

ATC Vet — QV03AN02.

NOTE. Carbon dioxide is about 1⁄ times as heavy as air.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Carbon Dioxide). A colourless gas. Soluble 1 in about 1 of water by volume at 20° and at a pressure of 101 kpA. Store liquefied under pressure in suitable containers.

The BP 2008 directs that carbon dioxide should be kept in approved metal cylinders which are painted grey and carry a label stating 'Carbon Dioxide'. In addition, 'Carbon Dioxide' or the symbol 'CO_2' should be stencilled in paint on the shoulder of the cylinder.

USP 31 (Carbon Dioxide). A colourless, odourless gas. Its solutions are acid to litmus. One volume dissolves in about 1 volume of water. Store in cylinders.

Adverse Effects

Above a concentration of 6%, carbon dioxide causes headache, dizziness, confusion, palpitations, hypertension, dyspnoea, increased depth and rate of respiration, and CNS depression. Concentrations of about 20% and higher produce convulsions and loss of consciousness; inhalation of 50% carbon dioxide is reported to produce central effects similar to anaesthetics. The inhalation of high concentrations may produce respiratory acidosis.

Abrupt withdrawal of carbon dioxide after prolonged inhalation commonly produces pallor, hypotension, dizziness, severe headache, and nausea or vomiting.

Skin contact with solid carbon dioxide may cause frostbite.

Uses and Administration

Carbon dioxide has been added to the oxygen in certain types of pump oxygenators to maintain the carbon dioxide content of the blood.

Although carbon dioxide stimulates respiration, it is seldom used for this purpose. Treatment of carbon monoxide poisoning with carbon dioxide/oxygen mixtures is discouraged due to the risk of respiratory acidosis.

Inhalation of carbon dioxide has been tried for relief of intractable hiccup (p.976). Carbonated vehicles are useful for masking the unpleasant taste of some medicinal preparations.

Solid carbon dioxide, or 'dry ice' has a temperature of –80° and has been used to treat warts (p.1584) and naevi by cryotherapy.

Carbon dioxide may be used as the insufflating gas for laparoscopy and as a contrast agent in radiography (p.1474).

Carbon Monoxide *(USAN)*

Anglies monoksidas; Carbone, monoxyde de; Carbonei monoxidum; Hiilimonoksidi; Karbon Monoksit; Kolmonoxid; Monóxido de carbono; Węgla tlenek.

CO = 28.01.

CAS — 630-08-0.

Description. Carbon monoxide is a colourless, odourless, tasteless, highly flammable gas.

Adverse Effects

Carbon monoxide is produced by incomplete combustion of organic materials and is highly toxic when inhaled; infants, small children, and elderly people are particularly susceptible. Although the number of cases of poisoning in countries such as the UK has fallen as the availability of coal gas has declined and as changes have been made to motor vehicles to improve their exhaust fumes, carbon monoxide is still a major cause of poisoning. Common sources of carbon monoxide include poorly maintained and ventilated heating systems and improperly burnt fuel in domestic fires.

When inhaled, carbon monoxide combines with haemoglobin in the blood to form carboxyhaemoglobin, which is unable to transport oxygen; the symptoms of carbon monoxide poisoning are largely due to anoxia. The skin and tissues may turn a classic cherry red in patients poisoned with carbon monoxide although this is seen most often after death.

The symptoms of carbon monoxide poisoning are varied and depend on the degree and duration of exposure. Unconsciousness may occur suddenly but is commonly preceded by headache, dizziness, weakness, nausea, and vomiting, which may be misdiagnosed as a viral illness or food poisoning. Other symptoms may include skin lesions, excessive sweating, pyrexia, increased respiration, mental dullness and confusion, visual disturbances, convulsions, hypotension, tachycardia or other cardiac arrhythmias, myocardial ischaemia, and possibly myocardial infarction. Death may result from respiratory failure, pulmonary oedema, cardiovascular failure, or cerebral damage. The lethal concentration of carboxyhaemoglobin in the blood is about 50% or more. Concentrations over 1000 ppm of carbon monoxide in inspired air may be fatal in 1 hour. Neurological and psychiatric sequelae may develop some weeks later in the survivors of severe poisoning and therefore a prolonged follow-up of such patients is advised; symptoms include memory impairment, apathy, mutism, irritability, personality change, gait disturbance, and urinary and faecal incontinence. Chronic carbon monoxide exposure may present as a non-specific illness with headache, nausea, and flu-like symptoms.

Treatment of Adverse Effects

The patient should be removed from the contaminated atmosphere and an effective airway established. Oxygen (100%) should be given until the blood carboxyhaemoglobin concentration has fallen below dangerous levels (usually 5%). Management is then usually symptomatic and supportive with attention being given to the possible need to treat or correct any cardiovascular disorders, metabolic acidosis, or cerebral oedema. Hyperbaric oxygen therapy may be considered in pregnant patients or in severe poisoning (if the patient is, or has been, unconscious; if the carboxyhaemoglobin concentration exceeds 20%; or if there are neurological symptoms or cardiac complications) but is of unproven benefit (see below) and its use is controversial.

Hyperbaric oxygen therapy. The use of hyperbaric oxygen therapy in the management of carbon monoxide poisoning is controversial.[1] It is of theoretical benefit since it increases the rate at which carboxyhaemoglobin dissociates, and beneficial results have been reported in patients with carbon monoxide poisoning.[2,3] Its use has therefore been widely recommended, particularly in patients with severe poisoning. However, the availability of hyperbaric oxygen is limited, and it remains unclear which patients should receive therapy; a systematic review considered its value unproven.[1] A controlled trial[4] comparing hyperbaric oxygen with normobaric oxygen (at higher levels than commonly used) in patients with severe poisoning found no benefit from hyperbaric oxygen, but a later study[5] using a different regimen did find a reduction in cognitive sequelae. Hyperbaric oxygen has been successfully used in pregnant patients with carbon monoxide poisoning[6] and its use should possibly be considered earlier in pregnant patients due to the risks to the fetus from hypoxia.

Uses

Carbon monoxide has been used in low concentrations as a tracer gas in measurements of lung function. Carbon monoxide labelled with carbon-11 may also be used to assess the blood volume.

Chlorofluorocarbons

CFCs; Clorofluorocarbonos.

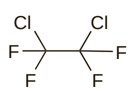
Cryofluorane *(rINN)*

CFC-114; Criofluorano; Cryofluoranum; Dichlorotetrafluoroethane; Propellant 114; Refrigerant 114; Tetrafluorodichloroethane. 1,2-Dichloro-1,1,2,2-tetrafluoroethane.

Криофлуоран

$C_2Cl_2F_4$ = 170.9.

CAS — 76-14-2.



Pharmacopoeias. In *USNF.*

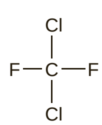
USNF 26 (Dichlorotetrafluoroethane). A clear, colourless gas having a faint ethereal odour. Store in airtight cylinders at a temperature not exceeding 40°.

Dichlorodifluoromethane

CFC-12; Diclorodifluorometano; Difluorodichloromethane; Propellant 12; Refrigerant 12.

CCl_2F_2 = 120.9.

CAS — 75-71-8.



Pharmacopoeias. In *USNF.*

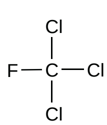
USNF 26 (Dichlorodifluoromethane). A clear, colourless gas having a faint ethereal odour. Store in airtight cylinders at a temperature not exceeding 40°.

Trichlorofluoromethane

CFC-11; Fluorotrichloromethane; Propellant 11; Refrigerant 11; Trichloromonofluoromethane; Triclorofluorometano.

CCl_3F = 137.4.

CAS — 75-69-4.



NOTE. Trichlorofluoromethane is a gas above 24°.

Pharmacopoeias. In *USNF.*

USNF 26 (Trichloromonofluoromethane). A clear, colourless gas having a faint ethereal odour. Store in airtight cylinders at a temperature not exceeding 40°.

Profile

Chlorofluorocarbons are used as refrigerants and as aerosol propellants (p.1688). They may also be used as a spray for topical anaesthesia, the intense cold produced by the rapid evaporation of the spray making the tissues insensitive.

Preparations

Proprietary Preparations (details are given in Part 3)

Helium

E939; Helio; Hélium.

He = 4.002602.

CAS — 7440-59-7.

ATC — V03AN03.

ATC Vet — QV03AN03.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Helium). A colourless, inert gas. Store as a compressed gas or liquid at cryogenic temperatures, in appropriate containers.

USP 31 (Helium). A colourless, odourless, tasteless gas which is not combustible and does not support combustion. Very slightly soluble in water. Store in cylinders.

Profile

As helium is less dense than nitrogen, breathing a mixture of 80% helium and 20% oxygen requires less effort than breathing air. Thus mixtures containing various concentrations of oxygen ('Heliox') have been used in patients with respiratory disorders. Due to the low solubility of helium, mixtures of helium and oxygen are used by divers or others working under high pressure to prevent the development of decompression sickness (caisson disease); they are preferred to compressed air as they do not cause nitrogen narcosis. Helium has been used in pulmonary function testing.

Breathing helium increases vocal pitch and causes voice distortion. Cerebral artery gas embolism has been reported after inhalation of helium from a pressurised container.

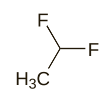
Difluoroetano; Ethylene Fluoride; HFC-152a; Propellant 152a; Refrigerant 152a. 1,1-Difluoroethane.

$C_2H_4F_2$ = 66.05.

CAS — 75-37-6.



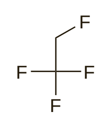
Norflurane *(BAN, USAN, rINN)*

Fluorocarbon 134a; GR-106642X; HFA-134a; HFC-134a; Norflurano; Norfluranum; Propellant 134a; Refrigerant 134a. 1,1,1,2-Tetrafluoroethane.

Норфлуран

$C_2H_2F_4$ = 102.0.

CAS — 811-97-2.



Profile

Hydrofluorocarbons are used as refrigerants and as aerosol propellants (p.1688). They are nonchlorinated and cause less ozone depletion than chlorinated fluorocarbons, which may lead to less detrimental effects on the environment. They are being used to replace chlorinated fluorocarbons as propellants in medicinal inhalers.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***USA:*** Gebauers Spray & Stretch.

Hydrogen Sulfide

Hydrogen Sulphide; Siarkowodór; Sulfuro de hidrógeno; Sulphuretted Hydrogen.

H_2S = 34.08.

CAS — 7783-06-4.

Description. Hydrogen sulfide is a colourless flammable gas with a characteristic odour.

Adverse Effects

Hydrogen sulfide is a common industrial hazard and is encountered in such places as chemical works, mines, sewage works, and stores of decomposing protein. Concentrations of 0.1 to 0.2% in the atmosphere may be fatal in a few minutes. At concentrations of about 0.005% and above hydrogen sulfide causes anosmia and its unpleasant odour is no longer detectable. Pulmonary irritation, oedema, and respiratory failure usually occur after acute poisoning; prolonged exposure to low concentrations may cause severe conjunctivitis with photophobia and corneal opacity, irritation of the respiratory tract, cough, nausea, vomiting and diarrhoea, pharyngitis, headache, dizziness, and lassitude. There are some similarities to poisoning with cyanides.

◊ General references.

1. WHO. Hydrogen Sulfide. *Environmental Health Criteria 19*. Geneva: WHO, 1981. Available at: http://www.inchem.org/documents/ehc/ehc/ehc019.htm (accessed 05/07/04)

Treatment of Adverse Effects

In poisoning with hydrogen sulfide the patient should be removed from the contaminated atmosphere and an effective airway established. Inhalation of amyl nitrite or parenteral therapy with sodium nitrite have been suggested; this produces methaemoglobin, which may bind sulfide. Oxygen should be given; hyperbaric oxygen therapy has also been suggested. The conjunctival sacs should be carefully washed out if eye irritation is severe. Management is then usually symptomatic and supportive.

◊ References.

1. Gorman DF. Problems and pitfalls in the use of hyperbaric oxygen for the treatment of poisoned patients. *Med Toxicol Adverse Drug Exp* 1989; **4:** 393–9.

Uses

Hydrogen sulfide is widely used in many industrial processes.

Isobutane

E943b; Isobutano; 2-Methylpropane.

C_4H_{10} = 58.12.

Pharmacopoeias. In *USNF.*

USNF 26 (Isobutane). A colourless gas. It is highly flammable and explosive. Store in airtight cylinders at a temperature not exceeding 40°.

Profile

Isobutane is used as an aerosol propellant (p.1688).

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austral.:*** Histofreezer†; ***Fr.:*** Cliptol Sport†; Freeze; ***UK:*** Histofreezer; ***USA:*** Compound W Freeze Off.

Nitrogen

Azot; Azotas; Azote; Dusík; E941; Kvävgas; Nitrogén; Nitrogenium; Nitrógeno; Nitrogenum; Stickstoff; Typpi.

N_2 = 28.0134.

CAS — 7727-37-9.

ATC — V03AN04.

ATC Vet — QV03AN04.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Nitrogen). The monograph applies to nitrogen for medicinal use. A colourless, odourless gas. Soluble 1 in about 62 of water and 1 in about 10 of alcohol by volume at 20° and at a pressure of 101 kpA. Store as a compressed gas or a liquid in appropriate containers.

The BP 2008 directs that nitrogen should be kept in approved metal cylinders, the shoulders of which are painted black and the remainder grey. The cylinder should carry a label stating 'Nitrogen'.

Ph. Eur. 6.2 (Nitrogen, Low-oxygen). The monograph applies to nitrogen used in the production of an inert atmosphere for finished medicinal products that are particularly sensitive to degradation by oxygen. A colourless, odourless gas. Soluble 1 in about 62 of water and 1 in about 10 of alcohol by volume at 20° and at a pressure of 101 kpA. Store as a compressed gas or a liquid in appropriate containers.

USNF 26 (Nitrogen). A colourless, odourless, tasteless gas. It is non-flammable and does not support combustion. Soluble 1 in about 65 of water v/v and 1 in about 9 of alcohol v/v at 20° and at a pressure of 760 mmHg. Store in cylinders.

USNF 26 (Nitrogen 97 Percent). It contains not less than 97% v/v of nitrogen. Store in cylinders or in a low-pressure collecting tank.

Adverse Effects

Nitrogen narcosis has been reported after use of nitrogen at high pressure as in deep-water diving. Under high pressure, nitrogen dissolves in blood and lipid. If decompression is too rapid, nitrogen effervesces from body stores producing gas emboli and leads to the syndrome of decompression sickness. Skin contact with liquid nitrogen causes frostbite or burns.

4. Kim DH, Lee HJ. Evaporated liquid nitrogen-induced asphyxia: a case report. *J Korean Med Sci* 2008; **23:** 163–5.

Uses and Administration

Nitrogen is used as a diluent for pure oxygen or other active gases and as an inert gas to replace air in containers holding oxidisable substances. Liquid nitrogen is used as a cryotherapeutic agent for the removal of warts (p.1584) and for preservation of tissues and organisms.

Oxygen

Deguonis; E948; Happi; Kyslík; Ossigeno; Oxigén; Oxígeno; Oxygène; Oxygenium; Oxygenum; Sauerstoff; Tlen.

O_2 = 31.9988.

CAS — 7782-44-7.

ATC — V03AN01.

ATC Vet — QV03AN01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Oxygen). A colourless, odourless gas. Soluble 1 in about 32 of water by volume at 20° and at a pressure of 101 kPa. Store as a compressed gas or liquid in appropriate containers.

The BP 2008 directs that oxygen should be kept in approved metal cylinders, the shoulders of which are painted white and the remainder black. The cylinder should carry a label stating 'Oxygen'. In addition, 'Oxygen' or the symbol 'O_2' should be stencilled in paint on the shoulder of the cylinder.

Ph. Eur. 6.2 (Air, Medicinal; Aer Medicinalis; Medical Air BP 2008). It is compressed ambient air containing not less than 20.4% and not more than 21.4% of oxygen. A colourless, odourless gas. Soluble 1 in about 50 of water by volume at 20° and at a pressure of 101 kPa. Store as a gas in suitable containers.

Ph. Eur. 6.2 (Air, Synthetic Medicinal; Aer Medicinalis Artificiosus; Synthetic Air BP 2008). It is a mixture of nitrogen and oxygen containing between 21.0% and 22.5% of oxygen. A colourless, odourless gas. Soluble 1 in about 50 of water by volume at 20° and at a pressure of 101 kPa. Store as a compressed gas in suitable containers.

USP 31 (Oxygen). A colourless, odourless, tasteless gas that supports combustion more energetically than does air. Soluble 1 in about 32 of water v/v and 1 in about 7 of alcohol v/v at 20° and at a pressure of 760 mmHg. Store in cylinders or in a pressurised storage tank.

USP 31 (Medical Air). A natural or synthetic mixture of gases consisting largely of nitrogen and oxygen. It contains not less than 19.5% and not more than 23.5% of oxygen. Store in cylinders or in a low pressure collecting tank.

USP 31 (Oxygen 93 Percent). It contains not less than 90% v/v and not more than 96% v/v of oxygen, the remainder consisting mostly of argon and nitrogen. Store in cylinders or in a low-pressure collecting tank.

Adverse Effects

Oxygen toxicity depends upon both the inspired pressure (a function of concentration and barometric pressure) and the duration of exposure, the safe duration decreasing as the pressure increases. At lower pressures of up to 2 atmospheres absolute, pulmonary toxicity occurs before CNS toxicity; at higher pressures, the reverse applies. Symptoms of pulmonary toxicity include a decrease in vital capacity, cough, and substernal distress. Symptoms of CNS toxicity include nausea, mood changes, vertigo, twitching, convulsions, and loss of consciousness.

Hyperbaric oxygen therapy. In a review of hyperbaric oxygen therapy[1] the following were mentioned as potential complications: barotrauma (ear or sinus trauma, tympanic membrane rupture, or rarely pneumothorax or air embolism); oxygen toxicity (CNS toxicity or pulmonary toxicity); and reversible visual changes.

1. Grim PS, *et al.* Hyperbaric oxygen therapy. *JAMA* 1990; **263:** 2216–20.

Retinopathy of prematurity. In the 1940s and 1950s an epidemic of retinopathy of prematurity, affecting perhaps 10 000 babies, was attributed to excessive use of oxygen in neonates. This resulted in the use of oxygen being reduced or curtailed and the incidence of the condition fell dramatically. However, in the 1970s and later an unexpected resurgence of retinopathy of prematurity occurred (probably *not* due to excessive oxygen use). It was suggested[1,2] that oxygen plays only a minor part and that retinopathy of prematurity is a multifactorial condition that affects the most immature and sick children; the increased incidence may reflect the improved survival of these very premature neonates. A study[3] of supplemental oxygen in infants with prethreshold retinopathy of prematurity suggested that therapy was safe, but a beneficial effect could not be confirmed. However, a retrospective study[4] in premature neonates given supplemental oxygen found that retinopathy of prematurity was more common in those maintained at higher oxygen saturations.

Precautions

Any fire or spark is highly dangerous in the presence of increased oxygen concentrations especially when oxygen is used under pressure.

Metal cylinders containing oxygen should be fitted with a reducing valve by which the rate of flow can be controlled. It is important that the reducing valve should be free from all traces of oil or grease, as otherwise a violent explosion may occur. Combustible material soaked in liquid oxygen is potentially explosive and the low temperature of liquid oxygen may cause unsuitable equipment to become brittle and crack. Liquid oxygen should not be allowed to come into contact with the skin as it produces severe 'cold burns'.

Oxygen intended for aviation or mountain rescue must have a sufficiently low moisture content to avoid blocking of valves by ice on freezing.

High concentrations of oxygen should be avoided in patients whose respiration is dependent upon hypoxic drive, otherwise carbon dioxide retention and respiratory depression may ensue.

Neonates. The use of supplemental oxygen in neonates is controversial.[1] Although the use of 100% oxygen for the resuscitation of asphyxiated term neonates has been standard, there is some evidence that the use of room air (21% oxygen) is equally effective and possibly safer than 100% oxygen although a systematic review[2] concluded that there was insufficient evidence for recommendations to be made. Guidelines[3,4] for neonatal resuscitation state that the use of less concentrated oxygen or room air in preference to 100% oxygen is reasonable, but that supplemental oxygen should be available if room air is used initially. Use of supplemental oxygen in preterm neonates has been associated with an increased risk of retinopathy of prematurity, although other factors are probably also involved (see under Adverse Effects, above). However, another study[5] has reported that supplemental oxygen has beneficial effects on sleep patterns in premature neonates. Although there is some evidence for a link between neonatal oxygen therapy and childhood cancer, this remains to be confirmed.[6]

Uses and Administration

Oxygen is given by inhalation to correct hypoxaemia in conditions causing respiratory failure (below) and in conditions where the oxygen content of the air breathed is inadequate such as high-altitude disorders (p.1168). Oxygen is of value in the treatment of poisoning with a number of substances, including carbon monoxide (p.1688), cyanides (p.2045), and dichloromethane (p.2021). It provides enhanced oxygenation in inhalation injury. Oxygen is also given by inhalation to subjects working in pressurised spaces and to divers to reduce the concentration of nitrogen inhaled. It is used as a diluent of volatile and gaseous anaesthetics.

Oxygen is usually given by means of nasal prongs or via a face mask; these can usually deliver concentrations of up to 60%. Tight-fitting anaesthetic-type masks, or delivery via an endotracheal tube or oxygen tent, can provide higher concentrations of up to 100%. Face masks are often used for domiciliary oxygen therapy when flow rates are 2 or 4 litres/minute. Oxygen is usually supplied compressed in metal cylinders although oxygen concentrators, which produce oxygen-enriched air, are useful for domiciliary therapy, especially in patients using large quantities of oxygen. Oxygen may also be supplied at low temperature in insulated containers as liquid oxygen.

In respiratory failure in conditions not usually associated with retention of carbon dioxide, such as pneumonia, pulmonary oedema, or fibrosing alveolitis, oxygen should be given in high concentrations (usually 40 to 100%). Concentrations of 40 to 60% should be used in acute severe asthma even though carbon dioxide retention may have increased as the patient's condition deteriorated. High concentrations of oxygen should always be reduced as soon as possible to the lowest concentration needed to correct hypoxaemia in order to prevent development of any associated oxygen toxicity, including increased carbon dioxide retention. High concentrations of oxygen should be used in carbon monoxide poisoning and, in selected patients, treatment with hyperbaric oxygen considered.

In respiratory failure associated with chronic obstructive pulmonary disease (conditions such as chronic bronchitis and emphysema) oxygen is usually given initially at an inspired concentration of up to 28%. High concentrations are to be avoided as they may enhance carbon dioxide retention and narcosis.

Oxygen at a pressure greater than 1 atmosphere absolute, i.e. hyperbaric oxygen therapy (below), is given by enclosing the patient in a special high-pressure chamber. It may be used in carbon monoxide poisoning, as an adjunct in the treatment of severe anaerobic infections, especially gas gangrene, and for the treatment of decompression sickness and gas emboli.

Hyperbaric oxygen therapy. The use of hyperbaric oxygen therapy, which involves the intermittent inhalation of 100% oxygen under a pressure of greater than 1 atmosphere in a specialised chamber, has been reviewed.[1-3] In the 1960s hyperbaric therapy was used for disorders such as *myocardial infarction, stroke, senility,* and *cancer* but clinical studies and experience have shown little benefit and enthusiasm has since waned. Hyperbaric oxygen therapy has also been tried in *multiple sclerosis* but there is little evidence of benefit. There are, however, other disorders for which the evidence supporting the efficacy of hyperbaric oxygen is much stronger.

Hyperbaric oxygen is a safe and effective primary therapy for *decompression sickness* and *air or gas embolism.* The effect is achieved through the mechanical reduction in bubble size in the blood brought about by an increase in ambient pressure; the increased oxygenation of blood due to the additional pressure used for these conditions (often 6 rather than 2 or 3 atmospheres) is also beneficial.

The role of hyperbaric oxygen therapy in *carbon monoxide poisoning* is unclear but it should be considered in selected patients (see p.1688). Its mechanism of action is not fully understood; it increases the rate at which carboxyhaemoglobin concentrations decline, increases intracellular delivery of oxygen, and may also reduce lipid peroxidation and thus spare neuronal cell membranes.

Hyperbaric oxygen is used as adjunctive therapy in *clostridial infections (gas gangrene)* (p.171). Early treatment appears to reduce systemic toxic reactions (probably by inhibiting the production of alpha toxin by the anaerobic bacteria, *Clostridium*) thus enabling patients to tolerate surgery more readily; additionally there is a clearer demarcation of viable and nonviable tissue. *Necrotising fasciitis* (p.180) is another infection in which hyperbaric oxygen therapy may be useful.

There is some evidence that hyperbaric oxygen may be useful in other types of *wounds.* In an *acute crush injury* therapy may reduce oedema via vasoconstriction and reverse ischaemia by increased oxygen delivery. In *problem wounds,* including venous ulcers, therapy may increase the tissue oxygen tension and stimulate angioneogenesis but it is emphasised that it is adjunctive therapy and not a replacement for meticulous local care. Hyperbaric oxygen therapy might also reduce the risk of major amputation in patients with chronic *diabetic foot ulcer.*[4,5] Improved healing of leg ulcers has been reported[6] with use of hyperbaric oxygen therapy in patients with livedoid vasculopathy. Other wounds in which therapy may be beneficial include thermal burns and compromised skin grafts and flaps. The management of burns and wounds is described on p.1578 and p.1585, respectively.

Radiation therapy can damage normal adjacent tissue resulting in tissue hypoxia and eventual cell death. Hyperbaric oxygen therapy appears to aid in salvaging such tissue by stimulating angioneogenesis in marginally viable tissue and has been demonstrated to be beneficial in osteoradionecrosis, radiation-induced haemorrhagic cystitis (p.2178), and other radiation-damaged soft tissue.[7]

There has been interest in the use of hyperbaric oxygen in children with *cerebral palsy,* although a randomised study[8] found that it was no better than pressurised air. However, improved neurological outcomes have been reported with hyperbaric oxygen therapy in neonates with hypoxic-ischaemic encephalopathy.[9]

Respiratory failure. Respiratory failure occurs when the arterial plasma partial pressure of oxygen (P_aO_2) and of carbon dioxide (P_aCO_2) cannot be maintained within normal physiological limits.[1] Respiratory failure can be classified into 2 types, both of which are characterised by a low P_aO_2 (hypoxaemia). However, in type I the P_aCO_2 is normal or low whereas in type II, referred to as ventilatory failure, P_aCO_2 is raised (hypercapnia). Some conditions, for example asthma, can produce either type of respiratory failure.

Management of respiratory failure mainly involves giving oxygen to reverse hypoxaemia, and specific therapy for any underlying condition. Respiratory stimulants may be considered in some situations.

In type I respiratory failure oxygen is used in high concentrations. Nasal prongs and certain face masks can provide concentrations of up to 60% but if concentrations higher than this are needed then tight-fitting anaesthetic-type masks or methods of delivery such as endotracheal intubation have to be used.

In type II respiratory failure both high and low concentrations are used according to need.

Patients with *acute severe asthma* (p.1108) should usually be given oxygen at high concentrations of 40 to 60%. In patients with exacerbations of chronic respiratory disorders such as *chronic obstructive pulmonary disease* (COPD, p.1112) the aim is to improve hypoxaemia without increasing hypercapnia and respiratory acidosis.[2] The initial concentration of oxygen to give in COPD exacerbations is controversial. During the transfer to hospital, UK guidelines[3] recommend starting at 40% and titrating upwards if the oxygen saturation falls below 90% and downwards if the patient becomes drowsy or if the saturation exceeds 93 to 94%. Special care is needed for patients with known type II respiratory failure, especially if they require a long ambulance journey or receive oxygen at home for a prolonged period before an ambulance arrives, as uncontrolled oxygen therapy can result in suppression of respiratory drive, carbon dioxide narcosis, and respiratory arrest. In hospital, arterial blood gases should be used to guide treatment. Other guidelines[4] consider that lower initial oxygen concentrations of 24 to 28% are usually sufficient. Patients with exacerbations of chronic ventilatory failure already have an increased central drive to the respiratory muscles and therefore respiratory stimulants such as doxapram have a limited role but may be indicated for short-term use if hypercapnia worsens as a result of oxygen. For most patients with chronic obstructive pulmonary disease, non-invasive ventilation is the initial treatment of choice for hypercapnic ventilatory failure during exacerbations.[3] Respiratory stimulants may be considered in the management of *postanaesthetic hypoventilation.* Although naloxone can reverse respiratory depression caused by opioid analgesics careful dosage adjustment is required as it can also abolish analgesia. Specific antagonists such as naloxone and flumazenil are also used to treat hypoventilation associated with opioid and benzodiazepine overdosage, respectively. If oxygen therapy fails to raise P_aO_2 in respiratory failure and there is worsening hypercapnia and respiratory acidosis the use of artificial ventilation should be considered.

Severe respiratory failure in *neonates* may result from various disorders. Use of surfactant or inhaled nitric oxide may be of benefit in some cases but extracorporeal membrane oxygenation (ECMO), where blood is removed from the neonate, oxygenated, and re-injected in a continuous circuit that also removes carbon dioxide, may be required.[5] ECMO has also been used in older children and in adults,[6] but is less well established.

This chapter describes the principal drugs used in the treatment of gastrointestinal disorders, and the choice of treatment for some of the main disorders.

Gastrointestinal Drug Groups

Antacids

Antacids are basic compounds that neutralise hydrochloric acid in the gastric secretions. They are used in the symptomatic management of gastrointestinal disorders associated with gastric hyperacidity such as dyspepsia, gastro-oesophageal reflux disease, and peptic ulcer disease (see below).

Antacids do not reduce the volume of hydrochloric acid secreted and elevation of the gastric pH may actually promote an increase in acid secretion. However, this is usually minor and short-lived except after large doses of calcium carbonate. Antacids are normally given between meals and at bedtime when symptoms of gastric hyperacidity usually occur; the presence of food in the stomach can prolong the neutralising activity. Some calculate doses as mEq or mmol of acid-neutralising capacity, but the relationship between neutralising capacity and beneficial effect is not straightforward. Other factors, including formulation (liquid preparations are more effective than solids) and duration of action (relatively insoluble antacids are longer acting) are also important.

Aluminium salts tend to produce constipation and to delay gastric emptying, while magnesium salts have the reverse effect; a combination of the two may reduce adverse gastrointestinal effects. Another advantage of combined antacid formulations is that a slow-acting antacid such as aluminium hydroxide may be combined with a more rapidly acting drug such as magnesium hydroxide to improve the onset and duration of effect. Alternatively, complexes containing both aluminium and magnesium may be used, such as almasilate, hydrotalcite, and magaldrate. Other drugs that may be combined with antacid formulations include simeticone, which acts as a defoaming agent to reduce excess gas in the stomach, and alginates, which form a gel or foam on the surface of the stomach contents thereby impeding reflux and protecting the oesophageal mucosa from acid attack.

Calcium carbonate and sodium bicarbonate are both rapidly acting but have disadvantages: calcium carbonate is usually reserved for short-term treatment because of the risks of rebound acid secretion and metabolic alkalosis, while sodium bicarbonate is absorbed and is contra-indicated in patients who must control sodium intake (e.g. in heart failure, hypertension, renal failure, cirrhosis, or pregnancy).

Antacids may interact with numerous other drugs, affecting the rate and extent of their absorption, and in some cases their renal elimination. Changes in gastric pH affect the dissolution of other drugs, and together with altered gastric emptying can markedly influence absorption. Aluminium compounds in particular are noted for their propensity to adsorb other drugs and to form insoluble complexes that are not absorbed. Antacids that alter urinary pH will affect renal clearance of drugs that are weak acids or bases. Several mechanisms may play a part in any particular interaction. Interactions can be minimised by giving antacids and other medication 2 to 3 hours apart.

Antacids in this chapter include aluminium salts, magnesium salts, and calcium carbonate. For sodium bicarbonate, see p.1673.

Described in this chapter are

Aceglutamide Aluminium, p.1704	Basic Aluminium Carbonate, p.1706
Alexitol Sodium, p.1704	Bismuth Compounds, p.1710
Almagate, p.1705	Calcium Carbonate, p.1714
Almasilate, p.1705	Dihydroxyaluminum Sodium Carbonate, p.1723
Aloglutamol, p.1705	Hydrotalcite, p.1733
Aluminium Glycinate, p.1706	Magaldrate, p.1742
Aluminium Hydroxide, p.1706	Magnesium Carbonate, p.1743
Aluminium Hydroxide-Magnesium Carbonate Co-dried Gel, p.1707	Magnesium Hydroxide, p.1743
Aluminium Phosphate, p.1707	Magnesium Oxide, p.1744
Aluminium Sodium Silicate, p.1707	Magnesium Trisilicate, p.1744

Antidiarrhoeals

Antidiarrhoeals are used as adjuncts in the symptomatic treatment of diarrhoea (see below), although the main aim in the management of *acute* diarrhoea is the correction of fluid and electrolyte depletion with rehydration therapy; this is especially important in infants and young children and antidiarrhoeals are not generally recommended for this age group. Their use is also limited in *chronic* diarrhoea since treatment aimed at the underlying disorder will often alleviate the diarrhoea.

Described in this chapter are drugs that reduce intestinal motility such as the opioid analogues diphenoxylate and loperamide, and adsorbents such as attapulgite and kaolin. Bulking agents (which include bran and ispaghula) have also been used for diarrhoea and for adjusting faecal consistency in patients with colostomies.

Described in this chapter are

Albumin Tannate, p.1704	Ispaghula, p.1737
Attapulgite, p.1709	Kaolin, p.1738
Bismuth Compounds, p.1710	Lidamidine, p.1740
Bran, p.1712	Loperamide, p.1741
Chalk, p.1716	Racecadotril, p.1765
Difenoxin, p.1723	Smectites, p.1771
Diphenoxylate, p.1724	Zaldaride, p.1778

Antiemetics

Antiemetics are a diverse group of drugs used to treat or prevent nausea and vomiting, including that associated with cancer therapy, anaesthesia, and motion sickness (see below).

The choice of drug depends partly on the cause of nausea and vomiting. For example, hyoscine or an antihistamine are used in motion sickness whereas dopamine antagonists (such as metoclopramide and domperidone) and serotonin 5-HT_3-receptor antagonists (5-HT_3 antagonists), such as ondansetron, are ineffective. Conversely, nausea and vomiting associated with cancer chemotherapy is often hard to control and special regimens have been devised including the use of the 5-HT_3 antagonists, dexamethasone, and, more recently, the neurokinin-1 receptor antagonist aprepitant.

Described in this chapter are

Alizapride, p.1704	Granisetron, p.1733
Aprepitant, p.1708	Indisetron, p.1736
Azasetron, p.1709	Itopride, p.1737
Bromopride, p.1713	Mecloxamine Citrate, p.1744
Cerium Oxalate, p.1715	Metoclopramide, p.1747
Clebopride, p.1722	Metopimazine, p.1750
Difenidol, p.1723	Nabilone, p.1750
Dolasetron, p.1725	Ondansetron, p.1756
Domperidone, p.1726	Palonosetron, p.1759
Dronabinol, p.1728	Ramosetron, p.1765
Fosaprepitant, p.1732	Tropisetron, p.1777
Ginger, p.1732	

Antisecretory drugs

Antisecretory drugs are used in the treatment and prophylaxis of peptic ulcer disease (below); some are also employed in other disorders associated with gastric hyperacidity such as gastro-oesophageal reflux disease and dyspepsia (below). They may be divided into:

- *Histamine H_2-receptor antagonists* (H_2-antagonists), which act by blocking histamine H_2-receptors on gastric parietal cells, thereby antagonising the normal stimulatory effect of endogenous histamine on gastric acid production. Those described in this chapter include cimetidine, famotidine, nizatidine, and ranitidine.
- *Proton pump inhibitors*, which act by blocking the enzyme system responsible for active transport of protons into the gastrointestinal lumen, namely the hydrogen/potassium adenosine triphosphatase (H^+/K^+ ATPase) of the gastric parietal cell, also known as the 'proton pump'. Those described in this chapter include lansoprazole, omeprazole, pantoprazole, and rabeprazole.
- *Selective antimuscarinics*, which block cholinergic stimulation of gastric acid production with fewer adverse effects than less selective antimuscarinics (see Atropine, p.1221), but have largely been superseded. Pirenzepine (p.1762) is an example.
- *Prostaglandin analogues*, which inhibit gastric acid secretion by a direct action on the parietal cell and may also inhibit gastrin release and possess cytoprotective properties. Misoprostol (p.2013) is an example.

Described in this chapter are

Cimetidine, p.1716	Omeprazole, p.1753
Ebrotidine, p.1728	Pantoprazole, p.1760
Eseridine Salicylate, p.1729	Rabeprazole, p.1765
Esomeprazole, p.1729	Ranitidine Bismuth Citrate, p.1768
Famotidine, p.1730	Ranitidine, p.1766
Lafutidine, p.1739	Revaprazan, p.1768
Lansoprazole, p.1739	Roxatidine, p.1769
Niperotidine, p.1751	Urogastrone, p.1778
Nizatidine, p.1751	

Antispasmodics

Antispasmodics are drugs used for their relaxant action on smooth muscle, either direct or through an antimuscarinic action on the parasympathetic innervation. They play a role in the management of gastrointestinal spasm and irritable bowel syndrome (below) as well as other disorders associated with smooth muscle spasm. Those described in this chapter are mainly antimuscarinics; drugs in other chapters that may be used for relaxation of smooth muscle include calcium-channel blockers (p.1154) and nitrates (p.1155), as well as drugs with less well defined mechanisms of action such as papaverine (p.2191).

Described in this chapter are

Alverine Citrate, p.1708	Methanthelinium Bromide, p.1747
Butropium Bromide, p.1713	Methylbenactyzium Bromide, p.1747
Buzepide Metiodide, p.1714	Octatropine Methylbromide, p.1752
Ciclonium Bromide, p.1716	Oxapium Iodide, p.1759
Cimetropium Bromide, p.1720	Oxyphencyclimine Hydrochloride, p.1759
Clidinium Bromide, p.1722	Oxyphenonium Bromide, p.1759
Dicycloverine Hydrochloride, p.1722	Parapenzolate Bromide, p.1761
Difemerine Hydrochloride, p.1723	Pargeverine Hydrochloride, p.1761
Dihexyverine Hydrochloride, p.1723	Peppermint Leaf, p.1761
Diisopromine Hydrochloride, p.1724	Peppermint Oil, p.1761
Drofenine Hydrochloride, p.1727	Phenamazide Hydrochloride, p.1761
Fentonium Bromide, p.1731	Pipenzolate Bromide, p.1762
Hyoscine, p.1733	Piperidolate Hydrochloride, p.1762
Hyoscine Butylbromide, p.1734	Pipethanate Ethobromide, p.1762

Laxatives

Laxatives (purgatives or cathartics) promote defaecation and are used in the treatment of constipation (see below) and for bowel evacuation before investigational procedures, such as endoscopy or radiological examination, or before surgery.

Laxatives are frequently used for self-medication. Abuse of laxatives is a well-known phenomenon that may occasionally lead to toxicity.

Laxatives may be classified according to their mode of action. There is, however, a degree of overlap between the various groups and in some cases the precise mechanisms of action are not fully understood. Many traditionally used laxatives have fallen from use owing to the violence of their action or their adverse effect profile.

- *Bulk laxatives* (bulk-forming laxatives or bulking agents) cause retention of fluid and an increase in faecal mass resulting in stimulation of peristalsis. Owing to their hydrophilic nature, bulk laxatives may also be used to control diarrhoea and to regulate the consistency of effluent in colostomy patients. Those described in this chapter include bran, ispaghula, and sterculia.
- *Stimulant laxatives* (contact laxatives) act by directly stimulating nerve endings in the colonic mucosa, thereby increasing intestinal motility. It is this group of laxatives which is most commonly associated with abuse. Those described in this chapter include bisacodyl, cascara, phenolphthalein, senna, and sodium picosulfate.
- *Osmotic laxatives* act by increasing intestinal osmotic pressure thereby promoting retention of fluid within the bowel. Those described in this chapter include saline laxatives such as magnesium citrate, magnesium hydroxide, and sodium sulfate (for magnesium sulfate and sodium phosphate see p.1679 and p.1682 respectively). Lactulose may also be classified as an osmotic laxative because its breakdown products exert a similar effect. Also included in this group are the hyperosmotic laxatives such as glycerol (p.2314) and sorbitol (p.1965), and the macrogols (p.2336).
- *Faecal softeners* (emollient laxatives) are claimed to act by decreasing surface tension and increasing penetration of intestinal fluid into the faecal mass. Those described in this chapter include docusate (which is also believed to have a stimulant action).

For the lubricant laxative liquid paraffin see p.2030.

Described in this chapter are

Mucosal protectants

Cytoprotective drugs (mucosal protectants) play a role in the management of peptic ulcer disease (below). They may be divided into:

- *Chelates or complexes*, which coat the gastric mucosa preferentially at sites of ulceration by forming an adherent complex with proteins. Those described in this chapter include sucralfate and tripotassium dicitratobismuthate (which also has an antibacterial role in regimens aimed at eradicating *Helicobacter pylori*)
- *Miscellaneous drugs* include liquorice and its derivatives, such as carbenoxolone, which may act by stimulating the synthesis of protective mucus

Described in this chapter are

Benexate, p.1710
Carbenoxolone, p.1714
Cetraxate, p.1716
Dosmalfate, p.1727
Ebrotidine, p.1728
Ecabet, p.1728
Enoxolone Aluminium, p.1729
Gefarnate, p.1732
Irsogladine, p.1736
Liquorice, p.1740
Nocloprost, p.1752
Ornoprostil, p.1759
Plaunotol, p.1763
Polaprezinc, p.1763
Rebamipide, p.1768
Sofalcone, p.1772
Sucralfate, p.1772
Sulglicotide, p.1775
Teprenone, p.1776
Tripotassium Dicitratobismuthate, p.1711
Troxipide, p.1778

Prokinetic drugs

Prokinetic drugs stimulate the motility of the gastrointestinal tract. Gastrointestinal smooth muscle exhibits intrinsic motor activity which is modified by autonomic innervation, local reflexes, and gastrointestinal hormones. This activity produces peristaltic waves, which move the gut contents from stomach to anus, and segmentations, which encourage digestion. Prokinetic drugs may act at various points within this complex system to enhance gastrointestinal movement. Those described in this chapter include metoclopramide, cisapride, and domperidone. Other drugs with prokinetic properties include parasympathomimetics such as bethanechol (p.2265) or neostigmine (p.631), and the macrolide antibacterial erythromycin (p.269).

Described in this chapter are

Aclatonium Napadisilate, p.1704
Bromopride, p.1713
Cinitapride, p.1720
Cisapride, p.1720
Clebopride, p.1722
Domperidone, p.1726
Itopride, p.1737
Linaclotide Acetate, p.1740
Lubiprostone, p.1742
Metoclopramide, p.1747
Mosapride, p.1750
Renzapride, p.1768
Tegaserod, p.1776

Management of Gastrointestinal Disorders

The management of some gastrointestinal disorders is discussed below.

Aspiration syndromes

Regurgitation and aspiration of gastric contents (Mendelson's syndrome) is a potential cause of morbidity and mortality associated with anaesthesia, especially in obstetrics and in emergency surgery. Chemical pneumonitis and respiratory distress result from the acid aspiration, the risk of which is increased by the drugs given as adjuncts to anaesthesia such as opioid analgesics and atropine.

Apart from good anaesthetic technique, including a prohibition on oral intake before elective procedures, efforts to **prevent** or reduce the problem have focussed mainly on increasing the pH of gastric contents to above 2.5, and in reducing gastric volume. However, there is little evidence to show that reduced gastric acidity or volume is associated with decreased morbidity or mortality in patients who have aspirated gastric contents,[1] and some do not recommend the routine pre-operative use of pharmacological prophylaxis in patients undergoing elective surgery with no apparent increased risk for pulmonary aspiration.[1] Similarly there is little evidence to support the routine use of prophylactic drugs in women undergoing normal labour (particularly with the increased use of regional anaesthetic techniques).[2]

The *H_2-antagonists* decrease gastric acid secretion and may decrease gastric fluid volume. However, they do not affect the pH of fluid already in the stomach; they must therefore be given some time before anaesthesia, which limits their value in emergency procedures. Cimetidine is considered effective in most patients, although where more prolonged reduction of acidity is required H_2-antagonists with a longer duration of action such as ranitidine or famotidine may be preferred. Nizatidine has the advantage of a relatively rapid onset of action.[3] The *proton pump inhibitors* have also been tried, but results have been variable. Combination with a prokinetic drug may produce better results.[4]

Because of the lack of effect of antisecretory drugs on the pH of existing gastric fluid H_2-antagonists may be combined with *antacids* to neutralise gastric acidity. Although magnesium trisilicate has been extensively used[5] without apparent problems particulate antacids are potentially toxic to the lung, which is why soluble antacids such as sodium citrate have been widely favoured. An effervescent formulation of sodium citrate with cimetidine has been reported to raise gastric pH above 2.5 in more than 98% of patients undergoing caesarean section.[6]

A third component of prophylactic regimens for acid aspiration may be use of a *prokinetic drug* such as metoclopramide. These increase gastric emptying and thereby decrease the volume of stomach contents, and also increase pressure at the lower oesophageal sphincter. The ability of metoclopramide to reverse the effects of opioids on gastric emptying appears to depend on the route: 10 mg given intravenously after opioid analgesia is reported to be effective in promoting gastric emptying, whereas the same dose intramuscularly is not.[7]

If aspiration occurs, pulmonary damage may result within seconds; **treatment** has included removal of any particulate matter, and measures to maintain the airway and ensure adequate oxygenation. Corticosteroids have been used but are no longer considered helpful.[8]

Constipation

The pattern of normal defaecation is extremely variable, which makes constipation hard to define, and to some extent subjective. However, expert consensus considers that it occurs if 2 or more of the following features are present for at least 12 weeks in the previous year: less than 3 defaecations in a week, or hard or lumpy stool, straining, feeling of incomplete evacuation or anorectal blockage, or need for manual assistance, on at least a quarter of occasions.[1] New onset constipation, especially in patients over 50 years of age, or accompanying symptoms such as anaemia, abdominal pain, weight loss, or overt or occult blood in the stool should provoke urgent investigation because of the risk of malignancy or other serious bowel disorder.[2-5] Constipation can be a symptom of a range of disorders or of drug toxicity[2,5,6] and appropriate management of any underlying cause is required. It tends to be more common in the elderly, in women, and in late pregnancy.[1,2]

Certain subtypes of constipation have been identified: patients may be subdivided according to whether intestinal transit time is slow or normal, or whether there is pelvic floor dysfunction (dyssynergia; outlet obstruction; anismus).[2,3,5,7]

There is relatively little evidence to guide management. In general, stepped or graded management is favoured, beginning with advice on lifestyle (including exercise and adequate hydration), and dietary modification if appropriate.[2,4-6,8] An increase in fibre intake, preferably through a high-fibre diet, is useful in patients with normal transit times although it is less beneficial in slow-transit constipation.[5,7] In patients with pelvic floor dysfunction, biofeedback training may be instituted.[3,5,7]

Where lifestyle changes and dietary modification are insufficient, a laxative may be considered. Because of the lack of clear evidence to guide the choice of laxative, practice varies considerably. Many favour the use of either a bulk laxative or an osmotic laxative as a first choice option,[2-4,7] with stimulant laxatives tending to be reserved as a second-line option, and diphenylmethane derivatives being preferred to anthraquinones.[2,3,6] For the treatment of opioid-induced constipation unresponsive to usual laxative therapy opioid antagonists such as *methylnaltrexone* have been tried.

- *Bulk laxatives* include bran, ispaghula, methylcellulose and related compounds, psyllium, or sterculia. Bulk laxatives are of particular value in those with small hard stools. However, they have a delayed onset of action (up to 72 hours) and they may exacerbate symptoms of flatulence, bloating, and cramping;[6] use should be avoided where these are severe. A gradual increase in dose may help reduce such effects.[7] They may not be the first choice for elderly patients who are frail or immobile since the resulting soft faeces may result in faecal incontinence,[9] and should only be given where fluid intake is adequate, because of the risk of obstruction.[7]

- *Osmotic laxatives* include saline laxatives such as magnesium hydroxide and magnesium sulfate, poorly absorbed sugars such as lactulose or sorbitol, and macrogols (often formulated with electrolytes). Some favour the use of macrogol 3350 or 4000, for which there is reasonable evidence of benefit in chronic constipation,[5,6] although in practice lactulose, which is less effective in the elderly than a combination of bulking and stimulant laxatives (see below), is widely used.[6] In the USA, a saline laxative such as magnesium hydroxide has been recommended,[3,4,7] although saline laxatives may not be acceptable to some patients because they can cause watery stool and urgency.
- *Stimulant laxatives* in current use include diphenylmethane derivatives such as bisacodyl or sodium picosulfate, and anthraquinone-containing drugs such as senna. They have a more rapid onset of action than bulk laxatives or lactulose, and are usually given at night to help produce a bowel motion the following morning. Many traditional stimulant laxatives have fallen from use because of adverse effects, and it has been widely thought that their prolonged use or abuse may irreversibly damage colonic nerves and muscles; however, the evidence for this is poor, and appropriate stimulant laxatives used at licensed doses are unlikely to cause significant harm.[10,11] Tolerance can occur but seems to be uncommon in the majority of users.[10,11] Combined preparations are also available, and a combination of senna and fibre has been found to be more effective than the osmotic laxative lactulose in elderly patients with chronic constipation.[12]
- *Other laxatives* include the docusates, surfactants that are used as stool softeners,[7] but their efficacy used alone for constipation is not well established;[4] perhaps for this reason, they are often formulated with a stimulant or osmotic laxative. Stool softeners would have potential value for patients with haemorrhoids or anal fissures, or those in whom straining is potentially hazardous (such as the elderly or those with existing cardiovascular disease). Liquid paraffin has also been used as a lubricant for the passage of stool,[7] but should be used with caution because of its adverse effects, which include anal seepage and the risks of granulomatous disease of the gastrointestinal tract or of lipoid pneumonia on aspiration. Although it has been recommended in some countries for constipation in children,[13,14] the UK CSM considers it should not be used in those under 3 years of age. Prokinetic drugs have theoretical advantages in patients with slow-transit constipation, but few suitable drugs are available,[5] although selective 5-HT_4 agonists such as tegaserod have been used in constipation-predominant irritable bowel syndrome (p.1699) and in chronic constipation.

Rectal administration of laxatives using enemas or suppositories is appropriate in patients requiring rapid relief from constipation. Phosphate enemas should be used with caution because of the risks of absorption of significant amounts of phosphate.[4] Glycerol and bisacodyl may be given as suppositories to promote faecal evacuation; they should not be used regularly, as changes in the rectal epithelium have been seen with bisacodyl, and the effect of glycerol on rectal mucosa is unclear.[4]

During *pregnancy* the preferred options for management are increased fluid intake, exercise, and dietary fibre;[2] bulking agents may be given as fibre supplements, and stimulant laxatives such as senna reserved for cases where these are ineffective.[2,15]

Faecal impaction is the inability to pass a hard collection of stool, and may result in overflow diarrhoea. Faecal impaction should be treated with a laxative enema and/or a lubricant and manual disimpaction.[4,5,9] Oral laxatives should not be used because of the risk of colonic perforation.[9] When all stool has been cleared, it is important to institute measures, often including regular laxatives, to prevent constipation and recurrent impaction.[5,7,9]

Decreased gastrointestinal motility

Decreased gastrointestinal motility may occur in any part of the gastrointestinal tract, with symptoms depending on the site. It is of varying aetiology and often secondary to some other disorder, such as infection, metabolic or electrolyte disturbance (for example in gastroparesis due to diabetic neuropathy—see also p.433), or insult to the gastrointestinal tract (for example, paralytic or adynamic ileus is frequently a consequence of abdominal surgery and is a serious adverse effect of some drugs).

Acute loss of gastrointestinal motility is often self-limiting once the underlying cause has been treated. Provided the ability of gastrointestinal smooth muscle to contract has not been lost, however, prokinetic drugs such as metoclopramide or domperidone, or erythromycin, or drugs capable of stimulating functional contraction including parasympathomimetics such as neostigmine or bethanechol, may be used. The opioid μ-receptor antagonist alvimopan has recently been introduced for the treatment of postoperative ileus. Injection of botulinum toxin into the pyloric sphincter may produce temporary symptomatic improvement in patients with refractory gastroparesis. Gastric electrical stimulation may also be an option.

Drugs are less successful in chronic conditions such as chronic intestinal pseudo-obstruction where neuromuscular function of the gastrointestinal tract has some intrinsic abnormality.

Diarrhoea

Diarrhoea is characterised by liquid stools and increased stool weight and frequency of defaecation. Although diarrhoea is commonly associated with infection (see Gastroenteritis, p.171), it may also result from the accumulation of nonabsorbed osmotically active solutes in the gastrointestinal lumen, as in lactase deficiency, or from the gastrointestinal effects of secretory stimuli other than the enterotoxins from an infection. It may also occur when intestinal motility or morphology is altered.

Acute diarrhoea may lead to excessive water and electrolyte loss and dehydration, and is potentially life-threatening in infants; frail and elderly patients are also at risk. Severe dehydration associated with acute diarrhoea (greater than 10% loss of body-weight), requires *intravenous rehydration therapy* with Ringer's lactate solution or normal saline.[1-4] Intravenous therapy is also needed for patients who are unable to drink. Otherwise, *oral rehydration therapy* to correct fluid and electrolyte depletion should form the basis of treatment for acute diarrhoea[1-5] and an oral rehydration solution containing essential electrolytes (sodium, potassium, chloride, and bicarbonate or citrate) and glucose is indicated regardless of the age of the patient or the cause of the diarrhoea. A rehydration phase, which involves the replenishment of fluid and electrolytes lost through the diarrhoea, is followed by a maintenance phase to replace continuing losses. Oral rehydration therapy does not stop diarrhoea, which usually continues for a limited period, although it can reduce stool output and vomiting. Oral rehydration therapy may need to be modified if the diarrhoea is associated with malnutrition.[6] (Malnourished children may also benefit from zinc supplementation in acute diarrhoea—see p.2000; vitamin A supplementation may also be important in reducing mortality—see p.1973.) The rationale for the composition of oral rehydration solutions is that glucose absorption is coupled to the active transport of electrolytes,[7] the absorption of which theoretically increases in efficiency as the ratio of carbohydrate to sodium approaches 1:1.

WHO originally recommended a solution containing 90 mmol/litre of sodium and 111 mmol/litre of glucose; this type of preparation has been used effectively in developing countries where diarrhoeas are commonly bacterial in origin. There is now evidence from studies and meta-analyses to suggest that solutions of reduced sodium content and osmolarity are safe and effective and may be preferable to the original standard WHO solution, even in developing countries,[8-11] and WHO and UNICEF now recommend a solution containing 75 mmol/litre of sodium and 75 mmol/litre of glucose, with a reduced total osmolarity of 245 mmol/litre.[12] Despite concerns about the possible increased risk of hyponatraemia with the use of the reduced osmolarity solutions in patients with cholera,[13-15] WHO and UNICEF have stated that hyponatraemia may also occur with the standard WHO formulation, and that there is no evidence to suggest that this transient hyponatraemia has had significant adverse clinical consequences for cholera patients.[12]

In developed countries viral diarrhoeas, which are associated with less electrolyte loss, are more common, and reduced osmolarity solutions are favoured.[2] Commercial preparations available in the UK, for example, usually provide 50 to 60 mmol/litre of sodium and 90 to 111 mmol/litre of glucose; the total osmolarity is slightly hypotonic (about 250 mmol/litre) to prevent possible induction of osmotic diarrhoea.[16] Similar preparations are available in other developed countries.[17]

Areas of debate have included the necessity for inclusion of citrate or bicarbonate,[16] and whether cereal-based rather than glucose-based rehydration solutions would be preferable. There is considerable evidence that cereal-based solutions tend to produce more rapid resolution of diarrhoea, although one study has suggested that the reduction in stool output is temporary,[18] and another found that a glucose-based solution was equally effective when combined with early re-introduction of feeding.[19] In 1994, a review of clinical studies concluded that a rice-based rehydration solution should be recommended for patients with cholera, but that there was no reason to change from WHO's glucose-based formulation for children with non-cholera diarrhoea.[20] A study in 48 patients with cholera compared the use of standard glucose-based oral rehydration therapy, standard therapy plus rice flour, and standard therapy plus amylase-resistant starch.[21] The addition of amylase-resistant starch to standard oral rehydration solution was shown to reduce stool output and to reduce the duration of diarrhoea,[21] although the methodology of this study was questioned[22] and further investigation of such solutions is required.

Home remedies[1] that have been used for oral rehydration include coconut water, rice water, soups, weak tea, and solutions of various salts and sugars; these may be of value when more conventional oral rehydration solutions are unavailable. The use of cordials and soft drinks with low pH and high osmolality, however, may exacerbate diarrhoea and dehydration.[17]

Oral rehydration therapy should be combined with *dietary measures*, particularly in children, to avoid malnutrition owing to low food intake during the illness, and as mentioned above, may need to be modified if the diarrhoea is associated with malnutrition. Breast feeding should be continued throughout rehydration therapy,[2,4,16] as such feeding may decrease stool output and shorten the duration of diarrhoea.[2] Dilution of formula feeds does not seem to be of clinical benefit and may even prolong symptoms.[4,7] Withholding food during diarrhoea in adults or children is not recommended.[1,10]

There is considerable interest in the potential use of probiotic bacteria, or prebiotic foods intended to stimulate the growth of beneficial species in the gastrointestinal tract, in the management of diarrhoea. Although meta-analyses have suggested that treatment with lactic-acid producing organisms may reduce stool frequency and disease duration in children with acute infectious diarrhoea,[23] and may reduce the risk of antibacterial-associated diarrhoea in children,[24] the role of probiotics and prebiotics remains to be established,[4,7] particularly since many commercial products are poorly characterised.

Oral rehydration therapy prevents dehydration, but does not necessarily shorten the duration of the diarrhoea, and patients therefore frequently desire the symptomatic relief provided by *drug therapy.* Use of such therapy should be balanced against the risk that it may distract from the need for oral rehydration therapy and may have undesirable adverse effects. WHO considers that antidiarrhoeal drug therapy is of limited value for acute infectious diarrhoea, does not reduce fluid and electrolyte loss, may delay the expulsion of causative micro-organisms, and should never be used in children.[25] However, it has been pointed out that extrapolating results in children to adult treatment is unwarranted; there is no good evidence that antidiarrhoeal drugs prolong illness or retard expulsion of pathogens, and no reason to withhold medication in otherwise healthy adults.[26] Short courses of antidiarrhoeals are often used in practice (frequently as self medication) if symptoms are causing discomfort.[3,26,27]

The main groups of antidiarrhoeal drugs are adsorbents such as attapulgite, kaolin, and pectin, and drugs that reduce intestinal motility such as diphenoxylate, loperamide, and codeine. Oral loperamide has been recommended as the treatment of choice, particularly for self-medication,[3,26] although bismuth salicylate, which has antisecretory properties, is probably equally effective,[3] and may be preferred in some countries such as the USA.[27] Other drugs with antisecretory properties are under investigation; they include the enkephalinase inhibitor racecadotril, which unlike other antidiarrhoeal drugs is of interest as a potential adjunct in children.[4] Bulk laxatives such as methylcellulose have also been used for symptomatic treatment because of their absorptive capacity.

Antibacterial and antiprotozoal drugs have been used for infective diarrhoeas, including the prophylaxis and treatment of travellers' diarrhoea (see Gastro-enteritis, p.171 and p.824), but their overuse encourages the development of resistance and prophylaxis is not recommended. Vaccines are being developed for the prevention of rotaviral diarrhoeas (p.2236).

Chronic diarrhoea may be associated with underlying disease and therefore symptomatic relief is less appropriate than treatment of the disease itself. For example, colestyramine will reduce the diarrhoea associated with bile acid malabsorption. Where the disease process responsible for chronic diarrhoea cannot be satisfactorily suppressed, however, symptomatic relief may be appropriate,[28] for example in diabetic diarrhoea (see under Diabetic Complications, p.433).

Diverticular disease

Diverticula are small hernias or pouches of mucosa that develop through the muscular wall of the gut (especially the colon) or other hollow organs; they increase in prevalence with increasing age. Diverticular disease (the presence of colonic diverticula) is usually asymptomatic, but may be associated with symptoms of abdominal pain and altered bowel habit (diverticulosis). Occasionally there may be severe life-threatening complications such as inflammation and necrosis of diverticula (diverticulitis), perforation, fistula formation, obstruction, or haemorrhage. There is some evidence that the use of NSAIDs may be associated with an increase in diverticular complications such as perforation.

In uncomplicated diverticular disease, treatment is with a high-fibre diet, gradually supplemented if necessary with a bulk laxative such as bran or ispaghula, to ease constipation, although the evidence to support such management is limited. Supplements may not relieve the other symptoms of diverticular disease. The antibacterial rifaximin may be of benefit in improving symptoms; giving rifaximin and fibre supplementation has been shown to be more effective than fibre supplementation alone. Rifaximin has also been combined with 5-aminosalicylates, chiefly mesalazine; the latter may be of benefit in maintaining remission. Use of probiotics, in the form of lactic-acid-producing organisms, after a non-absorbed antibacterial such as rifaximin has also produced some evidence of additional benefit. Antispasmodics such as antimuscarinics or mebeverine may be useful in relieving pain due to muscle spasm.

Diverticulitis requires treatment with broad-spectrum antibacterials and fluid support; analgesia may be needed for severe pain. If peritonitis or abscess develops, surgical intervention may be necessary. Surgical resection is usually considered when fistula, perforation, or obstruction are present.

Dumping syndrome

The word dumping in this context is used to describe the unnaturally rapid transport of gastric contents to the small intestine. The dumping syndrome is an important cause of morbidity after gastrointestinal surgery, and is thought to be due to the destruction of normal regulatory mechanisms in the upper gastrointestinal tract.[1,2] Early dumping begins within 10 to 30 minutes of the ingestion of a meal (typically, symptoms are triggered by hyperosmolar, carbohydrate-rich food) and has gastrointestinal symptoms (fullness, abdominal pain, nausea and vomiting, explosive diarrhoea) and vasomotor symptoms (sweating, weakness, dizziness, flushing, and palpitations). The effects are thought to be due to fluid shifts from the intravascular space to the bowel lumen. Some patients have late dumping, 1 to 4 hours after a meal, with only the vasomotor symptoms; it appears to be due to reactive hypoglycaemia caused by high carbohydrate concentrations in the small intestine.

The mainstays of therapy are dietary modifications, taking small frequent meals low in carbohydrate, followed by liquids 30 minutes later. Attempts to slow or reduce carbohydrate absorption have involved the use of dietary fibre (guar gum or pectin) or α-glucosidase inhibitors such as acarbose; acarbose and pectin have also been tried in combination.[3] However, such agents may themselves cause gastrointestinal disturbances and they do not seem to be helpful in most patients.[2] More recently, beneficial results with somatostatin have led to the use of its longer-acting analogue, octreotide.[2,4] Octreotide substantially reduces the symptoms of both early and late dumping, probably by slowing gastric emptying and by inhibiting the release of gastrointestinal mediators (peptide hormones such as neurotensin), and prevents hyperinsulinaemia and subsequent reactive hypoglycaemia. It may be given up to 2 hours before a meal.

In the minority of patients who do not respond to medical therapy surgery may be required.[1,2]

Dyspepsia

Dyspepsia, also commonly known as indigestion or heartburn, is a frequent but ill-defined disorder primarily associated with epigastric discomfort or pain. It may be a symptom of specific diseases such as peptic ulcer disease, gastro-oesophageal reflux disease, gastric carcinoma, chronic pancreatitis, or gallstones. However, in many patients there is no identifiable systemic disease, in which case it is known as non-ulcer dyspepsia or functional dyspepsia.

A number of reviews and recommendations have addressed the subject of dyspepsia,[1-7] and, in the UK, various authoritative guidelines have been issued.[8,9] The initial management of non-ulcer dyspepsia usually includes advice to avoid alcohol, caffeine, smoking, and aggravating foods, and to eat small regular meals to aid digestion. Results of studies of drugs for non-ulcer dyspepsia have been variable and difficult to evaluate since the condition tends to be self-limiting, and there is often a large placebo response.[10]

Drugs that suppress gastric acid such as antacids or antisecretory drugs are often used. Antacids may give some symptomatic relief, and are widely used for self-medication.[9] However, long-term use is inappropriate. Similarly, H_2-antagonists are often tried, especially for symptoms of reflux, and a systematic review[10] has suggested benefit, at least in a proportion of patients. Proton pump inhibitors (PPIs) are also widely used; although a systematic review considered their relative efficacy in non-ulcer dyspepsia versus H_2-antagonists to be unclear,[11] others[5-7] consider them superior to H_2-antagonists. They may be useful for on-demand therapy to manage symptoms long-term.[9]

It is not clear what role *Helicobacter pylori* plays in the pathology of non-ulcer dyspepsia. One meta-analysis found eradication to be of no benefit in non-ulcer dyspepsia,[12] but another, incorporating more patients, found that a small benefit existed,[13] although it noted that most patients positive for *H. pylori* will continue to have symptoms after eradication. As a result there has been much debate about the appropriateness of so-called 'test and treat' strategies, but UK[9] and US[4,5] guidelines consider them a valid alternative to a trial of a PPI in the initial management of uninvestigated dyspepsia.

Initial management of dyspepsia in patients under 55 years of age who do not have so-called 'alarm symptoms' (such as chronic gastrointestinal bleeding, unintentional weight loss, difficulty swallowing, persistent vomiting, iron deficiency anaemia, or epigastric mass) should therefore consist of either:[4,9]

- an empirical one-month course of a PPI, *or*
- testing for *Helicobacter pylori* and appropriate eradication therapy. Those who are *H. pylori*-negative should be prescribed an empirical trial of acid suppression with a PPI for 1 to 2 months

Patients over 55 years of age, or those with alarm symptoms, should be referred for endoscopy. After endoscopy, treatment should be targeted at the underlying diagnosis.[4]

Prokinetic drugs may be given, particularly if an underlying gastrointestinal motility disorder is suspected. Meta-analysis has suggested that prokinetic therapy may be more effective than an H_2-antagonist in non-ulcer dyspepsia,[10,14] but this may be due to publication bias.[10] In addition, cisapride is no longer available in many countries and evidence for domperidone or metoclopramide is limited. Results with motilin agonists (derivatives of erythromycin) and 5-HT_3 antagonists have been disappointing to date.[3] Other approaches to drug therapy include the use of an insoluble bismuth salt, and the use of antispasmodics. Antidepressants may have a limited role in some patients,[5,7] and various herbal medications have been tried, though the quality of any studies is generally poor.[7]

Gastrointestinal spasm

Pain or discomfort of the gastrointestinal tract may be due to spasm of the smooth muscle of the gut; such pain and spasm may be associated with the irritable bowel syndrome (see below), dyspepsia (see above), or diverticular disease (see above). Antispasmodic drugs have traditionally been used in patients thought to have gastrointestinal spasm, and have mainly been of two types: antimuscarinics such as dicycloverine, and direct smooth muscle relaxants such as mebeverine; use of antimuscarinics, in particular, has tended to be limited by concern about their adverse effects.

Colic is a general term used to describe spasmodic or griping pain, usually of the viscera, and when not otherwise qualified is often understood to refer to pain in the gastrointestinal tract. Infant colic is common in the first few months of childhood,[1] and tends to be managed by non-pharmacological measures and assessment of the feeding technique. Elimination of cows' milk protein appears to be of benefit, but use of a low-lactose formula is not.[1] Tilactase has been added to feeds to aid lactose digestion but the extent of any benefit is unclear. Traditional remedies such as gripe water, which contains essential oils of dill or fennel and is mildly carminative, are of dubious efficacy. Antimuscarinic antispasmodics, although effective[1] may be associated with adverse effects, and are no longer considered appropriate.[2] Simeticone suspension, given before feeds, is commonly used but has been found to be no better than placebo.[2,3] It has been reported that sucrose, given as a 12% solution, improves infant colic.[4]

Gastro-oesophageal reflux disease

Gastro-oesophageal reflux disease results from the reflux of gastric or duodenal contents into the oesophagus. Symptoms include heartburn, acid regurgitation, and dysphagia (difficulty in swallowing); oesophageal inflammation and ulceration (reflux oesophagitis), and stricture formation may occur. Extra-oesophageal symptoms may include cough, horseness, and asthma. Some patients develop Barrett's oesophagus (below), which is a risk factor for oesophageal cancer (p.664).

Lifestyle advice on weight loss, raising the head of the bed, stopping smoking, and avoidance of alcohol and aggravating foods such as chocolate and coffee is often given as part of initial **management**,[1-5] although the evidence for most of these interventions other than weight loss and bed position is lacking.[3]

Patients often manage initial mild symptoms with over-the-counter therapies, including *antacids* and antisecretory drugs. Although the placebo response is often high, meta-analysis has shown some additional symptomatic benefit from antacids, *histamine H_2-antagonists*, and in particular for combinations of an antacid with an alginate;[6] such combinations are believed to form an alkaline 'raft' above the stomach contents that impedes reflux and protects the oesophageal mucosa.

The symptoms and management of gastro-oesophageal reflux disease may overlap with those of dyspepsia (see above), and initial symptomatic management is likely to be similar.[4] Patients who do not have alarm symptoms that would indicate a need for prompt endoscopy should be treated with an appropriate dose of a *proton pump inhibitor* (PPI) for 1 to 2 months.[4,5] Such treatment is more effective for empirical management than an H_2-antagonist,[7] and is appropriate therapy for endoscopy-negative disease[7] as well as for patients with reflux oesophagitis.[8] There is no evidence for the superiority of any particular PPI, nor for greater benefit from doubling doses in patients with reflux oesophagitis.[7]

A significant minority of patients do not, however, respond to PPIs; reasons may include poor compliance, nocturnal acid breakthrough, non-acid reflux, and hypersensitivity to acid.[4,5] Trying an alternative PPI or increasing the dose has been suggested[4] (despite the lack of evidence to support this[7]). However, in refractory cases, giving a proton pump inhibitor with an H_2-antagonist may be more effective than just increasing the dose of the former.[4,9]

Alternatively, a *prokinetic drug* such as metoclopramide may improve gastro-oesophageal sphincter function and accelerate gastric emptying. These appear to be as effective as H_2-antagonists,[1] although they are probably less effective than PPIs.[7] An H_2-antagonist used with cisapride may be more effective than either drug alone.[1] However, concern over the risk of cardiotoxicity and potential for serious interactions with cisapride has led to severe restrictions on its use.

In patients with mild disease, a trial of withdrawal of drug therapy is appropriate after successful initial treatment.[1] Short courses of therapy as and when symptoms demand (intermittent treatment) may be effective in uncomplicated disease.[10] However, most patients with oesophagitis relapse when treatment is withdrawn, and long-term **maintenance** therapy is likely to be required.[1,4,5] As in acute management, PPIs appear to be the most effective maintenance treatment, although the 'step-down' approach of reduced maintenance doses, which is widely favoured,[4,5] may produce less benefit than continuing to give full dose PPIs.[11] H_2 antagonists were found to be of marginal benefit for maintenance, although they did give some symptomatic relief, and although prokinetic drugs (cisapride) and sucralfate were also reported to be more effective than placebo their value was considered dubious.[11] Another approach is to use a combination for maintenance, and in one study omeprazole with cisapride provided more effective maintenance than ranitidine or cisapride alone or in combination.[12] Again, however, cisapride is now unlikely to be used in practice because of the risks.

Helicobacter pylori **eradication** does not heal or prevent relapse of gastro-oesophageal reflux disease,[1] and some epidemiological evidence has appeared to suggest that *H. pylori* infection protects against gastro-oesophageal reflux disease.[13] However, there is no clinical evidence that eradication of *H. pylori* exacerbates gastro-oesophageal reflux disease or significantly increases the risk of its development.[14,15]

In patients who have a poor response to drug therapy, or in those with complications such as oesophageal stricture or ulceration, **surgery** to re-establish gastro-oesophageal competence may be considered.[1,4,5] Submucosal implants and various other endoscopic techniques have also been investigated.[4] Although surgery is as effective as drug treatment, it carries greater associated risks, and many patients continue to require antisecretory drugs.[4]

Investigational approaches to drug therapy include the development of drugs with GABAergic actions similar to those of baclofen (but without its CNS effects), cholecystokinin antagonists such as loxiglumide, and cannabinoid CB_1 agonists; motilin receptor agonists such as alemcinal and mitemcinal do not appear to be of much benefit.[16]

A minority of patients with gastro-oesophageal reflux disease develop **Barrett's oesophagus** (columnar lined oesophagus, CLO), in which the normal oesophageal squamous lining is replaced with a metaplastic columnar epithelium. This is most common in patients with long-standing disease but may represent part of a spectrum of possible responses to acid reflux rather than a progression from less severe to more severe disease.[4] The abnormal epithelium in Barrett's oesophagus shows dysplastic changes that may progress to oesophageal adenocarcinoma. However, not all patients go on to develop cancer, and many aspects of management are controversial.

Management of acid reflux, as for other forms of gastro-oesophageal reflux disease, is the mainstay of management.[17-20] Long-term treatment with PPIs appears to be effective;[19] the use of maximal doses, perhaps in combination with an H_2-antagonist at night, is advocated by some[20] but evidence to support twice daily (double) dosing is lacking.[19] As the altered epithelium is relatively less sensitive to acid, symptom control does not necessarily equate to suppression of reflux.[20] There is a lack of good evidence that control of acid reflux produces anything other than limited regression of the abnormal epithelium, or alters the risk of progression to malignancy,[19,20] although there are some results that suggest benefit.[21,22] Some evidence suggests that additional chemoprevention with aspirin or another NSAID might offer benefits in reducing cancer risk,[19,23] but this remains investigational. The roles of screening, surveillance, and endoscopic ablation therapy or photodynamic therapy (5-aminolaevulinic acid or porfimer) remain matters of debate.[17,19,20]

In **infants**, gastro-oesophageal reflux is common but usually resolves spontaneously with increasing age and requires no treatment. Occasionally, it may be associated with complications such as failure to thrive, oesophagitis, and pulmonary symptoms of acid regurgitation, but can be managed by upright positioning and the use of thickened foods; drug therapy is controversial,[24] and the evidence base is poor.[25] It has been suggested that where drug therapy is needed, an alginate-antacid combination may be appropriate initially;[24] PPIs are probably safe but are not well studied in infants.[25] Cisapride has been given[24,25] but the risk of cardiotoxicity makes the use of cisapride in infants extremely problematic (see p.1720). Metoclopramide may have some benefit but again this must be weighed against the risk of adverse effects.[26] Evidence of benefit with domperidone is poor,[27] and it too has the potential for serious adverse effects, but restrictions on cisapride have led to its over-use.[25] Erythromycin has been investigated in infants with food intolerance, though not in gastro-oesophageal reflux itself; there is a risk of promoting bacterial resistance from such use.[25]

Gastro-oesophageal reflux is commonly encountered during normal **pregnancy**, and is generally managed by lifestyle and dietary modifications.[28] If drug therapy is required, nonsystemically absorbed antacids or sucralfate should be tried first. If these are ineffective, ranitidine may be tried. Proton pump inhibitors are reserved for women with severe or complicated reflux disease,[28] due to concerns about their safety in pregnancy, although the relative risk associated with exposure seems to be quite low (see under Precautions of Omeprazole, p.1755).

Haemorrhoids

Haemorrhoids ('piles') are venous swellings of the tissues around the anus: those above the dentate line (the point where the modified skin of the outer anal canal becomes gut epithelium), which usually protrude into the anal canal, are termed internal haemorrhoids, while those below this point are called external haemorrhoids. Due to internal pressure, internal haemorrhoids tend to congest, bleed, and eventually prolapse; with external haemorrhoids painful thrombosis may develop.[1-3]

Initial treatment of internal haemorrhoids involves a high-fibre diet and avoidance of straining at stool, so bulk laxatives and faecal softeners may be indicated.[2] The prime objective of drug therapy is to control the acute bleeding phase so that definitive therapy can be scheduled.[1] Small bleeding haemorrhoids may be injected with a sclerosing agent such as oily phenol injection, but rubber band ligation, or perhaps a technique such as infra-red coagulation, is more effective and associated with fewer complications.[3-5] More severe and prolonged prolapse generally requires surgery.[2,3,6] Surgical excision to remove the clot is used for thrombosed external haemorrhoids.[7]

An enormous range of mainly topical drug treatments is available for symptomatic relief, but in many cases their value is at best unproven.

Topical preparations are usually made up in a lubricating or emollient base. Local anaesthetics may be included to relieve pain, and corticosteroids may be used where infection is not present: preparations containing either group of drugs are intended only for short-term use. Inclusion of antibacterials is thought to be of little value and may encourage the development of resistant organisms. Some preparations include heparinoids. Other agents frequently included for their soothing properties include various bismuth salts, zinc oxide, hamamelis, resorcinol, and peru balsam.[2,3] Topical nitrates have also been used.[1]

Bioflavonoids and various derivatives of aesculus may also be included in topical preparations; they have also been given systemically in some countries as have some other compounds such as calcium dobesilate and tribenoside, presumably for their supposed action on venous capillary walls. Oral micronised bioflavonoid preparations may reduce symptoms as an adjunct to surgery.[1,6,8]

Other agents that have been used in the treatment of haemorrhoids include pilewort (ficaria) and combinations of yeast extract with shark-liver oil.

Hepatic encephalopathy

Hepatic encephalopathy (portal systemic encephalopathy) is a metabolically related dysfunction of the brain associated with abnormalities of liver function. It may be acute, as in patients with fulminant hepatic failure, or chronic, with acute episodes precipitated by some triggering factor, as in patients with cirrhosis or other chronic liver disease.

Treatment is aimed at identifying and correcting any precipitating factor, decreasing the production and absorption of ammonia in the gut, and increasing metabolism of ammonia in the tissues. Precipitating factors include infection, increased protein load due to gastrointestinal haemorrhage or high protein intake, alcohol abuse, electrolyte imbalance, and certain drugs (notably anxiolytics, hypnotics, and diuretics).

Restriction of dietary protein intake is a mainstay of short-term treatment, but in the long-term, care must be taken to provide adequate protein to avoid malnutrition. A daily protein intake of 0.5 to 1.5 g/kg has been recommended.[1-3] There is some evidence that vegetable protein is better tolerated than animal protein.[4,5] Giving branched-chain amino acids (valine, isoleucine, and leucine) by infusion or as dietary supplements may facilitate adequate protein intake in some patients.[1,3-5] Supplementation with ornithine aspartate has been used to increase metabolic conversion of ammonia to urea and glutamine.[2,4,5] Sodium benzoate has also been tried.[4,5]

Active drug treatment may begin with bowel cleansing by means of a magnesium sulfate enema, especially if the patient is constipated. Lactulose is then the treatment of choice in many cases, particularly in the elderly, the constipated, and those with renal impairment. It is usually given orally although it may be used rectally[2,5] or by nasogastric tube[2] when oral use is not feasible.[5] It reduces colonic pH and absorption of ammonia and aromatic amino acids. The lactulose analogue lactitol is also used.[6] However, a recent meta-analysis[7] was unable to find sufficient evidence to support or refute the use of nonabsorbable disaccharides, such as lactulose and lactitol, for hepatic encephalopathy. The disaccharidase inhibitor voglibose has been tried to reduce intestinal uptake of disaccharides and promote fermentation, with effects similar to lactulose.[5]

Alternatively, locally active antibacterials have been given to reduce the urease-producing bacteria.[2] Neomycin is the traditional drug but adverse effects such as ototoxicity and nephrotoxicity may be a problem, particularly if used long-term. Metronidazole is also used,[4] and rifaximin has been tried. A combination of lactulose and neomycin[4] or metronidazole has been tried in patients who fail to respond to single-drug therapy.

In low grade chronic recurrent encephalopathy *Lactobacillus acidophilus* or *Enterococcus faecium* SF68 have been tried orally in an attempt to produce a more favourable bowel flora. Results have been inconsistent.[5,8] *Helicobacter pylori* is a urease-producing organism, but the relevance of *H. pylori* infection to hepatic encephalopathy is unclear.[9]

Investigational therapy has also attempted to affect cerebral function directly. Flumazenil, a benzodiazepine antagonist, has been tried, on the basis of the suspected role of endogenous benzodiazepine-like agonists.[2,10] A systematic review[11] concluded that flumazenil did produce short-term improvement of hepatic encephalopathy but had no effect on recovery or survival; it might be considered for patients with chronic liver disease and hepatic encephalopathy but routine clinical use was not recommended. Similarly, although dopaminergics such as levodopa or bromocriptine have been given, on the grounds that impaired dopaminergic neurotransmission may play a role in the syndrome,[2] evidence to support their use was not forthcoming from a systematic review.[12]

Liver transplantation (p.1815) is the ultimate therapy for end-stage cirrhosis, acute liver failure, or patients with severe refractory hepatic encephalopathy.[4]

Inflammatory bowel disease

Inflammatory bowel disease (IBD) covers chronic non-specific inflammatory conditions of the gastrointestinal tract, of which the two major forms are *Crohn's disease* and *ulcerative colitis*.

Crohn's disease is characterised by thickened areas of the gastrointestinal wall, with inflammation extending through all layers, deep ulceration and fissuring of the mucosa, and the presence of granulomas; affected areas may occur in any part of the gastrointestinal tract, interspersed with areas of relatively normal tissue; the terminal ileum is frequently involved. Symptoms depend on the site of disease but may include abdominal pain, diarrhoea, fever, weight loss, and rectal bleeding. Extra-intestinal manifestations may include joint inflammation, skin lesions, mouth ulcers, and liver disorders.

In **ulcerative colitis**, disease is confined to the colon and rectum, inflammation is superficial but continuous over the affected area, and granulomas are rare. In mild disease, the rectum alone may be affected (proctitis); in severe disease, ulceration is extensive and much of the mucosa may be lost, with an increased risk of toxic dilatation of the colon, a potentially life-threatening complication. Symptoms include diarrhoea and rectal bleeding. The extra-intestinal manifestations are similar to those of Crohn's disease.

Drug treatments.

Although there are important differences between Crohn's disease and ulcerative colitis which affect their management, the broad principles of treatment, and the drugs used, are similar.[1-6] The aminosalicylate derivatives are generally the first choice in mild to moderate active disease, and are of particular value for maintenance treatment of ulcerative colitis; the role of maintenance treatment in Crohn's disease is less well established. Corticosteroids are also used in the initial treatment of active disease, dosage and route varying with disease site and severity. Immunosuppressant or biological therapy may be helpful in severe or chronic active disease. For Crohn's disease an elemental diet (see p.1923) may have some value in active disease, but diet plays a lesser role in ulcerative colitis.

- Oral sulfasalazine, a **5-aminosalicylate** derivative (5-aminosalicylic acid linked to sulfapyridine), is of value in producing remission of mild ulcerative colitis;[7] results in Crohn's disease have been more equivocal.[5,8]

  The discovery that 5-aminosalicylate was the active component of sulfasalazine led to the development of numerous derivatives, including mesalazine (5-aminosalicylic acid itself, either used rectally, or orally in slow-release or enteric-coated form), olsalazine (2 molecules of 5-aminosalicylic acid joined by an azo bond), and a variety of forms, such as balsalazide, in which the active moiety was joined to inert carriers. All the above have been shown to be effective in active ulcerative colitis, and may be better tolerated than sulfasalazine, since many of the latter's adverse effects are due to its sulfonamide portion. In patients who can tolerate sulfasalazine, the newer drugs have no clinical advantage for remission induction.[7] Nevertheless, the risk of adverse effects on starting sulfasalazine therapy has led to increasing use of the newer derivatives. The 5-aminosalicylates are also recommended for the maintenance of remission in ulcerative colitis;[3,4,9] in contrast, although they are often used in practice it is unclear that they are of value for maintenance in patients with Crohn's disease.[3,5,6,10]
- The other major group of drugs used in the treatment of IBD is the **corticosteroids**, particularly for more severe ulcerative colitis, and in Crohn's disease. Rectal use may be appropriate in some patients with distal ulcerative colitis or proctitis; oral prednisone or prednisolone is often used in more severe and extensive disease, and in the most severe cases intravenous corticosteroids (usually hydrocortisone or methylprednisolone) may be given. Unfortunately, treatment of IBD is often prolonged, and adverse effects remain a problem, hence the interest in poorly absorbed or rapidly metabolised corticosteroids such as beclometasone, budesonide, or tixocortol. Oral budesonide is more effective than mesalazine in inducing remission in Crohn's disease and although it may be slightly less effective than conventional corticosteroids, adverse effects are reduced.[11] Corticosteroids are not suitable for maintenance of remission in IBD,[3,12] and inability to withdraw corticosteroid treatment without precipitating relapse (corticosteroid dependence) is a therapeutic challenge.
- Other drugs used in active IBD include **immunosuppressants**. The majority of studies have been with azathioprine, or its metabolite mercaptopurine. Because they have a slow onset of action (months) their use in acute disease is limited, but they are of benefit in remission induction in patients with chronically active disease, particularly corticosteroid-resistant or corticosteroid-dependent disease; they may also be used for maintenance in both ulcerative colitis and Crohn's disease, often in combination with other drugs.[3-6,13] Low-dose intramuscular methotrexate also appears to be useful in active Crohn's disease (although evidence for the oral route is lacking),[14] but does not appear to be of value in ulcerative colitis.[4,6] Conversely, ciclosporin has not generally proved useful in chronically active inflammatory bowel disease but may have some value in the short-term treatment of acute severe ulcerative colitis.[6,15] Tacrolimus also appears to be of benefit in severe ulcerative colitis,[6] and possibly in Crohn's disease;[16] mycophenolate mofetil has been tried, although the limited evidence is equivocal.[16]
- Of increasing importance in the management of severe or refractory forms of IBD are the so-called '**biological therapies**', comprising in particular anti-tumour-necrosis factor antibodies such as infliximab, adalimumab, and certolizumab pegol. These have been shown to be effective for induction therapy and maintenance in both ulcerative colitis and Crohn's disease.[6,17] The anti-integrin antibody natalizumab is effective in inducing remission in Crohn's disease.[18] Thalidomide, a tumour necrosis factor inhibitor, has also been tried in Crohn's disease with some benefit,[16,19] but another such inhibitor, pentoxifylline, was ineffective.[20]
- **Metronidazole** is useful in fistulising perineal Crohn's disease and may be used in colonic Crohn's disease. It is usually given for 3 months. Ciprofloxacin is an alternative, and has also been given with metronidazole,[21,22] although the combination may not be very well tolerated. There has been interest in the possible causal role of *Mycobacterium paratuberculosis* in Crohn's disease,[23] but a study of 2 years of antituberculous therapy with clarithromycin, rifabutin, and clofazimine in patients with Crohn's disease found no evidence of sustained benefit, suggesting that the organism probably did not play a significant role.[24] Antibacterials do not have a role in ulcerative colitis, except for infection prophylaxis in severe attacks.
- Many **other drugs** are being or have been tried in IBD, including immunoglobulins, some interleukins, interferons, ICAM-antisense oligonucleotides such as alicaforsen, the anti-CD3 antibody visilizumab, short-chain fatty acids, heparin, factor XIII, rosiglitazone, and aminosalicylic acid (4-aminosalicylic acid as opposed to 5-aminosalicylic acid). There have been some short-term responses to the anti-integrin antibody, MLN-02,[25] and to the anti-interleukin-12 antibody, ABT-874.[26] There is limited evidence of improvement in disease severity from the use of the granulocyte-macrophage colony-stimulating factor sargramostim,[27] which is thought able to stimulate intestinal innate immune defence processes that may be impaired in Crohn's disease. Nicotine has been tried in ulcerative colitis, based on the observation that the disease is rare in smokers. Studies have suggested that nicotine, supplied via transdermal patch, may have benefit in active disease,[28] although it is ineffective for maintenance.[29] Rectal and oral formulations of nicotine are under investigation.

Nutritional and dietary therapies.

Correction of nutritional deficiencies may be necessary in severe IBD, but dietary modification may also have therapeutic effects. In Crohn's disease, enteral feeding, often with an elemental diet is effective in inducing remission (p.1923), although corticosteroids are more effective;[30] there is also some evidence of benefit in maintaining remission.[31] Elemental diets are useful in children and those unable to tolerate corticosteroids. The role of omega-3 fatty acids has been investigated: when given orally as enteric-coated formulations, they appear to be of benefit in maintaining remission in Crohn's disease.[32] In contrast, failure to find evidence of benefit in maintaining remission in ulcerative colitis[33] may have been due to the failure to use such formulations.

There has been some interest in manipulation of the bowel flora through use of lactobacilli and other probiotic bacteria. There have been some reports of benefit in ulcerative colitis,[34,35] and probiotics may be useful in the management of pouchitis,[3,4] but there is no good evidence to date of benefit in Crohn's disease.[36] The observation that inflammatory bowel disease is uncommon in developing countries where most people carry helminths has led to preliminary studies of bowel colonisation using *Trichuris suis* ova (porcine whipworm) in active Crohn's disease[37] and ulcerative colitis.[38]

Surgery.

In patients with ulcerative colitis surgical colectomy is curative, and may avoid the risks of long-term corticosteroid therapy and the increased risk of bowel cancer to which patients with inflammatory bowel disease are subject. Formation of an ileoanal pouch, which acts as a reservoir for the ileal contents, avoids the necessity for a standard ileostomy and maintains a degree of continence in suitable patients. Curative surgery is not possible in Crohn's disease, since recurrence elsewhere in the gut is almost inevitable, but resection of the affected area becomes necessary in many patients during the course of their illness.

CHOICE OF THERAPY

Ulcerative colitis.

- ACTIVE DISEASE:
  - ***mild to moderate***

    In mild to moderate *distal* disease topical mesalazine, preferably in combination with an oral aminosalicylate (mesalazine, balsalazide, or olsalazine), is the treatment of choice.[3,4] Selected patients may benefit from oral sulfasalazine. Patients intolerant of topical mesalazine may be given a topical corticosteroid instead, though they are less effective.[39] Suppositories are suitable for *proctitis* but foam or liquid enemas are required for more proximal disease (*proctocolitis*).[3] Patients who fail to improve on a combination of oral aminosalicylate with topical mesalazine or corticosteroid may require an oral corticosteroid (e.g. prednisone or prednisolone 40 mg daily).[3,4,6]

    In *left-sided* or more *extensive* ulcerative colitis the preferred therapy is an oral aminosalicylate;[3,4,6] olsalazine is best avoided in patients with *pancolitis* as it may be more likely to produce diarrhoea than mesalazine or balsalazide.[3] There is some evidence that the benefits of aminosalicylates are dose related,[4,6] and some controversy exists as to the optimum induction dose: use of higher doses initially may produce better responses,[4,6] but there is an increased risk of toxicity. Topical therapy is unlikely to be of benefit alone, but may be added for the relief of rectal symptoms.[3,6]

    Patients who fail to respond to oral aminosalicylates should be given an oral corticosteroid (as above). The corticosteroid should be reduced gradually (tapered) over several weeks once response is achieved.[3,4] Since long-term treatment with corticosteroids is undesirable, patients with *chronic active disease* who are at high risk of relapse when the corticosteroid is withdrawn (corticosteroid-dependent disease) should be treated with a thiopurine (azathioprine or mercaptopurine) as a corticosteroid sparing drug.[3,4] Thiopurines may also be effective in inducing remission in some patients who do not respond to oral corticosteroids, although their slow onset of action is problematic.[4] In patients with more extensive, moderate to severe disease, infliximab may be an option.[6]
  - ***severe***

    Patients who present with severe colitis or who fail to respond to maximal oral treatment should be admitted to hospital for treatment with intravenous corticosteroids.[3,4,6] Patients should be given appropriate supportive therapy (including nutritional support if the patient is malnourished, intravenous antibacterials for infection, and blood transfusion if markedly anaemic).[3,4] Those who fail to respond to intravenous corticosteroids within a few days should be considered for second-line treatment with ciclosporin,[3,4,6] or possibly infliximab or tacrolimus.[6] Patients who respond to intravenous ciclosporin may be given oral continuation treatment for 3 to 6 months.[3] Drug therapy is ineffective in up to 40% of patients with severe colitis,[4] and colectomy is an alternative.[3,4]
- MAINTENANCE:

  Lifelong maintenance therapy is generally recommended for patients with ulcerative colitis once remission is achieved, particularly in those with left-sided or more extensive disease, or those with distal disease who relapse more than once a year.[3,4] The treatment of choice is an oral aminosalicylate,[3,4,6] most often mesalazine,[6] although in those that can tolerate it sulfasalazine is possibly more effective.[9] Topical mesalazine has been used for maintenance in patients with distal disease,[3,6] but patients are less likely to be compliant.[3] Corticosteroids are ineffective in maintaining remission and associated with severe adverse effects on prolonged use. Azathioprine may be used for maintenance therapy, but is best reserved for patients who relapse frequently despite aminosalicylate maintenance, or who are unable to tolerate such therapy.[3] Patients with gastrointestinal intolerance of azathioprine may be tried cautiously with mercaptopurine; alternatively, surgery may be considered.[3] Infliximab is also effective for maintenance of remission, especially in patients who remain corticosteroid dependent despite alternative therapies.[6]

- POUCHITIS.

  Ileoanal pouch anastomosis allows for surgical removal of the colon without loss of continence or the need for an ostomy, but subsequent inflammation of the pouch (pouchitis) occurs in about half of all patients.[4] On the basis of limited evidence it is considered to be best treated by a short course of antibacterials (metronidazole or ciprofloxacin).[3,4] If these are ineffective, mesalazine or corticosteroids may be considered.[3] Use of a probiotic formulation, VSL-3, containing a mixture of bacteria, may also be of benefit.[3,4]

Crohn's disease.

- ACTIVE DISEASE:
  - ***mild to moderate***

    First-line therapy in mild to moderate Crohn's disease is a matter of some debate. Oral mesalazine is of limited benefit in *ileal* or *ileocaecal* disease,[5,6] and some consider that it should not be used at all,[6] although others recommend high doses as an appropriate initial therapy.[3] Aminosalicylates may be of more benefit in *colonic* disease, particularly sulfasalazine if it can be tolerated.[3,5,6] Others favour the use of oral budesonide as first-line therapy for mild to moderate ileocaecal disease;[5,6] although it is somewhat less effective than conventional oral corticosteroids, which are an option in more active disease,[3,5] it produces fewer adverse effects. Opinion also varies on the use of topical mesalazine in colonic disease,[3,5] although it is widely used.[5] Nutritional support (enteral feeding or the use of elemental diets) may be considered as an alternative to drug therapy or surgery in selected patients.[3]
  - ***moderate to severe***

    In outpatients with moderate to severe disease, and those who fail to respond to initial therapy with budesonide or aminosalicylates, conventional oral corticosteroids, typically in a dose corresponding to 40 mg of prednisolone daily (or up to 1 mg/kg daily), are recommended.[3,5,6] Once response has been achieved, dosage should be gradually tapered off.[3,5] In patients who have relapsed, azathioprine or mercaptopurine may be added,[5] but they are not best suited to induction of remission because of the delay in onset.[6] Methotrexate may be an alternative in selected patients.[5]

    In patients with severe extensive or *fulminant* disease intravenous corticosteroids should be given.[3,5,6] Adding intravenous metronidazole may be advisable, because of the difficulty of distinguishing active disease from a septic complication.[3] Infliximab should be considered in patients with disease *refractory* to corticosteroids;[3,5,6] adalimumab or certolizumab pegol may be alternatives.[6]
  - ***fistulising disease***

    Simple perianal fistulae can be treated with metronidazole or ciprofloxacin.[3,6] Azathioprine or mercaptopurine are also potentially effective,[3] while infliximab is recommended in patients who do not respond to other treatment.[3,6] An alternative to infliximab is adalimumab.[6] Surgery is appropriate for complex or persistent fistulae.[3,6]
  - ***chronic active and corticosteroid dependent disease***

    Azathioprine or mercaptopurine are the drugs of choice in corticosteroid dependent disease.[3] If they are ineffective or not tolerated, intramuscular methotrexate may be considered;[5] it is also considered appropriate for the management of chronic active disease.[3] Infliximab is generally reserved for patients who fail first-line therapy, as an alternative to surgical resection.[3]
- MAINTENANCE:

  The most important intervention in maintaining remission in patients with Crohn's disease is probably to persuade those who smoke to stop smoking.[3] Mesalazine appears to be of limited benefit at best for the maintenance of remission,[3,5,10,40] although it is widely used,[6] and the other aminosalicylates are considered inappropriate.[3,5] Corticosteroids are also not effective for maintenance,[3,5,12] although budesonide may delay relapse for a limited period.[5,6] In patients who required corticosteroids to achieve remission, the usual drug treatment for maintenance is a thiopurine (azathioprine or mercaptopurine).[3,5,6] In patients who achieved remission with intramuscular methotrexate, it may be continued for maintenance;[3] it is also an option in patients intolerant of thiopurines.[5] Thiopurine maintenance may need to be continued for several years,[5] or even indefinitely.[6] Infliximab is also an option for maintenance, particularly in patients brought to remission with the same drug,[3,5] or those who cannot maintain remission or who remain corticosteroid dependent despite the use of maintenance immunosuppression.[6] Alternatives may be adalimumab or certolizumab pegol.[6] The use of omega-3 fatty acids (fish oils) has been investigated for maintenance of remission in Crohn's disease, with some apparent benefit.[32]

Irritable bowel syndrome

Irritable bowel syndrome is a functional gastrointestinal disorder of abdominal pain and altered bowel habit; pain is characteristically relieved by defaecation and may be associated with increase or decrease in stool frequency. There may be abdominal bloating. Women are more often affected than men. Most patients have symptoms intermittently, with flares lasting several days followed by periods of remission.[1] Patients may be classified as having different subtypes of the syndrome, depending on the nature of the main symptoms.

Given the heterogeneity of the condition, only a minority of patients will respond to any given treatment, and this together with a high placebo response rate limits the evidence base for treatment.[1-3] The mainstay of treatment is explanation and reassurance, coupled with sensible advice about lifestyle.[1,4] Dietary modification should involve increasing the amount of vegetable fibre in the diet initially (but see below); some patients respond to exclusion of particular foods but this is probably best reserved for more refractory cases, and should not be allowed to compromise proper nutrition.[1]

Formal psychological therapies may be appropriate in some patients, especially if they have other psychological problems such as marked anxiety or depression, or are unwilling to consider symptomatic drug therapy.[1] Hypnotherapy may have a role in refractory patients,[1] but a systematic review, although noting promising results, was unable to confirm benefit.[5]

Many drug treatments have been tried in irritable bowel syndrome. Short-term drug therapy may be useful in managing symptoms,[1-4,6-9] and should be directed according to which predominate:

- in patients in whom *diarrhoea* is predominant, loperamide may be considered; it is preferred to other opioid antidiarrhoeal drugs because it does not pass the blood-brain barrier. Alternatively, colestyramine may be of benefit. The 5-HT_3 antagonist alosetron is also available in some countries for use in women with severe symptoms unresponsive to conventional therapy; it was previously withdrawn due to gastrointestinal toxicity
- in *constipation-predominant* forms of the syndrome fibre supplementation is often advocated. However, insoluble fibre, such as bran, may exacerbate pain and bloating in some patients, and if fibre supplements are to be given, soluble fibre, such as ispaghula, is preferable.[1] The benefits of bulking agents in general have been questioned.[9] An osmotic laxative or stool softener may

be added in patients who fail to respond to fibre, but stimulant laxatives should be avoided or used only occasionally.[1] Tegaserod, a partial agonist at 5-HT_4 receptors, has also been effective in this group of patients

- in patients with *abdominal pain*, 'as-needed' antispasmodics may be tried. These should be taken before meals if abdominal pain occurs principally after eating. Examples include alverine, dicycloverine, hyoscine, mebeverine, peppermint oil, and pinaverium. A systematic review considered the evidence of benefit to be greatest for hyoscine derivatives and pinaverium;[9] it was unable to show benefit for tricyclic antidepressants against abdominal pain, although low-dose tricyclics have been suggested for second-line use in patients unresponsive to antispasmodics.[1] Analgesic use should be minimised
- patients whose symptoms are associated with mild or masked *depression* may obtain benefit from antidepressant therapy; a depressed patient with increased bowel frequency and abdominal pain may benefit from a tricyclic antidepressant, which slows intestinal transit. It has been suggested that patients with constipation may be better treated with an SSRI.

Many other drugs have been tried in irritable bowel syndrome, but results have mostly been variable.[2,3] Interest in new pharmacological approaches has included investigation of cholecystokinin antagonists (loxiglumide and dexloxiglumide); new 5-HT_3-antagonists such as cilansetron and 5-HT_4-agonists such as ATI-7505 as well as compounds with mixed actions such as renzapride; κ-opioid agonists such as asimadoline and possibly μ-opioid antagonists such as alvimopan; the 2,3-benzodiazepine receptor modulator dextofisopam; chloride channel activators such as lubiprostone; melatonin; non-absorbed antibacterials such as neomycin or rifaximin, or more promisingly the use of probiotic mixtures of lactic acid-producing organisms; guanylate cyclase-C agonists (linaclotide); and recombinant human nerve growth factors.[10,11] Many herbal medicines have also been tried: a systematic review found the studies mostly to be small and of poor quality, but suggested that there was evidence of benefit for some herbal combinations including Chinese traditional medicines such as tongxie yaofang.[12]

Microscopic colitis

Microscopic colitis covers the diseases collagenous colitis and lymphocytic colitis, which are characterised by chronic, watery, non-bloody diarrhoea with intra-epithelial lymphocytic infiltration; in collagenous colitis this is accompanied by a thickened band of collagen immediately below the surface epithelium of the colonic mucosa.[1-4] Although originally considered to be rare, more recent studies have suggested an increased incidence;[2-4] differentiating from the diarrhoea-predominant form of irritable bowel syndrome (p.1699) may be difficult. It has been suggested that the disease is more common in middle-aged women,[2] but others dispute this.[3]

The evidence base for management is limited, and is complicated by the fact that the disease may remit spontaneously.[2-4] Initial measures may include dietary modification, with avoidance of caffeine[2,3] or lactose-containing foods.[2] A possible association with NSAIDs has been suggested; such drugs should be withdrawn, or their use minimised, if possible.[2,3] Drug treatment has been largely empirical, and relapse is quite common once treatment stops. Antidiarrhoeal treatment with loperamide or fibre supplements has been proposed initially.[1-3,5] Systematic review[6] has suggested that budesonide (see also p.1521), and probably bismuth salicylate, are of benefit in collagenous colitis, and they may be considered for second-line therapy.[3] Data from a small study suggested that bismuth salicylate might also be beneficial for lymphocytic colitis, although no firm conclusions could be drawn.[7] In unresponsive patients, sulfasalazine or another 5-aminosalicylate may be considered;[1-3] it has been suggested that mesalazine or olsalazine may be less effective (though better tolerated) than sulfasalazine.[1,2] Other drugs that may be tried in resistant cases include colestyramine, antibacterials such as metronidazole or erythromycin, oral prednisolone, or immunosuppressants such as azathioprine, mercaptopurine, or methotrexate.[1-3,5] Octreotide and verapamil have also been reported to relieve symptoms.[3]

Mouth ulceration

Recurrent ulceration of the oral mucosa is usually idiopathic and self-limiting and is known as recurrent aphthous stomatitis or recurrent aphthous ulceration. However, oral ulcers (canker sores) may also be caused by mechanical trauma, nutritional deficiencies (particularly iron, folic acid, or vitamin B_{12}), drug reactions, or underlying disease such as Behçet's syndrome (p.1499).

Management includes identifying any underlying disease or nutritional deficiency and treating these as appropriate. Usually no underlying cause can be found, and treatment is purely symptomatic; it may include topical anti-inflammatories, local anaesthetics, antiseptics, astringents, or antihistamines. The value of many of these drugs in reducing symptoms remains anecdotal, and no treatments have yet been proven to reduce the incidence of recurrences.

Where ulceration is due to minor trauma frequent use of a warm saline or compound thymol glycerin mouthwash may be all that is required to relieve discomfort and swelling. Alternatively, pain relief may be obtained with local anaesthetics or analgesics, but their effectiveness in oral ulceration is limited by their relatively short duration of action when applied topically. Salicylates are widely used, mainly as choline salicylate gel, although they themselves have the potential for local irritation and ulceration. Benzydamine spray or mouthwash may also be helpful. Lidocaine, as a gel or lozenges, may be of value in pain that has not responded to other measures. Topical corticosteroids are probably the most effective symptomatic treatment for recurrent aphthous stomatitis. Pellets or lozenges of hydrocortisone are allowed to dissolve next to an ulcer, or triamcinolone in an oral paste formulation may be used, although the paste may sometimes be difficult to apply. Mouthwashes have been employed particularly when ulceration is widespread in the mouth and a dexamethasone mouthwash has been used effectively. The healing properties of carbenoxolone have also been employed as a gel or mouthwash, and the mast-cell stabilising agent amlexanox is also used as an oral paste.

Mechanical protection may be provided by a paste or powder of carmellose sodium, although application may be difficult.

Use of an antiseptic mouthwash such as chlorhexidine or povidone-iodine may be helpful, since secondary bacterial infection can delay healing. Chlorhexidine is also available as a gel. Tetracyclines, used as mouthwashes, reportedly reduce ulcer pain and duration, but their potential for adverse effects if swallowed must be borne in mind. Use of hydrogen peroxide 3% is inadvisable, as it can cause ulceration, but application of a 1.5% solution to individual ulcers, with a topical corticosteroid, may be helpful in producing resolution.

A wide variety of other drugs have been tried in aphthous ulceration. Sucralfate may be of benefit. Drugs such as levamisole and thalidomide, although possibly beneficial, are unlikely to be suitable in most cases because of their adverse effects, although thalidomide is used, for example, for aphthous stomatitis in patients with AIDS. Pentoxifylline, which, like thalidomide, inhibits tumour necrosis factor production, has been used in patients with minor recurrent aphthous ulceration. Systemic corticosteroids are generally reserved for cases with severe underlying disease.

Nausea and vomiting

Vomiting follows stimulation of the vomiting centre in the medulla of the brain. This may be via the chemoreceptor trigger zone, which is sensitive to many drugs and to certain metabolic disturbances, or from actions on other areas such as the vestibular apparatus of the ear (in motion sickness), the cerebral cortex (in psychogenic vomiting), and multiple peripheral receptors. In adults vomiting is almost invariably preceded by a sensation of nausea.

In situations where it can be anticipated, such as motion sickness, surgery, and cancer therapy, antiemetic drugs are given prophylactically, but if this fails they may need to be given therapeutically. Vomiting of unknown origin should ideally not be treated until the underlying cause has been found. If vomiting is prolonged, dehydration, hypokalaemia, and alkalosis may occur and replacement of fluid and electrolytes may be necessary, especially in young children and the elderly.

Cancer chemotherapy. Nausea and vomiting are common adverse effects of cancer chemotherapy and for many patients represent a major drawback to treatment. Once experienced, anticipatory vomiting may occur at the sight of medical staff or a needle and this problem may be severe enough in some cases to hinder or prevent further treatment.

Antineoplastic or cytotoxic drugs may induce vomiting by both a central action on the chemoreceptor trigger zone and a peripheral action on the gastrointestinal tract. The cerebral cortex is probably responsible for anticipatory vomiting. Mechanisms involving 5-HT_3-receptors are important in the pathogenesis of *acute cisplatin-associated vomiting*, whereas different mechanisms are probably involved in *delayed emesis*.

The emetic potential of antineoplastics varies in terms of severity and incidence. A risk classification system, based on the proportion of patients who experience emesis in the absence of effective antiemetic prophylaxis, has been developed. Although there are slight variations in published lists,[1-3] examples of risk for some common drugs include:

- *high (more than 90% frequency of emesis)* and can be very severe with chlormethine, cisplatin, high-dose cyclophosphamide, dacarbazine, dactinomycin, and streptozocin
- *moderate (30 to 90% frequency of emesis)* with carboplatin, more modest doses of cyclophosphamide, doxorubicin, epirubicin, irinotecan, high-dose methotrexate, and oxaliplatin

- *low (10 to 30% frequency of emesis)* with etoposide, fluorouracil, lower doses of methotrexate, and taxanes
- *minimal (less than 10% frequency of emesis)* with bleomycin, oral chlorambucil, fludarabine, oral methotrexate, rituximab, and vinca alkaloids

Emetogenicity may depend to some extent on the dose, route, and schedule of chemotherapy. Some combination therapy has resulted in a higher incidence of vomiting than would be expected from the constituents.

The *onset and duration* of vomiting also varies from drug to drug. For cisplatin the onset may be between 4 and 8 hours after a dose, while the duration may be up to 48 hours or occasionally even longer; a persistent feeling of nausea, and sometimes vomiting, lasting for several days may also occur. After chlormethine, vomiting may begin within a half to 2 hours, whereas after cyclophosphamide there may be a latent interval of 9 to 18 hours, but in both cases vomiting is generally less prolonged than with cisplatin. *Acute emesis* (that occurring within 24 hours of chemotherapy) has generally been easier to control than *delayed emesis* (that occurring more than 24 hours after chemotherapy) or *anticipatory emesis*. In patients whose regimens are given over several days delayed emesis from the initial doses may overlap with acute emesis from later doses.

MANAGEMENT. Guidelines for the management of nausea and vomiting associated with chemotherapy have been produced.[1-3] It is important that effective antiemetic prophylaxis is given from the first course of chemotherapy, to avoid subsequent problems with anticipatory vomiting. With the antiemetic drugs now available it should be possible to control acute emesis; delayed emesis has proved more resistant but new treatments are becoming available. Drugs used in antiemetic regimens have included:

- dopamine antagonists such as metoclopramide, domperidone, and some phenothiazines such as prochlorperazine
- corticosteroids such as dexamethasone
- 5-HT_3 antagonists such as ondansetron
- neurokinin-1 (NK-1) receptor antagonists such as aprepitant
- cannabinoids such as nabilone
- benzodiazepines such as lorazepam
- antihistamines such as diphenhydramine

The choice depends on the emetogenicity of the cancer chemotherapy regimen, as well as factors such as the age of the patient.

- For prophylaxis of *acute emesis* associated with *highly emetogenic chemotherapy*, a 5-HT_3 antagonist with dexamethasone and aprepitant (or fosaprepitant) is recommended.[1-3] At equipotent doses, dolasetron, granisetron, ondansetron, and tropisetron are effective and equally safe.[1,2] Palonosetron, which has a prolonged action, may also be used. High-dose metoclopramide was formerly used, but frequently caused extrapyramidal adverse effects, particularly in patients under 30 years of age; diphenhydramine was used to reduce these effects
- For prophylaxis of *acute emesis* associated with *moderately emetogenic chemotherapy*, dexamethasone with a 5-HT_3 antagonist is suggested.[1-3] Aprepitant (or fosaprepitant) may be added for patients given an anthracycline and cyclophosphamide or other chemotherapy drugs of moderate emetic risk
- Dexamethasone alone may be used for prophylaxis with chemotherapy of *low emetic risk*;[1-3] alternatives include prochlorperazine or metoclopramide.[2] No routine prophylactic antiemetic needs to be given for chemotherapy of *minimal emetic risk*;[1-3] however, as-needed or prophylactic use of dexamethasone, a phenothiazine, or metoclopramide is common, particularly for patients with poor emetic control during previous therapy[1]
- Lorazepam may be used for its amnestic, sedative, and anxiolytic effects as an adjunct to antiemetics when *anticipatory emesis* is a problem
- Good control of acute emesis is important in preventing *delayed emesis*. In addition, for prophylaxis of delayed emesis from highly emetogenic chemotherapy, a combination of dexamethasone with aprepitant may be used. After moderately emetogenic chemotherapy, prophylaxis with a single drug such as dexamethasone, a 5-HT_3 antagonist, or metoclopramide (with or without diphenhydramine) may be sufficient.[1-3] Aprepitant or dexamethasone alone has been suggested for patients given an anthracycline with cyclophosphamide[1,3]

Cannabinoids such as dronabinol and nabilone have been used for chemotherapy-induced nausea and vomiting, usually as second-line drugs. Although they have some advantages because of their effects on mood, their use is limited by adverse effects.[4]

If *breakthrough emesis* occurs, management is often difficult. The general principle of treatment is to add an additional antiemetic from a different class; multiple concurrent drugs, perhaps in alternating schedules or by alternating routes may need to be considered. Since oral dosage may not be feasible because of ongoing vomiting, treatment is often given by the rectal or intravenous routes.[2] More intensive prophylactic treatment should be considered in subsequent courses.

Motion sickness has been described as a normal reaction to stimuli that occur during passive transportation and to which the individual is not adapted. The term embraces all forms of travel sickness including sea sickness, car sickness, train sickness, and air sickness. It is a type of vertigo in which autonomic symptoms predominate, therefore signs and symptoms include pallor, sweating, increased salivation, yawning, malaise, and hyperventilation.

MANAGEMENT. The aim is to *prevent* motion sickness and antiemetics are more effective if given prophylactically before nausea and vomiting has developed. The principal drugs used are the antimuscarinic hyoscine and some of the centrally acting antihistamines.[5,6] In some countries dexamfetamine has been tried,[6] although its adverse effects and the risk of abuse make it an unlikely choice. Antiemetic drugs *not* effective against motion sickness include metoclopramide, domperidone, chlorpromazine, and 5-HT_3 antagonists. Ginger has been tried. Evidence for the value of wrist acupressure is equivocal.[6]

For short-term protection against motion sickness hyoscine hydrobromide has been shown to be effective.[7] It can be taken by mouth about 30 minutes before a journey followed by further doses every 6 hours if necessary. Transdermal hyoscine has a longer duration of action, but the patches need to be applied to the skin several hours before travelling.

There is little good evidence comparing the effectiveness of antihistamines with hyoscine against motion sickness,[7] but they are often better tolerated. They are usually given by mouth and include cinnarizine, cyclizine, dimenhydrinate, meclozine, and promethazine; all have similar efficacy, but differ in onset and duration of action and in the extent of adverse effects such as drowsiness. Their antimuscarinic properties may contribute to their effects. Non-sedating antihistamines (e.g. astemizole and terfenadine) penetrate poorly into the CNS and do not appear to be effective against motion sickness.

Once motion sickness has developed, gastric motility is inhibited and oral antiemetics are unlikely to be effective. Where intramuscular injection is feasible, promethazine appears to be the most effective treatment. If exposure is likely to be prolonged, transdermal hyoscine may be useful, but will not provide benefit for some hours.[6]

Palliative care. Nausea and vomiting are common in terminal illness, and may be prolonged. Causes may include gastric irritation or stasis, bowel obstruction, renal failure, hypercalcaemia, raised intracranial pressure, infection, or the effects of drugs or radiation; anxiety, cough, and pain may exacerbate the condition.[8-10]

MANAGEMENT. Management will depend on the cause of the nausea and vomiting.[9] The evidence base for many antiemetics in terminal care is poor; it is perhaps best for metoclopramide, but evidence for many common and apparently effective interventions, such as haloperidol, cyclizine, and levomepromazine, is conflicting.[11] However, guidelines have been developed, either empirically or based on considerations of the likely causes. Recommendations include:[9]

- any correctable causes should be managed appropriately, and treatment for exacerbating conditions (such as anxiety) given
- an appropriate antiemetic should be given immediately, and repeated as often as necessary. If nausea is continuous or vomiting frequent, subcutaneous injection or continuous subcutaneous infusion may be preferred to the oral route. The usual initial choice for palliative care in the UK is between metoclopramide (preferred if the cause is gastric stasis, gastritis, or functional bowel obstruction), haloperidol (favoured in drug-induced vomiting, hypercalcaemia, and renal failure), and cyclizine (raised intracranial pressure, motion sickness, organic bowel obstruction)
- if treatment fails an alternative drug may be considered, or combination therapy may be necessary (prokinetics such as metoclopramide should not be combined with antimuscarinic drugs as their actions are antagonistic). Dexamethasone (usually added to the regimen), or levomepromazine or olanzapine (broad-spectrum antiemetics; these are usually substituted for the previous regimen) are useful where first-line drugs fail. Olanzapine is usually used if levomepromazine is too sedative. Other phenothiazines, notably prochlorperazine, and the phenothiazine antihistamine promethazine, are sometimes still used, but chlorpromazine is less effective than levomepromazine where a broad-spectrum drug is required. The role of 5-HT_3 antagonists is limited but they may be useful in nausea and vomiting secondary to chemotherapy (above) or radiotherapy (below), or sometimes in bowel obstruction or renal failure
- if there is colic or a need to reduce secretions, hyoscine butylbromide should be given, alone or with cyclizine. If this is inadequate in patients with obstruction, octreotide may be helpful

Non-drug measures may include appropriate diet and avoidance of unpleasant odours, adequate hydration, and regular mouth care.[8] Acupressure and acupuncture may provide some benefit.[10]

Postoperative nausea and vomiting (PONV) is a common and distressing adverse effect of anaesthesia and surgery;[12-16] it is seen in some 20 to 30% of patients undergoing surgery under general anaesthesia,[13,14,17] and is perceived by patients as a problem comparable to postoperative pain.[18]

Risk factors for PONV include a history of motion sickness or previous PONV, female sex, not smoking, use of opioids during or after surgery, use of volatile inhaled anaesthetics or nitrous oxide, and prolonged surgery.[13-17,19,20] It is widely considered that certain types of surgery carry an increased risk, but this is now being questioned.[13,14] A study comparing various predictive models found that none was perfect, but that a simplified model based on history, sex, smoking status, and opioid use was as effective as more complex methods.[19]

MANAGEMENT. Prediction of risk is of value since much of the management of PONV focuses on prevention. It is generally agreed that prophylaxis should be reserved for patients at moderate to high risk. In these, various strategies may be adopted to *reduce risk* where possible, including the use of regional anaesthesia or total intravenous anaesthesia with propofol (but see also p.1793), avoidance of nitrous oxide, minimal use of opioids, adequate hydration (especially with colloids), and possibly the use of intraoperative supplemental oxygen (although not all studies found this of benefit).[13,14] Avoidance of high-dose neostigmine (limiting the dose to a maximum of 2.5 mg in adults) has also been suggested.[14] There is evidence that some nonpharmacological interventions, such as acupuncture of the P6 point, may also be effective, especially for nausea.[21]

Many types of drugs have been tried as *prophylactic antiemetics*. These include the 5-HT_3 antagonists, phenothiazines such as prochlorperazine, butyrophenones such as droperidol, antihistamines such as promethazine, cyclizine, or dimenhydrinate, and some other drugs such as dexamethasone and hyoscine.[16,20] A large and well-designed multicentre study (the IMPACT trial) has shown that ondansetron, droperidol, and dexamethasone are of similar efficacy;[22] it also confirmed that avoidance of volatile anaesthetics and nitrous oxide was of as much benefit in preventing PONV as use of a prophylactic antiemetic. The evidence suggests that other 5-HT_3 antagonists are of similar efficacy to ondansetron.[14] Evidence for some of the older drugs is less extensive, although benefit has often been shown in individual studies.[13,14] Systematic reviews have confirmed the benefit of prophylaxis with dimenhydrinate[23] and transdermal hyoscine[24] but have suggested that metoclopramide, which has been widely used, is in fact of little value in preventing PONV,[25,26] perhaps because the doses used are too low.[26] However, another systematic review[27] included metoclopramide in a list of drugs that reliably prevented PONV compared with placebo; other drugs listed were cyclizine, dexamethasone, dolasetron, droperidol, granisetron, ondansetron, and tropisetron. Ginger root has also been suggested, but again does not seem to be effective in this context,[28] although there is some evidence of benefit for intramuscular ephedrine.[29] Clonidine has also been reported to produce benefit,[30,31] possibly secondary to reduced sympathetic tone and lower use of inhalation anaesthetics and opioids. Neurokinin-1 antagonists such as aprepitant may also be effective.[20]

In patients at moderate risk of PONV, therefore, in addition to risk reduction, use of a single prophylactic antiemetic may be considered:[13,14] this might be a 5-HT_3 antagonist, droperidol (although concerns about effects on QT interval have restricted its availability), or dexamethasone; or perhaps transdermal hyoscine, dimenhydrinate, or another drug such as promethazine or a heterocyclic phenothiazine (prochlorperazine or perphenazine). In patients at higher risk, or in whom nausea and vomiting would be particularly problematic, a combination of antiemetics from different classes should be given,[13,14] since the IMPACT study has shown that the effects of such interventions are additive.[22]

If PONV develops, *treatment* will depend on whether prophylaxis was given. In patients who have received no prophylaxis, or only dexamethasone, a small dose of a 5-HT_3 antagonist has been recommended.[13,14] If PONV occurs within 6 hours of surgery despite antiemetic prophylaxis, additional doses of the same drug convey no further benefit, and treatment with drugs from another class is recommended.[14,16,20] Beyond this time any suitable drug may be used, but dexamethasone and transdermal hyoscine are not recommended for treatment because of their slow onset of action.[14]

Pregnancy. Nausea and vomiting or 'morning sickness' is common in the first trimester of pregnancy, but is generally mild and does not require drug therapy. Dietary modification such as eating small frequent carbohydrate meals is widely thought to be helpful.[32] A systematic review has suggested that pyridoxine, which has been shown to be of benefit, should be tried first if drug therapy is required.[32] Benefit has also been reported with ginger root,[32,33] but evidence of benefit from stimulation of the P6 acupuncture point is ambiguous.[32] A number of antihistamines such as buclizine, dimenhydrinate, hydroxyzine, meclozine, promethazine, and thiethylperazine have also been tried, and appear to be more effective than placebo,[32] but there are obvious concerns about potential effects on the fetus (see Pregnancy, under Precautions for Antihistamines, p.563). Although no real evidence of a teratogenic effect exists,[34] therapy has tended to be reserved for severe cases, and short-term use.

Persistent vomiting and severe nausea may progress to *hyperemesis gravidarum* if adequate hydration cannot be maintained; the condition occurs in up to 1% of pregnancies.[35] Management of hyperemesis includes hospitalisation for intravenous fluid and electrolyte replacement, and this is usually sufficient. Routine thiamine supplementation, by mouth if tolerated, otherwise parenterally, has been recommended to reduce the risk of Wernicke's encephalopathy[35,36] (p.1977), although there is some dissent from this view.[37] If hyperemesis fails to respond to rehydration, antiemetics should be used; options include domperidone, phenothiazines, and antihistamines.[35] It has been suggested that hyperemesis unresponsive to conventional therapy may respond to oral prednisolone or intravenous hydrocortisone.[35] There have also been anecdotal reports of ondansetron being used successfully in life-threatening hyperemesis gravidarum unresponsive to conventional treatment,[38] although a double-blind pilot study found it to be no more effective than promethazine.[39] A systematic review found no evidence of benefit for any intervention in hyperemesis gravidarum.[32]

Radiotherapy. The risk of emesis with radiotherapy varies with the treatment given, particularly the area of the body irradiated. However, emetic risk, and recommendations for use of antiemetics, are less clearly defined than in the situation of chemotherapy-induced nausea and vomiting.[1] Use of a prophylactic 5-HT_3 antagonist is usually recommended in patients receiving radiation to the upper abdomen. Dexamethasone may be added for those receiving total body irradiation.[1,2] For radiotherapy of minimal emetogenic potential, treatment on an as-needed only basis has been suggested.[1]

Oesophageal motility disorders

Oesophageal disorders, many due to disturbances in oesophageal motility, may produce non-cardiac chest pain, similar to that of angina pectoris, from which they must be differentiated.

Achalasia is obstruction caused by failure of the lower oesophageal sphincter to relax and permit passage of food into the stomach. It is accompanied by dilatation and abnormal peristalsis in the oesophagus, which becomes a reservoir for the unassimilated matter; symptoms include dysphagia and sometimes pain. The treatment of choice is mechanical dilatation of the sphincter or, if necessary, surgery. Laparoscopic techniques have reduced the risks associated with surgery, and this may become the preferred treatment. Taking isosorbide dinitrate or nifedipine before eating results in some improvement in achalasia, but these drugs have a role only as a temporary measure, or when other options are not suitable. Sildenafil is under investigation. More recently, injection of botulinum toxin into the lower oesophageal sphincter has been found to be effective, but remission in the long-term is better with mechanical dilatation than botulinum toxin. Therefore, it has been recommended that botulinum toxin be reserved for patients thought to be at risk from mechanical dilatation or surgery.

Oesophageal spasm, although frequently asymptomatic, can produce dysphagia and pain. Drug treatment of diffuse oesophageal spasm, or its variant 'nutcracker oesophagus' which is characterised by high amplitude peristalsis in the oesophagus, is often ineffective. Antimuscarinic antispasmodics, nitrates, and calcium-channel blockers have been tried in an attempt to relax the smooth muscle, but results are often disappointing; experience with nifedipine in patients with nutcracker oesophagus suggests that decrease in oesophageal pressure may not correlate with reduction in pain. As with achalasia, minimally invasive surgery is effective for these conditions. Sildenafil is also under investigation.

Peptic ulcer disease

Peptic ulceration is a common condition consisting of a distinct break in the gastrointestinal mucosa, usually of the stomach or duodenum. Duodenal ulcers are rarely malignant but gastric ulcers are more commonly associated with malignancy.

The aetiology of peptic ulcer disease is probably multifactorial but the bacterium *Helicobacter pylori* plays an important role. Abnormalities of normal mucosal defence mechanisms, and, in the case of gastric ulcer, reflux of duodenal contents into the stomach or delayed gastric emptying may also be involved. Other factors include emotional stress, smoking, alcohol, and drugs such as NSAIDs or corticosteroids.

Peptic ulcer disease usually presents as dyspeptic pain, sometimes associated with nausea, vomiting, anorexia, heartburn, or bloating. Patients may develop complications such as bleeding, obstruction, or perforation.

Certain simple measures such as bed rest, dietary modification, and cessation of smoking, may accelerate ulcer healing, but these play an adjuvant role, and the basis of treatment is pharmacological. Treatment is aimed at eradicating *H. pylori* with antibacterials and neutralising or inhibiting acid activity with antisecretory drugs. Surgical treatment is used in patients with acute complications such as perforation, haemorrhage, obstruction, or pyloric stenosis, or in patients with recurrent or intractable ulcer disease, or where there is suspicion of malignancy.

Anti-Helicobacter therapy. The presence of *H. pylori* should usually be confirmed before therapy to eradicate the infection is started. The urea breath test is the most widely used method to test for *H. pylori*, but may produce false-negatives if used during or too soon after treatment with proton pump inhibitors (see under Omeprazole, p.1755) or antibacterials. There is good evidence that eradication therapy has benefits both in healing ulcers and preventing recurrence, especially for duodenal ulcer.[1] Many different regimens have been tried, using various combinations of oral antibacterials with antisecretory drugs. Expert consensus is that any treatment regimen should achieve at least 80% eradication of *H. pylori*,[2] and the most appropriate regimen may therefore depend to some extent on local patterns of resistance.

The following recommendations have been made by an international expert group:[2]

- ***where clarithromycin resistance is below 15 to 20%***
  - **triple therapy** with a proton pump inhibitor (PPI), clarithromycin, and metronidazole (provided the prevalence of metronidazole resistance is less than 40%), for 14 days

    or

    PPI, clarithromycin, and amoxicillin, for 14 days

    or
  - **quadruple therapy** with a bismuth compound, a PPI, and two antibacterials, for 14 days. Such a regimen used in the UK (usually for rescue therapy, see below) comprises a proton pump inhibitor with tripotassium dicitratobismuthate, tetracycline, and metronidazole
  - treatment for 7 days rather than 14 may be acceptable where local studies show it to be effective (in the UK, the *BNF* considers that adverse effects and poor compliance are likely to offset any therapeutic gain from 14-day regimens)
- ***in areas of high clarithromycin resistance*** it may be appropriate to consider antibacterial susceptibility testing before beginning treatment; regimens that may be considered include:

  bismuth-containing quadruple therapy as above

  or

  PPI, amoxicillin, and metronidazole (provided metronidazole resistance is low)

  or

  PPI, tetracycline, and metronidazole
- testing to confirm eradication, at least 4 weeks after treatment, is recommended; a urea breath test is the preferred method
- rescue treatments in patients with refractory disease should be based on antibacterial susceptibility testing. In the UK, the *BNF* considers that the bismuth-based quadruple therapy regimen referred to above may be effective.
- other antibacterials that have been investigated in eradication regimens (mainly as rescue treatments) include rifabutin and levofloxacin, although there might be concerns about selecting for mycobacterial resistance if the former were to be used widely, and increasing fluoroquinolone resistance may limit the value of the other

There is some evidence that a **sequential regimen** of a PPI (pantoprazole) with amoxicillin for 5 days, followed by the PPI with a nitroimidazole antibacterial (tinidazole) and clarithromycin for a further 5 days, is more effective than a standard 10-day triple therapy regimen, especially in patients with clarithromycin-resistant strains of *H. pylori*.[3] The potential value of such regimens remains to be more widely demonstrated.[2,4]

The use of **dual therapy** regimens comprising a PPI and an antibacterial is no longer recommended. Similarly, although acid suppressive therapy has sometimes been continued after completing eradication therapy, the *BNF* considers this unnecessary, unless the ulcer is large or complicated by bleeding or perforation.

Before the advent of *H. pylori* eradication therapy, drug treatment of gastric and duodenal ulcers relied mainly on antisecretory therapy. Four to 8 weeks of H_2-antagonist or proton pump inhibitor therapy was required for ulcer healing. Because of the high incidence of relapse, these drugs were then often given as maintenance therapy. Numerous other drugs were formerly used in peptic ulcer disease before the development of H_2-antagonists and proton pump inhibitors, including antacids, antimuscarinics such as pirenzepine, and mucosal protectants such as sucralfate.

NSAID-induced ulceration. The ulcerogenic effects of NSAIDs have been attributed to inhibition of prostaglandin synthesis and mucosal cell proliferation, and the ulcers they cause may differ from non-iatrogenic ulcers in their pathology and prognosis.[5,6] Although considered to be independent risk factors for peptic ulcer disease, *H. pylori* infection and NSAID use may act synergistically in peptic ulceration and ulcer bleeding.[7,8] If peptic ulceration develops during treatment with an NSAID the drug should be withdrawn if possible. If this can be done, the ulcer may be treated with an antisecretory drug such as an H_2-antagonist or PPI given for 4 to 8 weeks. If NSAIDS have to be continued, *treatment* is with antisecretory drugs or the prostaglandin analogue misoprostol.[5,6] Ulcers tend to heal more slowly with H_2-antagonists if NSAIDs are continued, whereas the rate of ulcer healing with PPIs appears not to be affected. There is also some evidence that omeprazole is more effective at healing NSAID-associated ulceration than misoprostol.[9] Patients at high risk of NSAID-associated gastrointestinal complications, including those with a history of these events, should receive *prophylactic therapy*.[5,6] A systematic review[10] concluded that misoprostol, PPIs, and double-dose H_2 antagonists are effective at preventing chronic NSAID-associated gastric and duodenal ulcers. Standard doses of H_2-antagonists prevent NSAID-associated duodenal ulceration, but appear to be less effective in preventing gastric ulceration. Another systematic review also found that misoprostol, and probably PPIs, were effective in reducing the risk of symptomatic NSAID-associated ulceration, as was the use of specific inhibitors of cyclo-oxygenase-2 such as celecoxib;[11] combination of a cyclo-oxygenase-2 inhibitor with a PPI may be appropriate in very high risk patients.[12] After healing of NSAID-associated ulceration, omeprazole prophylaxis was more effective than ranitidine,[13] and was more effective and better tolerated than misoprostol.[9] Whether *H. pylori* eradication is appropriate in patients receiving long-term NSAIDs remains debatable. There is some evidence that eradication reduces the risk of bleeding in patients who have not previously taken NSAIDs,[2,14] and testing and eradication in patients taking PPIs long-term for prevention of NSAID-induced ulceration has been advocated by an expert consensus, since there is evidence that combination of *H. pylori* infection and long-term acid suppression may accelerate the development of pre-malignant changes in the stomach.[2] However, PPI maintenance is more effective than *H. pylori* eradication in preventing ulcer recurrence or bleeding in patients taking NSAIDs,[2] and there is no convincing evidence that eradication speeds ulcer healing.[14]

Stress ulceration may occur in the stomach or the duodenum following major physical trauma such as burns or surgery, or after severe sepsis or illness. H_2-antagonists and sucralfate are widely used for the prevention of stress ulceration in high-risk patients in intensive care units,[15-17] and is increasingly used, though with little evidence, in less severely ill patients.[18] Pirenzepine is used in a few countries, and some[15] prefer it in neurosurgical patients and those with head trauma. H_2-antagonists may be given by mouth, nasogastric tube, or by the intravenous route (intermittent or continuous). It has been suggested that the rise in gastric pH which results from such use may predispose patients to nosocomial pneumonia due to bacterial overgrowth in the stomach and retrograde colonisation of the pharynx. Sucralfate does not increase gastric pH, and meta-analysis has indicated that it may be as effective as an H_2-antagonist in reducing bleeding, and is associated with lower rates of pneumonia and mortality.[19] The findings of a subsequent large randomised study[20] by the same authors were at odds with those of this meta-analysis, suggesting that intravenous ranitidine was more effective than sucralfate given orally or via nasogastric tube in reducing clinically significant gastrointestinal bleeding. Moreover, there was no difference in rate of ventilator-associated mortality between ranitidine and sucralfate recipients. A further meta-analysis[21] has in turn raised doubts about the efficacy of ranitidine; no significant benefit was found for ranitidine, compared with placebo, in the prevention of bleeding. One clinical guideline suggests that, given the conflicting evidence, the choice between antacids, H_2-antagonists, and sucralfate be made on an institutional basis.[16] PPIs are also used for stress ulcer prophylaxis, although the evidence base for such use is lacking.[17]

Bleeding ulcer. Peptic ulceration is responsible for about 50% of all cases of upper gastrointestinal bleeding: the condition is potentially life-threatening and in severe cases prompt resuscitation with intravenous fluids and blood may be required. About 80% of patients will stop bleeding spontaneously without recurrence, but the remaining 20% are at risk of severe morbidity or death,[22] and early stratification into low- and high-risk categories on the basis of clinical and endoscopic criteria is important for proper management.[22,23] No treatment may be needed for low-risk patients, but those with a clot in an ulcer bed should undergo irrigation and appropriate treatment of the underlying lesion, and high-risk patients should be given immediate endoscopic injection therapy for haemostasis.[22]

Many different solutions have been used for endoscopic injection, including adrenaline (alone or with sclerosants such as monoethanolamine or lauromacrogol), alcohol, fibrin glue, sodium tetradecyl sulfate, thrombin, or saline (normal or hypertonic); none has been clearly shown to be superior.[22] Adrenaline injection will achieve haemostasis in up to 95% of patients although bleeding will recur in up to 20% of these; there is little evidence that addition of sclerosants reduces the rate of rebleeding, and their use may lead to life-threatening necrosis of the injected area.[23] Thermal, laser, or multipolar (coaptive) or plasma electrocoagulative endoscopic techniques are also of benefit, and again there is no clear evidence to prefer one over another.[22] Combining injection with thermal coagulation may be of greater benefit than either alone; UK guidelines consider it may be better in a subset of patients with active arterial bleeding, although it is not considered to offer additional benefit in most patients,[23] while subsequent Canadian guidelines consider the combination superior.[22] The use of mechanical clips may also be effective,[22,23] especially for actively bleeding large vessels.[23] If endoscopic treatments fail to stop bleeding, or rebleeding occurs, further endoscopic therapy may be considered, but otherwise patients require surgery.[22,23]

There is good evidence from systematic review[24] that treatment with PPIs reduces rebleeding and surgery in patients with acute bleeding peptic ulcers; one such review did not show reduced mortality,[24] although others consider it to have been demonstrated.[22] An intravenous bolus of a PPI followed by continuous infusion is recommended in patients who have undergone successful endoscopic therapy.[22,23] There is no evidence that any PPI is superior to others.[22,25] Some suggest that high-dose PPI therapy (oral or intravenous, depending on the degree of risk) should also be considered in patients awaiting endoscopy.[22]

In contrast, there is no evidence that H_2-antagonists are of benefit in the treatment of acute nonvariceal bleeding, and somatostatin, octreotide, or tranexamic acid are not recommended.[22,23]

Eradication of *H. pylori* is recommended in those patients positive for the organism;[22,23] eradication therapy is superior to antisecretory drugs alone in preventing rebleeding.[26]

Zollinger-Ellison syndrome

Zollinger-Ellison syndrome is a rare disorder characterised by the presence of a gastrin-producing tumour (gastrinoma), which leads to hypersecretion of gastric acid and consequent peptic ulcer disease (often with complications such as perforation or bleeding), diarrhoea, or malabsorption. Gastrinomas usually occur in the non-beta islet cells of the pancreas or in the duodenal wall. Up to two-thirds are malignant. About 20 to 25% of cases are seen in patients with multiple endocrine neoplasia type 1 (MEN-1) syndrome.

Initial treatment is aimed at controlling the hypersecretion of gastric acid with an antisecretory drug. Giving enough medication just to control symptoms is not considered adequate, and it is important that acid secretion is reduced below 10 mmol/hour. Intravenous H_2-antagonists or proton pump inhibitors may be required initially. Once the symptoms have been controlled the tumour can be investigated for surgical removal. When complete removal is not possible then antisecretory therapy is continued indefinitely. A proton pump inhibitor is the drug of choice; it profoundly reduces acid secretion with once- or twice-daily use, although relatively high doses are required compared with those used in other conditions. An H_2-antagonist such as cimetidine or ranitidine may be used as an alternative to omeprazole, and, as with omeprazole, daily doses are higher than those used for other conditions; they are given in 3 or 4 divided doses. The somatostatin analogue octreotide can be used to reduce serum gastrin, but has to be given subcutaneously, and is not well tolerated.

Parietal cell vagotomy may be performed to reduce acid secretion if the tumour is not found, to allow lower doses of antisecretory drugs to be used.

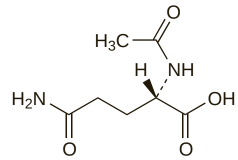
Aceglutamide Aluminium *(USAN, rINNM)*

Aceglutamida de aluminio; Acéglutamide d'Aluminium; Aluminii Aceglutamidum; KW-110. Pentakis (N^2-acetyl-L-glutaminato)tetrahydroxytrialuminium.

Алюминий Ацеглутамид

$C_{35}H_{59}Al_3N_{10}O_{24}$ = 1084.8.

CAS — 12607-92-0.



(aceglutamide)

Pharmacopoeias. In *Jpn.*

Profile

Aceglutamide aluminium, a complex of aceglutamide with aluminium hydroxide, is an antacid with general properties similar to those of aluminium hydroxide (p.1706). It is given orally in a usual dose of 700 mg three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Jpn: Glumal.

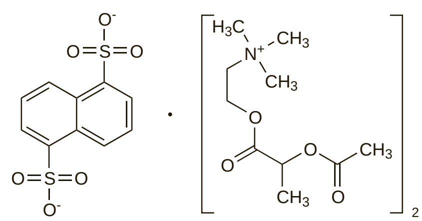
Aclatonium Napadisilate *(BAN, rINN)*

Aclatonii Napadisilas; Aclatonium Napadisylate; Celatonium Napadisilate; Choline Naphthalene-1,5-Disulphonate (2:1) Dilactate Diacetate; Napadisilate d'Aclatonium; Napadisilato de aclatonio; SKF-100916-J; TM-723. 2-(2-Acetoxypropionyloxy)ethyltrimethylammonium naphthalene-1,5-disulphonate (2:1).

Аклатония Нападизилат

$2C_{10}H_{20}NO_4,C_{10}H_6O_6S_2$ = 722.8.

CAS — 55077-30-0.



Profile

Aclatonium napadisilate is a cholinergic agonist given orally for its prokinetic properties in the management of decreased gastrointestinal motility (p.1694) after gastrointestinal surgery, and to relieve symptoms of biliary dyskinesia and chronic gastritis.

Preparations

Proprietary Preparations (details are given in Part 3)
Jpn: Abovis.

Аликафорсен

$C_{192}H_{244}N_{75}O_{98}P_{19}S_{19}$ = 6368.2.

CAS — 185229-68-9.

Alicaforsen Sodium *(USAN, rINNM)*

Alicaforsen Nonadecasodium; Alicaforsén sódico; Alicaforsen Sodique; Alicaforsenum Natricum; Isis-2302.

Аликафорсен Натрий

$C_{192}H_{225}N_{75}Na_{19}O_{98}P_{19}S_{19}$ = 6785.8.

CAS — 331257-52-4.

Profile

Alicaforsen is an antisense oligonucleotide that inhibits the production of the cellular adhesion molecule ICAM-1, which plays a role in the inflammatory response involved in inflammatory bowel disease. It has been tried in ulcerative colitis and pouchitis, and with less success in Crohn's disease.

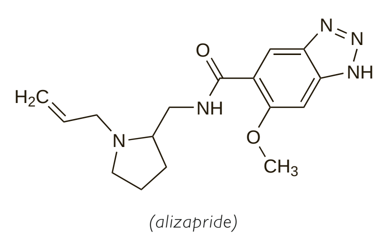
Alizapride Hydrochloride *(rINNM)*

Alizapride, Chlorhydrate d'; Alizapridi Hydrochloridum; Hidrocloruro de alizaprida. *N*-(1-Allyl-2-pyrrolidinylmethyl)-6-methoxy-1*H*-benzotriazole-5-carboxamide hydrochloride.

Ализаприда Гидрохлорид

$C_{16}H_{21}N_5O_2,HCl$ = 351.8.

CAS — 59338-93-1 (alizapride); 59338-87-3 (alizapride hydrochloride).
ATC — A03FA05.
ATC Vet — QA03FA05.



(alizapride)

Adverse Effects and Precautions

As for Metoclopramide, (see p.1748).

Pharmacokinetics

Alizapride is well absorbed from the gastrointestinal tract. It is mainly excreted unchanged in the urine and has an elimination half-life of about 3 hours.

Uses and Administration

Alizapride is a substituted benzamide similar to metoclopramide (p.1749), which is used to control nausea and vomiting (p.1700) associated with a variety of disorders. It is given as the hydrochloride but doses are expressed in terms of the base. Alizapride 50 mg is equivalent to about 55.8 mg of alizapride hydrochloride.

Alizapride hydrochloride is given in usual oral doses equivalent to 75 to 300 mg of alizapride daily in divided doses. For children's doses, see below. It is also given by intravenous or intramuscular injection in doses equivalent to 50 to 200 mg of alizapride daily.

For patients receiving cancer chemotherapy usual daily doses equivalent to alizapride 2 to 5 mg/kg have been given intravenously or intramuscularly in 2 divided doses, one 30 minutes before and one 4 to 8 hours after the cytotoxic regimen. For highly emetic regimens requiring doses above 5 mg/kg it may be given by intravenous infusion over 15 minutes every 2 hours for 5 doses, starting 30 minutes before the cytotoxic. It has been recommended that the total dose given with a course of chemotherapy does not exceed 4.5 g.

Administration in children. Alizapride hydrochloride has been given to children for the symptomatic treatment of nausea and vomiting in oral doses equivalent to 5 mg/kg of alizapride daily.

Preparations

Almagate *(BAN, USAN, rINN)*

Almagaatti; Almagát; Almagat; Almagatas; Almagato; Almagatum; LAS-3876. Aluminium trimagnesium carbonate heptahydroxide dihydrate.

Альмагат

$AlMg_3(CO_3)(OH)_7,2H_2O = 315.0.$
CAS — 66827-12-1 (almagate); 72526-11-5 (anhydrous almagate).
ATC — A02AD03.
ATC Vet — QA02AD03.

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Almagate). A white or almost white, fine crystalline powder. It contains 15.0 to 17.0% aluminium calculated as aluminium oxide, 36.0 to 40.0% magnesium calculated as magnesium oxide, and 12.5 to 14.5% carbonic acid calculated as carbon dioxide. Practically insoluble in water, in alcohol, and in dichloromethane. It dissolves with effervescence and heating in dilute mineral acids. The filtrate of a 4% suspension in water has a pH of 9.1 to 9.7. Store in airtight containers.

Profile

Almagate is a hydrated aluminium-magnesium hydroxycarbonate. It is an antacid with general properties similar to those of aluminium hydroxide (p.1706) and magnesium carbonate (p.1743). It is given orally in doses of 1 to 1.5 g.

Preparations

Proprietary Preparations (details are given in Part 3)
Mex.: Almax; ***Spain:*** Almax; Deprece†; Obetine.

Almasilate *(BAN, rINN)*

Almasilato; Almasilatum; Aluminium Magnesium Silicate Hydrate; Magnesium Aluminosilicate Hydrate; Magnesium Aluminum Silicate Hydrate.

Алмазилат

$Al_2O_3.MgO.2SiO_2,xH_2O = 262.4$ (anhydrous).
CAS — 71205-22-6; 50958-44-6.
ATC — A02AD05.
ATC Vet — QA02AD05.

Profile

Almasilate is an artificial form of aluminium magnesium silicate hydrate. It is an antacid (p.1692) that is given orally in doses of up to about 1 g.

A hydrated native aluminium magnesium silicate (p.2141) is used as a suspending, thickening, and stabilising agent in pharmaceutical preparations. Attapulgite (p.1709) is another native form.

Preparations

Proprietary Preparations (details are given in Part 3)
Austria: Gelusil†; ***Ger.:*** Gelusil; Megalac; Simagel; ***Spain:*** Alubifar.

Алоэ Барбадосское (Barbados aloes); Алоэ Капское (Cape aloes)
CAS — 8001-97-6; 67479-27-0 (aloe gum).

NOTE. Do not confuse with Aloe vera (p.1588).

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US.*
Ph. Eur. 6.2 (Aloes, Barbados; Aloe barbadensis). The concentrated and dried juice of the leaves of *Aloe barbadensis.* It contains not less than 28% of hydroxyanthracene derivatives expressed as barbaloin and calculated with reference to the dried drug. Dark brown masses, slightly shiny or opaque with a conchoidal fracture, or a brown powder. Partly soluble in boiling water; soluble in hot alcohol. Store in airtight containers. Protect from light.
The BP 2008 lists Curaçao Aloes as an approved synonym.
Ph. Eur. 6.2 (Aloes, Cape; Aloe capensis). The concentrated and dried juice of the leaves of various species of *Aloe*, mainly *Aloe ferox* and its hybrids. It contains not less than 18% of hydroxyanthracene derivatives expressed as barbaloin and calculated with reference to the dried drug. Dark brown masses tinged with green and having a shiny conchoidal fracture, or a greenish-brown powder. Partly soluble in boiling water; soluble in hot alcohol; practically insoluble in ether. Store in airtight containers. Protect from light.
USP 31 (Aloe). The dried latex of the leaves of *Aloe barbadensis* (*A. vera*) known in commerce as Curaçao Aloe, or of *A. ferox* and its hybrids, known in commerce as Cape Aloe (Liliaceae). It yields not less than 50% of water-soluble extractive. It has a characteristic, somewhat sour and disagreeable, odour. Curaçao Aloe is brownish-black, opaque masses with a fractured, uneven, waxy, and somewhat resinous surface. Cape Aloe is dusty to dark brown irregular masses, the surfaces of which are often covered with a yellowish powder. Its fracture is smooth and glassy.

Adverse Effects and Precautions

As for Senna, p.1769, although aloes has a more drastic and irritant action.

Uses and Administration

Aloes is an anthraquinone stimulant laxative (p.1693) but other less toxic drugs are generally preferred.

Homoeopathy. Aloes have been used in homoeopathic medicines under the following names: Aloe; Cape aloes; Aloe capensis; Aloe socotrina; Alo. soc.

Preparations

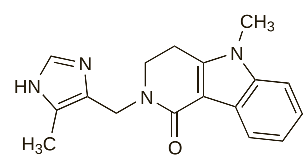
Alosetron Hydrochloride *(BANM, USAN, rINNM)*

Alosétron, Chlorhydrate d'; Alosetroni Hydrochloridum; GR-68755C; Hidrocloruro de alosetrón. 2,3,4,5-Tetrahydro-5-methyl-2-[(5-methyl-imidazol-4-yl)methyl]-1*H*-pyrido[4,3-*b*]indol-1-one hydrochloride.

Алосетрона Гидрохлорид

$C_{17}H_{18}N_4O,HCl = 330.8.$
CAS — 122852-42-0 (alosetron); 122852-69-1 (alosetron hydrochloride).
ATC — A03AE01.
ATC Vet — QA03AE01.



(alosetron)

Adverse Effects

Serious gastrointestinal adverse effects have occurred with alosetron, and as a result, it was withdrawn from the market in the USA and subsequently reintroduced with more restricted indications. These adverse effects include severe constipation leading to obstruction, ileus, perforation, impaction, toxic megacolon, and secondary ischaemia, as well as ischaemic colitis. Fatalities have been reported.

Other gastrointestinal effects reported include abdominal distension and pain, nausea, reflux, and haemorrhoids. Adverse effects reported rarely include cardiac arrhythmias, cholecystitis, altered bilirubin levels, tremor, headache, myalgia, malaise, fatigue, and CNS effects such as confusion, anxiety, depression, and sedation. Urticaria, skin reactions, nail disorders, and alopecia can occur. Hyperglycaemia, hypoglycaemia, and disorders of calcium and phosphate metabolism have been reported.

Incidence of adverse effects. The incidence of serious gastrointestinal adverse effects with alosetron has been reviewed.[1] Pooled data from clinical studies suggested that the rate of ischaemic colitis in patients taking alosetron was about 0.15%, or 6.4 cases per 1000 patient-years. Results from postmarketing surveillance (before and after its temporary withdrawal from the

US market) were estimated to represent a rate of 1 case per 1000 patient-years. Serious complications of constipation did not seem to be increased in the population of alosetron users.

1. Chang L, *et al.* Incidence of ischemic colitis and serious complications of constipation among patients using alosetron: systematic review of clinical trials and post-marketing surveillance data. *Am J Gastroenterol* 2006; **101:** 1069–79.

Precautions

Alosetron should be stopped immediately in patients who develop constipation or symptoms of ischaemic colitis such as new or worsening abdominal pain or blood in the stool. Treatment with alosetron should not be resumed in patients who develop ischaemic colitis.

Alosetron should not be used in patients with a history of severe or chronic constipation, intestinal obstruction or stricture, toxic megacolon, or gastrointestinal perforation or adhesions. It is also contra-indicated in patients with a history of ischaemic colitis, impaired intestinal circulation, thrombophlebitis, or hypercoagulable state, and those with current or previous inflammatory bowel disease or diverticulitis.

Alosetron should not be used in those with severe hepatic impairment or a history thereof; it should be used with caution in patients with mild to moderate hepatic impairment. Elderly patients may be at increased risk of severe complications if constipation develops.

Interactions

Plasma concentrations of alosetron are markedly increased, and its half-life prolonged roughly threefold, when given with fluvoxamine; such a combination should be avoided. Licensed product information recommends that use with other more moderate inhibitors of cytochrome P450 isoenzyme CYP1A2 (such as quinolone antibacterials and cimetidine) should be avoided unless clinically necessary, because of the risk of similar interactions. Ketoconazole also increases plasma alosetron concentrations; care should be taken if alosetron is used with this or other potent inhibitors of the CYP3A4 isoenzyme (including clarithromycin, telithromycin, HIV-protease inhibitors, voriconazole, and itraconazole).

Pharmacokinetics

Alosetron is rapidly absorbed from the gastrointestinal tract; peak plasma concentrations are reached about 1 hour after an oral dose. Plasma concentrations are 30 to 50% lower in men than in women given the same oral dose; clearance is lower in women. Bioavailability is about 60%; the extent and rate of absorption are slightly reduced by food. Plasma protein binding is about 82%. Alosetron is extensively metabolised via cytochrome P450 isoenzymes, particularly CYP1A2, although CYP2C9 and CYP3A4 also play a role. Numerous metabolites are excreted in the urine and faeces; only 6% of a dose is recovered unchanged from the urine. The terminal elimination half-life of alosetron is reported to be about 1.5 hours.

◊ References.

Uses and Administration

Alosetron is a 5-HT_3 antagonist used in the treatment of severe diarrhoea-predominant irritable bowel syndrome (p.1699) in women who have not responded to conventional therapy; effectiveness in men has not been established. It is given orally as the hydrochloride but doses are expressed in terms of the base; alosetron hydrochloride 1.12 mg is equivalent to about 1 mg of alosetron.

The initial dose is the equivalent of alosetron 500 micrograms twice daily for 4 weeks; if tolerated, the dose may then be increased if necessary to 1 mg twice daily. If symptoms are not adequately controlled after 4 weeks of treatment with the higher dose, alosetron should be stopped.

Basic Aluminium Carbonate

Aluminium Hydroxycarbonate; Aluminum Carbonate, Basic *(USAN)*; Carbonato básico de aluminio.

Основный Углекислый Алюминий

Profile

Basic aluminium carbonate is a combination of aluminium hydroxide and aluminium carbonate. It is an antacid with general properties similar to those of aluminium hydroxide (below).

Basic aluminium carbonate has also been given orally as a phosphate binder in the treatment of hyperphosphataemia. For a discussion of the choice of phosphate binders, see Renal Osteodystrophy, p.1086.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Port.:*** Gastropensan.

Aluminium Formate

Aluminium Triformate.

Муравьинокислый Алюминий; Формиат Алюминия

$Al(CHO_2)_3,3H_2O = 216.1.$

CAS — 7360-53-4 (anhydrous aluminium formate).

Profile

Aluminium formate has astringent properties and has been used in topical preparations for mouth disorders.

ATC Vet — QA02AB07.

Pharmacopoeias. In *Br.* and *US.*

BP 2008 (Aluminium Glycinate). A white or almost white, odourless or almost odourless, powder. It contains 34.5 to 38.5% of Al_2O_3 calculated on the dried substance, and not more than 12% loss of weight on drying. Practically insoluble in water and in organic solvents; it dissolves in dilute mineral acids and in aqueous solutions of alkali hydroxides. A 4% suspension in water has a pH of 6.5 to 7.5.

USP 31 (Dihydroxyaluminum Aminoacetate). A white, odourless, powder. It may contain small amounts of aluminium oxide and aminoacetic acid. It loses not more than 14.5% of its weight on drying. Insoluble in water and in organic solvents; soluble in dilute mineral acids and in solutions of fixed alkalis. A 4% suspension in water has a pH of 6.5 to 7.5.

Profile

Aluminium glycinate is an antacid with general properties similar to those of aluminium hydroxide (below). It has been given in doses of up to 1 g by mouth.

Preparations

USP 31: Dihydroxyaluminum Aminoacetate Magma.

Proprietary Preparations (details are given in Part 3)

Алюминий Гидроксид

CAS — 21645-51-2 [$Al(OH)_3$].

ATC — A02AB01.

ATC Vet — QA02AB01.

NOTE. Algeldrate (*USAN*, *pINN*) is defined as a hydrated aluminium hydroxide with the general formula of $Al(OH)_3,xH_2O$.

Compounded preparations of aluminium hydroxide may be represented by the following names:

- Co-magaldrox *x/y* (*BAN*)—where *x* and *y* are the strengths in milligrams of magnesium hydroxide and aluminium hydroxide respectively.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Aluminium Oxide, Hydrated; Dried Aluminium Hydroxide BP 2008). It contains the equivalent of 47 to 60% Al_2O_3. It is a white or almost white, amorphous powder. Practically insoluble in water; it dissolves in dilute mineral acids and in solutions of alkali hydroxides. Store in airtight containers at a temperature not exceeding 30°.

Ph. Eur. 6.2 (Aluminium Hydroxide, Hydrated, for Adsorption; Aluminii Hydroxidum Hydricum ad Adsorptionem). A white or almost white, translucent, viscous, colloidal gel. A supernatant may be formed upon standing. A clear or almost clear solution is obtained with alkali hydroxide solutions and with mineral acids. pH 5.5 to 8.5. Store at a temperature not exceeding 30°. Do not allow to freeze.

USP 31 (Aluminum Hydroxide Gel). A suspension of amorphous aluminium hydroxide in which there is a partial substitution of carbonate for hydroxide. It is a white viscous suspension from which small amounts of clear liquid may separate on standing. It has a pH of between 5.5 and 8.0. Store in airtight containers. Avoid freezing.

USP 31 (Dried Aluminum Hydroxide Gel). An amorphous form of aluminium hydroxide in which there is a partial substitution of carbonate for hydroxide. It contains the equivalent of not less than 76.5% of $Al(OH)_3$ and may contain varying quantities of basic aluminium carbonate and bicarbonate. The labelling requirements states that 1 g of dried aluminium hydroxide gel is equivalent to 765 mg of $Al(OH)_3$. It is a white, odourless, tasteless, amorphous powder. Insoluble in water and in alcohol; soluble in dilute mineral acids and in solutions of fixed alkali hydroxides. A 4% aqueous dispersion has a pH of not more than 10.0. Store in airtight containers.

Adverse Effects and Precautions

Aluminium hydroxide, like other aluminium compounds, is astringent and may cause constipation; large doses can cause intestinal obstruction.

Excessive doses, or even normal doses in patients with low-phosphate diets, may lead to phosphate depletion accompanied by increased bone resorption and hypercalciuria with the risk of osteomalacia.

Aluminium salts are not, in general, well absorbed from the gastrointestinal tract, and systemic effects are therefore rare in patients with normal renal function. However, care is necessary in patients with chronic renal impairment: osteomalacia or adynamic bone disease, encephalopathy, dementia, and microcytic hypochromic anaemia have been associated with aluminium accumulation in such patients given large doses of aluminium hydroxide as a phosphate-binding agent. Similar adverse effects have also been associated with the aluminium content of dialysis fluids.

Aluminium hydroxide used as an adjuvant in adsorbed vaccines has been associated with the formation of granulomas.

Children. For the suggestion that aluminium-containing antacids should not be used in infants, see Toxicity, below.

Porphyria. Aluminium hydroxide is considered by some to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals.*

UK licensed product information states that aluminium hydroxide may be unsafe in patients with porphyria undergoing haemodialysis.

Toxicity. References to aluminium toxicity in dialysis patients and the possible association between aluminium ingestion and Alzheimer's disease are included under Aluminium (see p.2254).

Aluminium accumulation does not generally appear to be significant in patients with normal renal function taking therapeutic doses of aluminium-containing antacids, and there is little evidence that such antacids are a risk factor for Alzheimer's disease.[1] Elevated plasma-aluminium concentrations have been reported in infants with normal renal function given aluminium-containing antacids but there were no obvious signs of toxicity.[2] There have, however, been reports of phosphate depletion and rickets in a few infants caused by the use of antacids containing magnesium and aluminium hydroxides. In these cases the antacid had been started within a few months of birth and continued for up to 8 months. In reports that described a total of 3 infants,[3,4] the authors suggested that the use of soya-based infant feeding formulas, the phytates of which can interfere with mineral absorption, may have exacerbated the phosphate-binding effect of the antacid. In another case[5] a dosing error resulted in the infant receiving an excessive dose of antacid for 6 months. The *BNFC* advises against the use of any aluminium-containing antacid in neonates and infants.

Aluminium accumulation resulting in osteomalacia or encephalopathy with seizures and dementia has been reported in children with renal failure (but not on dialysis) treated with aluminium-containing phosphate binders.[6-10] In an adult male patient with severe chronic renal failure who was not on dialysis, self-medication with antacids for at least 3 years resulted in aluminium toxicity associated with encephalopathy, bone disease, and microcytic anaemia.[11] Aluminium-containing antacids should therefore be used with caution in patients with chronic renal failure, especially in children.

Oral citrate salts increase the absorption of aluminium from the gastrointestinal tract[12] and patients with renal failure taking aluminium compounds should avoid citrate-containing preparations, which include many effervescent or dispersible tablets.[13,14] Ascorbic acid has also been reported to enhance aluminium absorption.[15]

Interactions

As outlined on p.1692, aluminium compounds used as antacids interact with many other drugs, both by alterations in gastric pH and emptying, and by direct adsorption and formation of complexes that are not absorbed. Interactions can be minimised by giving the aluminium compound and any other medication 2 to 3 hours apart. The absorption of aluminium from the gastrointestinal tract may be enhanced if aluminium compounds are taken with citrates or ascorbic acid (see Toxicity, above).

Pharmacokinetics

Aluminium hydroxide, given orally, slowly reacts with the hydrochloric acid in the stomach to form soluble aluminium chloride, some of which is absorbed. The presence of food or other factors that decrease gastric emptying prolongs the availability of aluminium hydroxide to react and may increase the amount of aluminium chloride formed. About 100 to 500 micrograms of the cation is reported to be absorbed from standard daily doses of an aluminium-containing antacid, leading to about a doubling of usual aluminium concentrations in the plasma of patients with normal renal function.

Absorbed aluminium is eliminated in the urine, and patients with renal failure are therefore at particular risk of accumulation (especially in bone and the CNS), and aluminium toxicity (see above).

The aluminium compounds remaining in the gastrointestinal tract, which account for most of a dose, form insoluble, poorly absorbed aluminium salts in the intestines including hydroxides, carbonates, phosphates and fatty acid derivatives, which are excreted in the faeces.

Uses and Administration

Aluminium hydroxide is used as an antacid (p.1692). It is given orally in doses of up to about 1 g, between meals and at bedtime. In order to reduce the constipating effects, aluminium hydroxide is often given with a magnesium-containing antacid, such as magnesium oxide or magnesium hydroxide.

Aluminium hydroxide binds phosphate in the gastrointestinal tract to form insoluble complexes and reduces phosphate absorption. It may thus be used to treat hyperphosphataemia in patients with chronic renal failure (although aluminium accumulation may be a problem—see Renal Osteodystrophy, p.1086) or associated secondary hyperparathyroidism (p.1087). With this use the dose must be adjusted to the individual patient's requirement but up to about 10 g daily may be given orally in divided doses with meals.

Aluminium hydroxide is also used as an adjuvant in adsorbed vaccines.

Polymyositis and dermatomyositis. Corticosteroids form the basis of the management of polymyositis (p.1510) but the calcinosis that may occur in dermatomyositis does not always respond well. Aluminium hydroxide 1.68 to 2.24 g daily produced clinical improvement with complete clearing of most calcified nodules after 1 year in a patient with calcinosis cutis complicating juvenile dermatomyositis.[1] The calcified masses are made up of hydroxyapatite and amorphous calcium phosphate and reduction in phosphate absorption by aluminium hydroxide probably helped to reverse their formation. Subsequent cases[2,3] have also reported benefit from aluminium hydroxide treatment in the management of calcinosis.

Aluminium Hydroxide-Magnesium Carbonate Co-dried Gel

F-MA 11; Hidróxido de aluminio y carbonato de magnesio desecado, gel de.

Profile

Aluminium hydroxide-magnesium carbonate co-dried gel is a co-precipitate of aluminium hydroxide and magnesium carbonate dried to contain a proportion of water for antacid activity. It is an antacid with general properties similar to those of aluminium hydroxide (above) and magnesium carbonate (p.1743). It has been given in oral doses of about 450 to 900 mg, usually 3 times daily after meals and before bedtime.

Алюминия Фосфат

CAS — 7784-30-7 ($AlPO_4$).

ATC — A02AB03.

ATC Vet — QA02AB03.

Pharmacopoeias. In *Viet.*

Eur. (see p.vii) includes hydrated aluminium phosphate and also a gel. *US* includes as a gel.

Ph. Eur. 6.2 (Aluminium Phosphate, Hydrated; Aluminii Phosphas Hydricus; Dried Aluminium Phosphate BP 2008). A white or almost white powder. Very slightly soluble in water; practically insoluble in alcohol. It dissolves in dilute solutions of alkali hydroxides and mineral acids. A 4% suspension in water has a pH of 5.5 to 7.2. Store in airtight containers.

Ph. Eur. 6.2 (Aluminium Phosphate Gel; Aluminii Phosphatis Liquamen). It is aluminium phosphate in gel form containing 19 to 21% of $AlPO_4$. Practically insoluble in water, in alcohol, and in dichloromethane. It dissolves in dilute solutions of mineral acids. pH 6.0 to 8.0. Store in airtight containers.

USP 31 (Aluminum Phosphate Gel). A 4 to 5% suspension of aluminium phosphate ($AlPO_4$) in water and has a pH of 6.0 to 7.2. It is a white viscous suspension from which small amounts of water separate on standing. Store in airtight containers.

Profile

Aluminium phosphate is an antacid with general properties similar to those of aluminium hydroxide (p.1706), but it does not produce phosphate depletion.

Aluminium phosphate is also used as an adjuvant in adsorbed vaccines.

Preparations

USP 31: Aluminum Phosphate Gel.

Alverine Citrate *(BANM, USAN, rINNM)*

Alvérine, citrate d'; Alverini citras; Citrato de alverina; Dipropyline Citrate; Phenpropamine Citrate. *N*-Ethyl-3,3′-diphenyldipropylamine citrate.

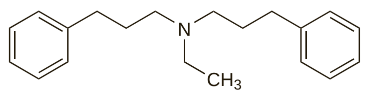
Альверина Цитрат

$C_{20}H_{27}N,C_6H_8O_7$ = 473.6.

CAS — 150-59-4 (alverine); 5560-59-8 (alverine citrate).

ATC — A03AX08.

ATC Vet — QA03AX08.



(alverine)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Alverine Citrate). A white or almost white crystalline powder. Slightly soluble in water and in dichloromethane; sparingly soluble in alcohol. A 0.5% solution in water has a pH of 3.5 to 4.5. Protect from light.

Adverse Effects and Precautions

Nausea, headache, pruritus, rash, and dizziness have been reported. Allergic reactions, including anaphylaxis, have also occurred. Alverine is contra-indicated in patients with intestinal obstruction or paralytic ileus.

Effects on the liver. Acute hepatitis was attributed to alverine citrate in 2 separate cases.[1,2] Evidence of an immune reaction, including antinuclear antibodies, was found in 1 case.[1]

1. Malka D, *et al.* Acute hepatitis caused by alverine associated with anti-lamin A and C autoantibodies. *J Hepatol* 1997; **27:** 399–403.
2. Arhan M, *et al.* Alverine citrate induced acute hepatitis. *World J Gastroenterol* 2004; **10:** 2303–4.

Pharmacokinetics

Alverine is absorbed from the gastrointestinal tract after oral doses and is rapidly metabolised to an active metabolite, peak plasma concentrations of which occur 1 to 1.5 hours after an oral dose. Further metabolism to inactive metabolites occurs; metabolites are excreted in the urine by active renal secretion.

Uses and Administration

Alverine is an antispasmodic that acts directly on intestinal and uterine smooth muscle. It is used for the relief of smooth muscle spasm in the treatment of gastrointestinal disorders such as irritable bowel syndrome (p.1699). It is also used in the treatment of dysmenorrhoea (p.6).

Alverine citrate is given to adults and adolescents from the age of 12 years in oral doses of 60 to 120 mg one to three times daily. Alverine has also been given by suppository as the base. Alverine citrate 67.3 mg is equivalent to about 40 mg of alverine.

Irritable bowel syndrome. Alverine citrate is widely used as an antispasmodic in the management of irritable bowel syndrome. However, a 12-week study[1] in 107 patients found that alverine citrate was no better than placebo for the relief of symptoms and improvement in general well-being. A marked placebo effect occurred and symptomatic improvement was reported by at least half the placebo group.

1. Mitchell SA, *et al.* Alverine citrate fails to relieve the symptoms of irritable bowel syndrome: results of a double-blind, randomized, placebo-controlled trial. *Aliment Pharmacol Ther* 2002; **16:** 1187–95.

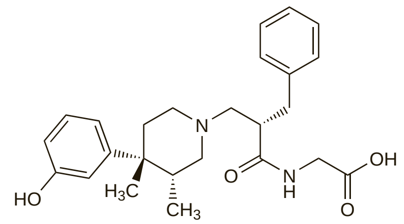
CAS — 156053-89-3 (anhydrous alvimopan); 170098-38-1 (alvimopan dihydrate).



(anhydrous alvimopan)

Profile

Alvimopan is a peripherally acting selective antagonist of opioid μ-receptors that is used in the treatment of postoperative ileus. It is given in a 12-mg oral dose between 30 minutes and up to 5 hours before surgery followed by 12 mg twice daily beginning the day after surgery for a maximum of 7 days. Alvimopan is also under investigation for opioid-induced constipation.

Aprepitant *(USAN, rINN)*

Aprépitant; Aprepitantum; L-754030; MK-869; MK-0869. 3-[((2*R*,3*S*)-3-(*p*-Fluorophenyl)-2-{[(α*R*)-α-methyl-3,5-bis(trifluoromethyl)benzyl]oxy}morpholino)methyl]-Δ^2-1,2,4-triazolin-5-one.

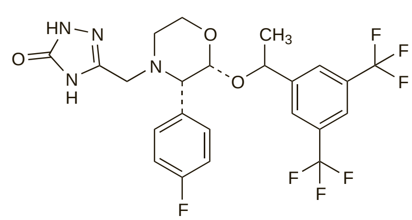
Апрепитант

$C_{23}H_{21}F_7N_4O_3$ = 534.4.

CAS — 170729-80-3.

ATC — A04AD12.

ATC Vet — QA04AD12.



Adverse Effects and Precautions

The most common adverse effects associated with aprepitant are headache, constipation, diarrhoea, dyspepsia, anorexia, fatigue, hiccups, eructation, and dizziness. Increases in alanine aminotransferase (ALT) or aspartate aminotransferase (AST) concentrations are common. Other reported effects have included abdominal pain, oedema, tinnitus, and flushing. Epigastric discomfort, dysgeusia, dry mouth, and stomatitis have also occurred. Thirst, polyuria, dysuria, haematuria, urinary frequency, arthralgia, myalgia, bradycardia, hyperglycaemia, disorientation, euphoria, anxiety, photosensitivity, and skin disorders have been reported. Anaemia and febrile neutropenia may occur. Other adverse effects reported include hypertension or hypotension, hyponatraemia, hypokalaemia, insomnia, miosis, reduced visual acuity, weight changes, sensory disturbances, throat irritation, sneezing, abnormal bowel sounds, acid reflux, perforating duodenal ulcer, dyspnoea, cough, wheezing, and hyperhidrosis. Conjunctivitis, pharyngitis, respiratory-tract infections, urinary-tract infections, candidiasis, and herpes simplex can occur. Stevens-Johnson syndrome and angioedema with urticaria have been reported.

Licensed product information recommends caution in patients with severe hepatic impairment as clinical data are lacking in this patient group.

Interactions

During its use for 3 or 4 days in the prevention of nausea and vomiting associated with cancer chemotherapy, aprepitant produces moderate inhibition of the cytochrome P450 isoenzyme CYP3A4. Exposure to oral CYP3A4 substrates may increase substantially; the effect of aprepitant on intravenous CYP3A4 substrates is expected to be less. However, on cessation of aprepitant a transient mild induction of CYP3A4 may become apparent with a maximum effect reached 3 to 5 days later; this effect is maintained for a few days then slowly declines and is clinically insignificant about 2 weeks after stopping aprepitant. Caution is therefore required when using it with drugs that are primarily metabolised by this isoenzyme. Aprepitant should not be given with astemizole, cisapride, pimozide, or terfenadine as increased plasma concentrations of these drugs could cause serious life-threatening reactions. As aprepitant is also a substrate for CYP3A4, other drugs that inhibit or induce this isoenzyme may in turn increase or decrease plasma concentrations of aprepitant.

When aprepitant is used to prevent postoperative nausea and vomiting, in a single lower dose than that used with cancer chemotherapy, the effect of aprepitant on CYP3A4 is not expected to be clinically significant.

Aprepitant also causes a delayed induction of CYP2C9 and may lower plasma concentrations of drugs metabolised by this isoenzyme, such as warfarin, phenytoin, or tolbutamide.

Aprepitant may increase systemic exposure to corticosteroids; when given together it is recommended that the usual dose of oral dexamethasone be reduced by 50%, and the dose of methylprednisolone by about 25% when given intravenously, and by 50% when given orally. It should be noted that the dose of dexamethasone in the regimens recommended for nausea and vomiting associated with cancer chemotherapy already accounts for this interaction (see Administration, below).

The efficacy of oral contraceptives might be reduced by aprepitant. Licensed product information suggests that alternative methods of contraception should be used during and for 1 to 2 months after stopping any dose of aprepitant.

Pharmacokinetics

Aprepitant is absorbed from the gastrointestinal tract with peak plasma concentrations achieved after about 4 hours. Bioavailability is about 60% at usual doses. It crosses the blood-brain barrier; plasma protein binding is reported to be more than 95%. Aprepitant undergoes extensive hepatic metabolism, mainly via oxidation by the cytochrome P450 isoenzyme CYP3A4; the isoenzymes CYP1A2 and CYP2C19 mediate minor metabolic pathways. The resultant metabolites have weak activity and are excreted in the urine and in the faeces. Aprepitant is not excreted unchanged in the urine. The terminal half-life is about 9 to 13 hours.

◊ References.

1. Majumdar AK, *et al.* Pharmacokinetics of aprepitant after single and multiple oral doses in healthy volunteers. *J Clin Pharmacol* 2006; **46:** 291–300.

Uses and Administration

Aprepitant is a neurokinin-1 (NK_1) receptor antagonist used in the management of nausea and vomiting (p.1700). It is given orally in doses up to 125 mg, with a corticosteroid and a 5-HT_3 antagonist, in the prevention of acute and delayed nausea and vomiting associated with highly emetogenic or moderately emetogenic cancer chemotherapy (for details, see Administration, below).

For the prevention of postoperative nausea and vomiting a single oral dose of aprepitant 40 mg may be given within the 3 hours before induction of anaesthesia.

Administration. Licensed product information for aprepitant suggests the following 4-day regimen for the prevention of acute and delayed nausea and vomiting associated with highly emetogenic cancer chemotherapy:

- day 1: aprepitant 125 mg (given 1 hour before chemotherapy) with oral dexamethasone 12 mg and intravenous ondansetron 32 mg (both 30 minutes before chemotherapy)
- days 2 and 3: aprepitant 80 mg with oral dexamethasone 8 mg in the morning
- day 4: oral dexamethasone 8 mg in the morning.

In patients receiving moderately emetogenic chemotherapy, a 3-day regimen has been suggested as follows:

- day 1: aprepitant 125 mg (given 1 hour before chemotherapy) with oral dexamethasone 12 mg (30 minutes before chemotherapy); ondansetron is given in 2 doses of 8 mg by mouth, one taken 30 to 60 minutes before chemotherapy, and one taken 8 hours after the first dose
- days 2 and 3: aprepitant 80 mg in the morning.

Administration in renal impairment. A study in 8 patients with severe renal impairment (24-hour creatinine clearance less than 30 mL/minute per 1.73 m^2) and 8 patients with end-stage renal disease requiring haemodialysis found that pharmacokinetic parameters of aprepitant were not sufficiently different from those in 16 matched controls to warrant dosage adjustment in renal impairment.[1] Licensed product information concurs with this.

Attapulgite

Atapulgit; Atapulgita.

Аттапульгит

CAS — 1337-76-4; 12174-11-7.

ATC — A07BC04.

ATC Vet — QA07BC04.

Pharmacopoeias. In *Br.*

Activated attapulgite is included in *Br., It.,* and *US.* Colloidal activated attapulgite is included in *US.*

BP 2008 (Attapulgite). A purified native hydrated aluminium magnesium silicate essentially consisting of the clay mineral palygorskite. A light, cream or buff, very fine powder, free or almost free from gritty particles. A 5% suspension in water has a pH of 7.0 to 9.5.

BP 2008 (Activated Attapulgite). Attapulgite that has been carefully heated to increase its adsorptive capacity.

USP 31 (Activated Attapulgite). Processed native aluminium magnesium silicate which has been carefully heated. It is a cream-coloured, micronised, nonswelling powder, free from gritty particles. Insoluble in water.

USP 31 (Colloidal Activated Attapulgite). A native aluminium magnesium silicate that has been purified. It is a cream-coloured, micronised, nonswelling powder, free from gritty particles. Insoluble in water. A 10% suspension in water has a pH of 7.0 to 9.5.

◊ NOTE. Another native aluminium magnesium silicate is described on p.2141.

Profile

Attapulgite is highly adsorbent and is used in a wide range of products including fertilisers, pesticides, and pharmaceuticals. Activated attapulgite is an adsorbent antidiarrhoeal used as an adjunct in the management of diarrhoea (p.1694) in a daily dose of up to 9 g orally in divided doses.

Balsalazide Sodium *(BANM, rINNM)*

Balsalazida sódica; Balsalazide Disodium *(USAN)*; Balsalazide Sodique; Balsalazine Disodium; BX-661A; Natrii Balsalazidum. 5-[4-(2-Carboxyethylcarbamoyl)phenylazo]salicylic acid, disodium salt, dihydrate.

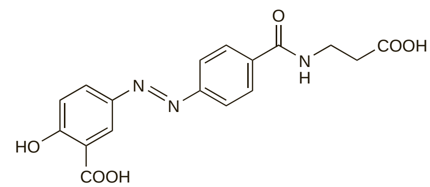
Натрий Балсалазид

$C_{17}H_{13}N_3Na_2O_6,2H_2O = 437.3.$

CAS — 80573-04-2 (balsalazide); 150399-21-6 (balsalazide disodium dihydrate).

ATC — A07EC04.

ATC Vet — QA07EC04.



(balsalazide)

Adverse Effects and Precautions

As for Mesalazine, p.1745. If a blood dyscrasia is suspected treatment should be stopped immediately and a blood count performed. Patients or their carers should be told how to recognise signs of haematotoxicity and should be advised to seek immediate medical attention if symptoms such as fever, sore throat, mouth ulcers, bruising, or bleeding develop. Balsalazide should not be used in patients with severe hepatic impairment or moderate or severe renal impairment; care is required in those with lesser degrees of hepatic or renal impairment, and in asthma, bleeding disorders, or active peptic ulcer disease.

◊ Reviews.

1. Baker DE. Safety of balsalazide therapy in the treatment of inflammatory bowel disease. *Rev Gastroenterol Disord* 2005; **5:** 135–41.

Hypersensitivity. A case of acute pericarditis, cholestasis, and vasculitis resulting from hypersensitivity to balsalazide has been reported.[1] The authors noted similarities to mesalazine-associated pericarditis and lupus-like syndrome (see Effects on the Cardiovascular System, p.1745).

1. Adhiyaman V, *et al.* Hypersensitivity reaction to balsalazide. *BMJ* 2000; **320:** 613.

Pharmacokinetics

Very little of an oral dose of balsalazide is absorbed via the upper gastrointestinal tract, and almost the entire dose reaches its site of action in the colon intact. It is broken down by the colonic bacterial flora into 5-aminosalicylic acid (mesalazine), which is active, and 4-aminobenzoylalanine, which is considered to be an inert carrier. About 25% of the released mesalazine is absorbed and acetylated, as described under mesalazine (p.1746). A small proportion of 4-aminobenzoylalanine is absorbed and acetylated by first-pass metabolism through the liver. The acetylated metabolites are excreted in the urine.

Uses and Administration

Balsalazide consists of mesalazine linked to 4-aminobenzoylalanine via an azo bond. This bond is broken by colonic bacteria, releasing the active mesalazine (p.1746). Balsalazide sodium is given in the treatment of mild to moderate active ulcerative colitis (p.1697), in an oral dose of 2.25 g three times daily until remission or for up to 12 weeks. For maintenance of remission of ulcerative colitis a dose of 1.5 g twice daily is recommended, adjusted as necessary up to 6 g daily. For doses in children, see below.

◊ Reviews.

1. Muijsers RBR, Goa KL. Balsalazide: a review of its therapeutic use in mild-to-moderate ulcerative colitis. *Drugs* 2002; **62:** 1689–705.

Administration in children. Balsalazide sodium is not licensed in the UK for use in children under 18 years of age. However, the *BNFC* suggests that, in those aged 12 years and over, 2.25 g may be given orally three times daily for an acute attack of mild to moderate ulcerative colitis, until remission occurs, or for up to 12 weeks. For maintenance, 1.5 g twice daily is recommended, adjusted according to response up to a maximum of 6 g daily.

In the USA, licensed doses in children aged 5 to 17 years are 750 mg three times daily by mouth, or 2.25 g three times daily; treatment may be continued for up to 8 weeks.

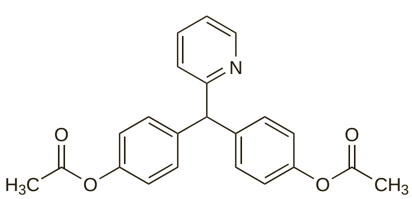
Bisacodyl *(BAN, rINN)*

Bisacodilo; Bisacodylum; Bisakodil; Bisakodilis; Bisakodyl; Bisakodyyli; Biszakodil. 4,4′-(2-Pyridylmethylene)di(phenyl acetate).

Бисакодил

$C_{22}H_{19}NO_4 = 361.4.$

CAS — 603-50-9.
ATC — A06AB02; A06AG02.
ATC Vet — QA06AB02; QA06AG02.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Bisacodyl). A white or almost white crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; soluble in acetone. It dissolves in dilute mineral acids. Protect from light.

USP 31 (Bisacodyl). A white to off-white crystalline powder. Practically insoluble in water; soluble in benzene; soluble 1 in 210 of alcohol, 1 in 2.5 of chloroform, and 1 in 275 of ether; sparingly soluble in methyl alcohol.

Bisacodyl Tannex *(BANM, USAN, rINNM)*

CAS — 1336-29-4.
ATC — A06AB02; A06AG02.
ATC Vet — QA06AB02; QA06AG02.

Adverse Effects

Bisacodyl and other stimulant laxatives may cause abdominal discomfort such as colic or cramps. Prolonged use or overdosage can result in diarrhoea with excessive loss of water and electrolytes, particularly potassium; there is also the possibility of developing an atonic non-functioning colon. Hypersensitivity reactions, including angioedema and anaphylactoid reactions, have been reported rarely. When given rectally, bisacodyl sometimes causes irritation and may cause proctitis or sloughing of the epithelium. To avoid gastric irritation bisacodyl tablets are enteric-coated.

Precautions

As with other laxatives, prolonged use should be avoided. Bisacodyl should not be given to patients with intestinal obstruction or acute abdominal conditions such as appendicitis; care should also be taken in patients with inflammatory bowel disease. It should not be used in patients with severe dehydration. The suppositories should preferably be avoided in patients with anal fissures, proctitis, or ulcerated haemorrhoids.

Handling. Inhalation of bisacodyl powder and contact with eyes, skin, and mucous membranes should be avoided.

Pharmacokinetics

On oral or rectal use bisacodyl is converted to the active desacetyl metabolite bis(*p*-hydroxyphenyl)-pyridyl-2-methane by intestinal and bacterial enzymes. Absorption from the gastrointestinal tract is minimal with enteric-coated tablets or suppositories; the small amount absorbed is excreted in the urine as the glucuronide. Bisacodyl is mainly excreted in the faeces.

Uses and Administration

Bisacodyl is a diphenylmethane stimulant laxative (p.1693) used for the treatment of constipation (p.1693) and for bowel evacuation before investigational procedures or surgery. Its action is mainly in the large intestine and it is usually effective within 6 to 12 hours after oral doses, within 15 to 60 minutes after rectal use by suppository, and within 5 to 20 minutes when given as an enema. Bisacodyl tablets should be swallowed whole and should not be taken within 1 hour of milk or antacids.

For constipation, bisacodyl is given in usual doses of 5 to 10 mg daily as enteric-coated tablets given at night or 10 mg as a suppository or enema given in the morning. Oral doses of 10 to 20 mg are given for complete bowel evacuation, followed by 10 mg as a suppository the next morning. For doses in children, see below.

A complex of bisacodyl with tannic acid (bisacodyl tannex) has been given with a barium sulfate enema before radiographic examination of the colon.

Administration in children. For **constipation**, the following oral doses of bisacodyl are recommended for children, to be taken at night:

- 4 to 10 years: 5 mg
- over 10 years: 5 to 10 mg

Alternatively, the following rectal doses are recommended, to be inserted in the morning:

- under 10 years: 5 mg
- over 10 years: 10 mg

The *BNFC* gives similar doses, but limits the use of suppositories in children to those aged over 2 years.

For **bowel clearance before surgery or radiological investigation**, the following doses are recommended:

- 4 to 10 years: 5 mg orally the night before, followed by 5 mg as a suppository the next morning
- over 10 years: 10 to 20 mg orally the night before, followed by 10 mg as a suppository the next morning

The *BNFC* gives similar doses but allows for the use of oral doses for 2 nights before the procedure, followed, if necessary, by the rectal dose 1 hour before the procedure.

Preparations

BP 2008: Bisacodyl Suppositories; Gastro-resistant Bisacodyl Tablets;
USP 31: Bisacodyl Delayed-release Tablets; Bisacodyl Rectal Suspension; Bisacodyl Suppositories.

Bismuth Compounds

Bismuto, compuestos de.

Висмут Соединения

Bismuth compounds have been used for their astringent and antidiarrhoeal properties in a variety of gastrointestinal disorders, and have been applied topically in skin disorders and anorectal disorders such as haemorrhoids. Certain salts are active against *Helicobacter pylori* and are used in the treatment of peptic ulcer disease.

Bismuth Aluminate *(USAN)*

Aluminato de bismuto; Aluminum Bismuth Oxide.

Алюминат Висмута

$Bi_2(Al_2O_4)_3,10H_2O = 952.0.$

CAS — 12284-76-3 (anhydrous bismuth aluminate).

Pharmacopoeias. In *Chin.* and *Fr.*

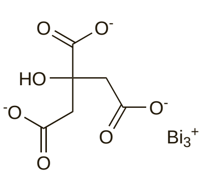
Bismuth Citrate

Citrato de bismuto.

Цитрат Висмута

$BiC_6H_5O_7 = 398.1.$

CAS — 813-93-4.



NOTE. Do not confuse with bismuth subcitrate potassium (p.1711) or tripotassium dicitratobismuthate (colloidal bismuth subcitrate, p.1711).

Pharmacopoeias. In *US*.

USP 31 (Bismuth Citrate). A white, amorphous or crystalline powder. Insoluble in water and in alcohol; soluble in dilute ammonia solution and in solutions of alkali citrates. Store in airtight containers. Protect from light. Prevent exposure to temperatures above 40°.

Bismuth Oxide

Bismuth Trioxide; Óxido de bismuto.

Оксид Висмута

$Bi_2O_3 = 466.0.$

CAS — 1304-76-3.

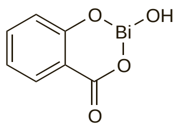
Bismuth Salicylate

Basic Bismuth Salicylate; Bázisos bizmut-szalicilát; Bismuth Oxysalicylate; Bismuth, sous-salicylate de; Bismuth Subsalicylate *(USAN)*; Bismuthi subsalicylas; Bismuto subsalicilatas; Salicilato de bismuto; Salicylan bismutitý zásaditý; Vismutsubsalicylat; Vismuttisubsalisylaatti.

Салицилат Висмута

$C_7H_5BiO_4$ = 362.1.

CAS — 14882-18-9.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Bismuth Subsalicylate). A complex of bismuth and salicylic acid. It contains not less than 56% and not more than 59.4% of Bi, calculated with reference to the dried substance. A white or almost white powder. Practically insoluble in water and in alcohol; dissolves in mineral acids with decomposition. Protect from light.

USP 31 (Bismuth Subsalicylate). A basic salt corresponding to $C_7H_5BiO_4$ and containing not less than 56.0% and not more than 59.4% of Bi and not less than 36.5% and not more than 39.3% of total salicylates. It is a fine, odourless, white to off-white microcrystalline powder. Practically insoluble in water, in alcohol, and in ether. It reacts with alkalis and mineral acids. Store in airtight containers. Protect from light.

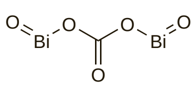
Bismuth Subcarbonate *(USAN)*

Basic Bismuth Carbonate; Basisches Wismutkarbonat; Bázisos bizmutkarbonát; Bism. Carb.; Bismuth Carbonate; Bismuth Oxycarbonate; Bismuth, sous-carbonate de; Bismuthi subcarbonas; Bismuto subkarbonatas; Bismutylum Carbonicum; Carbonato de Bismutila; Subcarbonato de bismuto; Uhličitan bismutitý zásaditý; Vismutsubkarbonat; Vismuttisubkarbonaatti.

Основный Углекислый Висмут

CBi_2O_5 = 510.0.

CAS — 5892-10-4 (anhydrous bismuth subcarbonate); 5798-45-8 (bismuth subcarbonate hemihydrate).



(anhydrous bismuth subcarbonate)

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Bismuth Subcarbonate). A white or almost white powder. Practically insoluble in water and in alcohol. It dissolves in mineral acids with effervescence. Protect from light.

USP 31 (Bismuth Subcarbonate). A white or almost white powder. Practically insoluble in water, in alcohol, and in ether; dissolves in dilute acids with effervescence. Protect from light.

Bismuth Subcitrate Potassium *(USAN)*

1001277; Biskalcitrate potassium; Bismuth Biscalcitrate; Bismuth biskalcitrate. Bismuth pentapotassium dihydroxide bis(2-hydroxypropane-1,2,3-tricarboxylate hydrate).

Основный Калиевый Цитрат Висмута

$C_{12}H_{14}BiK_5O_{17}$ = 834.7.

CAS — 880149-29-1.

NOTE. Do not confuse with bismuth citrate (p.1710) or tripotassium dicitratobismuthate (colloidal bismuth subcitrate, p.1711).

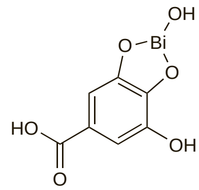
Bismuth Subgallate *(USAN)*

Basic Bismuth Gallate; Basisches Wismutgallat; Bázisos bizmutgallát; Bism. Subgall.; Bismuth Oxygallate; Bismuth, sous-gallate de; Bismuthi subgallas; Bismuto subgalatas; Bizmut Subgalat; Bizmutu galusan zasadowy; Gallan bismutitý zásaditý; Subgalato de bismuto; Vismutsubgallat; Vismuttisubgallaatti.

Основный Галловокислый Висмут

$C_7H_5BiO_6$ = 394.1.

CAS — 99-26-3.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Bismuth Subgallate). A complex of bismuth and gallic acid. It contains not less than 48% and not more than 51% of Bi, calculated with reference to the dried substance. A yellow powder. Practically insoluble in water and in alcohol; dissolves in mineral acids with decomposition and in alkali hydroxides, producing a reddish-brown liquid. Protect from light.

USP 31 (Bismuth Subgallate). A basic salt containing 52 to 57% of Bi_2O_3 when dried at 105° for 3 hours. It is an odourless amorphous bright yellow powder. Practically insoluble in water, in alcohol, in chloroform, and in ether; insoluble in very dilute mineral acids; dissolves readily with decomposition in warm, moderately dilute hydrochloric, nitric, or sulfuric acids; readily dissolves in solutions of alkali hydroxides to form a clear yellow liquid which rapidly becomes deep red. Store in airtight containers. Protect from light.

Bismuth Subnitrate

Basic Bismuth Nitrate; Basisches Wismutnitrat; Bázisos bizmut-nitrát; Bism. Subnit.; Bismuth Hydroxide Nitrate Oxide; Bismuth Nitrate, Heavy; Bismuth Oxynitrate; Bismuth, sous-nitrate de; Bismuth (Sous-Nitrate de) Lourd; Bismuthi subnitras; Bismuthyl Nitrate; Bismuto subnitratas; Bismuto subnitratas sunkusis; Bizmut Subnitrat; Bizmutu azotan zasadowy; Bizmutu(III) azotan zasadowy; Magistery of Bismuth; Nitrato de Bismutilo; Subazotato de Bismuto; Subnitrato de bismuto; Vismutsubnitrat; Vismuttisubnitraatti; White Bismuth.

Основный Азотнокислый Висмут

$Bi_5O(OH)_9(NO_3)_4$ = 1462.0.

CAS — 1304-85-4.

ATC — A02BX12.

ATC Vet — QA02BX12.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*

Fr. also includes Bismuth (Sous-Nitrate de) Léger (Bismuthi Subnitras Levis) which is described as a variable mixture of bismuth hydroxide, carbonate, and subnitrate.

Ph. Eur. 6.2 (Bismuth Subnitrate, Heavy). It contains not less than 71% and not more than 74% of Bi, calculated with reference to the dried substance. A white or almost white powder. Practically insoluble in water and in alcohol; dissolves in mineral acids with decomposition.

USP 31 (Bismuth Subnitrate). A basic salt containing not less than 79% of Bi_2O_3 calculated on the dried basis. It is a white, slightly hygroscopic powder. Practically insoluble in water and in alcohol; readily dissolves in nitric and hydrochloric acids.

Tripotassium Dicitratobismuthate

Bizmut Subsitrat; Colloidal Bismuth Subcitrate; Dicitratobismutato tripotásico; Tripotasyum Disitratobizmutat.

Висмут Трикалия Дицитрат

CAS — 57644-54-9.

ATC — A02BX05.

ATC Vet — QA02BX05.

NOTE. Do not confuse with bismuth citrate (p.1710) or bismuth subcitrate potassium (p.1711).

Adverse Effects, Treatment, and Precautions

The bismuth compounds listed above are insoluble or very poorly soluble, and bismuth toxicity does not appear to be common if they are used for limited periods. However, excessive or prolonged dosage may produce symptoms of bismuth poisoning, and for this reason long-term systemic therapy is not recommended. Reversible encephalopathy (see below) was once a problem in some countries, notably France and Australia; bone and joint toxicity had also occurred, sometimes associated with the encephalopathy. This led to restrictions on the use of bismuth salts and a virtual disappearance of these toxic effects.

Nausea and vomiting have been reported. Darkening or blackening of the faeces and tongue may occur due to conversion to bismuth sulfide in the gastrointestinal tract.

The effects of *acute bismuth intoxication* include gastrointestinal disturbances, skin reactions, stomatitis, and discoloration of mucous membranes; a characteristic blue line may appear on the gums. There may be renal failure and liver damage.

Other adverse effects may not be related to the bismuth content. With bismuth subnitrate given orally there is a risk of the nitrate being reduced in the intestines to nitrite and the development of methaemoglobinaemia. Absorption of salicylate occurs from oral bismuth salicylate and therefore the adverse effects, treatment of adverse effects, and precautions of aspirin (p.20) should be considered.

Gastric lavage should be considered in overdosage; activated charcoal by mouth and the use of a chelating agent such as dimercaprol, succimer, or unithiol have been recommended (see also Overdosage, below). Renal function should be monitored for 10 days after acute overdosage.

Bismuth compounds should not be given to patients with moderate to severe renal impairment.

Encephalopathy. Reviews[1,2] and reports[3-11] of bismuth encephalopathy. Many of the original reports implicated bismuth subgallate or subnitrate, in most but not all cases at high doses or for prolonged periods; toxicity has also occurred with other salts.[6-9] Patients receiving the subcitrate (480 mg daily) or the subnitrate (1.8 g daily) for 8 weeks in the treatment of *Helicobacter pylori* infection, showed no evidence of neurological changes compared with a control group.[12]

TOPICAL APPLICATION. Encephalopathy has been associated with the use of bismuth iodoform paraffin paste (BIPP) for the packing of wound cavities after surgery to the head and neck, although there is some debate as to whether the bismuth or the iodoform component is responsible—see p.1650.

Overdosage. Bismuth salicylate or tripotassium dicitratobismuthate in recommended doses are rarely associated with serious adverse effects but there are reports of renal failure,[1-6] encephalopathy,[7-9] and neurotoxicity[1] in acute[1-6,8] or chronic[7,9] overdose. Bismuth has been detected in the blood, urine, stools, and kidneys of these patients; a blood concentration of 1.6 micrograms/mL was found[2] 4 hours after an oral dose of 9.6 g.

The optimal treatment of bismuth overdosage is unknown. Gastric lavage, purgation, and hydration should be considered, even if the patient presents late, as bismuth may be absorbed from the colon.[1,2] Chelating agents may be effective; unithiol has been reported to increase the renal clearance of bismuth with a reduction in the blood concentration.[7] Haemodialysis may be necessary[1-3] but whether this hastens tissue clearance is uncertain. Haemodialysis plus unithiol treatment has been reported to successfully eliminate bismuth.[6] Peritoneal dialysis has also been effectively used in a paediatric patient.[5]

Prolonged ingestion of bismuth salicylate in excessive doses by an elderly diabetic was associated with hearing disturbances, vertigo, acid–base abnormalities and mild clotting disturbances.[10] The toxicity was thought to be due to the salicylate component.

Toxicity from non-conventional use. The FDA has warned against use of an injectable product called bismacine or chromacine, which contains large amounts of bismuth. There are reports of death or serious adverse effects associated with its use. Although unlicensed for any use, bismacine has apparently been used in alternative medicine to treat Lyme disease.[1]

1. FDA. FDA warns consumers and health care providers not to use bismacine, also known as chromacine (issued 21st July 2006). Available at: http://www.fda.gov/bbs/topics/NEWS/2006/NEW01415.html (accessed 28/01/08)

Interactions

Bismuth salts given orally reduce the absorption of tetracyclines, possibly by chelation or by reducing tetracycline solubility as a result of increasing the gastric pH. This interaction can be minimised by separating doses of the two drugs by a couple of hours. The clinical significance of this interaction to the use of bismuth salts for peptic ulcer disease is unclear; tripotassium dicitratobismuthate or bismuth salicylate have been given at the same time as tetracycline as part of triple therapy for the eradication of *Helicobacter pylori*.

Antisecretory drugs. Pretreatment with *omeprazole* resulted in about a threefold increase in absorption of bismuth from tripotassium dicitratobismuthate in 6 healthy subjects.[1] The mean peak plasma concentration of bismuth after a single dose of 240 mg of tripotassium dicitratobismuthate was increased from 36.7 to 86.7 nanograms/mL after omeprazole suggesting an increased risk of toxicity from combined therapy. The mechanism was thought to be the increase in gastric pH produced by the antisecretory drug as similar results had been reported with *ranitidine*.[2] However, the clinical significance of these interactions to the use of antisecretory drugs with bismuth compounds for eradication of *Helicobacter pylori* is unclear; bismuth compounds have been combined with proton pump inhibitors or H_2 antagonists in short-term regimens as part of triple or quadruple therapy.

2. Nwokolo CU, *et al.* The effect of histamine H_2-receptor blockade on bismuth absorption from three ulcer-healing compounds. *Gastroenterology* 1991; **101:** 889–94.

Pharmacokinetics

Poorly soluble bismuth compounds are largely converted to insoluble bismuth oxide, hydroxide, and oxychloride in the acidic environment of the stomach. Most of the bismuth compounds included in this monograph are thus only slightly absorbed. Increased gastric pH may increase bismuth absorption—see Antisecretory Drugs, above. Unabsorbed bismuth is excreted in the faeces. Absorbed bismuth is distributed throughout body tissues, including bone, and is slowly excreted in the urine and bile. It has a plasma half-life of about 5 days and continues to be excreted for about 12 weeks after stopping therapy.

Uses and Administration

Some insoluble salts of bismuth are given orally for their supposed antacid action and for their mildly astringent action in various gastrointestinal disorders, including diarrhoea (p.1694) and dyspepsia (p.1695). Such salts include the aluminate, salicylate, subcarbonate, and subnitrate. Bismuth salicylate, which is given as an antidiarrhoeal and weak antacid in doses up to about 4 g daily in divided doses, possesses in addition the properties of the salicylates.

Tripotassium dicitratobismuthate is active against *Helicobacter pylori* and has been used as triple therapy (with metronidazole and either tetracycline or amoxicillin) to eradicate this organism and thereby prevent relapse of duodenal ulcer. It is also used as a mucosal protectant for the treatment of peptic ulcer disease (p.1702). Bismuth subcitrate potassium and bismuth salicylate are also active against *H. pylori* and have been used similarly in eradication regimens.

The usual oral dose of tripotassium dicitratobismuthate in benign gastric and duodenal ulceration is 240 mg twice daily, or 120 mg four times daily before food. Treatment is for a period of 4 weeks, extended to 8 weeks if necessary. Maintenance therapy with tripotassium dicitratobismuthate is not recommended although treatment may be repeated after a drug-free interval of one month. When used as part of triple therapy the usual dose of tripotassium dicitratobismuthate has been 120 mg four times daily for 2 weeks. The usual dose of bismuth salicylate as part of triple therapy is 525 mg four times daily for 2 weeks. Appropriate antisecretory treatment with a histamine H_2-antagonist or a proton pump inhibitor is usually added to these regimens.

A complex of bismuth citrate with ranitidine, ranitidine bismuth citrate (p.1768), is also used in the treatment of peptic ulcer disease.

Some insoluble salts of bismuth have been used topically in the treatment of skin disorders, wounds, and burns. Some have been used as ingredients of ointments or suppositories (sometimes containing more than one bismuth salt) in the treatment of haemorrhoids and other anorectal disorders (p.1697). Bismuth compounds that have been used topically and/or rectally include the oxide, subgallate, and subnitrate; bismuth resorcinol compounds have also been used. For the use of bismuth subnitrate and iodoform paste as a wound dressing, see Iodoform, p.1650.

Numerous other salts and compounds of bismuth have been promoted for various therapeutic purposes. Glycobiarsol was formerly given orally as an amoebicide.

Homoeopathy. Bismuth has been used in homoeopathic medicines under the following names: Bismuthum; Bismutum metallicum.

Bismuth oxide has been used in homoeopathic medicines under the following names: Bismuthum oxydatum; Bis. ox.

Bismuth subnitrate has been used in homoeopathic medicines under the following names: Heavy bismuth subnitrate; Bismuthi subnitras ponderosus; Bismutum subnitricum; Bism. sub.

Preparations

BPC 1954: Bismuth Subnitrate and Iodoform Paste;
USP 31: Bismuth Subsalicylate Magma; Bismuth Subsalicylate Oral Suspension; Bismuth Subsalicylate Tablets; Compound Resorcinol Ointment; Milk of Bismuth.

Bisoxatin Acetate *(BANM, USAN, rINNM)*

Acetato de bisoxatina; Bisoxatin Diacetate; Bisoxatine, Acétate de; Bisoxatini Acetas; Wy-8138. 2,2-Bis(4-hydroxyphenyl)-1,4-benzoxazin-3(2*H*,4*H*)-one diacetate.

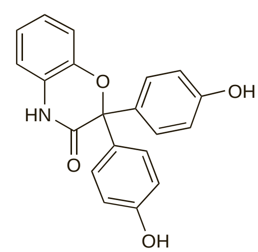
Бизоксатина Ацетат

$C_{24}H_{19}NO_6$ = 417.4.

CAS — 17692-24-9 (bisoxatin); 14008-48-1 (bisoxatin acetate).

ATC — A06AB09.

ATC Vet — QA06AB09.



(bisoxatin)

Profile

Bisoxatin acetate is a stimulant laxative that has been used in the treatment of constipation (p.1693).

Preparations

Proprietary Preparations (details are given in Part 3)
Belg.: Wylaxine; ***Venez.:*** Regoxal.

Bran

Crusca; Farelo; Kleie; Salvado; Son.

Отруби

Description. Bran consists of the fibrous outer layers of cereal grains. It contains celluloses, polysaccharides or hemicelluloses, protein, fat, minerals, and moisture and may contain part of the germ or embryo. Bran provides water-insoluble fibre and, depending on the source, may also provide water-soluble fibre (see also Dietary Role, below). It comprises about 12% of the weight of the grain and is a byproduct of flour milling. It is available in various grades.

Pharmacopoeias. *US* includes wheat bran.

USP 31 (Wheat Bran). The outer fraction of the cereal grain (comprising the pericarp, seed coat (testa), nucellar tissue, and aleurone layer) derived from *Triticum aestivum*, *T. compactum*, *T. durum*, or other common einkorn and emmer wheat cultivars. It is obtained by milling and processing the whole wheat grain, and is available in a variety of particle sizes depending on the degree of milling. It contains not less than 36% of dietary fibre. It is a light tan powder having a characteristic aroma. Practically insoluble in cold water and in alcohol.

Adverse Effects

Large quantities of bran may temporarily increase flatulence and abdominal distension, and intestinal obstruction may occur rarely.

Colonic atony. Colonic atony has been reported in patients who had increased their intake of dietary fibre to relieve constipation associated with systemic sclerosis.[1]

1. Gough A, *et al.* Dietary advice in systemic sclerosis: the dangers of a high fibre diet. *Ann Rheum Dis* 1998; **57:** 641–2.

Diarrhoea. A report of diarrhoea induced by a dramatic increase in fibre intake. Reduction of dietary fibre led to a return to normal bowel habit in 2 to 3 days.[1]

1. Saibil F. Diarrhea due to fiber overload. *N Engl J Med* 1989; **320:** 599.

Intestinal obstruction. Intestinal obstruction associated with excessive bran intake has been reported.[1-3]

1. Allen-Mersh T, De Jode LR. Is bran useful in diverticular disease? *BMJ* 1982; **284:** 740.
2. Cooper SG, Tracey EJ. Small-bowel obstruction caused by oat-bran bezoar. *N Engl J Med* 1989; **320:** 1148–9.
3. Miller DL, *et al.* Small-bowel obstruction from bran cereal. *JAMA* 1990; **263:** 813–14.

Precautions

Bran is contra-indicated in patients with intestinal obstruction or with undiagnosed abdominal symptoms. There is a particular risk of intestinal or oesophageal obstruction if bulk laxatives are swallowed dry; they should be taken with sufficient fluid and should not be taken immediately before going to bed. Wheat bran should be avoided in gluten enteropathies and coeliac disease.

Interactions

Bran may reduce the absorption of some drugs when given together by mouth. Interference with iron, zinc, and calcium absorption has been reported; calcium phosphate may be added to bran to neutralise fytic acid, which can contribute to such interference.

Uses and Administration

The main use of bran is as a bulk laxative and source of dietary fibre in the management of disorders of the gastrointestinal tract such as constipation (p.1693), especially in diverticular disease (p.1695); it is also widely used in irritable bowel syndrome, although its value has been questioned (see p.1699). It should always be taken with plenty of fluid.

Bran is used as the basis for some breakfast cereals.

Dietary role. There is no precise definition for the complex mixture of substances known as dietary fibre. It has been defined as *plant* polysaccharides and lignin resistant to hydrolysis by the digestive enzymes of humans but this covers many substances other than cell-wall and related polysaccharides. Non-starch polysaccharides are the major component of the plant cell wall and are used as an index of dietary fibre. They comprise water-soluble fibres such as pectins, gums, and mucilages and water-insoluble fibres such as cellulose. Wheat, maize, and rice contain mainly insoluble non-starch polysaccharides whereas oats, barley, and rye have a significant proportion of soluble fibres.[1] Because the USA originally included nondigestible *animal* carbohydrates in the definition of fibre, the Food and Nutrition Board in the USA proposed a new definition of fibre, whereby dietary fibre consists of nondigestible carbohydrates and lignin that are intrinsic and intact in plants, and functional fibre consists of isolated, nondigestible plant or animal carbohydrates that have beneficial physiological effects in humans. Total fibre is the sum of dietary and functional fibre.[2]

In the UK, dietary reference values (DRV) have been published for non-starch polysaccharides.[1] It has been proposed[1] that adult diets should contain an average for the population of 18 g daily (individual range 12 to 24 g daily) non-starch polysaccharide from a variety of foods whose constituents contain it as a naturally integrated component. Children should receive proportionately less non-starch polysaccharide according to body size. No evidence exists for benefit of intakes of non-starch polysaccharide in excess of 32 g daily, and therefore there is no advantage in exceeding this amount.

In the USA, an adult dietary fibre intake of 20 to 35 g daily has been suggested; children should consume an amount equivalent to their age plus 5 g daily.[3]

Disease prevention. Diseases such as colorectal cancer, ischaemic heart disease, diabetes mellitus, and obesity are common in affluent developed countries but occur rarely in rural Africa. This difference in disease patterns has been linked to the low fibre intake in developed countries compared with rural Africans. However, there are many other differences in diet and lifestyle, such as a lower intake of fat, protein, and sugar in rural Africans and less exposure to toxins and pollutants, any of which could contribute to the difference. The excessive consumption of energy-rich foods may be more to blame for diseases of affluence than is deficiency of dietary fibre.[1]

Results from large prospective cohort studies have been conflicting as to whether there is any *reduction in risk* of **colorectal cancer** associated with a high intake of dietary fibre, and have mostly failed to show a reduction in the *recurrence rate* of colorectal adenomas (although most adenomas do not develop into cancer, and so the relevance of these results is unclear[2]). A pooled analysis of 13 prospective cohort studies found a significant inverse association between dietary fibre intake and colorectal cancer. However, after adjusting for other risk factors, this association was attenuated and no longer statistically significant. There was some suggestion that intake of dietary fibre from cereals and from whole-grain foods were both associated with a weak reduction in the risk of rectal cancer.[3] Some have commented[4] that fibre is a broad term encompassing a wide range of organic material, which may have a large number of actions on digestive physiology. Furthermore, there is some concern that the use of fibre supplements is not entirely without harmful effects: it has been pointed out that fermentable fibre substrates can stimulate cell proliferation in the colon.[5] However, the role of cell proliferation as a marker for the development of colonic cancer is questioned by some authors.[6]

A small randomised crossover study[7] in patients with type 2 **diabetes mellitus** suggested that an increased intake of dietary fibre was associated with improved glycaemic control, decreased hyperinsulinaemia, and lower plasma lipid concentrations. In prospective cohort studies, inverse associations were found between whole-grain intake and the risk of type 2 diabetes mellitus;[8-11] in some studies, this inverse association persisted for cereal fibre intake,[9-11] but in one the protective effect of whole grain could not entirely be explained by fibre content.[8]

Fibre may act as an obstacle to energy intake by displacing available calories and nutrients from the diet, by increasing satiety, and by decreasing the absorption efficiency of the small intestine. Epidemiological studies support the hypothesis that a higher dietary fibre intake prevents **obesity**; populations that report higher fibre consumption also demonstrate lower obesity rates.[12] Weight gain was inversely associated with increases in the intake of whole grains but positively associated with increases in the intake of refined grains, emphasising the importance of distinguishing whole-grain from refined-grain products.[13]

A large prospective cohort study in men found an inverse association between whole-grain intake and the incidence of **coronary heart disease**; the finding was even stronger for bran intake. These associations were attenuated, but not eliminated, by adjustment for other risk factors for coronary heart disease.[14] There is some suggestion that diets high in fibre may have a moderate effect on blood pressure reduction.[15]

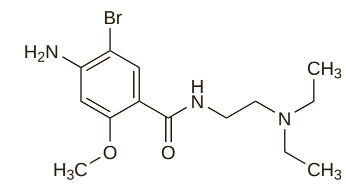
Bromopride *(rINN)*

Bromoprida; Bromopridum; CM-8252; VAL-13081. 4-Amino-5-bromo-*N*-(2-diethylaminoethyl)-*o*-anisamide.

Бромоприд

$C_{14}H_{22}BrN_3O_2$ = 344.2.
CAS — 4093-35-0.
ATC — A03FA04.
ATC Vet — QA03FA04.



Profile

Bromopride is a substituted benzamide similar to metoclopramide (p.1747), used in a variety of gastrointestinal disorders including nausea and vomiting (p.1700) and motility disorders. It is given in a usual oral dose of 20 to 60 mg daily in divided doses, or 20 mg daily by intramuscular or intravenous injection. The hydrochloride is also used.

Preparations

Proprietary Preparations (details are given in Part 3)
Braz.: Bilenzima; Bromoprid†; Digerex; Digesan; Digesprid; Digestil; Digestina; Digeston†; Pangest; Plamet; Pridecil; ***Ital.:*** Procirex; Valopride.

Multi-ingredient: ***Braz.:*** Digecap-Zimatico; Enziprid†; Lansoprid; Primeral; ***Port.:*** Modulanzime.

Buckthorn

Bacca Spinae Cervinae; Espino cerval; Kreuzdorn; Nerprun.

Жостер Слабительный; Крушина Слабительная

NOTE. Distinguish from Alder Buckthorn Bark (see Frangula Bark, p.1732) and from Sea Buckthorn (p.2384).

Pharmacopoeias. In *Ger.*

Profile

Buckthorn is the dried ripe fruit of *Rhamnus cathartica* (Rhamnaceae); the bark is also occasionally used. Buckthorn is an anthraquinone stimulant laxative.

Preparations

Proprietary Preparations (details are given in Part 3)

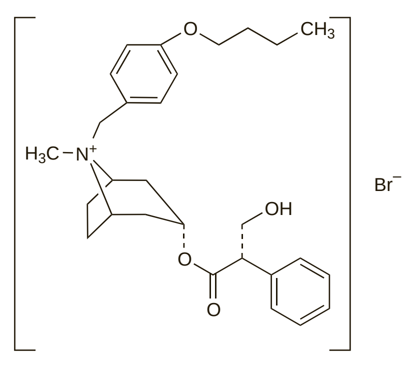
Multi-ingredient: ***Austral.:*** Neo-Cleanse; ***UK:*** Cleansing Herbs; Lion Cleansing Herbs.

Butropium Bromide *(rINN)*

Bromuro de butropio; Butropii Bromidum; Butropium, Bromure de. (−)-(1*R*,3*r*,5*S*)-8-(4-Butoxybenzyl)-3-[(*S*)-tropoyloxy]tropanium bromide.

Бутропия Бромид

$C_{28}H_{38}BrNO_4$ = 532.5.
CAS — 29025-14-7.



Pharmacopoeias. In *Jpn.*

Profile

Butropium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used in the symptomatic treatment of visceral spasms in an oral dose of 30 mg daily in 3 divided doses.

Preparations

Proprietary Preparations (details are given in Part 3)
Indon.: Coliopan; ***Jpn:*** Coliopan; ***Malaysia:*** Coliopan; ***Singapore:*** Coliopan†.

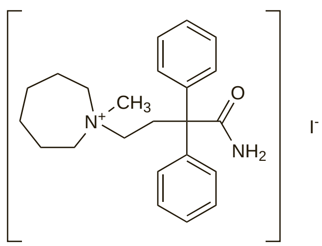
Buzepide Metiodide *(rINN)*

Buzépide, Métiodure de; Buzepidi Metiodidum; Diphexamide Iodomethylate; FI-6146; Metazepium Iodide; Metioduro de buzepida; R-661. 1-(3-Carbamoyl-3,3-diphenylpropyl)-1-methylperhydroazepinium iodide.

Бузепида Метйодид

$C_{23}H_{31}IN_2O = 478.4.$

CAS — 15351-05-0.



Profile

Buzepide metiodide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been given with other compounds for upper respiratory-tract disorders and in gastrointestinal disorders with smooth muscle spasm.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Fr.:*** Vesadol†; ***Ital.:*** Denoral†.

Calcium Carbonate

Calcii carbonas; Calcii Carbonas Praecipitatus (precipitated calcium carbonate); Calcium, carbonate de; Carbonato de calcio; Creta Preparada; E170; Kalcio karbonatas; Kalciumkarbonat; Kalcium-karbonát; Kalsiumkarbonaatti; Kalsiyum karbonat; Precipitated Calcium Carbonate; Precipitated Chalk; Uhličitan vápenatý; Wapnia węglan; Wapnia węglan strącony (precipitated calcium carbonate).

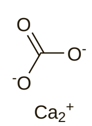
Кальция Карбонат

$CaCO_3 = 100.1.$

CAS — 471-34-1.

ATC — A02AC01; A12AA04.

ATC Vet — QA02AC01; QA12AA04.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Calcium Carbonate). A white or almost white powder. Practically insoluble in water.

USP 31 (Calcium Carbonate). A fine, white, odourless, microcrystalline powder. Practically insoluble in water; its solubility in water is increased by the presence of carbon dioxide or ammonium salts although the presence of any alkali hydroxide reduces its solubility; insoluble in alcohol; dissolves with effervescence in acetic acid, in hydrochloric acid, and in nitric acid.

Adverse Effects, Treatment, and Precautions

Calcium carbonate may occasionally cause constipation. Flatulence from released carbon dioxide may occur in some patients. High doses or prolonged use may lead to gastric hypersecretion and acid rebound. Like other calcium salts (see p.1676), calcium carbonate can cause hypercalcaemia, particularly in patients with renal impairment or after high doses. Alkalosis (p.1667) may also occur as a result of the carbonate anion. There have been rare reports of the milk-alkali syndrome, see below, and tissue calcification.

For precautions to be observed with the use of calcium carbonate, see Calcium, p.1676.

Milk-alkali syndrome. The milk-alkali syndrome of hypercalcaemia, alkalosis and renal impairment was first identified in the 1920s and may still occur in patients who ingest large amounts of calcium and absorbable alkali,[1,2] and in patients being treated for osteoporosis with calcium carbonate plus other drugs that may increase the absorption of calcium.[1] It is not uncommon as a cause of hypercalcaemia requiring hospitalisation.[1] The syndrome has also been reported in a patient taking recommended doses of antacids containing calcium carbonate for chronic epigastric discomfort,[3] and in a pregnant woman taking high, but not grossly excessive, doses of calcium (about 3 g of elemental calcium daily).[4] Metastatic calcification can develop.[5]

For reference to thiazide diuretics increasing the risk of the milk-alkali syndrome in patients taking moderately large doses of calcium carbonate, see p.1310.

1. Picolos MK, *et al.* Milk-alkali syndrome is a major cause of hypercalcaemia among non-end-stage renal disease (non-ESRD) inpatients. *Clin Endocrinol (Oxf)* 2005; **63:** 566–76.

3. Camidge R, Peaston R. Recommended dose antacids and severe hypercalcaemia. *Br J Clin Pharmacol* 2001; **52:** 341–2.
4. Gordon MV, *et al.* Life-threatening milk-alkali syndrome resulting from antacid ingestion during pregnancy. *Med J Aust* 2005; **182:** 350–1.
5. Duthie JS, *et al.* Milk-alkali syndrome with metastatic calcification. *Am J Med* 1995; **99:** 102–3.

Interactions

As for other calcium salts, p.1677.

As outlined on p.1692, antacids, including calcium salts, interact with many other drugs both by alterations in gastric pH and emptying, and by formation of complexes that are not absorbed. Interactions can be minimised by giving calcium carbonate and any other medication 2 to 3 hours apart.

Omeprazole. In a study[1] of 18 women over the age of 65, the use of omeprazole for a week significantly reduced the absorption of calcium from a calcium carbonate supplement given on an empty stomach. Fractional calcium absorption was reduced from 9.1% with placebo to 3.5% with omeprazole.

1. O'Connell MB, *et al.* Effects of proton pump inhibitors on calcium carbonate absorption in women: a randomized crossover trial. *Am J Med* 2005; **118:** 778–81.

Pharmacokinetics

Calcium carbonate is converted to calcium chloride by gastric acid. Some of the calcium is absorbed from the intestines and the unabsorbed portion is excreted in the faeces, as described for other calcium salts, p.1677.

Uses and Administration

Calcium carbonate is used as an antacid (p.1692), usually in oral doses of up to about 1.5 g. It is often given with other antacids, especially magnesium-containing antacids.

Calcium carbonate is also used as a calcium supplement in deficiency states and as an adjunct in the management of osteoporosis, as described under Calcium, p.1677.

Calcium carbonate binds phosphate in the gastrointestinal tract to form insoluble complexes and reduces phosphate absorption. It is used to treat hyperphosphataemia in patients with chronic renal failure (see Renal Osteodystrophy, p.1086) or associated secondary hyperparathyroidism (p.1087). For this purpose, initial doses of 2.5 g daily by mouth in divided doses have been given, increased to up to 17 g daily in divided doses as required. The *BNFC* suggests the following doses in infants and children, given 3 or 4 times daily with or before meals, and adjusted as necessary:

- 1 month to 1 year of age, 120 mg
- 1 to 6 years, 300 mg
- 6 to 12 years, 600 mg
- 12 to 18 years, 1.25 g

Calcium carbonate is also used as a food additive.

Homoeopathy. Native forms of calcium carbonate have been used in homoeopathic medicines under the following names: Calcarea Carbonica; Calc. Carb.; Calcium carbonicum Hahnemanni; Conchae; Calcium Carbonate of Hahnemann; Cal. carb.

Preparations

BP 2008: Alginate Raft-forming Oral Suspension; Calcium and Colecalciferol Tablets; Chewable Calcium Carbonate Tablets;

Carbenoxolone Sodium *(BANM, USAN, rINNM)*

Carbenoxolona sódica; Carbénoxolone Sodique; Disodium Enoxolone Succinate; Karbenoksolon Sodyum; Natrii Carbenoxolonum. 3β-(3-Carboxypropionyloxy)-11-oxo-olean-12-en-30-oic acid, Disodium Salt.

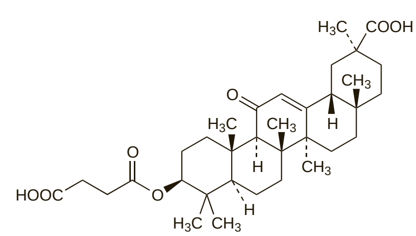
Натрий Карбеноксолон

$C_{34}H_{48}Na_2O_7 = 614.7.$

CAS — 5697-56-3 (carbenoxolone); 7421-40-1 (carbenoxolone disodium).

ATC — A02BX01.

ATC Vet — QA02BX01.



(carbenoxolone)

Pharmacopoeias. In *Br.*

BP 2008 (Carbenoxolone Sodium). A white or pale cream-coloured, hygroscopic powder. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in chloroform and in ether. A 10% solution in water has a pH of 8.0 to 9.2.

Adverse Effects, Treatment, and Precautions

Carbenoxolone sodium has mineralocorticoid-like effects and ingestion may produce sodium and water retention and hypokalaemia. This may cause or exacerbate hypertension, heart failure, oedema, alkalosis, and muscle weakness and damage, and systemic carbenoxolone should therefore be used with caution, if at all, in patients with cardiovascular disease. If hypokalaemia is prolonged, renal impairment can occur. Care is needed in pre-existing hepatic or renal impairment. Regular monitoring of weight and blood pressure is advised; if hypokalaemia, oedema, or a significant rise in blood pressure occurs, carbenoxolone therapy should be stopped. Potassium depletion may be corrected with potassium supplements. Systemic use of carbenoxolone sodium is contra-indicated in patients with hypokalaemia, in pregnancy, in the elderly, and in children.

◊ Muscle weakness,[1-5] muscle necrosis,[4] myopathy,[1] hypertension,[2] headache,[2] cardiac failure,[2] mental confusion,[4] areflexia,[3] renal tubular dysfunction,[5] and acute tubular necrosis[4] have all been associated with carbenoxolone-induced hypokalaemia. Carbenoxolone-induced hypertension may have precipitated the onset of fatal polyarteritis in a patient predisposed to this condition.[6]

6. Sloan J, Weaver JA. A case of polyarteritis developing after carbenoxolone therapy. *Ir Med J* 1968; **1:** 505–7.

Handling. Carbenoxolone sodium powder is irritant to nasal membranes.

Interactions

Because of the risk of toxicity, carbenoxolone should not be taken with digitalis glycosides unless serum-electrolyte concentrations are measured at weekly intervals and precautions are taken to avoid hypokalaemia.

Although amiloride or spironolactone relieve sodium and water retention, they antagonise the efficacy of systemic carbenoxolone and should not be used with it. The hypokalaemia associated with diuretics may be exacerbated by carbenoxolone.

Pharmacokinetics

Carbenoxolone sodium is absorbed from the gastrointestinal tract, mainly from the stomach. It is highly bound to plasma proteins. Carbenoxolone is chiefly excreted in the faeces via the bile. It appears to undergo enterohepatic circulation.

Uses and Administration

Carbenoxolone sodium is a synthetic derivative of glycyrrhizic acid (p.2316) that was formerly used as a mucosal protectant in peptic ulcer disease and has been given with antacids and alginic acid in gastro-oesophageal reflux disease.

Carbenoxolone sodium is one of many topical treatments for the symptomatic management of mouth ulceration (p.1700). It is usually used as a 2% gel; a 1% mouthwash has been used.

Mental function. High cortisol concentrations have been associated with poorer memory and neuronal loss in some patients. Carbenoxolone inhibits 11-β-hydroxysteroid dehydrogenase type 1, and thus may selectively lower intracellular cortisol. In a small crossover study in 10 healthy elderly men, carbenoxolone 100 mg three times daily by mouth for 4 weeks significantly improved verbal fluency compared with placebo, but did not influence visual or verbal memory, nonverbal reasoning, or processing speed. Twelve patients with stable type 2 diabetes were given carbenoxolone at the same dose for 6 weeks. Verbal memory was significantly improved compared with placebo, but verbal fluency and other scores were unaltered. All subjects were given amiloride 10 mg daily to prevent mineralocorticoid adverse effects (but see Interactions, above).[1]

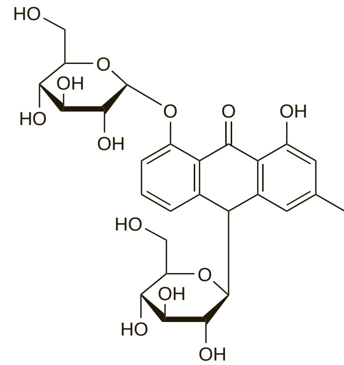
Casanthranol *(USAN)*

Casantranol.

Казантранол

CAS — 8024-48-4.



(cascaroside A)

Pharmacopoeias. In *US.*

USP 31 (Casanthranol). It is obtained from cascara. It contains not less than 20% of total hydroxyanthracene derivatives calculated on the dried basis, of which not less than 80% consists of cascarosides, both calculated as cascaroside A ($C_{27}H_{32}O_{14}$ = 580.5).

It is a light tan to brown, amorphous, hygroscopic powder. Freely soluble in water with some residue; partially soluble in methyl alcohol and in hot isopropyl alcohol; practically insoluble in acetone. Store in airtight containers at a temperature not exceeding 30°. Protect from light.

Profile

Casanthranol is an anthraquinone stimulant laxative with general properties similar to those of senna (p.1769). It is given in usual oral doses of 30 to 60 mg daily with a faecal softener. In severe cases a dose of 90 mg daily, or 60 mg twice daily, may be given.

Preparations

Жостер Пурша; Крушина Пурша

CAS — 8047-27-6; 8015-89-2 (cascara sagrada extract).
ATC — A06AB07.
ATC Vet — QA06AB07.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Cascara). The dried, whole or fragmented bark of *Rhamnus purshianus* (=*Frangula purshiana*). It contains not less than 8.0% of hydroxyanthracene glycosides of which not less than 60% consists of cascarosides, both expressed as cascaroside A ($C_{27}H_{32}O_{14}$ = 580.5). and calculated with reference to the dried drug. Protect from light.

USP 31 (Cascara Sagrada). The dried bark of *Rhamnus purshianus* (Rhamnaceae). It contains not less than 7% of total hydroxyanthracene derivatives calculated on the dried basis, of which not less than 60% consists of cascarosides, both calculated as cascaroside A. It has a distinct odour.

Profile

Cascara is an anthraquinone stimulant laxative with general properties similar to those of senna (p.1769). It has been used in the treatment of constipation in oral doses equivalent to about 20 mg of total hydroxyanthracene derivatives daily.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were receiving cascara, and the American Academy of Pediatrics considers[1] that it is therefore usually compatible with breast feeding.

Cerium Oxalate

Cerii Oxalas; Cerio, oxalato de; Ceriumoksalaatti; Ceriumoxalat.

Церия Оксалат

CAS — 139-42-4 (anhydrous cerous oxalate); 15053-73-3 (cerous oxalate decahydrate).
ATC — A04AD02.
ATC Vet — QA04AD02.

NOTE. Cerium oxalate has been defined as consisting of about 50% of cerous oxalate ($(C_2O_4)_3Ce_2,10H_2O$) with the oxalates of numerous other rare earths, especially lanthanum, praseodymium, and neodymium. Oxalates of the form $(C_2O_4)_3Ce_2,xH_2O$ are also referred to as cerium or cerous oxalate.

Profile

Cerium oxalate has been used as an antiemetic.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Spain:*** Novonausin†.

Certolizumab Pegol *(BAN, USAN, rINN)*

CDP-870; Certolizumab Pégol; Certolizumabum Pegolum; PHA-738144.

Цертолизумаб Пегол

CAS — 428863-50-7.
ATC — L04AB05.
ATC Vet — QL04AB05.

Adverse Effects and Precautions

As for Infliximab, p.69.

Interactions

As for Infliximab, p.71

Uses and Administration

Certolizumab pegol is a pegylated tumour necrosis factor antibody fragment. It is used in the treatment of patients with moderate to severe, active Crohn's disease (p.1697) who have had an inadequate response to conventional treatment. The initial dose is 400 mg given as two subcutaneous injections of 200 mg, repeated after 2 and 4 weeks. Patients who have a clinical response may then receive a maintenance dose of 400 mg every 4 weeks. Certolizumab pegol is also under investigation in the treatment of rheumatoid arthritis and psoriasis.

Jpn: Neuer.

Chalk

Creta; Prepared Chalk.

Мел

$CaCO_3 = 100.1.$

CAS — 13397-25-6.

Pharmacopoeias. In *Br.*

BP 2008 (Chalk). A native form of calcium carbonate freed from most of its impurities by elutriation and dried. It consists of the calcareous shells and detritus of various foraminifera and contains not less than 97.0% and not more than 100.5% of $CaCO_3$, calculated with reference to the dried substance.

White or greyish-white, odourless or almost odourless, amorphous, earthy, small friable masses, usually conical in form, or in powder. Practically insoluble in water; slightly soluble in water containing carbon dioxide; it absorbs water readily.

Profile

Chalk has been used as an adsorbent antidiarrhoeal. Calcium carbonate (precipitated chalk) is used as an antacid, calcium supplement, and phosphate binder, see p.1714.

Calabash chalk, also known as Calabar stone, la craie or argile, nzu, mabele, ebumba, or ulo, is ingested by some pregnant women to alleviate morning sickness. It is traditionally used by Nigerian or West African women in the form of blocks, pellets, or powders. Calabash chalk either occurs naturally or is produced from clay and mud which may be mixed with other ingredients including sand, wood ash, and sometimes, salt. However, it contains high levels of lead, as well as arsenic (see Contamination, below).

Contamination. Concern with regard to the safety of calabash chalk has arisen, particularly with regard to its lead and arsenic content.[1-3] Analysis of calabash chalk samples available in the UK found that the major component of calabash chalk was an aluminium silicate hydroxide from the kaolin clay group. Lead concentrations in the samples were found to be about 40 mg/kg, almost 40 times the EU recommended guidelines. Potentially toxic chromium concentrations (dependent on the oxidation state) were also found. Arsenic, cadmium, and mercury were not detectable in any of the analysed samples. Persistent organic pollutants were also identified in one sample.[1] Calabash chalk is traditionally used by pregnant women, often those from Nigerian and West African communities, as a remedy for morning sickness. Health authorities in various countries have issued warnings, and advised people, especially pregnant and breast-feeding women, not to consume calabash chalk.[2,3]

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Cimetidine). A white or almost white, polymorphic powder. Slightly soluble in water; soluble in alcohol; practically insoluble in dichloromethane. It dissolves in dilute mineral acids. Store in airtight containers. Protect from light.

USP 31 (Cimetidine). A white to off-white crystalline powder, odourless or with a slight mercaptan odour. Slightly soluble in water and in chloroform; soluble in alcohol and in macrogol 400; practically insoluble in ether; sparingly soluble in isopropyl alcohol; freely soluble in methyl alcohol. Store in airtight containers. Protect from light.

Cimetidine Hydrochloride *(BANM, USAN, rINNM)*

Cimétidine, chlorhydrate de; Cimetidin-hidroklorid; Cimetidin-hydrochlorid; Cimetidinhydroklorid; Cimetidini hydrochloridum; Cimetidino hidrochloridas; Hidrocloruro de cimetidina; Simetidiinihydrokloridi.

Циметидина Гидрохлорид

$C_{10}H_{16}N_6S,HCl = 288.8.$

CAS — 70059-30-2.
ATC — A02BA01.
ATC Vet — QA02BA01.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Cimetidine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water; sparingly soluble in dehydrated alcohol. A 1% solution in water has a pH of 4.0 to 5.0. Store in airtight containers. Protect from light.

USP 31 (Cimetidine Hydrochloride). Store in airtight containers. Protect from light.

Adverse Effects

Adverse reactions to cimetidine and other histamine H_2-antagonists are generally infrequent. The commonest adverse effects reported have been diarrhoea and other gastrointestinal disturbances, dizziness, tiredness, headache, and rashes.

Altered liver function tests have occurred and there have been rare reports of hepatotoxicity. Reversible confusional states, especially in the elderly or in seriously ill patients such as those with renal failure, have occasionally occurred. Other adverse effects that have been reported rarely are hypersensitivity reactions and fever, arthralgia and myalgia, blood disorders including agranulocytosis, leucopenia, and thrombocytopenia, acute pancreatitis, interstitial nephritis, hallucinations and depression, and cardiovascular disorders including bradycardia, tachycardia, and heart block. Rapid intravenous injection should be avoided as there have been rare associations with cardiac arrest and arrhythmias; transient hypotension has also been seen.

In patients such as the elderly, those with chronic lung disease, diabetes mellitus, or the immunocompromised, treatment with H_2-antagonists may be associated with an increased risk of developing community-acquired pneumonia.

Cimetidine has a weak anti-androgenic effect and gynaecomastia and impotence have also occasionally occurred in men; these are usually reversible.

Incidence of adverse effects. In a meta-analysis of 24 double-blind placebo-controlled studies,[1] the incidence of adverse effects with cimetidine was not significantly different from placebo. The most common adverse effects reported by patients taking cimetidine who were followed up for at least one year[2,3] were diarrhoea, headache, fatigue, skin rash or pruritus, and gynaecomastia. The incidence of adverse effects was dose-related and decreased with length of treatment.[3] No fatal adverse effect of cimetidine could be found in a mortality survey involving 9928 patients taking cimetidine and 9351 controls;[4] although the mortality rate was higher in the cimetidine patients, this was explained by the presence of underlying disease (known or unknown) before starting cimetidine treatment and the use of cimetidine to counter adverse gastric effects of other drugs. Follow-up of 9377 of these cimetidine-treated patients for a further 3 years[5] still revealed no fatal disorder attributable to cimetidine treatment and a steady fall in the excess death rate in cimetidine users was seen with increasing length of follow-up; by the fourth year there was little difference between the observed and expected death rate. Cimetidine still appeared to be safe after 10 years of follow-up.[6]

Carcinogenicity. An association between H_2-antagonists and gastric cancer was proposed after individual case reports, the finding of tumours in long-term high-dose *animal* studies, and the possibility that nitrites and nitroso compounds may be produced, but seemed of little clinical relevance.[1,2] The excess risk of gastric cancer reported in patients taking cimetidine[3-6] or ranitidine[6] decreases with time and there is no evidence for any long-term persistence of the effect.[6] The increased risk may be explained by misdiagnosis and inappropriate cimetidine treatment of existing malignancy.[3-5] An apparently protective effect has been seen for H_2-antagonist use starting 10 or more years before diagnosis of gastric cancer.[6]

The observed excess risk for cancers of the respiratory system is probably related to smoking, since this is causally related to both peptic ulcer and lung cancer and the excess risk does not decline with time.[3-5]

Effects on the blood. A review[1] in 1988 noted that leucopenia, thrombocytopenia, and pancytopenia have all been reported with cimetidine and ranitidine, with neutropenia and agranulocytosis occurring most often. There were also isolated reports of haemolytic anaemia and leucocytosis associated with cimetidine therapy. The overall incidence of cimetidine-associated blood cytopenia was estimated as 2.3 per 100 000 treated patients; the incidence for ranitidine was less and although there were reports with famotidine the incidence had not been determined. A subsequent case-control study,[2] concluded that the risk of hospitalisation due to neutropenia in patients receiving a 6-week course of cimetidine was no more than 1 in 116 000, while agranulocytosis did not occur in more than 1 in 573 000 patients.

A review[3] of the safety profile of famotidine noted that as of May 1992 there had been 60 reports of serious blood dyscrasias in patients receiving famotidine, of which 22 were considered possibly related to drug therapy (6 cases of pancytopenia or bone marrow depression, 5 of thrombocytopenia, 4 of leucopenia, 3 of combined leucopenia and thrombocytopenia, and 3 of agranulocytosis).

Effects on the cardiovascular system. Bradycardia,[1-4] AV block,[5,6] tachycardia,[7] and hypotension[4,8] have been reported during cimetidine treatment given by mouth and by intravenous injection or infusion. Although there are studies in patients[9] and healthy subjects[10,11] that have found no significant cardiovascular effects associated with cimetidine treatment, it is likely that a small proportion of patients are more susceptible to the cardiovascular effects of cimetidine. Caution is recommended if the drug is given intravenously to patients with cardiovascular disease (see Precautions, below).

Effects on the endocrine system. Cimetidine has dose-related mild anti-androgenic properties and reduced sperm counts and raised serum-prolactin concentrations have been reported in men during cimetidine treatment[1] as have gynaecomastia, breast tenderness, and impotence.[2] Those symptoms resolved after withdrawal of cimetidine,[1,2] reduction of the dose,[2] or transfer to ranitidine.[2]

A study by the Boston Collaborative Drug Surveillance Program, using data from 81 535 men in the UK, found that cimetidine was associated with an incidence of 3.29 cases of gynaecomastia per 1000 person years, representing a relative risk 7.2 times greater than that of non-users.[3] The period at highest risk seemed to be between the seventh and twelfth month after starting treatment, and the occurrence was related to dose, with most of the risk associated with doses over 1 g daily. This large study found no significant risk of gynaecomastia with ranitidine or omeprazole. However, there have been isolated reports of gynaecomastia or impotence with ranitidine (p.1766), nizatidine (p.1751), and famotidine (p.1730).

Effects on the eyes. Ocular pain, blurred vision, and a rise in intra-ocular pressure occurred in a patient with chronic glaucoma during treatment with cimetidine; ocular symptoms associated with raised intra-ocular pressure subsequently developed during ranitidine treatment.[1] However, a study suggested that cimetidine had no effect on intra-ocular pressure.[2] A cohort study involving 140 128 patients receiving anti-ulcer therapy, 68 504 of whom received cimetidine, found no evidence that any of the drugs were associated with a major increased risk of vascular or inflammatory disorders of the eye.[3]

Effects on the kidneys. A review[1] of the nephrotoxicity and hepatotoxicity of H_2-antagonists noted that mild elevation of serum-creatinine was relatively common after use of cimetidine but appeared to have no clinical significance. However, the authors found 25 published reports of acute interstitial nephritis associated with this class of drug (20 with cimetidine, 4 with ranitidine, and 1 with famotidine) and 16 cases reported to the Australian Drug Reaction Advisory Committee (ADRAC) between 1972 and 1999 (11 with cimetidine, 4 with ranitidine, and 1 with famotidine). Symptoms were mostly non-specific, and did not seem to be associated with the rash, arthralgia, and flank pain that may be seen in nephritis induced by other drugs. Nephritis invariably resolved when the drug was withdrawn; in 6 cases, rechallenge resulted in prompt return of clinical features, although there was some evidence that patients who developed nephrotoxicity with one H_2-antagonist might be able to tolerate substitution with another. The effect was rare (an earlier analysis estimated an incidence of around 1 in 100 000 treated patients[2]) but with the increasing availability of over-the-counter H_2-antagonist formulations it was important to be aware of the risk.

Effects on the liver. A cohort study[1] involving 108 891 patients given cimetidine, ranitidine, famotidine, or omeprazole between 1990 and 1993, found 33 cases meeting the authors' definition of clinically serious liver injury (cholestatic in 8 cases, hepatocellular in 15 and mixed in 10), most of whom presented with jaundice. Of these cases of liver injury, 12 were among current users of cimetidine, compared with 5 among users of ranitidine and 1 omeprazole user. It was estimated that the incidence of hepatotoxicity among patients using cimetidine was 2.3 cases per 10 000 users, and the adjusted relative risk was 5.5 times that of non-users. The relative risk for use of ranitidine or omeprazole was calculated at 1.7 and 2.1 respectively. The risk with cimetidine was greatest at high doses (800 mg daily or above) and at the beginning of therapy. For reports of liver damage with famotidine and cimetidine, see p.1730.

Effects on the nervous system. Cimetidine has been associated with a number of adverse neurological effects including confusion,[1-8] bizarre behaviour,[9] reversible brain stem syndrome (with ataxia, dysarthria, visual impairment, deafness, and paraesthesia),[10] coma,[8,11] convulsions,[7] encephalopathy,[12] visual hallucinations,[9,13,14] paranoia,[5] chorea,[15,16] myopathy,[17] and neuropathy.[18,19] These reactions occur mainly in patients who are elderly, critically ill, or with impaired renal or hepatic function, in whom there may be increased penetration of the blood-brain barrier by cimetidine. Single-dose studies in young healthy subjects[20] have found no adverse changes in performance, central nervous function, or subjective assessment of mood after oral cimetidine 200 or 400 mg.

There is no clear evidence that cimetidine is a more frequent cause of CNS reactions than ranitidine, famotidine, or nizatidine.[21]

Effects on the skin. Widespread erythrosis-like lesions in a 36-year-old man were probably induced by cimetidine.[1] There has been a report[2] of a skin eruption clinically consistent with erythema annulare centrifugum developing in a patient after 6 months of treatment with cimetidine; the eruption resolved after withdrawal of cimetidine and reappeared on rechallenge. The condition had not recurred during therapy with ranitidine. Erythema multiforme eruptions occurred after both cimetidine and famotidine in one patient (see p.1730). There have been reports of the Stevens-Johnson syndrome during cimetidine treatment in patients with a history of hypersensitivity to penicillin[3] or sulfonamides,[4] and a report of toxic epidermal necrolysis.[5]

Urticarial vasculitis[6] and alopecia[7] have also been associated with cimetidine treatment.

Infection. Treatment with H_2-antagonists may predispose patients to salmonella infection, probably because the decrease in gastric acidity reduces the gastric killing of ingested organisms.[1] The greatest increase in risk was seen in patients over 65 years of age.

There are conflicting data on whether the use of H_2-antagonists for prophylaxis of stress ulcers in critically ill patients increases the risk for pneumonia (see under Peptic Ulcer Disease, p.1702). However, a case-control study in a large cohort of patients in primary care suggested that the risk of developing pneumonia in these less-severely ill patients was increased by antisecretory drugs: the relative risk was 1.63 in patients receiving H_2-antagonists, and 1.89 in those prescribed a proton pump inhibitor; there was also some evidence of a dose-response relationship in the latter group.[2]

Data from case-control studies[3] suggest that gastric acid suppression by H_2-antagonists may also be a risk factor for *Clostridium difficile*-associated disease. A case-control study in very low birth-weight infants found that use of H_2-antagonists was associated with an increased incidence of necrotising enterocolitis.[4] The authors postulate that this could be due to bacterial overgrowth in a less acidic gastric environment.

Also available at: http://pediatrics.aappublications.org/cgi/reprint/117/2/e137 (accessed 09/04/08)

Malabsorption. Vitamin B_{12} deficiency has been reported in association with acid-suppressive therapy, including H_2-antagonists. The deficiency was thought to result from impaired release of vitamin B_{12} from food protein, which requires gastric acid and pepsin.[1]

1. Ruscin JM, *et al.* Vitamin B deficiency associated with histamine -receptor antagonists and a proton-pump inhibitor. *Ann Pharmacother* 2002; **36:** 812–16.

Overdosage. No serious toxic effects were noted in reports[1-3] of overdosage in patients who took cimetidine 5.2 to 20 g (including one patient who took about 12 g daily for 5 days[1]). Resultant plasma concentrations had been up to 57 micrograms/mL compared with a usual peak plasma concentration of 1 microgram/mL after a 200-mg dose. However, an overdose of about 12 g produced high pulse rate, dilated pupils, speech disturbances, agitation and disorientation in one patient[4] and respiratory depression in another patient who had chronic schizophrenia and was also taking trifluoperazine and hydroxyzine.[5] Also, fatal bradycardia has been reported after overdosage with an unknown amount of cimetidine and diazepam.[6] In a review of 881 cases of cimetidine overdose, excluding cases where several drugs were taken, it was concluded that the toxicity of cimetidine after acute overdose was very low.[7] No symptoms were observed in 79% of cases, which included ingestions of up to 15 g of cimetidine, and only 3 patients had moderate clinical manifestations (dizziness and bradycardia; CNS depression; vomiting). No patients had major medical outcomes and there were no fatalities. Gastric emptying was performed in 34% of cases but supportive measures and symptomatic treatment alone may be adequate. Forced diuresis does not appear to enhance the excretion of cimetidine from the body, and is not recommended.[3]

Precautions

Before giving cimetidine or other histamine H_2-antagonists to patients with gastric ulcers the possibility of malignancy should be considered since these drugs may mask symptoms and delay diagnosis. They should be given in reduced dosage to patients with renal impairment.

Intravenous injections of cimetidine should be given slowly and intravenous infusion is preferred, particularly for high doses and in patients with cardiovascular impairment.

Breast feeding. In the UK, manufacturers advise that mothers receiving cimetidine avoid breast feeding. Cimetidine is reported to be actively transported into breast milk, resulting in a milk:serum ratio 5.5 times higher than that expected with passive diffusion.[1] In one case, where cimetidine was detected in the milk of a nursing mother in concentrations higher than in her plasma, it was calculated[2] that the maximum amount of cimetidine that an infant could ingest assuming an intake of about 1 litre of milk daily and fed at the time of peak concentrations would be about 6 mg. However, the Committee on Drugs of the American Academy of Pediatrics has pointed out that there was no evidence of signs or symptoms attributable to the drug in the infant in this case,[3] despite 6 months of breast feeding, and cimetidine has been classified by that body as usually compatible with breast feeding.[4]

Burns. The clearance of cimetidine has been reported to be increased in burn patients, with the increase correlating to the size of the burn.[1] Despite another study that reported a decreased renal clearance (but an increased non-renal clearance) early in the evolution of burn injury,[2] it has been recommended that the dosage of cimetidine be increased in patients with burns, depending on the extent of injury. A requirement for increased dosage has also been noted in paediatric burns patients.[3]

Helicobacter pylori testing. In one study,[1] 2 of 11 patients with *Helicobacter pylori* infection had false-negative urea breath tests while receiving high dose ranitidine (600 mg daily). The breath test became positive again within 5 days of stopping therapy. The manufacturers of the breath test recommend it should not be performed for at least 2 weeks after stopping antisecretory drug therapy.

1. Chey WD, *et al.* Lansoprazole and ranitidine affect the accuracy of the C-urea breath test by a pH-dependent mechanism. *Am J Gastroenterol* 1997; **92:** 446–50.

Hepatic impairment. An increased resistance to H_2-receptor antagonists has been reported in patients with cirrhosis, see Ranitidine, p.1766. For a suggestion that dosage reduction of cimetidine may be required in patients with portal systemic encephalopathy, see Administration in Hepatic Impairment, below.

Porphyria. Cimetidine is considered to be unsafe in patients with porphyria although there is conflicting experimental evidence of porphyrinogenicity.

For reference to clinical and biochemical improvement in porphyric patients receiving cimetidine, see below.

Renal impairment. The clearance of cimetidine is reduced in renal impairment and dosage reduction is recommended (see under Administration in Renal Impairment, below).

Interactions

Cimetidine and other H_2-antagonists can reduce the absorption of drugs such as dasatinib, ketoconazole, and possibly itraconazole, whose absorption is dependent on an acid gastric pH. For the effect of itraconazole on cimetidine see Antifungals, below.

Cimetidine may inhibit the hepatic metabolism of many drugs by binding to cytochrome P450 isoenzymes, notably CYP1A2, CYP2C9, CYP2D6, and CYP3A4. Although many such interactions may occur, only a few are considered clinically significant, notably those with phenytoin, theophylline, lidocaine, and oral anticoagulants. Avoidance of the combination, or a reduction in the dosage of these drugs may be required.

◊ Cimetidine can affect a wide range of drugs[1-4] but these interactions are of clinical significance for only a few, particularly those that have a narrow therapeutic index where the risk of toxicity may necessitate adjustment of dosage. The majority of interactions are due to binding of cimetidine to cytochrome P450 isoenzymes in the liver with subsequent inhibition of microsomal oxidative metabolism and increased bioavailability or plasma concentrations of drugs metabolised by these enzymes. A few interactions are due to competition for renal tubular secretion. Other mechanisms of interaction such as changes in hepatic blood flow play only a minor role.

Significant or potentially significant interactions have occurred with

- antiepileptics such as phenytoin (p.500) and carbamazepine (p.475)
- biguanide antidiabetics (p.438)
- lidocaine (p.1864)
- nifedipine (p.1353)
- opioid analgesics (p.103)
- procainamide (p.1378)
- theophylline (p.1145)
- tricyclic antidepressants such as amitriptyline (p.380)
- warfarin and other oral anticoagulants (p.1430)
- zalcitabine (p.913)
- zolmitriptan (p.628)

Combinations of these drugs and cimetidine should be avoided or used with caution, with monitoring of effects or plasma-drug concentrations and reductions in dosage as appropriate.

Famotidine, nizatidine, and ranitidine do not inhibit cytochrome P450, and the potential for drug interactions is therefore reduced.

2. Somogyi A, Muirhead M. Pharmacokinetic interactions of cimetidine 1987. *Clin Pharmacokinet* 1987; **12:** 321–66.
3. Smith SR, Kendall MJ. Ranitidine versus cimetidine: a comparison of their potential to cause clinically important drug interactions. *Clin Pharmacokinet* 1988; **15:** 44–56.
4. Shinn AF. Clinical relevance of cimetidine drug interactions. *Drug Safety* 1992; **7:** 245–67.

Alcohol. Any interaction between H_2-antagonists and alcohol is generally thought unlikely to be clinically significant (see p.1627).

Antacids. Single-dose studies of the interaction between cimetidine and antacids[1] have shown reduced bioavailability of cimetidine as well as no interaction. The neutralising capacity of the antacid appears to be a factor in determining whether an interaction occurs and a dose with less than 50 mmol neutralising capacity will have little, if any, effect on cimetidine absorption. There is no evidence that the therapeutic efficacy of cimetidine is reduced and with long-term use of the combination the bioavailability of cimetidine is unlikely to be reduced.

1. Gugler R, Allgayer H. Effects of antacids on the clinical pharmacokinetics of drugs: an update. *Clin Pharmacokinet* 1990; **18:** 210–19.

Antifungals. *Itraconazole* increased the area under the concentration-time curve of cimetidine, and reduced the total plasma clearance and renal tubular secretory clearance of cimetidine in a pharmacokinetic study in 8 healthy subjects.[1] The authors proposed that this was due to inhibition of P-glycoprotein-mediated renal tubular secretion.

1. Karyekar CS, *et al.* Renal interaction between itraconazole and cimetidine. *J Clin Pharmacol* 2004; **44:** 919–27.

Antimuscarinics. The antimuscarinic *propantheline* delays gastric emptying and reduces intestinal motility and has been reported to reduce the bioavailability of cimetidine.[1]

1. Kanto J, *et al.* The effect of metoclopramide and propantheline on the gastrointestinal absorption of cimetidine. *Br J Clin Pharmacol* 1981; **11:** 629–31.

Prokinetic drugs. *Metoclopramide* may reduce the bioavailability of cimetidine possibly due to reduction of gastrointestinal transit time.[1-3] A similar interaction has been reported between cimetidine and the prokinetic drug *cisapride*.[4] The clinical significance of this interaction is questionable since such combinations may be clinically effective, although the use of cisapride is now restricted in many countries.

3. Barzaghi N, *et al.* Effects on cimetidine bioavailability of metoclopramide and antacids given two hours apart. *Eur J Clin Pharmacol* 1989; **37:** 409–10.
4. Kirch W, *et al.* Cisapride-cimetidine interactions; enhanced cisapride bioavailability and accelerated cimetidine absorption. *Ther Drug Monit* 1989; **11:** 411–14.

Sucralfate. Licensed product information for the mucosal protectant sucralfate states that it has been shown to reduce the bioavailability of cimetidine and other H_2 antagonists, presumably due to binding in the gastrointestinal tract. The effect can be avoided by separating doses of the two drugs by 2 hours, but it is not clear whether the interaction has a clinical significance.

Pharmacokinetics

Cimetidine is readily absorbed from the gastrointestinal tract and peak plasma concentrations are obtained after about an hour when given on an empty stomach; a second peak may be seen after about 3 hours. Food delays the rate and may slightly decrease the extent of absorption, with the peak plasma concentration occurring after about 2 hours.

The bioavailability of cimetidine after oral doses is about 60 to 70%. Cimetidine is widely distributed and has a volume of distribution of about 1 litre/kg and is weakly bound, about 20%, to plasma proteins. The elimination half-life from plasma is about 2 hours and is increased in renal impairment. Cimetidine is partially metabolised in the liver to the sulfoxide and to hydroxymethylcimetidine. About 50% of an oral dose, and 75% of an intravenous dose, is excreted unchanged in the urine in 24 hours. Cimetidine crosses the placental barrier and is distributed into breast milk.

Children. Renal function is limited in the first few months of life and half-lives of 1.1 to 3.7 hours have been reported for cimetidine in neonates.[1-3] A dosage regimen for neonates based on renal function has been suggested[1] with 15 to 20 mg/kg daily for full-term neonates, but with lower doses for premature neonates and those with renal dysfunction. However, single doses of 5 to 7 mg/kg may be sufficient to suppress gastric acid secretion in neonates.[3]

In older infants and children maturation of renal function is complete and the clearance of cimetidine is increased compared with that in adults while younger children show higher clearance values than older children. A typical dosage regimen for children is 30 mg/kg daily, in 3 or 4 divided doses.[4] However, even this dose might not produce optimal control of gastric acid.[5]

Uses and Administration

Cimetidine is a histamine H_2-antagonist and inhibits actions of histamine mediated by H_2-receptors such as gastric acid secretion and pepsin output. It is used where inhibition of gastric acid secretion may be beneficial, as in peptic ulcer disease, including stress ulceration (p.1702), gastro-oesophageal reflux disease (p.1696), selected cases of persistent dyspepsia (p.1695), pathological hypersecretory states such as the Zollinger-Ellison syndrome (p.1704), and in patients at risk of acid aspiration (p.1693) during general anaesthesia or child birth. Cimetidine may also be used to reduce malabsorption and fluid loss in patients with the short bowel syndrome and to reduce the degradation of enzyme supplements given to patients with pancreatic insufficiency.

Cimetidine may be given orally, by the nasogastric route, or parenterally by the intravenous or intramuscular routes; the total daily dose by any route should not normally exceed 2.4 g. Although some formulations are prepared as the hydrochloride, strengths and doses are expressed in terms of the base. Cimetidine 100 mg is equivalent to about 114.4 mg of cimetidine hydrochloride. Doses should be reduced in renal impairment and may also need to be reduced in hepatic impairment (see below).

SPECIFIC DISEASE DOSES.

In the management of benign **gastric** and **duodenal ulceration** a single daily oral dose of 800 mg at bedtime is recommended, which should be given for at least 4 weeks in the case of duodenal, and for at least 6 weeks in the case of gastric, ulcers. Where appropriate a maintenance dose of 400 mg may then be given once daily at bedtime, or twice daily in the morning and at bedtime. Other regimens have also been used for treatment and maintenance.

In **gastro-oesophageal reflux disease** the recommended oral dose is 400 mg four times daily (with meals and at bedtime), or 800 mg twice daily, for 4 to 8 weeks. In pathological hypersecretory conditions, such as the **Zollinger-Ellison syndrome**, an oral dose of 300 or 400 mg four times daily is normally used, although sometimes higher doses may be necessary.

Doses of 200 to 400 mg orally, by nasogastric tube, or parenterally (200 mg only for direct intravenous injection) every 4 to 6 hours are recommended for the management of patients at risk from **stress ulceration** of the upper gastrointestinal tract. In patients at risk of developing the **acid aspiration syndrome**, an oral dose of 400 mg may be given 90 to 120 minutes before the induction of anaesthesia, or at the start of labour (in obstetric practice), and doses of up to 400 mg (by the parenteral route if appropriate, see below) may be repeated at intervals of 4 hours if required.

Doses of up to 200 mg four times daily have been taken for non-ulcer **dyspepsia**; 100 mg at night has been used in the prophylaxis of nocturnal heartburn.

To reduce the degradation of pancreatic enzyme supplements, patients with **pancreatic insufficiency**, as in cystic fibrosis (p.166), may be given oral cimetidine 800 to 1600 mg daily in 4 divided doses, 60 to 90 minutes before meals.

PARENTERAL ADMINISTRATION.

In the UK, the usual dose of cimetidine by intravenous injection is 200 mg, which should be given slowly over at least 5 minutes and may be repeated every 4 to 6 hours. If a larger dose is required, or if the patient has cardiovascular impairment, intravenous infusion is recommended. For an intermittent intravenous infusion the recommended dose is 200 to 400 mg every 4 to 6 hours if necessary. For a continuous intravenous infusion the recommended rate is 50 to 100 mg/hour. The usual intramuscular dose is 200 mg which may be repeated at intervals of 4 to 6 hours. In the USA, parenteral dosage recommendations are 300 mg every 6 to 8 hours by intramuscular injection or by slow intravenous injection over at least 5 minutes. The same dosage may be given by intermittent intravenous infusion over 15 to 20 minutes; for continuous intravenous infusion the recommended rate is 37.5 mg/hour, which may be preceded by 150 mg as an intravenous loading dose. However, a rate of 50 mg/hour is recommended for prevention of stress ulceration.

CHILDREN'S DOSES.

For **children** over one year of age 25 to 30 mg/kg daily may be given in divided doses, by mouth or parenterally. Under 1 year of age, 20 mg/kg daily in divided doses has been used (see also Children, under Pharmacokinetics, above).

Administration in hepatic impairment. The bioavailability of cimetidine may be increased in patients with cirrhosis[1,2] and a dosage reduction of up to 40% has been suggested in patients with portal systemic encephalopathy.[3] However, UK and US licensed drug information does not include recommendations for dosage adjustment in hepatic impairment.

1. Gugler R, *et al.* Altered disposition and availability of cimetidine in liver cirrhotic patients. *Br J Clin Pharmacol* 1982; **14:** 421–30.
2. Cello JP, Øie S. Cimetidine disposition in patients with Laennec's cirrhosis during multiple dosing therapy. *Eur J Clin Pharmacol* 1983; **25:** 223–9.
3. Ziemniak JA, *et al.* Hepatic encephalopathy and altered cimetidine kinetics. *Clin Pharmacol Ther* 1983; **34:** 375–82.

Administration in renal impairment. The dosage of cimetidine should be reduced in patients with renal impairment; suggested doses according to creatinine clearance (CC) are:

- CC over 50 mL/minute: normal dosage
- CC 30 to 50 mL/minute: 200 mg four times daily
- CC 15 to 30 mL/minute: 200 mg three times daily
- CC 0 to 15 mL/minute: 200 mg twice daily

Cimetidine is removed by haemodialysis, but not significantly removed by peritoneal dialysis.

Bladder disorders. Cimetidine effectively relieved symptoms in patients with painful bladder disease (encompassing conditions including cystitis, painful bladder syndrome, and urethral syndrome), especially suprapubic pain and nocturia, despite no apparent histological change in the bladder mucosa after treatment.[1]

1. Thilagarajah R, *et al.* Oral cimetidine gives effective symptom relief in painful bladder disease: a prospective, randomized, double-blind placebo-controlled trial. *BJU Int* 2001; **87:** 207–12.

Dapsone toxicity. Cimetidine might reduce the haemolysis and methaemoglobinaemia associated with dapsone. For references supporting this suggestion, see Effects on the Blood, under Dapsone, p.261.

Diagnostic use. Cimetidine blocks renal tubular secretion of creatinine and has been used experimentally to improve the accuracy of estimations of glomerular filtration rate from creatinine clearance in patients with renal disease.[1] Best results were achieved with a bolus dose of 1.2 g and the use of such a high dose was questioned.[2]

1. van Acker BAC, *et al.* Creatinine clearance during cimetidine administration for measurement of glomerular filtration rate. *Lancet* 1992; **340:** 1326–9.
2. Agarwal R. Creatinine clearance with cimetidine for measurement of GFR. *Lancet* 1993; **341:** 188.

Echinococcosis. Cimetidine has been given with albendazole to increase its effect (by inhibiting its metabolism) in the treatment of echinococcosis (p.136).

Immunomodulation. Studies in *mice* and humans have shown that H_2-antagonists have an immunoregulatory effect.[1] T-lymphocyte suppressor cells have histamine H_2 receptors and cimetidine has been reported to reduce activity of these cells, thus enhancing immune response.[1,2] There is also some evidence that it enhances cellular immunity, notably natural killer cell activity.[3] This discovery has led to the investigation of cimetidine in a number of disorders associated with alteration of the immune response including eosinophilic fasciitis, herpesvirus infections, mucocutaneous candidiasis,[4] hypogammaglobulinaemia,[5] and various malignancies.[1]

EOSINOPHILIC FASCIITIS. Eosinophilic fasciitis is a scleroderma-like syndrome of inflammation of the muscle fascia and associated eosinophilia and hypergammaglobulinaemia. Although it responds well to corticosteroid therapy in most cases, cimetidine has also been tried. The effect of cimetidine on eosinophilic fasciitis is unpredictable with both remission[1-4] and lack of response[5,6] having been reported in a few patients.

HERPESVIRUS AND PAPILLOMAVIRUS INFECTIONS. Although there have been numerous isolated and anecdotal reports of a beneficial response to cimetidine in patients with infections due to various *herpesviruses* (p.853), including genital herpes simplex,[1] infectious mononucleosis,[2,3] and herpes zoster[4-7] some of these reports have been criticised[8,9] mainly on the grounds that the majority of cases of herpes zoster will resolve within 2 to 3 weeks whether any treatment is given or not. Also, a double-blind placebo-controlled study involving 63 patients with herpes zoster[10] found no evidence that cimetidine relieved the pain or accelerated the rate of healing of lesions.

There are reports[11] of benefit from the use of cimetidine in patients with *viral warts* (p.1584), but controlled studies have failed to show significant benefit.[12,13]

MALIGNANT NEOPLASMS. Because of its immunomodulatory effects cimetidine has been tried, with some reported benefit,[1-3] as an adjuvant in the management of a variety of malignant neoplasms such as those of the gastrointestinal tract (see p.664). However, a large randomised study[4] failed to show any benefit for cimetidine compared with placebo in gastric cancer. A similar study with ranitidine also failed to show any significant benefit.[5]

3. Matsumoto S. Cimetidine and survival with colorectal cancer. *Lancet* 1995; **346:** 115.
4. Langman MJS, *et al.* Prospective, double-blind, placebo-controlled randomized trial of cimetidine in gastric cancer. *Br J Cancer* 1999; **81:** 1356–62.
5. Primrose JN, *et al.* A prospective randomised controlled study of the use of ranitidine in patients with gastric cancer. *Gut* 1998; **42:** 17–19.

Mastocytosis. Cimetidine, alone or with an antihistamine (histamine H_1-antagonist), has been reported to relieve gastrointestinal symptoms,[1,2] pruritus, and urticaria[3,4] in patients with mastocytosis (p.1138).

1. Hirschowitz BI, Groarke JF. Effect of cimetidine on gastric hypersecretion and diarrhea in systemic mastocytosis. *Ann Intern Med* 1979; **90:** 769–71.
2. Linde R, *et al.* Combination H1 and H2 receptor antagonist therapy in mastocytosis. *Ann Intern Med* 1980; **92:** 716.

Paracetamol toxicity. It has been suggested that cimetidine might be of use in the treatment of paracetamol poisoning (see p.108) because of its inhibition of the cytochrome P450 system. However, there appears to be no evidence to support the claims of benefit made in some anecdotal reports.[1]

1. Kaufenberg AJ, Shepherd MF. Role of cimetidine in the treatment of acetaminophen poisoning. *Am J Health-Syst Pharm* 1998; **55:** 1516–19.

Porphyria. There are reports[1-3] of patients with acute intermittent porphyria (p.1448) showing clinical and biochemical improvement during treatment with cimetidine. Cimetidine is, however, considered to be unsafe in patients with porphyria (see under Precautions, above).

1. Baccino E, *et al.* Cimetidine in the treatment of acute intermittent porphyria. *JAMA* 1989; **262:** 3000.

3. Cherem JH, *et al.* Cimetidine and acute intermittent porphyria. *Ann Intern Med* 2005; **143:** 694–5.

Skin disorders. Cimetidine has been used alone[1-8] or with an antihistamine (H_1-antagonist)[5,8,9] in various skin disorders. H_2-antagonists such as cimetidine and ranitidine have produced improvement in certain types of *urticaria* (p.1584), especially those associated with cold or angioedema. Their routine use in urticaria is controversial, but in practice their addition to conventional treatment can be tried in resistant cases.[10-12] Little additional benefit has been found with combination therapy in dermographic urticaria.[13] Although they may act by antagonism of H_2-receptors on cutaneous blood vessels, other mechanisms of action may be involved.[8] Patients with *pruritus* (p.1582) of various causes may also respond to H_2-antagonists,[1,2,6,7,9] but studies in larger groups of patients have demonstrated no benefit.[3-5,14]

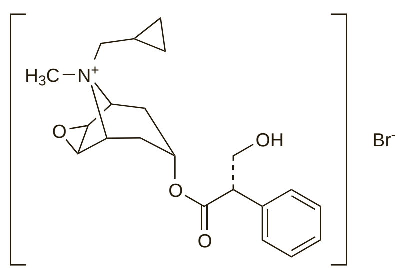
Cimetropium Bromide *(rINN)*

Bromuro de cimetropio; Cimetropii Bromidum; Cimétropium, Bromure de; DA-3177; Hyoscine-*N*-(cyclopropylmethyl) Bromide. 8-(Cyclopropylmethyl)-6β,7β-epoxy-3α-hydroxy-1αH,5αH-tropanium bromide, (−)-(*S*)-tropate.

Циметропия Бромид

$C_{21}H_{28}BrNO_4$ = 438.4.
CAS — 51598-60-8.
ATC — A03BB05.
ATC Vet — QA03BB05.



Profile

Cimetropium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used as an antispasmodic in the treatment of gastrointestinal disorders, in usual doses of 50 mg two or three times daily orally or by rectal suppository. It has also been given intramuscularly or intravenously in usual doses of 5 mg.

Adverse Effects

The most commonly reported adverse effects with cisapride are gastrointestinal disturbances including abdominal cramps, borborygmi, and diarrhoea. Headache and lightheadedness may also occur. Hypersensitivity (including rash, pruritus, and bronchospasm), convulsions, extrapyramidal effects, and increased urinary frequency, have occasionally been reported. Cases of arrhythmia, including ventricular tachycardia, ventricular fibrillation, torsade de pointes, and QT interval prolongation have occurred rarely; fatalities have resulted, and have led to severe restrictions on its use (see Effects on the Heart, below). There have been a few cases of disturbances in liver function among patients receiving cisapride.

Incidence of adverse effects. A comparison of data from prescription-event monitoring in over 13 000 recipients of cisapride and from a further 9726 recipients involved in a controlled study showed that diarrhoea, in about 2 to 4% of patients, was the commonest adverse effect reported.[1] Other relatively common adverse effects were headache, abdominal pain, nausea and vomiting, and constipation, all in around 1 to 1.5% of patients. There were 46 reports in the prescription-event monitoring data of increased urinary frequency (plus a further 20 among the controlled study patients), and 5 reports of arrhythmias.

1. Wager E, *et al.* A comparison of two cohort studies evaluating the safety of cisapride: prescription-event monitoring and a large phase IV study. *Eur J Clin Pharmacol* 1997; **52:** 87–94.

Effects on the heart. Seven reports[1] of cardiac effects associated with cisapride were submitted to the WHO Programme for International Drug Monitoring between 1989 and 1991. They included palpitations in 4, tachycardia and hypertension in 1, and extrasystole in 2. Subsequent reports implicated cisapride in the development of prolonged QT interval and torsade de pointes or ventricular fibrillation or both.[2,3] By December 1999 the FDA had received 341 reports of heart rhythm abnormalities associated with cisapride use, including 80 reports of deaths. Most patients were either receiving other drugs known to impair cisapride metabolism (see Interactions, below) or had other factors predisposing to arrhythmias. In the light of earlier reports of cardiac effects and of evidence for a direct effect of cisapride on the heart at therapeutic concentrations, in 1998 the UK CSM **contra-indicated**[2] the use of cisapride in patients receiving drugs that could inhibit cisapride metabolism or that prolong the QT interval, as well as in patients with a history of QT interval prolongation, ventricular arrhythmia, or torsade de pointes, or other risk factors for arrhythmia (see Precautions, below). Neonates[4] (especially of low gestational age[5]) are vulnerable to cisapride-induced QT interval prolongation, and the CSM also specifically contra-indicated use in premature neonates[2] and noted that there were insufficient data to support use in children up to the age of 12. Other studies have also noted a prolongation of QT interval in children.[6,7] However, some commentators have questioned the general contra-indication in prematurity,[8] and one retrospective analysis estimated the rate of serious adverse events such as arrhythmia in premature newborns to be less than 1 in 11 000, excluding those cases related to concurrent treatment with a contra-indicated drug or to overdose.[9] Conversely, others emphasise the lack of objective evidence of benefit for cisapride in most paediatric indications.[10] The European Society of Paediatric Gastroenterology, Hepatology and Nutrition has published recommendations on the use of cisapride in paediatric gastro-oesophageal reflux disease,[11] including that the total daily dose of cisapride should rarely exceed 800 micrograms/kg, and that ECG monitoring should be performed before and after 3 days of treatment in certain groups such as premature infants.

The use of cisapride has also been the subject of warnings and restrictions in other countries. In the USA, prescribing information was amended in January 2000 to recommend that all patients should receive an ECG before beginning cisapride therapy and extending the contra-indications to use; the drug was subsequently **withdrawn** from general supply, remaining available only in severely restricted cases. In July 2000 cisapride was also withdrawn completely from the UK market.[12] In Europe, the European Commission decided that cisapride-containing products could be maintained with restricted indications; all patients given cisapride should be enrolled in either a study or registry of clinical safety, or a study of clinical effectiveness.[13] Despite a withdrawal of cisapride from general supply, a retrospective cohort study in South Korea found that it was still in use there up to 2 years later; in many instances cisapride had been given with contra-indicated drugs, which was associated with an increase in the risk of all-cause mortality.[14]

Effects on the respiratory system. Chest tightness, wheezing, and a fall in peak flow rate occurred in a patient with severe brittle asthma after taking cisapride 10 mg.[1] Four other cases of bronchospasm associated with cisapride were discussed in a subsequent report;[2] in 2 of these cases symptoms resolved on withdrawal and recurred on rechallenge.

2. Pillans P. Bronchospasm associated with cisapride. *BMJ* 1995; **311:** 1472.

Effects on the urinary tract. There had been 12 cases of urinary disturbances associated with use of cisapride[1] reported to the Australian Adverse Drug Reactions Advisory Committee between March 1991 and July 1993. Five reports were of urinary incontinence, 8 involved frequency, and individual reports involved cystitis, hesitancy, and urinary retention. The majority of the cases involved women, and most patients were elderly.

1. Boyd IW, Rohan AP. Urinary disorders associated with cisapride. *Med J Aust* 1994; **160:** 579–80.

Precautions

Cisapride should not be used when stimulation of muscular contractions might adversely affect gastrointestinal conditions as in gastrointestinal haemorrhage, obstruction, perforation, or immediately after surgery.

Cisapride is **contra-indicated** in the following patients:

- those receiving potent inhibitors of the cytochrome P450 isoenzyme CYP3A4 such as macrolide antibacterials, azole antifungals, HIV-protease inhibitors, or nefazodone (see also Interactions, below)
- those taking other drugs that predispose to electrolyte disturbances or that prolong the QT interval
- those with a personal or family history of QT interval prolongation
- those with a history of ventricular arrhythmia or torsade de pointes

Furthermore, it should not be given to those with other risk factors for arrhythmia including:

- clinically significant heart disease
- uncorrected electrolyte disturbances (particularly hypokalaemia and hypomagnesaemia)
- renal failure
- respiratory failure

Use is also contra-indicated in premature infants for up to 3 months after birth.

Cisapride should be used with caution and in reduced doses in patients with hepatic or renal impairment. All patients should have their ECG, serum electrolytes, and renal function monitored before and during treatment.

Care should be taken not to exceed the recommended dose.

Breast feeding. No adverse effects have been observed in breast-fed infants whose mothers were receiving cisapride, and the American Academy of Pediatrics considers[1] that it is therefore usually compatible with breast feeding.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 07/05/04)

Interactions

Cisapride is metabolised by the cytochrome P450 isoenzyme CYP3A4. Use with drugs that significantly inhibit this enzyme is contra-indicated as it may result in increased plasma concentrations of cisapride and hence a greater risk of QT interval prolongation and ventricular arrhythmias. Examples of such drugs include the azole antifungals ketoconazole, fluconazole, itraconazole, and miconazole; the macrolide antibacterials troleandomycin, azithromycin, erythromycin, and clarithromycin; the NNRTIs delavirdine and efavirenz; and the HIV-protease inhibitors. Nefazodone may interact similarly.

Cisapride should not be used in patients receiving other medication known to prolong the QT interval, including quinine or halofantrine, terfenadine, astemizole, certain antiarrhythmics such as amiodarone or quinidine, some antidepressants such as amitriptyline, phenothiazine antipsychotics, and sertindole. Cimetidine may enhance cisapride bioavailability. Grapefruit juice also increases the bioavailability of cisapride and they should not be taken together. In addition, drugs such as potassium-sparing diuretics, or insulin in acute settings, can result in altered electrolyte balance, and use with cisapride may also increase the risk of arrhythmias.

Antimuscarinics and possibly opioid analgesics may antagonise the gastrointestinal effects of cisapride. Because cisapride increases intestinal motility it may affect the absorption of other drugs, either diminishing absorption from the stomach or enhancing absorption from the small intestine. Prothrombin times may be increased in some patients receiving oral anticoagulants, and the effects of alcohol and some other CNS depressants may be enhanced.

H_2-antagonists. *Cimetidine*[1] but not *ranitidine*[2] has been reported to enhance the bioavailability of oral cisapride, possibly by inhibition of cisapride metabolism (cimetidine is an inhibitor of the cytochrome P450 isoenzyme CYP3A4). Cisapride conversely increases the rate of absorption and decreases the oral bioavailability of both cimetidine[1] and ranitidine (see p.1766).

Pharmacokinetics

Cisapride is readily absorbed from the gastrointestinal tract, with peak plasma concentrations achieved 1 to 2 hours after an oral dose. It undergoes extensive first-pass metabolism in the liver and gut wall, resulting in an absolute bioavailability of 35 to 40%. The main metabolic pathways are oxidative *N*-dealkylation by the cytochrome P450 isoenzyme CYP3A4, producing the major metabolite norcisapride, and aromatic hydroxylation. More than 90% of a dose is excreted as metabolites in the urine and faeces in about equal amounts. A small amount is distributed into breast milk. The elimination half-life is about 10 hours. Cisapride is about 98% bound to plasma proteins.

Uses and Administration

Cisapride is a substituted benzamide used for its prokinetic properties. It stimulates gastrointestinal motility, probably by increasing the release of acetylcholine in the gut wall at the level of the myenteric plexus, increases the resting tone of the lower oesophageal sphincter, and increases the amplitude of lower oesophageal contractions. Gastric emptying is accelerated and the mouth-to-caecum transit time is reduced. Colonic peristalsis is also increased which decreases colonic transit time. Cisapride apparently lacks antidopaminergic effects (unlike metoclopramide, p.1747, to which it is chemically related) or direct parasympathomimetic activity and it does not affect prolactin release or gastric secretion. It is reported to be an agonist at serotonin-4 ($5\text{-}HT_4$) receptors.

Cisapride has been used mainly in the treatment of gastro-oesophageal reflux disease (p.1696), in disorders associated with decreased gastric motility (p.1694), and in non-ulcer dyspepsia. However, as mentioned under Effects on the Heart, above, its use is severely restricted by its propensity to cause cardiac arrhythmias, and it has been withdrawn completely in many countries, including the UK.

Cisapride is given as the monohydrate, but doses are calculated in terms of the anhydrous substance. Cisapride monohydrate 10.39 mg is equivalent to about 10 mg of anhydrous cisapride. It is taken orally 15 to 30 minutes before a meal and at bedtime, if necessary. Where still licensed, a usual oral dose is 5 to 10 mg three to four times daily up to a maximum daily dose of 40 mg. For discussion of dosage and use in children, see below.

Doses of cisapride should be reduced in patients with hepatic or renal impairment (see below).

Administration in children. Where still licensed, neonates, infants, and children have been given cisapride 200 micrograms/kg orally three or four times daily up to a maximum daily dose of 800 micrograms/kg. However, there are particular safety concerns over the use of cisapride in children because of the risk of cardiac arrhythmias (see Effects on the Heart, above). Special care is needed in neonates and cisapride is contra-indicated in premature neonates for 3 months after birth due to the increased risk of QT interval prolongation in this patient group.

Its efficacy has also been questioned and a systematic review[1] of the use of cisapride in children found no clear evidence that cisapride had a statistically significant effect in reducing symptoms of gastro-oesophageal reflux disease compared with placebo.

1. Augood C, *et al.* Cisapride treatment for gastro-oesophageal reflux in children. Available in The Cochrane Database of Systematic Reviews; Issue 4. Chichester: John Wiley; 2003 (accessed 10/01/07).

Administration in hepatic or renal impairment. In patients with hepatic impairment the dose of cisapride should be half the usual dose, followed by adjustment depending on clinical response. In cases where renal impairment is not considered to contra-indicate the use of cisapride, a similar reduction in dose has been recommended.

ATC Vet — QA03FA06.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Clebopride Malate). A white or almost white, crystalline powder. Sparingly soluble in water and in methyl alcohol; slightly soluble in dehydrated alcohol; practically insoluble in dichloromethane. The pH of a 1% solution in water is 3.8 to 4.2. Protect from light.

Profile

Clebopride is a substituted benzamide similar to metoclopramide (p.1747), that is used for its antiemetic and prokinetic actions in nausea and vomiting (p.1700) and various other gastrointestinal disorders. It is given as the malate but doses are expressed in terms of the base. Clebopride malate 679 micrograms is equivalent to about 500 micrograms of clebopride.

Clebopride malate is given in a usual oral dose equivalent to clebopride 0.5 mg three times daily before meals or 0.5 to 1 mg by intramuscular or intravenous injection for acute symptoms. For dosage in children see below.

Administration in children. Adolescents aged 12 to 20 years may be given clebopride malate orally in a dose equivalent to clebopride 250 micrograms three times daily. An oral dose of 15 to 20 micrograms/kg daily in 3 divided doses may be used for children under 12; the following doses have been recommended:

- 1 to 4 years: 50 micrograms 3 times daily
- 4 to 8 years: 100 micrograms 3 times daily
- 8 to 10 years: 150 micrograms 3 times daily
- 10 to 12 years: 200 micrograms 3 times daily

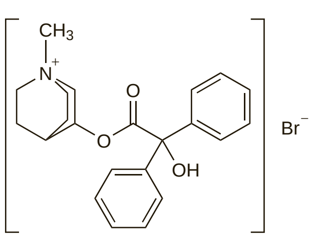
Clidinium Bromide *(BAN, USAN, rINN)*

Bromuro de clidinio; Clidinii Bromidum; Clidinium, Bromure de; Klidiniumbromid; Klidiniumbromidi; Klidinyum Bromür; Ro-2-3773. 3-Benziloyloxy-1-methylquinuclidinium bromide.

Клидиния Бромид

$C_{22}H_{26}BrNO_3$ = 432.4.
CAS — 7020-55-5 (clidinium); 3485-62-9 (clidinium bromide).



Pharmacopoeias. In *US.*

USP 31 (Clidinium Bromide). A white or nearly white, practically odourless, crystalline powder. Soluble in water and in alcohol; slightly soluble in ether and in benzene. Store in airtight containers. Protect from light.

Profile

Clidinium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used alone or more often with chlordiazepoxide in the symptomatic treatment of peptic ulcer disease and other gastrointestinal disorders.

Preparations

USP 31: Chlordiazepoxide Hydrochloride and Clidinium Bromide Capsules.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Libraxin; ***Canad.:*** Apo-Chlorax; Librax; ***Chile:*** Gastrolen; Lerogin; Libraxin; Lironex†; Sedogastrol†; Tensoliv; ***Fin.:*** Librax; ***Fr.:*** Librax; ***Gr.:*** Distedon; Librax; ***Hong Kong:*** Bralix; Librax; Medocalum†; ***India:*** Equirex; Normaxin; Spasrax; ***Indon.:*** Braxidin; Cliad; Klidibrax; Librax; Melidox; Renagas; ***Israel:*** Nirvaxal; ***Ital.:*** Librax; ***Malaysia:*** Apo-Chlorax†; Liblan; ***Port.:*** Librax; ***S.Afr.:*** Librax; ***Singapore:*** Apo-Chlorax; Chlobax; Librax; Medocalum; ***Switz.:*** Librax; Librocol; ***Thai.:*** Kenspa; Librax; Pobrax†; Tumax; Zepobrax†; ***Turk.:*** Klipaks; Librax; ***USA:*** Clindex; Librax; ***Venez.:*** Librax.

Colocynth

Bitter Apple; Bitter Cucumber; Colocinto; Colocynth Pulp; Colocynthis; Coloquinte; Coloquintidas; Koloquinthen.

Колоцинт

NOTE. The synonym Bitter Apple has also been applied to the fruits of *Solanum incanum.*

Profile

Colocynth is the dried pulp of the fruit of *Citrullus colocynthis* (Cucurbitaceae). It has a drastic purgative and irritant action and has been superseded by less toxic laxatives.

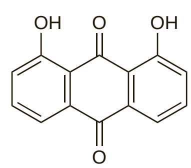
Homoeopathy. Colocynth has been used in homoeopathic medicines under the following names: Colocynthis; Coloc.

Dantron *(BAN, rINN)*

Antrapurol; Chrysazin; Danthron; Dantrón; Dantrone; Dantroni; Dantronum; Dianthon; Dioxyanthrachinonum. 1,8-Dihydroxyanthraquinone.

Дантрон

$C_{14}H_8O_4$ = 240.2.
CAS — 117-10-2.
ATC — A06AB03.
ATC Vet — QA06AB03.



NOTE. Compounded preparations of dantron may be represented by the following names:

- Co-danthramer *x/y* (*BAN*)—where *x* and *y* are the strengths in milligrams of dantron and poloxamer respectively
- Co-danthrusate (*BAN*)—dantron 5 parts and docusate sodium 6 parts (w/w).

Pharmacopoeias. In *Br.*

BP 2008 (Dantron). An orange, odourless or almost odourless, crystalline powder. Practically insoluble in water; very slightly soluble in alcohol; soluble in chloroform; slightly soluble in ether; dissolves in solutions of alkali hydroxides.

Adverse Effects and Precautions

As for Senna, p.1769. Dantron may colour the urine pink or red. Discoloration and superficial sloughing of perianal skin can occur after prolonged contact, therefore dantron should not be used in infants wearing nappies (diapers) and should be used with caution in incontinent patients. The mucosa of the large intestine may be discoloured with prolonged use or high dosage.

In *rodents*, dantron has been associated with the development of intestinal and liver tumours. Consequently, its use has been restricted, see Uses and Administration, below.

◊ References to adverse effects occurring with dantron-containing laxatives include individual cases of leucopenia with liver damage,[1] greyish-blue skin discoloration,[2] and orange vaginal discharge.[3] There has also been a report of intestinal sarcoma in an 18-year-old girl with a history of prolonged use of a dantron-containing laxative.[4] In May 2000 the UK CSM restricted the use of dantron to terminally ill patients on the grounds that preclinical evidence had increased and dantron was now established as a potential human carcinogen.[5]

2. Darke CS, Cooper RG. Unusual case of skin discoloration. *BMJ* 1978; **1:** 1188–9.
3. Greer IA. Orange periods. *BMJ* 1984; **289:** 323.
4. Patel PM, *et al.* Anthraquinone laxatives and human cancer: an association in one case. *Postgrad Med J* 1989; **65:** 216–17.
5. Committee on Safety of Medicines/Medicine Control Agency. Danthron restricted to constipation in the terminally ill. *Current Problems* 2000; **26:** 4. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON007462&RevisionSelectionMethod=LatestReleased (accessed 08/11/06)

Breast feeding. The American Academy of Pediatrics[1] state that, although usually compatible with breast feeding, use of dantron by breast-feeding mothers has been reported to cause increased bowel activity in the infant.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 08/11/06)

Pharmacokinetics

Dantron is metabolised by bacteria in the colon. Dantron or its metabolites are absorbed from the gastrointestinal tract, as indicated by discoloration of urine in some patients. Dantron or its metabolites are excreted in the faeces and the urine, and also in other secretions including breast milk.

Uses and Administration

Dantron is an anthraquinone stimulant laxative but, unlike senna (p.1769), it is not a glycoside. It is given orally to treat constipation (p.1693) and is effective within 6 to 12 hours. However, because of concern over *rodent* carcinogenicity it has been withdrawn in some countries, and its use restricted in others. In the UK, it may be used only in terminally ill patients.

Dantron is given in doses of 25 to 75 mg when given with poloxamer 188 (p.1918) as co-danthramer, and in doses of 50 to 150 mg when given with docusate sodium (p.1725) as co-danthrusate. Doses are usually given at bedtime. For doses in children, see below.

Administration in children. Children under 12 years have been given dantron 12.5 to 25 mg orally as co-danthramer or 50 mg as co-danthrusate. Doses are usually given at bedtime. Children aged 12 years and over may be treated with the adult dose (see Uses and Administration, above).

The *BNFC* recommends similar doses to these, but restricts the use of co-danthramer to children aged 2 years and over, and the use of co-danthrusate to those aged 6 years and over.

Dantron should not be used in infants wearing nappies (diapers) as it may cause discoloration and superficial sloughing of the skin.

Preparations

BP 2008: Co-danthrusate Capsules.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Braz.:*** Fenogar†; ***Chile:*** Modane; ***Irl.:*** Ailax; Codalax; Cotron; ***Mex.:*** Modaton; ***NZ:*** Codalax†; Conthram†; ***UK:*** Ailax†; Capsuvac; Codalax; Danlax; Normax.

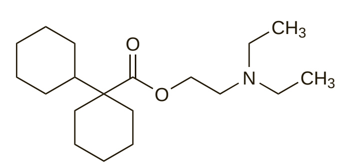
Dicycloverine Hydrochloride

(BANM, rINNM)

Cloridrato de Diciclovenina; Dicikloverin-hidroklorid; Dicikloverino hidrochloridas; Dicyclomine Hydrochloride; Dicyclovérine, chlorhydrate de; Dicycloverini hydrochloridum; Dicykloverin-hydrochlorid; Dicykloverinhydroklorid; Disykloveriinihydrokloridi; Hidrocloruro de diciclovenina. 2-Diethylaminoethyl bicyclohexyl-1-carboxylate hydrochloride.

Дицикловерина Гидрохлорид

$C_{19}H_{35}NO_2,HCl$ = 345.9.
CAS — 77-19-0 (dicycloverine); 67-92-5 (dicycloverine hydrochloride).
ATC — A03AA07.
ATC Vet — QA03AA07.



(dicycloverine)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Dicycloverine Hydrochloride). A white or almost white, crystalline powder. It shows polymorphism. Soluble in water; freely soluble in alcohol and in dichloromethane. A 1% solution in water has a pH of 5.0 to 5.5.

USP 31 (Dicyclomine Hydrochloride). A fine white, practically odourless, crystalline powder. Soluble 1 in 13 of water, 1 in 5 of alcohol, 1 in 2 of chloroform and of glacial acetic acid, and 1 in 770 of ether. pH of a 1% solution in water is between 5.0 and 5.5.

Adverse Effects, Treatment, and Precautions

As for Atropine Sulfate, p.1219. Dicycloverine hydrochloride should not be given to infants younger than 6 months of age.

Apnoea. Reports[1-3] of severe apnoea in infants aged 5 to 10 weeks associated with the use of dicycloverine.

1. Williams J, Watkin-Jones R. Dicyclomine: worrying symptoms associated with its use in some small babies. *BMJ* 1984; **288:** 901.
2. Edwards PDL. Dicyclomine in babies. *BMJ* 1984; **288:** 1230.
3. Spoudeas H, Shribman S. Dicyclomine in babies. *BMJ* 1984; **288:** 1230.

Pregnancy. For a review of the risks to the fetus of antiemetic therapy during pregnancy, with particular reference to *Debendox* (*Bendectin*: dicycloverine with doxylamine and pyridoxine), see under Antihistamines on p.563.

Interactions

As for antimuscarinics in general (see Atropine Sulfate, p.1220).

Uses and Administration

Dicycloverine hydrochloride is a tertiary amine antimuscarinic with effects similar to but weaker than those of atropine (p.1219); it also has a direct antispasmodic action.

Dicycloverine is used in gastrointestinal spasm, particularly that associated with the irritable bowel syndrome. For adults, 10 to 20 mg of dicycloverine hydrochloride is given orally 3 times daily; in the USA, up to 40 mg four times daily has been recommended where adverse effects permit. Children aged 6 months to 2 years may be given 5 to 10 mg up to 3 or 4 times daily; doses are usually given 15 minutes before meals. Children aged 2 to 12 years may be given 10 mg three times daily.

Dicycloverine hydrochloride may be given intramuscularly in doses of 20 mg given 4 times daily to patients in whom oral therapy is temporarily impractical, but should not be used for longer than 1 to 2 days.

Preparations

BP 2008: Dicycloverine Oral Solution; Dicycloverine Tablets;
USP 31: Dicyclomine Hydrochloride Capsules; Dicyclomine Hydrochloride Injection; Dicyclomine Hydrochloride Syrup; Dicyclomine Hydrochloride Tablets.

Difemerine Hydrochloride *(rINNM)*

Difémérine, Chlorhydrate de; Difemerini Hydrochloridum; Hidrocloruro de difemerina; UP-57. 2-Dimethylamino-1,1-dimethylethyl benzilate hydrochloride.

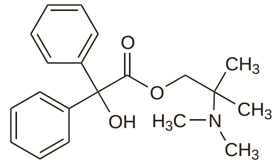
Дифемерина Гидрохлорид

$C_{20}H_{25}NO_3,HCl = 363.9.$

CAS — 80387-96-8 (difemerine); 70280-88-5 (difemerine hydrochloride).

ATC — A03AA09.

ATC Vet — QA03AA09.



(difemerine)

Profile

Difemerine hydrochloride is an antimuscarinic with effects similar to those of atropine (p.1219) and was used in the symptomatic treatment of visceral spasms.

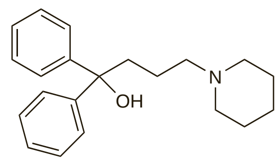
Difenidol Hydrochloride *(BANM, rINNM)*

Difénidol, Chlorhydrate de; Difenidoli Hydrochloridum; Diphenidol Hydrochloride *(USAN)*; Hidrocloruro de difenidol; SKF-478 (difenidol); SKF-478-A; SKF-478-J (difenidol embonate). 1,1-Diphenyl-4-piperidinobutan-1-ol hydrochloride.

Дифенидола Гидрохлорид

$C_{21}H_{27}NO,HCl = 345.9.$

CAS — 972-02-1 (difenidol); 3254-89-5 (difenidol hydrochloride); 26363-46-2 (difenidol embonate).



(difenidol)

Pharmacopoeias. In *Chin.* and *Jpn.*

Profile

Difenidol hydrochloride is an antiemetic that probably acts through the chemoreceptor trigger zone. It is claimed to control vertigo by means of a specific effect on the vestibular apparatus. Difenidol also has a weak peripheral antimuscarinic action.

It has been used in the treatment of some forms of nausea and vomiting (p.1700) such as those associated with surgery, radiotherapy, and cancer chemotherapy. It has also been used for the symptomatic treatment of vertigo (p.565), nausea and vomiting due to Ménière's disease (p.564), and other labyrinthine disturbances.

It has been given in oral doses equivalent to 25 to 50 mg of difenidol every 4 hours as required. Difenidol hydrochloride has also been given parenterally.

Preparations

Proprietary Preparations (details are given in Part 3)

Braz.: Vontrol†; ***Chile:*** Vontrol; ***Hong Kong:*** Cephadol; ***Jpn:*** Cephadol; ***Malaysia:*** Cephadol; ***Mex.:*** Biomitin; Diphafen; Hemetiken; Lansenol; Nautrol; Normavom; Serratol; Sons; Vontrol; Voxamine; ***Philipp.:*** Cephadol; ***Singapore:*** Cephadol†; ***Thai.:*** Cephadol.

Difenoxin *(BAN, USAN, rINN)*

Difenoxilic Acid; Difenoxina; Difénoxine; Difenoxinum; Diphenoxylic Acid; McN-JR-15403-11. 1-(3-Cyano-3,3-diphenylpropyl)-4-phenylpiperidine-4-carboxylic acid.

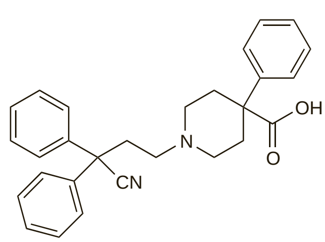
Дифеноксин

$C_{28}H_{28}N_2O_2 = 424.5.$

CAS — 28782-42-5.

ATC — A07DA04.

ATC Vet — QA07DA04.



Difenoxin Hydrochloride *(BANM, rINNM)*

Difénoxine, Chlorhydrate de; Difenoxini Hydrochloridum; Difenoxylic Acid Hydrochloride; Diphenoxylic Acid Hydrochloride; Hidrocloruro de difenoxina; R-15403.

Дифеноксина Гидрохлорид

$C_{28}H_{28}N_2O_2,HCl = 461.0.$

CAS — 35607-36-4.

ATC — A07DA04.

ATC Vet — QA07DA04.

Profile

Difenoxin is the principal active metabolite of diphenoxylate (p.1724) and has similar actions and uses. It is given orally as the hydrochloride, but doses are in terms of the base; difenoxin hydrochloride 1.1 mg is equivalent to about 1 mg of difenoxin.

In the treatment of diarrhoea (p.1694), the usual dose in adults is the equivalent of difenoxin 2 mg initially, followed by 1 mg after each loose stool or every 3 to 4 hours as required, up to a maximum of 8 mg daily.

Preparations of difenoxin usually contain subclinical amounts of atropine sulfate in an attempt to discourage abuse.

Preparations

Proprietary Preparations (details are given in Part 3)

USA: Motofen.

Dihexyverine Hydrochloride *(USAN, rINNM)*

Dihexiverine Hydrochloride; Dihexyvérine, Chlorhydrate de; Dihexyverini Hydrochloridum; Hidrocloruro de dihexiverina; JL-1078. 2-Piperidinoethyl bicyclohexyl-1-carboxylate hydrochloride.

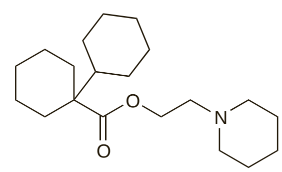
Дигексиверина Гидрохлорид

$C_{20}H_{35}NO_2,HCl = 358.0.$

CAS — 561-77-3 (dihexyverine); 5588-25-0 (dihexyverine hydrochloride).

ATC — A03AA08.

ATC Vet — QA03AA08.



(dihexyverine)

Profile

Dihexyverine hydrochloride is an antimuscarinic with effects similar to those of atropine (p.1219). It has been given in the symptomatic treatment of gastrointestinal spasm.

Preparations

Proprietary Preparations (details are given in Part 3)

Fr.: Spasmodex†.

Dihydroxyaluminum Sodium Carbonate

Aluminium Sodium Carbonate Hydroxide; Carbonato sódico de dihidroxialuminio; Dihidroksialüminyum Sodyum Karbonat; Dihydroksialuminiumnatriumkarbonaatti; Dihydroxialuminiinatrii Carbonas; Dihydroxialuminiumnatriumkarbonat; Dihydroxyaluminium Sodium Carbonate. Sodium (carbonato)dihydroxyaluminate(1-).

Дигидрооксиалюминия Натрия Карбонат

$CH_2AlNaO_5 = 144.0.$

CAS — 41342-54-5 (carbaldrate); 12011-77-7 (dihydroxyaluminium sodium carbonate); 16482-55-6 (dihydroxyaluminium sodium carbonate).

ATC — A02AB04.

ATC Vet — QA02AB04.

NOTE. The name Carbaldrate (*rINN*) has been applied to (CH_2AlNaO_5,nH_2O), a form of sodium (carbonato)dihydroxyaluminate(1-) hydrate.

Pharmacopoeias. In *US.*

USP 31 (Dihydroxyaluminum Sodium Carbonate). A fine white odourless powder. It loses not more than 14.5% of its weight on drying. Practically insoluble in water and in organic solvents;

The symbol † denotes a preparation no longer actively marketed

soluble in dilute mineral acids with the evolution of carbon dioxide. A 4% suspension in water has a pH of 9.9 to 10.2. Store in airtight containers.

Profile

Dihydroxyaluminum sodium carbonate is an antacid with general properties similar to aluminium hydroxide (p.1706) that is given in doses of about 300 to 600 mg by mouth.

Preparations

USP 31: Dihydroxyaluminum Sodium Carbonate Tablets.

Proprietary Preparations (details are given in Part 3)

Diisopromine Hydrochloride *(rINNM)*

Diisopromine, Chlorhydrate de; Di-isopromine Hydrochloride; Diisopromini Hydrochloridum; Hidrocloruro de diisopromina. *NN*-Di-isopropyl-3,3-diphenylpropylamine hydrochloride.

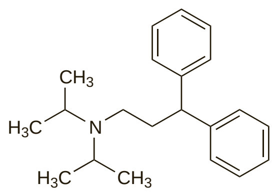
Диизопромина Гидрохлорид

$C_{21}H_{29}N,HCl$ = 331.9.

CAS — 5966-41-6 (diisopromine); 24358-65-4 (diisopromine hydrochloride).

ATC — A03AX02.

ATC Vet — QA03AX02.



(diisopromine)

Profile

Diisopromine hydrochloride is an antispasmodic used with sorbitol in various gastrointestinal disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Braz.:*** Biliflux†; ***S.Afr.:*** Agofell.

Diphenoxylate Hydrochloride

(BANM, rINNM)

Difenoksilaattihydrokloridi; Difenoksilat Hidroklorür; Difenoksilato hidrochloridas; Difenoxilát-hidroklorid; Difenoxilathydroklorid; Difenoxylát-hydrochlorid; Diphénoxylate, chlorhydrate de; Diphenoxylati hydrochloridum; Hidrocloruro de difenoxilato; R-1132. Ethyl 1-(3-cyano-3,3-diphenylpropyl)-4-phenylpiperidine-4-carboxylate hydrochloride.

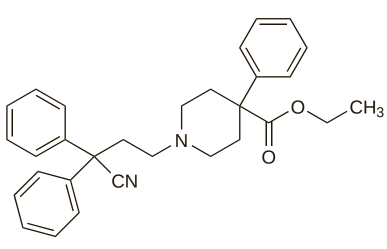
Дифеноксилата Гидрохлорид

$C_{30}H_{32}N_2O_2,HCl$ = 489.0.

CAS — 915-30-0 (diphenoxylate); 3810-80-8 (diphenoxylate hydrochloride).

ATC — A07DA01.

ATC Vet — QA07DA01.



(diphenoxylate)

NOTE. Compounded preparations of diphenoxylate hydrochloride may be represented by the following names:

- Co-phenotrope (*BAN*)—diphenoxylate hydrochloride 100 parts and atropine sulfate 1 part (w/w).

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Diphenoxylate Hydrochloride). A white or almost white, crystalline powder. Very slightly soluble in water; sparingly soluble in alcohol; freely soluble in dichloromethane. Protect from light.

USP 31 (Diphenoxylate Hydrochloride). A white odourless crystalline powder. Slightly soluble in water and in isopropyl alcohol; sparingly soluble in alcohol and in acetone; freely soluble in chloroform; practically insoluble in ether and in petroleum spirit; soluble in methyl alcohol. A saturated solution in water has a pH of about 3.3.

Dependence and Withdrawal

Preparations of diphenoxylate usually contain subclinical amounts of atropine sulfate in an attempt to discourage abuse. Short-term use of diphenoxylate with atropine in the recommended dosage carries a negligible risk of dependence, although prolonged use or use of high doses may produce dependence of the morphine type (see p.101).

Adverse Effects and Treatment

Diphenoxylate is related to the opioid analgesics (p.102), and its adverse effects and their treatment are similar, particularly in overdosage. Reported adverse effects include: gastrointestinal effects such as anorexia, nausea and vomiting, abdominal distension or discomfort, paralytic ileus, toxic megacolon, and pancreatitis; nervous system effects such as headache, drowsiness, dizziness, restlessness, euphoria, depression, numbness of the extremities; and hypersensitivity reactions including angioedema, urticaria, pruritus, and swelling of the gums. Signs of overdosage may be delayed and patients should be observed for at least 48 hours. Young children are particularly susceptible to the effects of overdosage.

The presence of subclinical doses of atropine sulfate in preparations containing diphenoxylate may give rise to the adverse effects of atropine in susceptible individuals or in overdosage—see Atropine Sulfate, p.1219.

Precautions

Diphenoxylate hydrochloride should be avoided in patients with jaundice, intestinal obstruction, antibiotic-associated colitis, or diarrhoea associated with enterotoxin-producing bacteria, and should be used with caution in patients with hepatic impairment. It should also be used with caution in young children, in whom response is more variable, and is not generally recommended for use in infants. Patients with inflammatory bowel disease receiving diphenoxylate should be carefully observed for signs of toxic megacolon and diphenoxylate stopped promptly should abdominal distension occur.

Interactions

Because of the structural relationship of diphenoxylate to pethidine (p.113) there is a theoretical risk of hypertensive crisis if diphenoxylate is used with MAOIs. Diphenoxylate may potentiate the effects of other CNS depressants such as alcohol, barbiturates, and some anxiolytics.

Pharmacokinetics

Diphenoxylate hydrochloride is well absorbed from the gastrointestinal tract. It is rapidly and extensively metabolised in the liver, mainly to diphenoxylic acid (difenoxin, p.1723), which has antidiarrhoeal activity; other metabolites include hydroxydiphenoxylic acid. It is excreted mainly as metabolites and their conjugates in the faeces; lesser amounts are excreted in urine. It may be distributed into breast milk.

Uses and Administration

Diphenoxylate hydrochloride is a synthetic derivative of pethidine (p.113) with little or no analgesic activity; it reduces intestinal motility and is used in the symptomatic treatment of acute and chronic diarrhoea (p.1694). It may also be used to reduce the frequency and fluidity of the stools in patients with colostomies or ileostomies.

Preparations of diphenoxylate usually contain subclinical amounts of atropine sulfate in an attempt to discourage abuse; UK preparations are all in the form of co-phenotrope (see above).

In **acute diarrhoea** the usual initial dose for adults is 10 mg orally, followed by 5 mg every six hours, later reduced as the diarrhoea is controlled. In the UK, diphenoxylate hydrochloride is not licensed for children under 4 years of age. Suggested initial doses for children are: 4 to 8 years, 2.5 mg three times daily; 9 to 12 years, 2.5 mg four times daily; over 12 years, 5 mg three times daily. While emphasising that antimotility drugs are not recommended for acute diarrhoea in children under 12 years of age, the *BNFC* allows for a dose of 1.25 mg three times daily for children aged 2 to 4 years. In the USA, diphenoxylate is not recommended for children under the age of 2 years and an initial dose of 0.3 to 0.4 mg/kg (up to an effective maximum of 10 mg) daily in 4 divided doses is suggested for children aged 2 to 12 years. (For the view that antidiarrhoeal drugs should not be used at all in children, see p.1694.)

Similar initial doses are used for **chronic diarrhoea**, and subsequently reduced as necessary. If clinical improvement is not seen after 10 days of treatment with the maximum daily dose of 20 mg (in adults) further use is unlikely to result in any benefit.

Diarrhoea. Co-phenotrope (see above) may be considered as an alternative to loperamide in the management of faecal incontinence in adults, see Diarrhoea, under Loperamide, p.1742.

Substance dependence. Diphenoxylate may be useful[1] in the symptomatic management of diarrhoea associated with opioid withdrawal syndromes (p.101).

Docusatos.

Docusate Calcium *(USAN)*

Dioctyl Calcium Sulfosuccinate; Dioctyl Calcium Sulphosuccinate; Docusato cálcico. Calcium 1,4-bis(2-ethylhexyl) sulphosuccinate.

Докузат Кальция

$C_{40}H_{74}CaO_{14}S_2$ = 883.2.

CAS — 128-49-4.

Pharmacopoeias. In *US.*

USP 31 (Docusate Calcium). A white amorphous solid with the characteristic odour of octil alcohol. Soluble 1 in 3300 of water; very soluble in alcohol, in macrogol 400, and in maize oil.

Docusate Potassium *(USAN)*

Dioctyl Potassium Sulfosuccinate; Dioctyl Potassium Sulphosuccinate; Docusato potásico. Potassium 1,4-bis(2-ethylhexyl) sulphosuccinate.

Докузат Калия

$C_{20}H_{37}KO_7S$ = 460.7.

CAS — 7491-09-0.

Pharmacopoeias. In *US.*

USP 31 (Docusate Potassium). A white amorphous solid with a characteristic odour suggestive of octil alcohol. Sparingly soluble in water; soluble in alcohol and in glycerol; very soluble in petroleum spirit.

Docusate Sodium *(BAN, USAN, rINN)*

Dioctyl Sodium Sulfosuccinate; Dioctyl Sodium Sulphosuccinate; Docusate sodique; Docusato de sodio; Docusato sódico; Docusatum Natricum; Dokusaattinatrium; Dokusát sodná sůl; Dokusatnatrium; Dokuzát-nátrium; Dokuzato natrio druska; DSS; Natrii docusas; Sodium Dioctyl Sulphosuccinate; Sodu dokuzynian. Sodium 1,4-bis(2-ethylhexyl) sulphosuccinate.

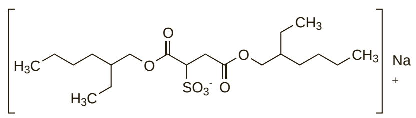
Докузат Натрий

$C_{20}H_{37}NaO_7S = 444.6$.

CAS — 577-11-7.

ATC — A06AA02.

ATC Vet — QA06AA02.



NOTE. Compounded preparations of docusate sodium may be represented by the following names:

- Co-danthrusate (*BAN*)—docusate sodium 6 parts and dantron 5 parts.

Pharmacopoeias. In *Eur.* (see p.vii) and *US*.

Ph. Eur. 6.2 (Docusate Sodium). White or almost white, hygroscopic, waxy masses or flakes. Sparingly soluble in water; freely soluble in alcohol and in dichloromethane. Store in airtight containers.

USP 31 (Docusate Sodium). A white wax-like plastic solid with a characteristic odour suggestive of octil alcohol. Slowly soluble 1 in 70 of water; freely soluble in alcohol and in glycerol; very soluble in petroleum spirit.

Adverse Effects and Precautions

Adverse effects occur rarely with docusates; diarrhoea, nausea, abdominal cramps, and skin rash have been reported. Anorectal pain or bleeding have occasionally occurred after rectal doses.

Like all laxatives, docusates should not be used when intestinal obstruction or undiagnosed abdominal symptoms are present; prolonged use should be avoided. Docusate sodium should not be given rectally to patients with haemorrhoids or anal fissures.

Docusate sodium should not be used to soften ear wax when the ear is inflamed or the ear drum perforated.

Hypersensitivity. Docusate salts are widely used as anionic surfactants in pharmaceutical formulations. Allergic contact dermatitis has been reported from one such preparation; patch testing confirmed the reaction to docusate sodium.[1]

1. Lee A-Y, Lee K-H. Allergic contact dermatitis from dioctyl sodium sulfosuccinate in a topical corticosteroid. *Contact Dermatitis* 1998; **38:** 355–6.

Pregnancy. Hypomagnesaemia in a neonate, manifested by jitteriness, was considered to be secondary to maternal hypomagnesaemia caused by maternal use of docusate sodium during pregnancy.[1]

1. Schindler AM. Isolated neonatal hypomagnesaemia associated with maternal overuse of stool softener. *Lancet* 1984; **ii:** 822.

Interactions

Docusates may enhance the gastrointestinal uptake of other drugs, such as liquid paraffin (and the two should not be given together). Dosage of anthraquinone laxatives may need to be reduced if used with docusates. It has also been suggested that giving docusates with aspirin increases the incidence of adverse effects on the gastrointestinal mucosa.

Pharmacokinetics

Docusate salts are absorbed from the gastrointestinal tract and excreted in bile. Docusate sodium is also distributed into breast milk.

Uses and Administration

Docusates are given as the calcium or sodium salt and are used as laxatives in the management of constipation (p.1693) or to reduce straining in patients with haemorrhoids (p.1697) or anal fissure. They are also used as adjuncts for bowel evacuation before abdominal radiological procedures. Docusate potassium has also been used.

Docusates are anionic surfactants which have been considered to act primarily by increasing the penetration of fluid into the faeces, but may also have other effects on intestinal fluid secretion, and probably act both as stimulants and as faecal softening agents.

The usual daily oral dose of docusate calcium is 240 mg. Docusate sodium is given in usual oral doses of 50 to 300 mg daily in divided doses, although doses of up to 500 mg daily may be used. (For administration in children, see below). The effect is usually seen within 12 to 72 hours. When used as an adjunct to abdominal radiological procedures, an oral dose of 400 mg is given with the barium meal. It is also given rectally as an enema in doses of 120 mg; the effect is usually seen in 5 to 20 minutes. Docusate sodium is also used with anthraquinone stimulant laxatives such as casanthranol (p.1715), dantron (p.1722), and senna (p.1769).

Docusate sodium is used for softening wax in the ear as ear drops containing 0.5 or 5%.

Docusate sodium and other docusate salts are widely used as anionic surfactants in pharmaceutical formulations.

Administration in children. Docusate sodium by mouth is licensed in the UK for the treatment of **chronic constipation** in children aged 6 months and over. More specific dose details are also provided in the *BNFC* as follows:

- 6 months to 2 years: 12.5 mg three times daily
- 2 to 12 years: 12.5 to 25 mg three times daily

Children aged 12 years and over may be given the adult doses for constipation, either orally or rectally (see Uses and Administration, above). Adult formulations are not licensed for use in children under 12 years.

In the USA, children aged 2 to 12 years may be given docusate sodium in doses of 50 to 150 mg daily, either as a single daily dose or in divided doses. Docusate *calcium* is generally only used in the USA for children aged 12 years and over.

Docusate sodium is also used as an **adjunct in abdominal radiological procedures**. UK licensed product information suggests that children may be given an oral dose of 75 mg (30 mL of docusate sodium paediatric solution 12.5 mg per 5 mL) with the barium meal. The *BNFC* recommends that those aged 12 years and over are given the usual adult dose (see above).

Ear wax removal. Cerumen or ear wax is a normal secretion of the ceruminous glands present in the lining of the external auditory canal. Excessive accumulation or impaction of ear wax may decrease hearing acuity, and may also produce dizziness, vertigo, reflex coughing, tinnitus, and otalgia.

Syringing of the external auditory canal with warm water may be used to remove wax from the ear. However, complications include pain, perforation of the ear drum, deafness, dizziness, vertigo, tinnitus, and infection.[1-6] Contra-indications to ear syringing include past perforation, ear infection, previous ear surgery; syringing may be difficult in children.[1,6]

A ceruminolytic agent may be given as ear drops to soften, loosen, or dissolve cerumen instead. They may also be used immediately before syringing, or for several days beforehand.[1-3,5,6] Traditionally, fixed oils such as arachis oil, olive oil, or almond oil have been used.[1] Some still advocate the use of olive oil to reduce the recurrence of impacted cerumen,[3] while others consider it to be ineffective.[5] Other ceruminolytics that have been reported as effective include docusates,[4,7,8] peroxides such as hydrogen peroxide or urea hydrogen peroxide,[4,9] and trolamine polypeptide oleate-condensate,[4,8] although some studies have found these to be no more effective in removing wax than a saline control.[10,11] Other agents that have been used include acetic acid,[4] choline salicylate,[12] methyltrypsin solution,[5] and an oily solution of paradichlorobenzene and chlorobutanol.[4,12] Glycerol and sodium bicarbonate solution have also been used. However, a comparative study *in vitro* of the efficacy of various wax dispersing agents found the most effective to be water, which had originally been included as a control,[13] and a systematic review[14] concluded that saline or water ear drops seemed to be as good as proprietary agents for the removal of ear wax, although there was a lack of good quality studies on which to base recommendations.

Ear candling is a traditional folk remedy that has been used to remove cerumen, but studies indicate it is ineffective, and may deposit wax in the ear canal or cause burn injuries.[3,4]

Dolasetron Mesilate *(BANM, rINNM)*

Dolasétron, Mésilate de; Dolasetron Mesylate *(USAN)*; Dolasetroni Mesilas; MDL-73147EF (dolasetron or dolasetron mesilate); Mesilato de dolasetrón. (6*R*,8*r*,9a*S*)-3-Oxoperhydro-2*H*-2,6-methanoquinolizin-8-yl indole-3-carboxylate methanesulphonate.

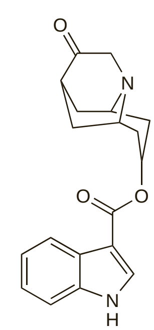
Доласетрона Мезилат

$C_{19}H_{20}N_2O_3,CH_4O_3S = 420.5$.

CAS — 115956-12-2 (dolasetron); 115956-13-3 (dolasetron mesilate).

ATC — A04AA04.

ATC Vet — QA04AA04.



(dolasetron)

Pharmacopoeias. In *US*.

USP 31 (Dolasetron Mesylate). A white to off-white powder. Freely soluble in water and in propylene glycol; slightly soluble in alcohol and in sodium chloride 0.9%. Protect from light.

Stability. A study[1] of the stability of two extemporaneous oral suspensions of dolasetron mesilate 10 mg/mL prepared from

The symbol † denotes a preparation no longer actively marketed

commercially available tablets found them to be stable for at least 90 days when stored at 3 to 5° and at 23 to 25°.

1. Johnson CE, *et al.* Stability of dolasetron in two oral liquid vehicles. *Am J Health-Syst Pharm* 2003; **60:** 2242–4.

Adverse Effects and Precautions

As for Ondansetron, p.1757. Diarrhoea, anorexia, and abdominal pain may also occur. Various ECG changes have been noted with dolasetron. Dolasetron should be used with caution in patients who have, or may develop, prolongation of the QT interval or other alterations in cardiac conduction intervals, and in those with electrolyte imbalances. Other adverse effects include dyspepsia, flatulence, taste disturbances, fever, chills or shivering, sleep disorders, fatigue, and drowsiness. There have been rare reports of intestinal obstruction, pancreatitis, jaundice, seizures, bronchospasm, cardiac arrhythmias, and oedema. Local reactions may occur on intravenous use. No dosage reduction is considered necessary in renal or hepatic impairment, despite possible reductions in clearance.

Effects on the cardiovascular system. For a discussion of the effects of 5-HT_3 antagonists on the cardiovascular system, see under Ondansetron, p.1757.

Phlebitis. Venous irritation has been reported after intravenous use of dolasetron; diluting subsequent doses with sodium chloride 0.9% and infusing it more slowly markedly reduced the frequency of phlebitis.[1]

1. Oshiro MM. Dolasetron-associated venous irritation. *Am J Health-Syst Pharm* 2000; **57:** 1533–4.

Interactions

Plasma concentrations of hydrodolasetron, the active metabolite of dolasetron, are increased by cimetidine and atenolol and decreased by rifampicin. Dolasetron should be used with caution in patients taking drugs that prolong the QT interval, including those likely to cause electrolyte disturbances (see also p.1757).

Pharmacokinetics

Dolasetron given orally or intravenously is rapidly converted to the active metabolite hydrodolasetron by carbonyl reductase, a ubiquitous enzyme. Peak plasma concentrations of hydrodolasetron occur 1 hour after oral, and 0.6 hours after intravenous, doses of dolasetron. The apparent oral bioavailability of dolasetron determined as hydrodolasetron is about 75%. It has a mean elimination half-life of about 7 to 8 hours.

Hydrodolasetron is partially metabolised by the cytochrome P450 isoenzymes CYP2D6 and CYP3A and about 50 to 60% is eliminated unchanged in the urine. Two thirds of a dose of dolasetron is recovered in the urine and one third in the faeces.

Clearance of hydrodolasetron is increased in children, but is not altered in the elderly. Clearance is reduced in severe hepatic impairment (Child-Pugh category B or C) and in severe renal impairment (creatinine clearance less than 10 mL/min) after oral use. After intravenous use, clearance is reduced in severe renal impairment but apparently unchanged in severe hepatic impairment.

Uses and Administration

Dolasetron is a 5-HT_3 antagonist with antiemetic actions similar to those of ondansetron (see p.1757). It is used as the mesilate in the prevention of nausea and vomiting (p.1700) associated with chemotherapy, and in the prevention and treatment of postoperative nausea and vomiting.

For *prevention* of acute **nausea and vomiting** associated with **chemotherapy** dolasetron mesilate may be given orally in a dose of 100 mg (in the USA) or 200 mg (in most other countries including the UK) within 1 hour before treatment. Alternatively, it may be given in a dose of 1.8 mg/kg, or 100 mg, by intravenous injection at a rate of up to 100 mg over 30 seconds about 30 minutes before chemotherapy; the same dose may be diluted to 50 mL with a suitable infusion solution and given intravenously over up to 15 minutes. To protect against delayed emesis, a further 200-mg dose may be given orally once daily; in Europe and the UK dolasetron may not normally be given for more than 4 consecutive days per chemotherapy cycle although some countries permit use for up to 7 days.

When given for the *prevention* of **postoperative** nausea and vomiting the recommended dose is usually 50 mg of dolasetron mesilate orally before induction of anaesthesia or 12.5 mg intravenously at the end of anaesthesia. In the USA, it is given as a 100-mg oral dose within 2 hours before surgery, or 12.5 mg intravenously about 15 minutes before the end of anaesthesia. The same intravenous dose may be given for the *treatment* of postoperative nausea and vomiting.

The use of dolasetron mesilate in **children** is licensed in some countries, including the USA. However, others have not licensed such use and in the UK it is contra-indicated in children and adolescents under 18 years of age because they may be at increased risk of acute changes in the QT interval, and there have been reports of cardiac conduction disorders, cardiac arrest, and myocardial infarction in children treated with dolasetron. In the USA, children over 2 years of age may be given dolasetron mesilate 1.8 mg/kg orally (within 1 hour before chemotherapy) or intravenously (about 30 minutes before chemotherapy), up to a maximum dose of 100 mg, to prevent acute chemotherapy-induced nausea and vomiting. For prevention of postoperative nausea and vomiting, 1.2 mg/kg by mouth, up to a maximum of 100 mg, may be given within 2 hours before surgery; or 350 micrograms/kg, up to a maximum of 12.5 mg, may be given intravenously 15 minutes before the end of anaesthesia. The same intravenous dose may be given to treat established postoperative nausea and vomiting.

Dompéridone, maléate de; Domperidoni maleas; Domperidonimaleaatti; Domperidonmaleat; Domperidon-maleát; Domperidon-maleinát; Domperidono maleatas; Maleato de domperidona.

Домперидона Малеат

$C_{22}H_{24}ClN_5O_2,C_4H_4O_4$ = 542.0.

CAS — 99497-03-7.

ATC — A03FA03.

ATC Vet — QA03FA03.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Domperidone Maleate). A white or almost white powder; it exhibits polymorphism. Very slightly soluble in water and in alcohol; sparingly soluble in dimethylformamide; slightly soluble in methyl alcohol. Protect from light.

Adverse Effects

Plasma-prolactin concentrations may be increased, which may lead to galactorrhoea or gynaecomastia. There have been reports of reduced libido, and rashes and other allergic reactions. Domperidone does not readily cross the blood-brain barrier and the incidence of central effects such as extrapyramidal reactions or drowsiness may be lower than with metoclopramide (p.1748); however, there have been reports of dystonic reactions.

Domperidone by injection has been associated with convulsions, arrhythmias, and cardiac arrest. Fatalities have restricted use by this route.

Effects on the cardiovascular system. Sudden death has occurred in cancer patients given domperidone *intravenously* in high doses.[1-3] Four cancer patients experienced cardiac arrest after high intravenous doses[4] and 2 of 4 similar patients had ventricular arrhythmias.[5] After such reports the injection has been withdrawn from general use in many countries, including the UK.

Prolongation of the QT interval has been reported in an infant given *oral* domperidone, with normalisation after the drug was stopped.[6]

1. Joss RA, *et al.* Sudden death in cancer patient on high-dose domperidone. *Lancet* 1982; **i:** 1019.

6. Rocha CMG, Barbosa MM. QT interval prolongation associated with the oral use of domperidone in an infant. *Pediatr Cardiol* 2005; **26:** 720–3.

Effects on the endocrine system. There have been reports of galactorrhoea with gynaecomastia[1] or mastalgia[2,3] generally associated with raised serum-prolactin concentrations. Gynaecomastia without galactorrhoea has also been reported.[4]

1. Van der Steen M, *et al.* Gynaecomastia in a male infant given domperidone. *Lancet* 1982; **ii:** 884–5.
2. Cann PA, *et al.* Galactorrhoea as side effect of domperidone. *BMJ* 1983; **286:** 1395–6.

4. Keating JP, Rees M. Gynaecomastia after long-term administration of domperidone. *Postgrad Med J* 1991; **67:** 401–2.

Extrapyramidal effects. There are reports of extrapyramidal symptoms,[1,2] including acute dystonic reactions[3] and neuroleptic malignant syndrome[4] in individual patients given domperidone.

1. Sol P, *et al.* Extrapyramidal reactions due to domperidone. *Lancet* 1980; **ii:** 802.

2. Debontridder O. Extrapyramidal reactions due to domperidone. *Lancet* 1980; **ii:** 802. Correction, *ibid.*; 1259.
3. Casteels-Van Daele M, *et al.* Refusal of further cancer chemotherapy due to antiemetic drug. *Lancet* 1984; **i:** 57.
4. Spirt MJ, *et al.* Neuroleptic malignant syndrome induced by domperidone. *Dig Dis Sci* 1992; **37:** 946–8.

Precautions

Domperidone is not recommended for chronic use or for the routine prophylaxis of postoperative nausea and vomiting. Domperidone should be used with great caution if given intravenously, because of the risk of arrhythmias, especially in patients predisposed to cardiac arrhythmias or hypokalaemia.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were given domperidone, and the American Academy of Pediatrics considers[1] that it is therefore usually compatible with breast feeding. However, the FDA in the USA has issued a warning against the use of domperidone to increase milk production because of the possibility of serious adverse effects.[2] Others have commented that these warnings were based on data from patients with malignant disease receiving high doses of intravenous domperidone, and that if the mother were taking smaller oral doses, the total amount of drug ingested by an infant would be extremely small. They recommend that low-dose domperidone should still be considered for lactating women with decreased milk supply who are unresponsive to non-pharmacological measures to enhance lactation. However, patients should be warned of the risk of arrhythmias at high doses, and women with known cardiac disease should not take domperidone.[3]

Interactions

As with other dopamine antagonists (see Metoclopramide, p.1749), there is a theoretical potential that domperidone may antagonise the hypoprolactinaemic effect of drugs such as bromocriptine. In addition, the prokinetic effects of domperidone may alter the absorption of some drugs. Opioid analgesics and antimuscarinics may antagonise the prokinetic effects of domperidone.

Domperidone is metabolised via the cytochrome P450 isoenzyme CYP3A4; use with ketoconazole has been reported to produce a threefold increase in plasma concentrations of domperidone, and an associated slight prolongation in QT interval. Similar increases in domperidone concentrations might theoretically be seen with other potent inhibitors of CYP3A4 such as erythromycin or ritonavir, and such combinations may be best avoided.

Pharmacokinetics

Although absorption is rapid, the systemic bioavailability of domperidone is only about 15% in fasting subjects given an oral dose; this is increased when domperidone is given after food. The low bioavailability is thought to be due to first-pass hepatic and intestinal metabolism. The bioavailability of rectal domperidone is similar to that after oral doses, although peak plasma concentrations are only about one-third that of an oral dose and are achieved after about an hour, compared with 30 minutes after an oral dose.

Domperidone is more than 90% bound to plasma proteins, and has a terminal elimination half-life of about 7.5 hours. It undergoes rapid and extensive hepatic metabolism. The main metabolic pathways are *N*-dealkylation by cytochrome P450 isoenzyme CYP3A4, and aromatic hydroxylation by CYP3A4, CYP1A2, and CYP2E1. About 30% of an oral dose is excreted in urine within 24 hours, almost entirely as metabolites; the remainder of a dose is excreted in faeces over several days, about 10% as unchanged drug. It does not readily cross the blood-brain barrier.

Small amounts of domperidone are distributed into breast milk; concentrations are 10 to 50% of those in maternal serum.

Uses and Administration

Domperidone is a dopamine antagonist with actions and uses similar to those of metoclopramide (p.1749). It is used as an antiemetic for the short-term treatment of nausea and vomiting of various aetiologies (p.1700). It is not considered suitable for chronic nausea and vomiting, nor for the routine prophylaxis of postoperative vomiting.

Domperidone is also used for its prokinetic actions in dyspepsia (p.1695) and has been tried in diabetic gastroparesis (see Diabetic Complications, p.433). It has been given with paracetamol in the symptomatic treatment of migraine (p.616).

Domperidone is used as the maleate in tablet preparations and as the base in suppositories and the oral suspension; doses are expressed in terms of the base. Domperidone maleate 12.73 mg is equivalent to about 10 mg of domperidone. Domperidone has been given parenterally, but this route has been associated with severe adverse effects (see above).

For the treatment of **nausea and vomiting** domperidone may be given in oral doses of 10 to 20 mg three or four times daily up to a maximum daily dose of 80 mg or it may be given rectally in a dose of 60 mg twice daily. For doses in children see below.

For the symptomatic management of non-ulcer **dyspepsia** similar oral doses of 10 mg taken up to four times daily (the last dose to be taken at night) have been recommended; if necessary, an increase in the dose to 20 mg may be prescribed. An initial course of treatment should not normally exceed 2 to 4 weeks. In **migraine**, a dose of 20 mg has been given orally up to every 4 hours, with paracetamol, as required, up to a maximum of 4 doses in 24 hours.

Administration in children. UK licensed product information states that children may be given domperidone in oral doses equivalent to 250 to 500 micrograms/kg three or four times daily; a total daily dose of 2.4 mg/kg or 80 mg, whichever is less, should not be exceeded. Alternatively, children weighing more than 15 kg may be given a rectal dose of 30 mg twice daily. The *BNFC* gives similar doses, but specifies use in children over 2 years; in those children over 35 kg, it allows an oral dose of 10 to 20 mg three or four times daily (maximum 80 mg daily) or a rectal dose of 60 mg twice daily.

Gastro-oesophageal reflux disease. A systematic review of the use of domperidone in infants and young children with gastro-oesophageal reflux (p.1696), which identified 4 randomised controlled studies of such use, considered that there was very little evidence of its efficacy in reducing symptoms.[1] Some suggest that it has been overused because of the lack of a suitable alternative after withdrawal of cisapride in many countries.[2]

2. Vandenplas Y, *et al.* The diagnosis and management of gastro-oesophageal reflux in infants. *Early Hum Dev* 2005; **81:** 1011–24.

Parkinsonism. Domperidone is used to control gastrointestinal effects of dopaminergic drugs given in the management of parkinsonism (p.791). It may be of use in those patients who experience peripheral effects with levodopa despite the use of peripheral dopa-decarboxylase inhibitors and for patients using dopamine agonists such as bromocriptine or apomorphine since peripheral dopa-decarboxylase inhibitors are ineffective for preventing the peripheral effects of these drugs. Although domperidone does not readily cross the blood-brain barrier there have been isolated reports of extrapyramidal effects associated with its use (see above). Consequently there has been concern over its potential to produce central effects and some consider that domperidone should only be used in patients with parkinsonism when safer antiemetic measures have failed.[1,2] However, this view has been contested both by the manufacturers and other authors.[3,4] In a subsequent review of the use of domperidone in Parkinson's disease it was considered[5] that domperidone might produce central blockade of the therapeutic effects of levodopa if given at a high oral dosage such as 120 mg daily for prolonged periods but also noted that such high doses were rarely required to control levodopa-induced vomiting.

Domperidone was found to significantly improve anorexia, nausea, vomiting, abdominal bloating, and regurgitation in patients taking levodopa.[6] Dysphagia and constipation were unaffected; these are thought to be more likely a reflection of the disease process. Doses ranged from 50 to 120 mg daily, with most patients responding to 80 mg daily. No central effects were noted.

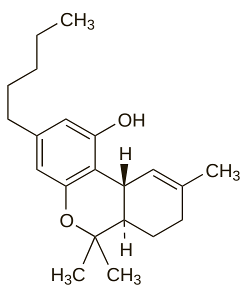
Dronabinol *(USAN, rINN)* ⊗

Dronabinolum; NSC-134454; Δ^9-Tetrahydrocannabinol; Δ^9-THC. (6a*R*,10a*R*)-6a,7,8,10a-Tetrahydro-6,6,9-trimethyl-3-pentyl-6*H*-dibenzo[*b*,*d*]pyran-1-ol.

Дронабинол

$C_{21}H_{30}O_2$ = 314.5.
CAS — 1972-08-3.
ATC — A04AD10.
ATC Vet — QA04AD10.



Pharmacopoeias. In *US*.

USP 31 (Dronabinol). Store at a temperature between 8° and 15° in airtight glass containers in an inert atmosphere. Protect from light.

Adverse Effects and Precautions

As for Nabilone, p.1750. The most frequent adverse effects of dronabinol include abdominal pain, nausea and vomiting, dizziness, euphoria, paranoid reactions, and somnolence. Seizures and seizure-like activity have been reported; dronabinol should be used with caution in those with a history of seizure disorders, and therapy should be stopped if seizures occur.

Abuse. The abuse liability of dronabinol was rated as being substantially lower than that of cannabis.[1]

1. WHO. WHO expert committee on drug dependence: thirty-third report. *WHO Tech Rep Ser 915* 2003. Available at: http://libdoc.who.int/trs/WHO_TRS_915.pdf (accessed 03/07/08)

Breast feeding. US licensed product information states that dronabinol is concentrated in breast milk and recommends that it should not be used in breast-feeding mothers.

Pharmacokinetics

After oral doses dronabinol is slowly and erratically absorbed from the gastrointestinal tract; the bioavailability of an oral dose is about 10 to 20%, due to extensive first-pass metabolism. Peak plasma concentrations of dronabinol and its 11-hydroxy metabolite are achieved about 2 to 4 hours after a dose by mouth. It is widely distributed and is extensively protein bound, with a volume of distribution of about 10 litres/kg. Elimination is biphasic, with an initial half-life of about 4 hours, and a terminal half-life of about 25 to 36 hours.

Dronabinol is extensively metabolised, mainly in the liver by cytochrome P450 isoenzymes; the primary metabolite, 11-hydroxydronabinol is also active. The 11-hydroxy metabolite is converted to other, more polar and acidic compounds which are excreted in faeces via the bile, and in the urine. About 50% of an oral dose is recovered in faeces within 72 hours and 10 to 15% in urine. Many of the metabolites have relatively prolonged half-lives, and accumulation may occur with repeated dosage.

Dronabinol is distributed into breast milk and crosses the placenta.

Uses and Administration

Dronabinol, the major psychoactive constituent of cannabis (p.2274), has antiemetic properties and is used for the control of **nausea and vomiting** associated with cancer chemotherapy (p.1700) in patients who have failed to respond adequately to conventional antiemetics.

The usual initial oral dose of dronabinol is 5 mg/m² given 1 to 3 hours before the first dose of the antineoplastic drug with subsequent doses being given every 2 to 4 hours after chemotherapy to a maximum of 4 to 6 doses daily. If necessary, the dose may be increased by increments of 2.5 mg/m² to a maximum dose of 15 mg/m², if adverse effects permit.

Dronabinol also has appetite-stimulant effects and is used in the treatment of **anorexia** associated with weight loss in patients with AIDS. For this purpose 2.5 mg may be taken twice daily, before lunch and supper, reduced to a single 2.5-mg dose in the evening in patients who tolerate the drug poorly. If necessary, and if adverse effects permit, doses may also be increased up to 20 mg daily in divided doses.

Dronabinol is used with cannabidiol, another cannabinoid, in a buccal spray preparation as adjunctive treatment for the symptomatic relief of **neuropathic pain** in multiple sclerosis in adults; this combination is also used as adjunctive analgesic treatment in adult patients with advanced cancer and is under investigation for a number of other conditions (see under Cannabis, p.2275).

Multiple sclerosis. Anecdotal evidence has suggested that cannabinoids might improve symptoms in patients with multiple sclerosis (p.892); a review[1] considered evidence of effectiveness to be lacking. In a large placebo-controlled study, treatment with dronabinol or oral cannabis extract had no benefit on objective assessment of spasticity;[2] however, there were improvements in walking time, and subjective improvements in both spasticity and pain. A subsequent small controlled study found dronabinol to have a modest but clinically relevant effect on central neuropathic pain in patients with multiple sclerosis.[3]

Dronabinol is used with cannabidiol, another cannabinoid, in a buccal spray preparation for the symptomatic relief of neuropathic pain in multiple sclerosis in adults.

Pharmacokinetics

Esomeprazole is rapidly absorbed after oral doses, with peak plasma levels occurring after about 1 to 2 hours. It is acid labile and an enteric-coated formulation has been developed. Bioavailability of esomeprazole increases with both dose and repeated administration to about 68 and 89% for doses of 20 and 40 mg respectively. Food delays and decreases the absorption of esomeprazole, but this does not significantly change its effect on intragastric acidity. Esomeprazole is about 97% bound to plasma proteins. It is extensively metabolised in the liver by the cytochrome P450 isoenzyme CYP2C19 to hydroxy and desmethyl metabolites, which have no effect on gastric acid secretion. The remainder is metabolised by the cytochrome P450 isoenzyme CYP3A4 to esomeprazole sulfone. With repeated dosage, there is a decrease in first-pass metabolism and systemic clearance, probably caused by an inhibition of the CYP2C19 isoenzyme. However, there is no accumulation during once daily use. The plasma elimination half-life is about 1.3 hours. Almost 80% of an oral dose is eliminated as metabolites in the urine, the remainder in the faeces.

Metabolism. As for omeprazole (p.1755), the cytochrome P450 isoenzyme CYP2C19 is involved in the metabolism of esomeprazole, and individuals who are deficient in this enzyme are poor metabolisers of esomeprazole. However, there is some suggestion that the metabolism of esomeprazole is less dependent on this genotype, as there may be a metabolic shift towards the CYP3A4-mediated pathway.[1]

1. Schwab M, *et al.* Esomeprazole-induced healing of gastro-esophageal reflux disease is unrelated to the genotype of CYP2C19: evidence from clinical and pharmacokinetic data. *Clin Pharmacol Ther* 2005; **78:** 627–34.

Uses and Administration

Esomeprazole is the *S*-isomer of the proton pump inhibitor omeprazole (p.1753) and is used similarly in the treatment of peptic ulcer disease and NSAID-associated ulceration (p.1702), in gastro-oesophageal reflux disease (p.1696), and the Zollinger-Ellison syndrome (p.1704). It is given as the magnesium or sodium salt but doses are calculated in terms of esomeprazole. Esomeprazole magnesium 22.2 mg and esomeprazole sodium 21.3 mg are each equivalent to about 20 mg of esomeprazole.

Usual doses for **peptic ulcer disease**, as a component of a triple therapy regimen with amoxicillin and clarithromycin, are the equivalent of 20 mg esomeprazole orally twice daily for 7 days, or 40 mg once daily for 10 days.

Oral doses of 20 mg daily, for 4 to 8 weeks, are used in the treatment of **NSAID-associated ulceration**; a dose of 20 mg daily may also be used for prophylaxis in patients at risk of such lesions who require continued NSAID treatment.

In the UK, the dose for treatment of severe (erosive) **gastro-oesophageal reflux disease** is 40 mg once daily for 4 weeks, extended for a further 4 weeks if necessary; in the USA, where doses of 20 or 40 mg daily are permitted for initial treatment, a further 4 to 8 weeks of treatment may be considered for patients who do not heal after 4 to 8 weeks. For maintenance, or for symptomatic disease without erosive oesophagitis, doses equivalent to 20 mg of esomeprazole daily may be used in both countries.

For the treatment of **Zollinger-Ellison syndrome**, the recommended initial oral dose of esomeprazole is 40 mg twice daily, which is then adjusted as needed. The majority of patients can be controlled on doses between 80 and 160 mg daily, although doses of 240 mg have been given. Doses above 80 mg daily should be given in 2 divided doses.

PARENTERAL DOSAGE.

Similar doses to the above may be given intravenously for gastro-oesophageal reflux disease and NSAID-associated ulceration. Esomeprazole is given as the sodium salt by slow intravenous injection over at least 3 minutes or by intravenous infusion over 10 to 30 minutes.

Doses of esomeprazole may need to be reduced in patients with hepatic impairment (see below).

Administration in children. UK licensed product information allows for the use of adult doses of esomeprazole (see Uses and Administration, above) in children over 12 years.

In the USA licensed doses, which may be given once daily for up to 8 weeks for the treatment of gastro-oesophageal reflux in children, are:

- 1 to 11 years: 10 mg
- 12 to 17 years: 20 or 40 mg

For healing erosive oesophagitis in children, the following doses based on body-weight are licensed in the USA to be given once daily for up to 8 weeks:

- less than 20 kg: 10 mg
- 20 kg or over: 10 or 20 mg

Administration in hepatic impairment. No dosage adjustment of esomeprazole is considered necessary for patients with mild to moderate hepatic impairment (Child-Pugh Classes A and B, respectively). For patients with severe hepatic impairment (Child-Pugh Class C), a daily dose of 20 mg should not be exceeded.

Administration in renal impairment. Although no dosage adjustment is considered necessary in patients with renal impairment, UK licensed product information advises caution in those with severe renal impairment, as experience in these patients is limited.

Adverse Effects

As for Cimetidine, p.1716. Unlike cimetidine, famotidine is reported to have little or no anti-androgenic effect, although there are isolated reports of gynaecomastia and impotence.

◊ General references.

Effects on the blood. For reports of blood dyscrasias, some serious, occurring with famotidine, see under Cimetidine p.1717.

Effects on the cardiovascular system. Famotidine 40 mg daily by mouth reduced cardiac output and stroke volume, compared with placebo, cimetidine, or ranitidine in healthy subjects.[1] Similar effects seen in another study[2] were delayed by pretreatment with ranitidine. However, other workers have found that oral famotidine had no effect on exercise capacity or left ventricular systolic function in healthy subjects,[3] and that famotidine 20 mg intravenously had no effect on any of the haemodynamic parameters measured in 11 critically ill patients.[4] As with other H_2-antagonists (p.1717), bradycardia and AV block has been reported with famotidine,[5] as has a case of QT prolongation.[6]

6. Endo T, *et al.* Famotidine and acquired long QT syndrome. *Am J Med* 2000; **108:** 438–9.

Effects on the endocrine system. Hyperprolactinaemia and breast engorgement occurred in a woman during the fourth month of treatment with famotidine 80 mg daily;[1] she had mistakenly been given twice the usual maximum dose. Recovery occurred when famotidine was withdrawn. Transient hyperprolactinaemia and galactorrhoea have also been reported in a woman after standard doses (40 mg daily) of famotidine.[2] There have been a few instances of impotence.[3]

3. Kassianos GC. Impotence and nizatidine. *Lancet* 1989; **i:** 963.

Effects on the kidneys. For mention of acute interstitial nephritis associated with H_2-antagonists, including famotidine, see under Cimetidine, p.1717.

Effects on the liver. Mixed hepatocellular jaundice[1] and acute hepatitis[2] have been associated with use of famotidine; in the latter case hepatitis later recurred when the patient was given cimetidine.

1. Ament PW, *et al.* Famotidine-induced mixed hepatocellular jaundice. *Ann Pharmacother* 1994; **28:** 40–2.
2. Hashimoto F, *et al.* Hepatitis following treatments with famotidine and then cimetidine. *Ann Pharmacother* 1994; **28:** 37–9.

Effects on the nervous system. Similarly to other H_2-antagonists (p.1717), CNS reactions have occurred with famotidine, particularly in the elderly and those with renal failure.[1-3] In one report,[1] convulsions and mental deterioration in 2 elderly patients with renal failure were associated with grossly elevated plasma and CSF concentrations of the drug; symptoms resolved within 3 days of withdrawing famotidine. In another elderly patient with renal impairment, delirium was associated with use of famotidine but did not occur with cimetidine.[4]

4. Yuan R-Y, *et al.* Delirium following a switch from cimetidine to famotidine. *Ann Pharmacother* 2001; **35:** 1045–8.

Effects on the skin. Toxic epidermal necrolysis or erythema multiforme have been reported after use of famotidine;[1,2] the second patient had a recurrence with cimetidine.

1. Brunner M, *et al.* Toxic epidermal necrolysis (Lyell syndrome) following famotidine administration. *Br J Dermatol* 1995; **133:** 814–15.
2. Horiuchi Y, Ikezawa K. Famotidine-induced erythema multiforme: cross-sensitivity with cimetidine. *Ann Intern Med* 1999; **131:** 795.

Fever. Famotidine 20 mg intravenously every 12 hours was associated with hyperpyrexia in a patient with facial and cranial trauma.[1] Rectal temperature in the 24 hours after starting famotidine was 40.5° and remained elevated for the 5 days of famotidine treatment, despite use of antipyretics. Withdrawal of famotidine resulted in a return to normal temperature within 24 hours.

1. Norwood J, *et al.* Famotidine and hyperpyrexia. *Ann Intern Med* 1990; **112:** 632.

Precautions

As for Cimetidine, p.1718.

Hepatic impairment. For a report of increased resistance to H_2-antagonists in patients with liver cirrhosis, see Ranitidine, p.1766.

Renal impairment. In patients with renal impairment, famotidine clearance is reduced and the elimination half-life increased, resulting in increased serum-drug concentrations and in some cases clinical sequelae (see Effects on the Nervous System, above). The half-life of famotidine in healthy subjects is about 3 hours, but in patients with a creatinine clearance less than 38 mL/minute[1] or those with end-stage renal disease[2] it has been reported to be 19.3 hours and 27.2 hours respectively. A 50% reduction in the dose of famotidine in patients with renal impairment has therefore been recommended. However, it may not be sufficient to adjust the dose only on the basis of creatinine clearance since famotidine is partly eliminated by tubular secretion, which may also be diminished.[1] A chart review[3] in patients with end-stage renal disease suggested that most patients would tolerate a dose of 20 mg daily, although a few might need further adjustment to prevent mental status changes.

Haemodialysis does not effectively remove famotidine from the systemic circulation. The proportion removed depends on the type of membrane used; with a high flux polysulfone membrane about 16% is reported to be removed, but only 6% with a cuprophan membrane.[2] Continuous ambulatory peritoneal dialysis is reported to remove about 5% of a dose.[2] Continuous haemofiltration may remove about 16% of a dose;[2] intermittent haemofiltration is reported to remove about 4%[4] or 8%.[2] Dosage supplements of famotidine are not required during or after dialysis or filtration procedures.

2. Gladziwa U, *et al.* Pharmacokinetics and dynamics of famotidine in patients with renal failure. *Br J Clin Pharmacol* 1988; **26:** 315–21.
3. Redmond AM, *et al.* Use of famotidine in adult patients with end-stage renal disease: assessment of dosing and mental status changes. *Am J Med Sci* 2005; **330:** 8–10.
4. Saima S, *et al.* Hemofiltrability of H -receptor antagonist, famotidine, in renal failure patients. *J Clin Pharmacol* 1990; **30:** 159–62.

Interactions

Unlike cimetidine (see p.1718) famotidine does not inhibit cytochrome P450, and therefore is considered to have little effect on the metabolism of other drugs. However, like other H_2-antagonists its effects on gastric pH may affect the absorption of some other drugs.

Antacids. Giving famotidine 40 mg with a 10-mL dose of antacid containing 800 mg *aluminium hydroxide* with 800 mg *magnesium hydroxide*,[1] resulted in a decrease in the bioavailability of famotidine that was considered clinically insignificant. Giving famotidine with a 30-mL dose of the same antacid resulted in a greater reduction in the absorption of famotidine from the gastrointestinal tract, but the interaction could be minimised by separating ingestion by 2 hours.[2]

1. Lin JH, *et al.* Effects of antacids and food on absorption of famotidine. *Br J Clin Pharmacol* 1987; **24:** 551–3.
2. Barzaghi N, *et al.* Impaired bioavailability of famotidine given concurrently with a potent antacid. *J Clin Pharmacol* 1989; **29:** 670–2.

Probenecid. Probenecid in a total dose of 1500 mg had a significant effect on the pharmacokinetics of famotidine 20 mg in 8 healthy subjects.[1] The maximum serum concentration of famotidine and the area under the concentration/time curve were significantly increased and renal clearance significantly reduced.

These effects were explained by inhibition of the renal tubular secretion of famotidine by probenecid.

1. Inotsume N, *et al.* The inhibitory effect of probenecid on renal excretion of famotidine in young, healthy volunteers. *J Clin Pharmacol* 1990; **30:** 50–6.

Theophylline. Although famotidine is considered not to interfere with the metabolism of other drugs there is a report of a clinically significant interaction with theophylline—see p.1145.

Pharmacokinetics

Famotidine is readily but incompletely absorbed from the gastrointestinal tract with peak concentrations in plasma occurring 1 to 3 hours after oral doses. The bioavailability of oral famotidine is about 40 to 45% and is not significantly affected by the presence of food.

The elimination half-life from plasma is reported to be about 3 hours and is prolonged in renal impairment. Famotidine is weakly bound, about 15 to 20%, to plasma proteins. A small proportion of famotidine is metabolised in the liver to famotidine *S*-oxide. About 25 to 30% of an oral dose, and 65 to 70% of an intravenous dose, is excreted unchanged in the urine in 24 hours, primarily by active tubular secretion. Famotidine is also found in breast milk.

◊ Reviews.

1. Echizen H, Ishizaki T. Clinical pharmacokinetics of famotidine. *Clin Pharmacokinet* 1991; **21:** 178–94.

Children. Famotidine 300 micrograms/kg intravenously was given to 10 children aged 2 to 7 years, after cardiac surgery and before extubation, to prevent aspiration.[1] This dose (equivalent to about 20 mg in adults) induced a rise in the intragastric pH within 1 hour of being given and the pH remained above 3.5 for about 9 hours. The mean elimination half-life was 3.3 hours, similar to the value in healthy adults and it was considered that doses in children need therefore only be adjusted according to body-weight and renal function. This conclusion was supported by a review of 8 studies in children over 1 year of age.[2] Conversely, in infants aged 5 to 19 days, the mean elimination half-life was prolonged (10.5 hours) secondary to reduced renal clearance.[3] This was confirmed by another study,[4] which indicated that reduced clearance was found in infants under 3 months of age, but that pharmacokinetics in older infants were similar to those previously reported for children and adults.

4. Wenning LA, *et al.* Pharmacokinetics of famotidine in infants. *Clin Pharmacokinet* 2005; **44:** 395–406.

Distribution into breast milk. The peak concentration of famotidine in breast milk, which occurred in 8 women 6 hours after an oral dose of 40 mg, was similar to the peak plasma concentration which occurred 2 hours after the dose.[1]

1. Courtney TP, *et al.* Excretion of famotidine in breast milk. *Br J Clin Pharmacol* 1988; **26:** 639P.

Enterohepatic recirculation. Some individuals have a second peak in the plasma concentration of famotidine, which could be due to enterohepatic recirculation. However, a maximum of 0.43% of a dose of famotidine was excreted in the bile of 2 patients following single doses of 20 mg intravenously or 40 mg by mouth indicating that significant recirculation had not occurred.[1]

1. Klotz U, Walker S. Biliary excretion of H -receptor antagonists. *Eur J Clin Pharmacol* 1990; **39:** 91–2.

Uses and Administration

Famotidine is a histamine H_2-antagonist with actions and uses similar to those of cimetidine (see p.1719).

Famotidine may be given orally or intravenously.

In the management of benign **gastric** and **duodenal ulceration** (p.1702) the dose is 40 mg daily orally at bedtime, for 4 to 8 weeks. A dose of 20 mg twice daily has also been given. A maintenance dose of 20 mg at bedtime may be given to prevent recurrence of duodenal ulceration. In **gastro-oesophageal reflux disease** (p.1696) the recommended oral dose is 20 mg twice daily for 6 to 12 weeks, or up to 40 mg twice daily if there is oesophageal ulceration. A maintenance dose of 20 mg twice daily may be given to prevent recurrence. For the short-term symptomatic relief of heartburn or non-ulcer **dyspepsia** (p.1695) a dose of 10 mg up to twice daily is suggested. In the **Zollinger-Ellison syndrome** (p.1704) the initial oral dose is 20 mg every 6 hours, increased as necessary; doses up to 800 mg daily have been used.

The usual dose of famotidine by the intravenous route is 20 mg and may be given by injection over at least 2 minutes or as an infusion over 15 to 30 minutes; the dose may be repeated every 12 hours.

Doses of famotidine should be reduced in patients with renal impairment (see below).

Administration. Although famotidine is most usually given as a film-coated tablet, an alternative wafer formulation, designed to dissolve on the tongue without the need for water, has also been developed.[1]

Parenteral formulations of famotidine are also available in some countries. Although licensed product information recommends that intravenous injections be given over at least 2 minutes, a study that compared rapid intravenous injection (over up to 1 minute) with slow intravenous infusion found both to be safe.[2] Continuous infusion has however been reported by others[3] to be more effective in the prevention of stress ulceration than bolus injection.

1. Schwartz JI, *et al.* Novel oral medication delivery system for famotidine. *J Clin Pharmacol* 1995; **35:** 362–7.
2. Fish DN. Safety and cost of rapid iv injection of famotidine in critically ill patients. *Am J Health-Syst Pharm* 1995; **52:** 1889–94.
3. Baghaie AA, *et al.* Comparison of the effect of intermittent administration and continuous infusion of famotidine on gastric pH in critically ill patients: results of a prospective, randomized, crossover study. *Crit Care Med* 1995; **23:** 687–91.

Administration in renal impairment. The dosage of famotidine should be reduced in patients with renal impairment. In the UK, a 50% reduction is suggested for patients whose creatinine clearance is less than 10 mL/minute; in the USA this reduction is recommended in all those with creatinine clearance less than 50 mL/minute. Alternatively, the dosage interval may be prolonged to 36 to 48 hours.

Immunomodulation. *MALIGNANT NEOPLASMS.* References[1-3] to the use of adjuvant famotidine in patients with malignant neoplasms, including use with interleukin-2 infusions.[2,3]

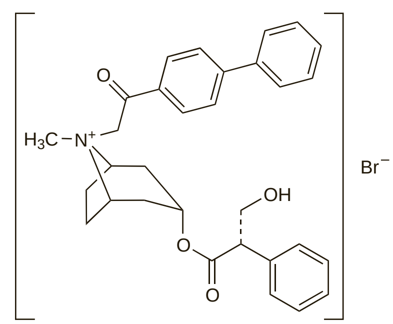
Fentonium Bromide *(rINN)*

Bromuro de fentonio; Fa-402; Fentonii Bromidum; Fentonium, Bromure de; Ketoscilium; *N*-(4-Phenylphenacyl)-1-hyoscyaminium Bromide; Z-326. (−)-(1*R*,3*r*,5*S*)-8-(4-Phenylphenacyl)-3-[(*S*)-tropoyloxy]tropanium bromide.

Фентония Бромид

$C_{31}H_{34}BrNO_4$ = 564.5.
CAS — 5868-06-4.
ATC — A03BB04.
ATC Vet — QA03BB04.



Profile

Fentonium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used to relieve visceral spasms.

Fig

Carica; Ficus; Higo.

Инжир; Фикус

Pharmacopoeias. In *Br.* and *Swiss.*

BP 2008 (Fig). The sun-dried succulent fruit of *Ficus carica* containing not less than 60.0% of water-soluble extractive. Store in a dry place.

Profile

Fig is a mild laxative and demulcent usually used with other laxatives.

Effects on the skin. Skin reactions and photodermatitis have followed application of home-made decoctions of fig leaves to the skin.[1,2]

1. Ozdamar E, *et al.* An unusual cause of burn injury: fig leaf decoction used as a remedy for a dermatitis of unknown etiology. *J Burn Care Rehabil* 2003; **24:** 229–33.

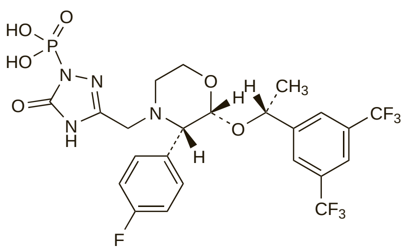
Fosaprepitant *(rINN)*

Fosaprépitant; Fosaprepitantum. {3-[((2*R*,3*S*)-2-{(1*R*)-1-[3,5-bis(Trifluoromethyl)phenyl]ethoxy}-3-(4-fluorophenyl)morpholin-4-yl)methyl]-5-oxo-4,5-dihydro-1*H*-1,2,4-triazol-1-yl}phosphonic acid.

Фозапрепитант

$C_{23}H_{22}F_7N_4O_6P$ = 614.4.

CAS — 172673-20-0.



Fosaprepitant Meglumine *(rINNM)*

Fosaprepitant Dimeglumine; Fosaprepitant meglumina; Fosaprépitant Méglumine; Meglumini Fosaprepitantum; MK-0517. 1-Deoxy-1-(methylamino)-D-glucitol {3-[((2*R*,3*S*)-2-{(1*R*)-1-[3,5-bis(trifluoromethyl)phenyl]ethoxy}-3-(4-fluorophenyl)-4-morpholinyl)methyl]- 2,5-dihydro-5-oxo-1*H*-1,2,4-triazol-1-yl}phosphonate.

Меглумина Фозапрепитант

$C_{23}H_{22}F_7N_4O_6P, 2C_7H_{17}NO_5$ = 1004.8.

CAS — 265121-04-8.

Stability. US licensed product information states that, once reconstituted and diluted as directed in sodium chloride 0.9%, a solution of fosaprepitant meglumine is stable for 24 hours at room temperature (at or below 25°).

Adverse Effects and Precautions

As for Aprepitant, p.1708.

Interactions

As for Aprepitant, p.1708.

Pharmacokinetics

Fosaprepitant is rapidly converted to aprepitant; for the pharmacokinetics of aprepitant, see p.1708.

Uses and Administration

Fosaprepitant is a prodrug of the antiemetic aprepitant (p.1708), which is a neurokinin-1 receptor antagonist. Fosaprepitant meglumine is used for the prevention of acute and delayed nausea and vomiting associated with highly emetogenic or moderately emetogenic cancer chemotherapy. Doses are expressed in terms of the base; 188 mg of fosaprepitant meglumine is equivalent to about 115 mg of fosaprepitant. A dose of fosaprepitant meglumine equivalent to 115 mg fosaprepitant may be given intravenously instead of oral aprepitant, with a corticosteroid and a 5-HT_3 antagonist (for details, see Administration, under Aprepitant, p.1709). The reconstituted dose of fosaprepitant is diluted in 110 mL of sodium chloride 0.9% to a final concentration of 1 mg/mL and infused over 15 minutes.

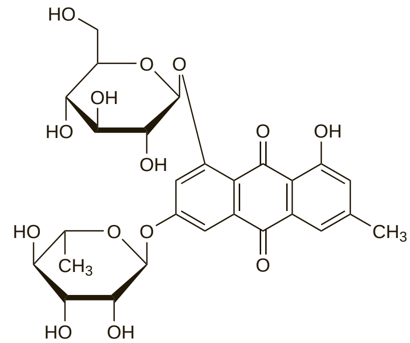
Кора Крушины

CAS — 8057-57-6 (frangula extract).



(glucofrangulin A)

NOTE. The name Buckthorn Bark has also been used; distinguish Frangula Bark from Buckthorn (p.1713) and from Sea Buckthorn (p.2384).

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Frangula Bark). The dried, whole or fragmented bark of the stems and branches of *Rhamnus frangula* (=*Frangula alnus*). It contains not less than 7.0% of glucofrangulins, expressed as glucofrangulin A ($C_{27}H_{30}O_{14}$ = 578.5) and calculated with reference to the dried drug. Protect from light.

Profile

Frangula bark is an anthraquinone stimulant laxative with actions and uses similar to those of senna (p.1769).

Homoeopathy. Frangula bark has been used in homoeopathic medicines under the following names: Frangula; Rhamnus frangula; Rham. fr.

Preparations

Ph. Eur.: Frangula Bark Dry Extract, Standardised.

Proprietary Preparations (details are given in Part 3)

Gefarnate *(BAN, rINN)*

DA-688; Géfarnate; Gefarnato; Gefarnatum; Geranyl Farnesylacetate. A mixture of stereoisomers of 3,7-dimethylocta-2,6-dienyl 5,9,13-trimethyltetradeca-4,8,12-trienoate.

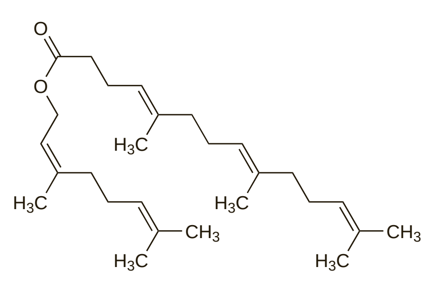
Гефарнат

$C_{27}H_{44}O_2$ = 400.6.

CAS — 51-77-4.

ATC — A02BX07.

ATC Vet — QA02BX07.



Profile

Gefarnate is a cytoprotective that has been used in the treatment of peptic ulcer disease and gastritis. An ophthalmic preparation is under investigation for the treatment of corneal and conjunctival epithelial disorders.

Ginger

Gengibre; Gingembre; Gyömbér gyökértörzs; Imbierų šakniastiebiai; Ingefära; Ingwer; Inkivääri; Jengibre; Zázvorový oddenek; Zingib.; Zingiber; Zingiberis rhizoma.

Имбирь

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US. US* also includes the powdered form.

Ph. Eur. 6.2 (Ginger). The dried, whole or cut rhizome of *Zingiber officinale*, with the cork removed, either completely or from the wide flat surfaces only. Whole or cut, it contains not less than 1.5% of essential oil, calculated with reference to the anhydrous drug. It has a characteristic aromatic odour. Protect from light.

The BP 2008 states that ginger may be known in commerce as unbleached ginger.

USP 31 (Ginger). The scraped, partially scraped, or unscraped rhizome of *Zingiber officinale* (Zingiberaceae), known in commerce as unbleached ginger. It contains not less than 4.5% of alcohol-soluble extractive and not less than 10% of water-soluble extractive. Store at 8° to 15°. Protect from light and moisture.

Profile

Ginger has carminative properties. It is used as a flavouring agent and has been tried for the prophylaxis of motion sickness and nausea and vomiting in pregnancy, although it does not seem to be effective for postoperative nausea and vomiting (p.1700).

Ginger oil is used in aromatherapy.

Homoeopathy. Ginger has been used in homoeopathic medicines under the following names: Zingiber; Zingiber officinale; Zing.

Granisetron Hydrochloride

(BANM, USAN, rINNM)

BRL-43694A; Granisétron, chlorhydrate de; Granisetron-hydrochlorid; Granisetronhydroklorid; Granisetroni hydrochloridum; Granisetronihydrokloridi; Granisetrono hidrochloridas; Hidrocloruro de granisetrón. 1-Methyl-*N*-(9-methyl-9-azabicyclo[3.3.1]non-3-yl)-1*H*-indazole-3-carboxamide hydrochloride.

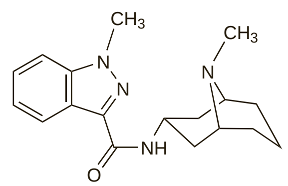
Гранисетрона Гидрохлорид

$C_{18}H_{24}N_4O,HCl = 348.9.$

CAS — 109889-09-0 (granisetron); 107007-99-8 (granisetron hydrochloride).

ATC — A04AA02.

ATC Vet — QA04AA02.



(granisetron)

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).

Ph. Eur. 6.2 (Granisetron Hydrochloride). A white or almost white powder. Freely soluble in water; sparingly soluble in dichloromethane; slightly soluble in methyl alcohol. A 1% solution in water has a pH of 4.0 to 6.5.

Adverse Effects and Precautions

As for Ondansetron, p.1757, although no dosage reduction is considered necessary in renal or hepatic impairment.

Carcinogenicity. The manufacturer (*Roche*) has reported an increased incidence of hepatic neoplasms in *rodents* given very high doses of granisetron for prolonged periods, but the clinical relevance of these results is unknown. Although mutagenicity and genotoxicity have not been seen in some tests, others have reported an increased incidence of polyploidy or unscheduled DNA synthesis in exposed cells.

Effects on the cardiovascular system. For a discussion of the effects of $5\text{-}HT_3$ antagonists on the cardiovascular system, see under Ondansetron, p.1757.

Interactions

The metabolism of granisetron is induced by phenobarbital.

Pharmacokinetics

Granisetron is rapidly absorbed after oral doses, with peak plasma concentrations occurring after about 2 hours. Oral bioavailability is about 60% as a result of first-pass hepatic metabolism. Granisetron has a large volume of distribution of around 3 litres/kg; plasma protein binding is about 65%. The pharmacokinetics exhibit considerable interindividual variation, and the elimination half-life after an intravenous dose is reported to be around 4 to 5 hours in healthy subjects but about 9 to 12 hours in cancer patients. It is metabolised in the liver, primarily by *N*-demethylation, with less than 20% of a dose recovered unchanged in urine, the remainder being excreted in faeces and urine as metabolites. Granisetron clearance is not affected by renal impairment, but is lower in the elderly and in patients with hepatic impairment.

Uses and Administration

Granisetron is a $5\text{-}HT_3$ antagonist with an antiemetic action similar to that of ondansetron (p.1757). It is used in the management of nausea and vomiting induced by cytotoxic chemotherapy and radiotherapy and for the prevention and treatment of postoperative nausea and vomiting (p.1700). Granisetron is given as the hydrochloride, but doses are expressed in terms of the base. Granisetron hydrochloride 1.1 mg is equivalent to about 1 mg of granisetron base.

For acute **nausea and vomiting** associated with **chemotherapy** granisetron is used in *prevention* and *treatment* in similar doses.

- In the UK, a dose equivalent to 3 mg of granisetron is diluted to a volume of 20 to 50 mL with a suitable infusion solution and given intravenously over 5 minutes before the start of chemotherapy; alternatively this dose may be given in 15 mL of infusion solution as a bolus over not less than 30 seconds. The dose may be repeated up to twice in 24 hours; doses should be given at least 10 minutes apart and a total daily dose of 9 mg should not be exceeded. The efficacy of granisetron may be enhanced by the use of dexamethasone. The recommended oral dose is 1 to 2 mg within one hour before therapy begins, then 2 mg daily as a single dose or in 2 divided doses.
- For use in children, an intravenous infusion of 40 micrograms/kg, up to a maximum total dose of 3 mg, has been recommended, diluted in 10 to 30 mL of infusion fluid and given over 5 minutes. This dose may be repeated once within 24 hours, but at least 10 minutes after the original infusion. Alternatively, children may be given 20 micrograms/kg (up to 1 mg) orally twice daily for up to 5 days during therapy; the first dose should be given within 1 hour before the start of chemotherapy.
- In the USA, lower intravenous doses of the equivalent of granisetron 10 micrograms/kg are recommended in both adults and children over 2 years of age, beginning within 30 minutes before chemotherapy. Oral doses are the same as those described for the UK above.

For the *prevention* of nausea and vomiting associated with **radiotherapy** the recommended adult oral dosage is 2 mg daily taken within 1 hour of irradiation. The drug has also been given intravenously for the *treatment and prevention* of nausea and vomiting associated with radiotherapy, in similar doses to those recommended above for emetogenic chemotherapy. In the UK, the *BNFC* has recommended similar oral and intravenous doses to those given above (for chemotherapy-induced nausea and vomiting) in both the treatment and prevention of radiotherapy-induced nausea and vomiting in children.

For the *prevention* of **postoperative** nausea and vomiting in adults 1 mg is diluted to 5 mL and given by intravenous injection over 30 seconds. Injection should be completed before induction of anaesthesia. The same dose may be given up to twice daily for the *treatment* of established postoperative nausea and vomiting.

Transdermal and intranasal formulations of granisetron are under investigation.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Aludal; Eumetic†; Granitron; Kytril†; Rigmoz†; ***Austral.:*** Kytril; ***Austria:*** Kytril; ***Belg.:*** Kytril; ***Braz.:*** Kytril; ***Canad.:*** Kytril; ***Chile:*** Kytril; ***Cz.:*** Emegar; Kytril; ***Denm.:*** Kytril; ***Fin.:*** Kytril; ***Fr.:*** Kytril; ***Ger.:*** Kevatril; ***Gr.:*** Granitron; Kytril; ***Hong Kong:*** Kytril; ***Hung.:*** Granigen; Kytril; ***India:*** Granicip; ***Indon.:*** Kytril; ***Irl.:*** Kytril; ***Israel:*** Kytril; Setron; ***Ital.:*** Kytril; ***Jpn:*** Kytril; ***Malaysia:*** Kytril; ***Mex.:*** Kytril; ***Neth.:*** Kytril; ***Norw.:*** Kytril†; ***NZ:*** Kytril; ***Philipp.:*** Kytril; ***Port.:*** Kytril; ***Rus.:*** Kytril (Китрил); ***S.Afr.:*** Kytril; ***Singapore:*** Kytril; ***Spain:*** Kytril; ***Swed.:*** Kytril; ***Switz.:*** Kytril; ***Thai.:*** Kytril; ***Turk.:*** Kytril; Setron; ***UK:*** Kytril; ***USA:*** Kytril; ***Venez.:*** Granicip; Kytril; Rubrum.

Hydrotalcite *(BAN, rINN)*

Hidrotalcita; Hidrotalsit; Hydrotalcit; Hydrotalcitum; Hydrotalsiitti. Aluminium magnesium carbonate hydroxide hydrate.

Гидроталцит

$Mg_6Al_2(OH)_{16}CO_3,4H_2O = 604.0.$

CAS — 12304-65-3.

ATC — A02AD04.

ATC Vet — QA02AD04.

NOTE. Compounded preparations of hydrotalcite may be represented by the following names:

- Co-simalcite *x/y* (*BAN*)—where *x* and *y* are the strengths in milligrams of simeticone and hydrotalcite respectively.

Pharmacopoeias. In *Br.*

BP 2008 (Hydrotalcite). A hydrated form of an aluminium magnesium basic carbonate corresponding to the formula $Al_2Mg_6(OH)_{16}CO_3,4H_2O$. It contains not less than 15.3% and not more than 18.7% of Al_2O_3 and not less than 36.0% and not more than 44.0% of MgO. The ratio of Al_2O_3 to MgO is not less than 0.40 and not more than 0.45. A white or almost white, free-flowing, granular powder. Practically insoluble in water; it dissolves in dilute mineral acids with slight effervescence. A 4% suspension in water has a pH of 8.0 to 10.0.

Profile

Hydrotalcite is an antacid (see p.1692) that is given in oral doses of up to about 1 g.

Preparations

BP 2008: Hydrotalcite Tablets.

Proprietary Preparations (details are given in Part 3)
Austria: Talcid; Talidat; ***Cz.:*** Rutacid; Talcid; Talidat; ***Ger.:*** Ancid; Megalac; Talcid; Talidat; ***Gr.:*** Talcid; ***Hung.:*** Talcid; Tisacid; ***Israel:*** Talcid†; ***Malaysia:*** Swecon; ***Mex.:*** Talcid; ***Neth.:*** Talcid; Talidat; Ultacit; ***Pol.:*** Malgacid; Rutacid; Talcid; Ulcetal; ***Port.:*** Talidat†; ***Rus.:*** Rutacid (Рутацид); Talcid (Тальцид); ***S.Afr.:*** Altacite; ***Spain:*** Talcid; ***Turk.:*** Talcid; ***Venez.:*** Baytalcid†.

Multi-ingredient: ***Indon.:*** Promag; ***Jpn:*** Eki Cabe; ***Philipp.:*** Simeco; ***UK:*** Altacite Plus.

Hyoscine *(BAN)*

Escopolamina; Hioscina; Hioscyna; Hyoscin; Hyoscinum; Hyoskiini; Scopolamine; Scopolaminum; Skopolamiini; Skopolamin; Skopolamina; Tropato de epoxitropina. (−)-(1*S*,3*s*,5*R*,6*R*,7*S*,8*s*)-6,7-Epoxy-3[(*S*)-tropoyloxy] tropane.

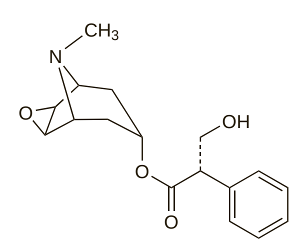
Гиосцин

$C_{17}H_{21}NO_4 = 303.4.$

CAS — 51-34-3.

ATC — A04AD01; N05CM05; S01FA02.

ATC Vet — QA04AD01; QN05CM05; QS01FA02.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of hyoscine:
Burundanga.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Hyoscine). A white or almost white, crystalline powder or colourless crystals. M.p. 66° to 70°. Soluble in water; freely soluble in alcohol.

Hyoscine Butylbromide *(BANM)*

Butilbromuro de hioscina; Butylscopolamine Bromide; Butylscopolaminii Bromidum; *N*-Butylscopolammonium Bromide; Butylscopolamonii Bromidum; Butylskopolaminium-bromid; Escopolamina, butilbromuro de; Hioscino butilbromidas; Hioszcin-butilbromid; Hiyosin Bütilbromür; Hyoscinbutylbromid; Hyoscine-*N*-butyl Bromide; Hyoscini butylbromidum; Hyoskiinibutyylibromidi; Scopolamine *N*-Butyl Bromide; Scopolamine Butylbromide; Scopolamine, butylbromure de; Scopolamini butylbromidum; Scopolomini Butylbromidum; Skopolamino butilbromidas; Szkopolamin-butilbromid. (−)-(1*S*,3*s*,5*R*,6*R*,7*S*,8*r*)-6,7-Epoxy-8-butyl-3-[(*S*)-tropoyloxy]tropanium bromide.

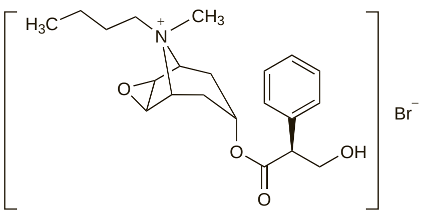
Гиосцина Бутилбромид

$C_{21}H_{30}BrNO_4$ = 440.4.

CAS — 149-64-4.

ATC — A03BB01.

ATC Vet — QA03BB01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn.*

Ph. Eur. 6.2 (Hyoscine Butylbromide). A white or almost white, crystalline powder. Freely soluble in water and in dichloromethane; sparingly soluble in dehydrated alcohol. A 5% solution in water has a pH of 5.5 to 6.5.

Hyoscine Hydrobromide *(BANM)*

Bromhidrato de Escopolamina; Escopolamina, hidrobromuro de; Hidrobromuro de hioscina; Hioscino hidrobromidas; Hioscyny bromowodorek; Hioszcin-hidrobromid; Hiyosin Hidrobromür; Hyoscinhydrobromid; Hyoscini hydrobromidum; Hyoskiinihydrobromidi; Ioscina Bromidrato; Scopolamine Bromhydrate; Scopolamine, bromhydrate de; Scopolamine Hydrobromide; Scopolamini hydrobromidum; Scopolamini Hydrobromidum Trihydricum; Skopolamiinihydrobromidi; Skopolamin-bromid trihydrát; Skopolaminhydrobromid; Skopolamino hidrobromidas; Szkopolamin-butilbromid. (−)-(1*S*,3*s*,5*R*,6*R*,7*S*)-6,7-Epoxytropan-3-yl (*S*)-tropate hydrobromide trihydrate.

Гиосцина Гидробромид

$C_{17}H_{21}NO_4,HBr,3H_2O$ = 438.3.

CAS — 114-49-8 (anhydrous hyoscine hydrobromide); 6533-68-2 (hyoscine hydrobromide trihydrate).

ATC — A04AD01; N05CM05; S01FA02.

ATC Vet — QA04AD01; QN05CM05; QS01FA02.

NOTE. HYO is a code approved by the BP 2008 for use on single unit doses of eye drops containing hyoscine hydrobromide where the individual container may be too small to bear all the appropriate labelling information.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Hyoscine Hydrobromide). A white or almost white, efflorescent, crystalline powder or colourless crystals. Freely soluble in water; soluble in alcohol. A 5% solution in water has a pH of 4.0 to 5.5. Store in well-filled airtight containers of small capacity. Protect from light.

USP 31 (Scopolamine Hydrobromide). Colourless or white crystals, or white granular powder. Is odourless and slightly efflorescent in dry air. Soluble 1 in 1.5 of water and 1 in 20 of alcohol; slightly soluble in chloroform; insoluble in ether. pH of a 5% solution in water is between 4.0 and 5.5. Store in airtight containers. Protect from light.

Hyoscine Methobromide *(BAN)*

Epoxymethamine Bromide; Escopolamina, metilbromuro de; Hyoscine Methylbromide; Methscopolamine Bromide; Metilbromuro de hioscina; Metobromuro de escopolamina; Metobromuro de hioscina; Scopolamine Methobromide; Scopolamine Methylbromide. (−)-(1*S*,3*s*,5*R*,6*R*,7*S*)-6,7-Epoxy-8-methyl-3-[(*S*)-tropoyloxy]tropanium bromide.

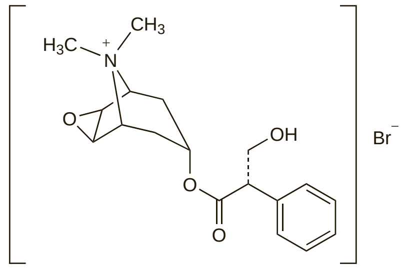
Гиосцина Метобромид

$C_{18}H_{24}BrNO_4$ = 398.3.

CAS — 155-41-9.

ATC — A03BB03; S01FA03.

ATC Vet — QA03BB03; QS01FA03.



Pharmacopoeias. In *US.*

USP 31 (Methscopolamine Bromide). Store in airtight containers. Protect from light.

Hyoscine Methonitrate *(BANM)*

Escopolamina, metilnitrato de; Hyoscine Methylnitrate; Methscopolamine Nitrate; Methylhyoscini Nitras; Methylscopolamine Nitrate; Methylscopolamini Nitras; Metilnitrato de hioscina; Metonitrato de escopolamina; Metonitrato de hioscina; Metylskopolaminnitrat; Metyyliskopolamiininitraatti; Scopolamine Methonitrate; Scopolamine Methylnitrate. (−)-(1*S*,3*s*,5*R*,6*R*,7*S*)-6,7-Epoxy-8-methyl-3-[(*S*)-tropoyloxy]tropanium nitrate.

Гиосцина Метонитрат

$C_{18}H_{24}N_2O_7$ = 380.4.

CAS — 6106-46-3.

ATC — A03BB03; S01FA03.

ATC Vet — QA03BB03; QS01FA03.

Adverse Effects, Treatment, and Precautions

As for Atropine Sulfate, p.1219. In contrast to atropine, hyoscine produces central depression at therapeutic doses and symptoms include drowsiness and fatigue. Toxic doses of hyoscine produce stimulation of the CNS in a similar manner to atropine. However, hyoscine does not stimulate the medullary centres and therefore does not produce the increases in respiration rate or blood pressure seen with atropine. Hyoscine may produce CNS stimulation rather than depression at therapeutic doses if used in the presence of pain without opioid analgesics; symptoms include excitement, restlessness, hallucinations, or delirium.

Patients who experience drowsiness should not drive or operate machinery. Caution has been advised in elderly patients and in patients with impaired liver, or kidney function, as adverse CNS effects have been stated to be more likely in these patients. There have been rare reports of an increase in frequency of seizures in epileptic patients.

The quaternary derivatives, such as the butylbromide, methobromide, or methonitrate, do not readily cross the blood-brain barrier, so central effects are rare.

Abuse. Hyoscine has been used by criminals to incapacitate and produce anterograde amnesia in their victims in crimes such as drug-facilitated rape ('date rape'), robbery, and kidnapping. In some countries in South America there has been a particular problem with the use of powders or extracts of plants containing hyoscine for such crimes. A powder, known locally as burundanga, prepared from the borrachero or borracchio tree (also referred to as cacao sabanero) has been blown into the victim's face or given in drinks, chocolate, or chewing gum.

Breast feeding. The American Academy of Pediatrics[1] states that there have been no reports of any clinical effect on the infant associated with the use of hyoscine by breast-feeding mothers, and that therefore it may be considered to be usually compatible with breast feeding.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 19/01/06)

Effects on the eyes. *ANISOCORIA.* Although bilateral mydriasis has occurred with the use of transdermal hyoscine, development of a unilateral fixed dilated pupil (anisocoria) may be due to contamination of a finger with hyoscine in handling the device, and then rubbing the eye.[1-6] Similarly, anisocoria has been attributed[7] to ocular contamination after handling broken hyoscine methobromide tablets.

Effects on the oesophagus. A patient developed pain on swallowing after 4 days of treatment with hyoscine. Endoscopy showed oesophageal ulceration, which healed completely after 8 weeks of esomeprazole treatment.[1]

1. Philcox S, Keegan A. A case of hyoscine-related oesophagitis. *Med J Aust* 2007; **186:** 650–1.

Effects on the skin. Contact dermatitis occurred in 16 men being treated for seasickness with transdermal hyoscine for 6 weeks to 15 months.[1]

1. Gordon CR, *et al.* Allergic contact dermatitis caused by transdermal hyoscine. *BMJ* 1989; **298:** 1220–1.

Porphyria. Hyoscine butylbromide has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Pregnancy. A report[1] of hyoscine toxicity in a neonate born to a mother who had received a total of 1.8 mg of hyoscine in divided doses with pethidine and levorphanol before delivery. The neonate was lethargic, barrel chested, and had a heart rate of 200 beats/minute. Symptoms subsided when physostigmine 100 micrograms was given intramuscularly.

1. Evens RP, Leopold JC. Scopolamine toxicity in a newborn. *Pediatrics* 1980; **66:** 329–30.

Withdrawal. A withdrawal syndrome of dizziness and nausea[1,2] can occur in patients who have used transdermal hyoscine patches for several days; hypersalivation and diarrhoea has also been described.[3] In reported cases, transdermal hyoscine had been used continuously for 7 or 10 days to prevent motion sickness. Symptoms usually begin 2 or 3 days after the last patch has been removed, and may last for a few days.

3. Feder RE. Transdermal scopolamine withdrawal syndrome. *Clin Neuropharmacol* 1999; **22:** 120.

Interactions

As for antimuscarinics in general (see Atropine Sulfate, p.1220).

The sedative effect of hyoscine may be enhanced by alcohol or other CNS depressants.

Pharmacokinetics

Hyoscine is readily absorbed from the gastrointestinal tract after oral doses of the hydrobromide. It is almost entirely metabolised, probably in the liver; only a small proportion of an oral dose is excreted unchanged in the urine. It crosses the blood-brain barrier and has been stated to cross the placenta. Hyoscine is also well absorbed after application to the skin.

The quaternary derivatives, such as the butylbromide or methobromide, are poorly absorbed from the gastrointestinal tract and do not readily pass the blood-brain barrier.

Uses and Administration

Hyoscine is a tertiary amine antimuscarinic with central and peripheral actions (see Action of Antimuscarinics, p.1221). It is a more powerful suppressant of salivation than atropine, and usually slows rather than increases heart rate, especially in low doses. Its central action differs from that of atropine in that it depresses the cerebral cortex and produces drowsiness and amnesia. Hyoscine hydrobromide is also a tertiary amine, whereas hyoscine butylbromide, hyoscine methobromide, and hyoscine methonitrate are quaternary ammonium derivatives.

Hyoscine and hyoscine hydrobromide are used in the management of motion sickness and other forms of nausea and vomiting; hyoscine hydrobromide is also given as a premedicant in anaesthesia, and to produce mydriasis and cycloplegia. Hyoscine butylbromide and other quaternary ammonium derivatives are used in conditions associated with visceral spasms. Hyoscine methobromide has also been employed as an adjunct in the treatment of peptic ulcer disease.

Other hyoscine salts or derivatives that have been used include hyoscine borate, hyoscine hydrochloride, and hyoscine oxide hydrobromide.

See under headings below for details of dosage and administration of hyoscine and its salts in specific indications.

Anaesthesia. The role of antimuscarinics, including hyoscine, in anaesthesia is discussed under Atropine on p.1221. For the use of hyoscine in the prevention of postoperative nausea and vomiting, see below.

For premedication hyoscine hydrobromide is injected subcutaneously or intramuscularly in doses of 200 to 600 micrograms, usually with papaveretum about half to one hour before induction of general anaesthesia. In the UK, a dose of 15 micrograms/kg is licensed in children (the *BNFC* suggests that this dose is appropriate from 1 to 12 years of age; older children may be given the adult dose). If necessary for acute use, the same doses may be given by intravenous injection.

Anoxic seizures. For mention of the use of transdermal hyoscine as an alternative to atropine in the management of reflex anoxic seizures in children, see p.1221.

Biliary and renal colic. Hyoscine has been used as an adjunct to opioid analgesics for symptomatic relief of biliary or renal colic (see p.5) although the evidence for such use is weak. Hyoscine butylbromide 20 mg is given by intramuscular or slow intravenous injection; this may be repeated after 30 minutes if necessary to a maximum daily dose of 100 mg. See also Palliative Care, below.

References.

1. Holdgate A, Oh CM. Is there a role for antimuscarinics in renal colic? A randomized controlled trial. *J Urol (Baltimore)* 2005; **174:** 572–5.

Cardiac disorders. Although hyoscine is not one of the conventional therapies for heart failure (p.1165) or myocardial infarction (p.1175), low-dose transdermal hyoscine can increase cardiac vagal activity and thereby reduce the autonomic imbalance seen in patients with these conditions.[1-3] Improved exercise tolerance has been reported after 1 week of treatment with transdermal hyoscine in a small open study in 14 patients with mild to moderate heart failure.[4]

Depression. Rapid reductions in severity of depression were seen after intravenous hyoscine hydrobromide 4 micrograms/kg was given to patients with major depressive disorders or bipolar disorders (see Depression, p.373). Repeat doses showed more benefit than single doses. Clinical effects persisted beyond the treatment period, which led the authors to conclude the effects were not due to anticholinergic euphoria. While noting that the optimal schedule and potential long-term use of hyoscine as an antidepressant needed further study, they also concluded that hyoscine could be a relatively safe and well-tolerated intervention for achieving a rapid initial antidepressant response.[1]

1. Furey ML, Drevets WC. Antidepressant efficacy of the antimuscarinic drug scopolamine: a randomized, placebo-controlled clinical trial. *Arch Gen Psychiatry* 2006; **63:** 1121–9.

Dysmenorrhoea. Hyoscine as the butylbromide or hydrobromide has been used for its antispasmodic action in the treatment of dysmenorrhoea. (p.6), but the *BNF* considers that antispasmodics do not generally provide significant relief.

Eye disorders. Hyoscine hydrobromide is used in the eye for its mydriatic and cycloplegic actions (p.1874) usually in a concentration of 0.25%. It has a faster onset and shorter duration of action than atropine although the effects may still persist for up to 3 to 7 days. It may be useful for patients who are hypersensitive to atropine.

Gastrointestinal disorders. Hyoscine has been used as an antispasmodic (p.1692) to relieve the pain of smooth muscle spasm associated with the gastrointestinal tract.[1]

In such conditions the licensed UK dose is 20 mg of hyoscine butylbromide intramuscularly or by slow intravenous injection, repeated after 30 minutes if necessary, up to a maximum of 100 mg daily; alternatively, 20 mg may be given orally four times daily. In irritable bowel syndrome (p.1699) the recommended oral starting dose is 10 mg three times daily which may be increased to 20 mg four times daily, if necessary. Children aged 6 to 12 years may be given 10 mg three times daily by mouth for gastrointestinal spasms. As an adjunct in the treatment of peptic ulcer disease; hyoscine methobromide has been licensed in the USA in a dose of 2.5 mg half an hour before meals and 2.5 to 5 mg at bedtime. Hyoscine may also be useful as an antispasmodic in diagnostic procedures of the gastrointestinal tract.

The antiemetic effect of hyoscine is discussed under Nausea and Vomiting, below.

1. Tytgat GN. Hyoscine butylbromide: a review of its use in the treatment of abdominal cramping and pain. *Drugs* 2007; **67:** 1343–57.

Hyperhidrosis. Adverse effects of antimuscarinics given orally generally preclude their use by this route for the management of hyperhidrosis (p.1580), but some, such as hyoscine, have been applied topically as alternatives to aluminium salts. Hyoscine hydrobromide applied as a 3% cream was successful in reducing gustatory sweating, consisting of flushing and sweating over the right mandible during eating, in a patient who had previously undergone surgical excision of the right submandibular salivary gland.[1] The use of transdermal or injectable hyoscine was reported[2] to be effective for the control of opioid-associated sweating in 2 patients receiving palliative care (see also below for other uses of hyoscine in palliative care).

1. Bailey BMW, Pearce DE. Gustatory sweating following submandibular salivary gland removal. *Br Dent J* 1985; **158:** 17–18.
2. Mercadante S. Hyoscine in opioid-induced sweating. *J Pain Symptom Manage* 1998; **15:** 214–15.

Nausea and vomiting. Hyoscine is an effective agent in the prevention of **motion sickness** and is one of the principal drugs used. It may be given orally for short-term protection or by transdermal patch for a prolonged duration of action.

In the UK, a usual oral dose of hyoscine hydrobromide is 300 micrograms taken 30 minutes before a journey, followed by 300 micrograms every 6 hours if required up to a maximum of 3 doses in 24 hours. Children aged 4 to 10 years may be given 75 to 150 micrograms and those over 10 years, 150 to 300 micrograms. Children aged 3 to 4 years may be given 75 micrograms 20 minutes before a journey, repeated if necessary to a maximum total dose of 150 micrograms in 24 hours. Hyoscine is also given via a transdermal patch which is placed behind the ear and supplies 1 mg over 3 days. The patch is licensed in the UK for adults and children aged 10 years and over and should be applied 5 to 6 hours before travelling or on the preceding evening and removed at the end of the journey.

An intranasal formulation of hyoscine hydrobromide has been investigated for the treatment and prevention of motion sickness.

Transdermal hyoscine has been used in adults and children for the prevention of **postoperative nausea and vomiting**.

Hyoscine hydrobromide has also been given by intravenous, subcutaneous, or intramuscular injection for its antiemetic effect in a usual dose of 300 to 600 micrograms.

The other drugs used in the management of motion sickness and postoperative nausea and vomiting are discussed on p.1700.

Palliative care. The *BNF* includes doses for hyoscine in palliative care. *Hyoscine hydrobromide* is used in palliative care to reduce excessive respiratory secretions. A dose of 400 to 600 micrograms may be given by subcutaneous injection every 4 to 8 hours. Alternatively 0.6 to 2.4 mg may be given over 24 hours by continuous subcutaneous infusion. In younger patients the *BNFC* suggests a dose of 10 micrograms/kg (up to a maximum of 600 micrograms) by subcutaneous or intravenous injection every 4 to 8 hours. Alternatively, 1.5 to 2.5 micrograms/kg per hour may be given by continuous subcutaneous or intravenous infusion. Care should be taken to avoid the discomfort of a dry mouth. Hyoscine may also be given as a transdermal patch in some countries.

Hyoscine hydrobromide may be given sublingually for the pain of bowel colic in a dose of 300 micrograms 3 times daily.

Hyoscine butylbromide is also used in palliative care in the treatment of bowel colic; however, it may not be adequate for the control of respiratory secretion. It is given as a subcutaneous infusion in a dose of 20 to 60 mg every 24 hours. A single subcutaneous dose of 20 mg reviewed after 30 minutes, has been suggested if it is tried for excessive respiratory secretion.[1]

The use of hyoscine in palliative care has been reviewed.[2,3] Hyoscine hydrobromide may be more effective than glycopyrronium bromide in drying secretions, and has a rapid onset of action, but it can produce both sedation and agitation; there is no clear evidence favouring one antimuscarinic over another.[1]

1. Bennett M, *et al.* Using anti-muscarinic drugs in the management of death rattle: evidence-based guidelines for palliative care. *Palliat Med* 2002; **16:** 369–74.

3. Spiller JA, Fallon M. The use of Scopoderm in palliative care. *Hosp Med* 2000; **61:** 782–4.

Urinary incontinence. Antimuscarinics have been used in the management of urge incontinence (p.2180) but the incidence of adverse effects can be high. Results of a small study[1] suggested that transdermal hyoscine might be of benefit in females with detrusor instability.

1. Muskat Y, *et al.* The use of scopolamine in the treatment of detrusor instability. *J Urol (Baltimore)* 1996; **156:** 1989–90.

Vertigo. Hyoscine has a long history of use in the management of vertigo, although other drugs are now preferred (p.565).

Preparations

BP 2008: Hyoscine Butylbromide Injection; Hyoscine Butylbromide Tablets; Hyoscine Eye Drops; Hyoscine Injection; Hyoscine Tablets;
USP 31: Methscopolamine Bromide Tablets; Scopolamine Hydrobromide Injection; Scopolamine Hydrobromide Ophthalmic Ointment; Scopolamine Hydrobromide Ophthalmic Solution; Scopolamine Hydrobromide Tablets.

Hyoscyamine *(BAN)*

Hiosciamina; Hyoscyamin; (−)-Hyoscyamine; *l*-Hyoscyamine; Hyoscyaminum; Hyoskyamiini. (−)-(1*R*,3*r*,5*S*)-Tropan-3-yl (*S*)-tropate.

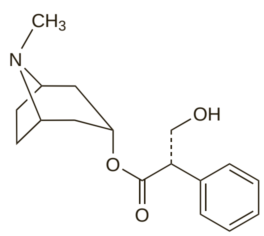
Гиосциамин

$C_{17}H_{23}NO_3$ = 289.4.

CAS — 101-31-5.

ATC — A03BA03.

ATC Vet — QA03BA03.



Description. Hyoscyamine is an alkaloid obtained from various solanaceous plants. It is the laevo-isomer of atropine into which it can be converted by heating or by the action of alkali.

Pharmacopoeias. In *US.*

USP 31 (Hyoscyamine). A white crystalline powder. M.p. 106° to 109°. Slightly soluble in water and in benzene; freely soluble in alcohol, in chloroform, and in dilute acids; sparingly soluble in ether. Its solutions are alkaline to litmus. Store in airtight containers. Protect from light.

Hyoscyamine Hydrobromide *(BANM)*

Bromidrato de Hiosciamina; Hiosciamina, hidrobromuro de; Hyoscyamine Bromhydrate.

Гиосциамина Гидробромид

$C_{17}H_{23}NO_3,HBr$ = 370.3.

CAS — 306-03-6.

ATC — A03BA03.

ATC Vet — QA03BA03.

Pharmacopoeias. In *US.*

USP 31 (Hyoscyamine Hydrobromide). White, odourless, crystals or crystalline powder. M.p. not less than 149°. Freely soluble in water; soluble 1 in 2.5 of alcohol, 1 in 1.7 of chloroform, and 1 in 2300 of ether. pH of a 5% solution in water is about 5.4. Store in airtight containers. Protect from light.

Hyoscyamine Sulfate

Hiosciamina, sulfato de; Hiosciamino sulfatas; Hioscyjaminy siarczan; Hioszciamin-szulfát; Hyoscyamin sulfát dihydrát; Hyoscyamine, sulfate d'; Hyoscyamine Sulphate *(BANM)*; Hyoscyamini sulfas; Hyoscyamini Sulfas Dihydricus; Hyoscyaminsulfat; Hyoscyaminum Sulfuricum; Hyoskyamiinisulfaatti; Iosciamina Solfato.

Гиосциамина Сульфат

$(C_{17}H_{23}NO_3)_2,H_2SO_4,2H_2O$ = 712.8.

CAS — 620-61-1 (anhydrous hyoscyamine sulfate); 6835-16-1 (hyoscyamine sulfate dihydrate).

ATC — A03BA03.

ATC Vet — QA03BA03.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Hyoscyamine Sulphate). A white or almost white, crystalline powder or colourless needles. Very soluble in water; sparingly soluble or soluble in alcohol. A 2% solution in water has a pH of 4.5 to 6.2. Store in airtight containers. Protect from light.

USP 31 (Hyoscyamine Sulfate). A white or almost white, crystalline powder or colourless needles. It is deliquescent and affected by light. Soluble 1 in 0.5 of water and 1 in 5 of alcohol; practically insoluble in ether. pH of a 1% solution in water is about 5.3.

Adverse Effects, Treatment, and Precautions

As for Atropine Sulfate, p.1219.

Interactions

As for antimuscarinics in general (see Atropine Sulfate, p.1220).

Uses and Administration

Hyoscyamine is a tertiary amine antimuscarinic with the actions of atropine (which is racemic hyoscyamine, see p.1219); hyoscyamine, the laevo-isomer, has about twice the potency of atropine since the dextro-isomer has only very weak antimuscarinic activity. Hyoscyamine is used mainly in the relief of conditions associated with visceral spasm. It has also been given for rhinitis and was formerly used in the treatment of parkinsonism.

Hyoscyamine is given in usual doses of 150 to 300 micrograms up to four times daily by mouth, but it is more usually employed as the sulfate; the hydrobromide is also used. Suggested doses of hyoscyamine sulfate are 125 to 250 micrograms orally or sublingually every four hours as needed, up to a maximum of 1.5 mg in 24 hours. Modified-release oral preparations of hyoscyamine sulfate are available in some countries; dosage is specific to a particular formulation. Hyoscyamine sulfate has also been given by injection.

Preparations

USP 31: Hyoscyamine Sulfate Elixir; Hyoscyamine Sulfate Injection; Hyoscyamine Sulfate Oral Solution; Hyoscyamine Sulfate Tablets; Hyoscyamine Tablets.

Proprietary Preparations (details are given in Part 3)

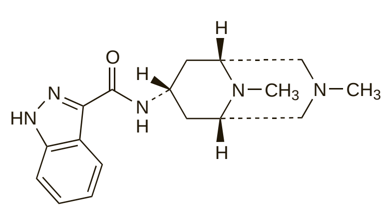
Индисетрона Гидрохлорид

$C_{17}H_{23}N_5O,2HCl$ = 386.3.

CAS — 141549-75-9 (indisetron); 160472-97-9 (indisetron dihydrochloride).



(indisetron)

Profile

Indisetron is a 5-HT_3-receptor antagonist with general properties similar to those of ondansetron (p.1756); it is also stated to be an antagonist at 5-HT_4 receptors. Indisetron hydrochloride is used as an antiemetic in the management of nausea and vomiting associated with chemotherapy.

Ipomoea

Ipomoea Root; Mexican Scammony Root; Orizaba Jalap Root; Scammony Root.

Ипомея

Ipomoea Resin

Ipomoea, resina de; Mexican Scammony Resin; Scammony Resin.

CAS — 9000-34-4.

Profile

Ipomoea is the dried root of *Ipomoea orizabensis* (Convolvulaceae). Ipomoea resin is a mixture of glycosidal resins obtained from ipomoea and it has a drastic purgative and irritant action. It has been superseded by less toxic laxatives.

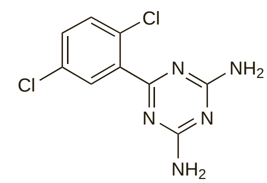
Irsogladine Maleate *(rINNM)*

Irsogladine, Maléate d'; Irsogladini Maleas; Maleato de irsogladina; MN-1695. 2,4-Diamino-6-(2,5-dichlorophenyl)-*S*-triazine maleate.

Ирсогладина Малеат

$C_9H_7Cl_2N_5.C_4H_4O_4$ = 372.2.

CAS — 57381-26-7 (irsogladine); 84504-69-8 (irsogladine maleate).



(irsogladine)

Profile

Irsogladine maleate is a cytoprotective drug that is used in the treatment of peptic ulcer disease (p.1702) in a usual oral dose of 4 mg daily. It has also been investigated for mucositis and mouth ulceration.

Mucositis. Irsogladine maleate 2 mg twice daily by mouth has been reported[1] to reduce the incidence of aphthous stomatitis in a small study in patients being treated with methotrexate for rheumatoid arthritis.

1. Yoshida T, Hirakata M. Therapeutic benefits of irsogladine maleate on aphthous stomatitis induced by methotrexate in rheumatoid arthritis. *J Rheumatol* 2003; **30:** 2082–3.

Preparations

Proprietary Preparations (details are given in Part 3)

Jpn: Gaslon N.

Isopropamide Iodide *(BAN, rINN)*

Ioduro de isopropamida; Isopropamide, Iodure d'; Isopropamidi Iodidum. (3-Carbamoyl-3,3-diphenylpropyl)di-isopropylmethylammonium iodide.

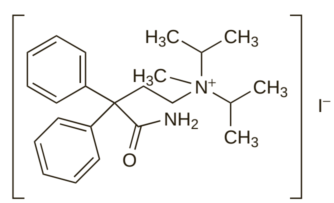
Изопропамида Йодид

$C_{23}H_{33}IN_2O$ = 480.4.

CAS — 7492-32-2 (isopropamide); 71-81-8 (isopropamide iodide).

ATC — A03AB09.

ATC Vet — QA03AB09.



Pharmacopoeias. In *US.*

USP 31 (Isopropamide Iodide). A white to pale yellow crystalline powder. Soluble 1 in 50 of water, 1 in 10 of alcohol, and 1 in 5 of chloroform; very slightly soluble in ether and in benzene. Protect from light.

Profile

Isopropamide iodide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used as an adjunct in the treatment of peptic ulcer disease, in the relief of gastrointestinal and urinary-tract disorders associated with smooth muscle spasm, in rhinitis, and for the relief of symptoms of colds.

Isopropamide bromide has been used similarly.

Preparations

USP 31: Isopropamide Iodide Tablets.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Plidex†; ***Braz.:*** Ornatrol†; ***Canad.:*** Stelabid†; ***Ital.:*** Raffreddoremed; Valtrax; ***Mex.:*** Stelabid.

Ispaghula

Egyiptomi útifűmag (ispaghula seed); Egyiptomi útifűmaghéj (ispaghula husk); Ispaghul, graine d' (ispaghula seed); Ispaghul (graine d'), tégument de la (ispaghula husk); Ispagula; Ispagula Kabuğu; Ispagulafrö (ispaghula seed); Ispagulafröskal (ispaghula husk); Ispagulansiemen (ispaghula seed); Ispagulansiemenkuori (ispaghula husk); Kepek; Kiaušininių gysločių sėklos (ispaghula seed); Kiaušininių gysločių sėklų luobelės (ispaghula husk); Łupina nasienna babki jajowatej (ispaghula husk); Nasienie babki jajowatej (ispaghula seed); Osemení jitrocele vejčitého (ispaghula husk); Plantaginis ovatae semen (ispaghula seed); Plantaginis ovatae seminis tegumentum (ispaghula husk); Psilio; Semeno jitrocele vejčitého (ispaghula seed); Zaragatona.

Шелуха Исфагулы (ispaghula husk)

Pharmacopoeias. Monographs for the husk and seed are included in *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Ispaghula Husk; Plantaginis Ovatae Seminis Tegumentum). The episperm and collapsed adjacent layers removed from the seeds of *Plantago ovata* (*P. ispaghula*). The powdered drug loses not more than 12.0% of its weight on drying. Protect from light.

Ph. Eur. 6.2 (Ispaghula Seed; Plantaginis Ovatae Semen). The dried ripe seeds of *Plantago ovata* (*P. ispaghula*). The powdered drug loses not more than 10.0% of its weight on drying. Protect from light.

USP 31 (Psyllium Husk). The cleaned, dried seed coat (epidermis), in whole or in powdered form, separated by winnowing and threshing from the seeds of *Plantago ovata* (known in commerce as Blond Psyllium, Indian Psyllium, or Ispaghula), or from *Plantago arenaria* (*Plantago psyllium*), known in commerce as Spanish or French Psyllium.

USP 31 (Plantago Seed). The cleaned, dried, ripe seed of *Plantago ovata*, or of *Plantago psyllium*, or of *Plantago indica* (*P. arenaria*).

Psyllium Hemicellulose *(USAN)*

CAS — 9034-32-6.

Pharmacopoeias. In *US.*

USP 31 (Psyllium Hemicellulose). The alkali soluble fraction of the husk from *Plantago ovata* consisting of highly substituted arabinoxylan polysaccharides. These polysaccharides are linear chains of xylose units to which are attached single units of arabinose and additional xylose. Rhamnose, galactose, glucose, and rhamnosyluronic acid residues are also present as minor constituents. It contains not less than 75.0% of dietary soluble fibre, calculated on the dried basis. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°.

Psyllium Seed

Blešníkové semeno; Bolhafűmag; Flea Seed; Loppfrö; Nasienie płesznika; Psilio, semilla de; Psyllii semen; Psyllium, graine de; Psylliuminsiemen; Smiltyninių gysločių sėklos.

ATC — A06AC01.

ATC Vet — QA06AC01.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *US* under the title of Plantago Seed.

Ph. Eur. 6.2 (Psyllium Seed). The ripe, whole, dry seeds of *Plantago afra* (*P. psyllium*) or *Plantago indica* (*P. arenaria*). It loses not more than 14.0% of its weight on drying. Protect from light and moisture.

USP 31 (Plantago Seed). The cleaned, dried, ripe seed of *Plantago ovata*, or of *Plantago psyllium*, or of *Plantago indica* (*P. arenaria*) (see also Ispaghula, above).

Adverse Effects and Precautions

Large quantities of ispaghula and other bulk laxatives may temporarily increase flatulence and abdominal distension; hypersensitivity reactions have been reported. There is a risk of intestinal or oesophageal obstruction and faecal impaction, especially if such compounds are taken with insufficient fluid. Therefore, they should always be taken with at least 150 mL of water or other liquid. Ispaghula and bulk laxatives should not be taken immediately before going to bed because reduced gastric motility may impair intestinal passage and cause obstruction. They should be avoided by patients who have difficulty swallowing.

Bulk laxatives should not be given to patients with pre-existing faecal impaction, intestinal obstruction, or colonic atony.

Hypersensitivity. Hypersensitivity reactions associated with the ingestion or inhalation of ispaghula or psyllium have been reported.[1-9] Symptoms have included rash, rhinitis, urticaria, bronchospasm, and anaphylactic shock; in one case, anaphylaxis was fatal.[9] In most patients, sensitisation was thought to have occurred during occupational exposure.

Interactions

Ispaghula and other bulk-forming laxatives may delay or reduce the gastrointestinal absorption of other drugs such as cardiac glycosides, coumarin derivatives, lithium, or vitamins (such as vitamin B_{12}) and minerals (such as calcium, iron, or zinc). Intervals of 30 minutes to 1 hour are recommended between ispaghula and other drugs or food, although some recommend as much as 3 hours between bulk-forming laxatives and other drugs. The dose of insulin may need to be reduced in diabetic patients taking ispaghula.

Lithium. For reference to ispaghula possibly reducing the absorption of lithium, see Gastrointestinal Drugs, p.405.

Uses and Administration

Ispaghula seed, ispaghula husk, and psyllium seed are bulk laxatives (p.1693). They absorb water in the gastrointestinal tract to form a mucilaginous mass which increases the volume of faeces and hence promotes peristalsis. They are used in the treatment of constipation (p.1693), especially in diverticular disease (p.1695) and irritable bowel syndrome (p.1699), and when excessive straining at stool must be avoided, for example after anorectal surgery or in the management of haemorrhoids. The ability to absorb water and increase faecal mass means that they may also be used in the management of diarrhoea (p.1694) and for adjusting faecal consistency in patients with colostomies.

The usual oral dose is about 3.5 g one to three times daily, although higher doses have been given. It should be taken immediately after mixing in at least 150 mL water or fruit juice. The full effect may not be achieved for up to 3 days.

Ispaghula is also given for mild to moderate hypercholesterolaemia as an adjunct to a lipid-lowering diet. The recommended dose is about 7 g daily.

Hyperlipidaemias. Preparations of ispaghula have been reported[1-4] to lower serum-cholesterol concentrations in patients with mild to moderate hypercholesterolaemia. They have also been given with reduced doses of a bile-acid binding resin in the treatment of hyperlipidaemia,[5] which is reported to be effective and better tolerated than full doses of the resin alone. Similarly, psyllium supplementation with 10 mg of simvastatin was found to be as effective in lowering cholesterol as 20 mg of simvastatin alone.[6] However, ispaghula or psyllium should be regarded as adjuncts to dietary modification rather than substitutes for it. For a discussion of the hyperlipidaemias and their management, see p.1169.

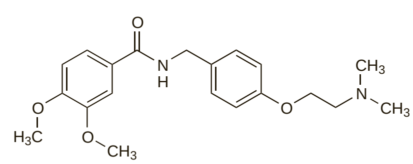
Itopride Hydrochloride *(rINNM)*

HC-803; Hidrocloruro de itoprida; HSR-803; Itopride, Chlorhydrate d'; Itopridi Hydrochloridum. *N*-{*p*-[2-(Dimethylamino)ethoxy]benzyl}veratramide hydrochloride.

Итоприда Гидрохлорид

$C_{20}H_{26}N_2O_4,HCl = 394.9.$

CAS — 122898-67-3 (itopride).



(itopride)

Profile

Itopride hydrochloride is a substituted benzamide with general properties similar to those of metoclopramide (p.1747) that has been used for its prokinetic and antiemetic actions in oral doses of 50 mg three times daily before meals.

◊ References.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.* Some pharmacopoeias do not differentiate between the heavy and light varieties.

Ph. Eur. 6.2 (Kaolin, Heavy). A purified, natural, hydrated aluminium silicate of variable composition. It is a fine, white or greyish-white, unctuous powder. Practically insoluble in water and in organic solvents.

BP 2008 (Light Kaolin). A native hydrated aluminium silicate, freed from most of its impurities by elutriation, and dried. It contains a suitable dispersing agent. It is a light, white, odourless or almost odourless, unctuous powder free from gritty particles. Practically insoluble in water and in mineral acids.

The BP 2008 directs that when Kaolin or Light Kaolin is prescribed or demanded, Light Kaolin shall be dispensed or supplied, unless it is ascertained that Light Kaolin (Natural) is required.

BP 2008 (Light Kaolin (Natural)). It is Light Kaolin which does not contain a dispersing agent. It is a light, white, odourless or almost odourless, unctuous powder free from gritty particles. Practically insoluble in water and in mineral acids.

The BP 2008 directs that when Kaolin or Light Kaolin is prescribed or demanded, Light Kaolin shall be dispensed or supplied, unless it is ascertained that Light Kaolin (Natural) is required.

USP 31 (Kaolin). A native hydrated aluminium silicate, powdered and freed from gritty particles by elutriation. It is a soft, white or yellowish-white powder or lumps with an earthy or clay-like taste and when moistened with water assumes a darker colour and develops a marked clay-like odour. Insoluble in water, in cold dilute acids, and in solutions of alkali hydroxides.

Profile

Light kaolin and light kaolin (natural) are adsorbent antidiarrhoeal agents that have been used as adjuncts to rehydration therapy in the management of diarrhoea (p.1694). Up to about 24 g daily may be taken orally in divided doses. Kaolin is often combined with other antidiarrhoeals, especially pectin.

Kaolin can form insoluble complexes with some drugs in the gastrointestinal tract and reduce their absorption; oral doses should not be taken at the same time.

Externally, light kaolin is used as a dusting powder. Kaolin is liable to be heavily contaminated with bacteria, and when used in dusting powders, it should be sterilised.

Heavy kaolin is used in the preparation of kaolin poultice, which is applied topically with the intention of reducing inflammation and alleviating pain (see Rubefacients and Topical Analgesia, p.5).

Light kaolin is also used as a food additive.

Preparations

BP 2008: Kaolin and Morphine Mixture; Kaolin Mixture; Kaolin Poultice.

Proprietary Preparations (details are given in Part 3)

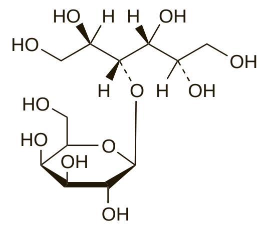
Lactitol *(BAN, rINN)*

E966; β-Galactosido-sorbitol; Lactit; Lactitolum; Lactobiosit; Lactositol; Laktitol; Laktitoli; Laktitolis. 4-*O*-(β-D-Galactopyranosyl)-D-glucitol.

Лактитол

$C_{12}H_{24}O_{11}$ = 344.3.
CAS — 585-86-4.
ATC — A06AD12.
ATC Vet — QA06AD12.



Pharmacopoeias. In *USNF. Eur.* (see p.vii) includes the monohydrate.

Ph. Eur. 6.2 (Lactitol Monohydrate). A white or almost white crystalline powder. Very soluble in water; slightly soluble in alcohol; practically insoluble in dichloromethane.

USNF 26 (Lactitol). It may be the anhydrous form, the monohydrate, or the dihydrate. White or light brown, odourless, crystals. It has a mild, sweet taste, and no aftertaste.

Profile

Lactitol is a disaccharide analogue of lactulose (below) and has similar actions and uses.

Lactitol monohydrate is used as an oral powder or solution in the management of hepatic encephalopathy (p.1697) and in constipation (p.1693). Lactitol monohydrate 1.05 g is equivalent to about 1 g of anhydrous lactitol.

In the treatment of hepatic encephalopathy, lactitol monohydrate is given in usual oral doses of 500 to 700 mg/kg daily in 3 divided doses at meal times. The dose is subsequently adjusted to produce 2 soft stools daily.

In the treatment of constipation, lactitol monohydrate is given in an initial dose of 20 g daily as a single dose with the morning or evening meal, subsequently adjusted to produce one stool daily. A dose of 10 g daily may be sufficient for many patients.

Doses should be mixed with food or liquid, and 1 to 2 glasses of liquid should be drunk with the meal.

Lactitol is a permitted sweetener in foods.

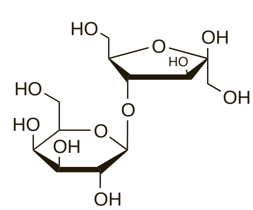
Lactulose *(BAN, USAN, rINN)*

Lactulosa; Lactulosum; Laktuliozė; Laktuloosi; Laktulos; Laktulosa; Laktüloz; Laktulóz. 4-*O*-β-D-Galactopyranosyl-D-fructose.

Лактулоза

$C_{12}H_{22}O_{11}$ = 342.3.
CAS — 4618-18-2.
ATC — A06AD11.
ATC Vet — QA06AD11.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn. Chin.* only contains specifications for a solution. *US* only contains specifications for a solution and a concentrated liquid.

Ph. Eur. 6.2 (Lactulose). A white or almost white, crystalline powder. Freely soluble in water; sparingly soluble in methyl alcohol; practically insoluble in toluene.

Ph. Eur. 6.2 (Lactulose, Liquid; Lactulose Solution BP 2008). An aqueous solution of lactulose. It contains not less than 62.0% w/v of lactulose; it may contain lesser amounts of other sugars including lactose, epilactose, galactose, tagatose, and fructose. It may contain a suitable antimicrobial preservative. It is a clear, colourless or pale brownish-yellow, viscous liquid. Miscible with water. It may be a supersaturated solution or may contain crystals that disappear on heating.

USP 31 (Lactulose Concentrate). A colourless to amber syrupy liquid that may exhibit some precipitation and darkening on standing. Miscible with water. Store in airtight containers preferably at a temperature between 2° and 30°.

Adverse Effects

Lactulose may cause abdominal discomfort associated with flatulence or cramps. Nausea and vomiting have occasionally been reported after high doses. Some consider the taste to be unpleasant; this can be minimised by dilution in water, fruit juice, or milk, or by mixing the dose with food. Prolonged use or excessive dosage may result in diarrhoea with excessive loss of water and electrolytes, particularly potassium. Hypernatraemia has been reported.

Lactic acidosis. Severe lactic acidosis developed in a patient with adynamic ileus who was being given lactulose for hepatic encephalopathy.[1]

1. Mann NS, *et al.* Lactulose and severe lactic acidosis. *Ann Intern Med* 1985; **103:** 637.

Precautions

Lactulose should not be given to patients with galactosaemia or intestinal obstruction. It should not be used in patients on a low galactose diet and care should be taken in patients with lactose intolerance or in diabetic patients because of the presence of some free galactose and lactose.

Pharmacokinetics

Taken orally, lactulose passes essentially unchanged into the large intestine where it is metabolised by saccharolytic bacteria with the formation of simple organic acids, mainly lactic acid and small amounts of acetic and formic acids. The small amount of absorbed lactulose is subsequently excreted unchanged in the urine.

Uses and Administration

Lactulose is a synthetic disaccharide osmotic laxative (p.1693) used in the treatment of constipation (p.1693) and in hepatic encephalopathy (p.1697). Lactulose is broken down by colonic bacteria mainly into lactic acid. This exerts a local osmotic effect in the colon resulting in increased faecal bulk and stimulation of peristalsis. It may take up to 48 hours before an effect is obtained. When larger doses are given for hepatic encephalopathy the pH in the colon is reduced significantly and the absorption of ammonium ions and other toxic nitrogenous compounds is decreased, leading to a fall in blood-ammonia concentration and an improvement in mental function.

Lactulose is usually given orally as a solution containing about 3.35 g of lactulose per 5 mL, with other sugars such as galactose and lactose; an oral powder formulation is also available in some countries. In the treatment of **constipation**, the usual initial dose is 10 to 20 g (15 to 30 mL) given daily in a single dose or in 2 divided doses; doses up to 45 mL daily of the solution (or up to 40 g of the reconstituted oral powder formulation) have been given. The dose is gradually adjusted according to the patient's needs. For doses in children, see below.

In **hepatic encephalopathy**, an oral dose of 60 to 100 g (90 to 150 mL) is given daily in 3 divided doses. The dose is subsequently adjusted to produce 2 or 3 soft stools each day. Lactulose solution 200 g (300 mL) mixed with 700 mL of water or sodium chloride 0.9% has been used as a retention enema; the enema is retained for 30 to 60 minutes, repeated every 4 to 6 hours until the patient is able to take oral medication.

2. Schumann C. Medical, nutritional and technological properties of lactulose: an update. *Eur J Nutr* 2002; **41** (suppl): I17–I25.

Administration in children. In the UK, children may be given the following oral doses of lactulose 3.35 g per 5 mL solution for constipation; doses may be adjusted according to response:

- 1 month to 1 year: 2.5 mL twice daily
- 1 to 5 years: 5 mL twice daily
- 5 to 10 years: 10 mL twice daily
- 10 to 18 years: 15 mL twice daily

Diagnosis and testing. *THE SUGAR ABSORPTION TEST.* In healthy individuals lactulose is largely unabsorbed from the gastrointestinal tract, but in, for example, coeliac disease there is increased permeability to disaccharides such as lactulose and a paradoxical decrease in the absorption of monosaccharides. This led to the development of the differential sugar absorption test in which 2 sugars are given simultaneously by mouth and the urinary recovery of each is determined; mannitol is commonly used as the monosaccharide component and lactulose as the disaccharide. Alternatives include mannitol plus cellobiose and rhamnose plus lactulose. This absorption test is useful in the investigation of intestinal disease.[1]

The lack of a standardised test solution has hampered comparison of test results. Although hyperosmolar solutions are better at determining intestinal damage,[2] some have preferred to use low osmolar solutions because of the risk of inducing osmotic diarrhoea, especially in children.

A study found the sugar absorption test to be strongly predictive of an organic cause of chronic diarrhoea; it may be useful in improving the selection of patients who need further evaluation.[3]

THE LACTOSE BREATH TEST (hydrogen breath test). Lactulose is converted by bacteria in the large bowel to short chain fatty acids with the production of small quantities of hydrogen gas. The hydrogen is rapidly absorbed and is exhaled in the breath and measurement of its production is used to measure orocaecal transit time and carbohydrate malabsorption. However, even small doses of lactulose shortens transit time, which may limit the value of this test.[4]

The test is also diagnostic for bacterial overgrowth in the small intestine, which is increased in irritable bowel syndrome. Although hydrogen is produced in most subjects, methane is also produced in up to 50% of healthy subjects, and data suggest there may be clinical implications to different gas profiles. A study found that the presence of methane was associated with constipation, and with constipation-predominant irritable bowel syndrome. Methane production was infrequent in diarrhoea-predominant irritable bowel syndrome and virtually absent in inflammatory bowel disease. Diarrhoea and inflammatory bowel disease were associated with hydrogen production. Whether the type of bacterial flora causally determines symptoms is as yet unknown.[5]

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Lansoprazole). A white or brownish powder. Practically insoluble in water; soluble in anhydrous alcohol; very slightly soluble in acetonitrile. It exhibits polymorphism. Store in airtight containers. Protect from light.

USP 31 (Lansoprazole). A white to brownish-white powder. Practically insoluble in water; freely soluble in dimethylformamide. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Adverse Effects and Precautions

As for Omeprazole, p.1753.

◊ Reviews.

1. Freston JW, *et al.* Safety profile of lansoprazole: the US clinical trial experience. *Drug Safety* 1999; **20:** 195–205.

Effects on the blood. For a report of thrombocytopenia with lansoprazole, see under Omeprazole, p.1753.

Effects on the endocrine system. For cases of gynaecomastia associated with lansoprazole, see p.1753.

Effects on the gastrointestinal tract. Glossitis (associated in some cases with black tongue or stomatitis) has been reported in a few patients taking lansoprazole as part of a triple therapy regimen for *Helicobacter pylori* elimination in peptic ulcer disease.[1] Discoloured tongue has been reported in a patient taking lansoprazole alone.[2]

An increase in gastritis occurred in patients infected with *Helicobacter pylori* when given long-term lansoprazole therapy.[3] For further discussion of the link between *H. pylori*, gastritis, and proton pump inhibitor use, see Gastrointestinal Tumours, p.1754.

For a suggestion that the incidence of diarrhoea may be greater with lansoprazole than omeprazole see Incidence of Adverse Effects, p.1753. Cases of microscopic colitis have been reported with use of lansoprazole.[4] UK licensed product information states that stopping therapy should be considered in the case of severe and/or persistent diarrhoea.

2. Scully C. Discoloured tongue: a new cause? *Br J Dermatol* 2001; **144:** 1293–4.
3. Berstad AE, *et al.* Helicobacter pylori gastritis and epithelial cell proliferation in patients with reflux oesophagitis after treatment with lansoprazole. *Gut* 1997; **41:** 740–7.
4. Hilmer SN, *et al.* Microscopic colitis associated with exposure to lansoprazole. *Med J Aust* 2006; **184:** 185–6.

Effects on the musculoskeletal system. For reference to a case of eosinophilia and myalgia related to lansoprazole therapy, see p.1753.

Effects on the skin. For mention of skin reactions to lansoprazole, see p.1754.

Interactions

As for Omeprazole, p.1755. Antacids and sucralfate may reduce the bioavailability of lansoprazole, and should not be taken within 1 hour of a dose of lansoprazole.

◊ For reference to a lack of effect of lansoprazole on diazepam, see Gastrointestinal Drugs, p.991, and for a clinically insignificant effect on theophylline clearance, see p.1145. For reference to glossitis occurring when lansoprazole was used with some antibacterials, see Effects on the Gastrointestinal Tract, above.

Pharmacokinetics

Lansoprazole is rapidly absorbed after oral doses, with peak plasma concentrations achieved after about 1.5 to 2 hours. Bioavailability is reported to be 80% or more even with the first dose, although the drug must be given in an enteric-coated form since lansoprazole is unstable at acid pH. Food slows the absorption of lansoprazole and reduces the bioavailability by about 50%. It is extensively metabolised in the liver, primarily by cytochrome P450 isoenzyme CYP2C19 to form 5-hydroxyl-lansoprazole and by CYP3A4 to form lansoprazole sulfone. Metabolites are excreted mainly in faeces via the bile; only about 15 to 30% of a dose is excreted in urine. The plasma elimination half-life is around 1 to 2 hours but the duration of action is much longer. Lansoprazole is about 97% bound to plasma protein. Clearance is decreased in elderly patients, and in hepatic impairment.

Metabolism. As for omeprazole (p.1755), the cytochrome P450 isoenzyme CYP2C19 (*S*-mephenytoin hydroxylase) is involved in the hydroxylation of lansoprazole, and individuals who are deficient in this enzyme are poor metabolisers of lansoprazole.[1,2] There is some suggestion that the effect of this genetic polymorphism on lansoprazole may be less than the effect on omeprazole.[3]

Uses and Administration

Lansoprazole is a proton pump inhibitor with actions and uses similar to those of omeprazole (p.1755). It is used in the treatment of peptic ulcer disease and in oth-

The symbol † denotes a preparation no longer actively marketed

er conditions where inhibition of gastric acid secretion may be beneficial.

Lansoprazole is usually given orally as capsules, dispersible tablets, or suspension containing enteric-coated granules. Once daily regimens are taken before food in the morning. An intravenous formulation is also available.

For the relief of acid-related **dyspepsia** (p.1695) intermittent courses of lansoprazole may be given in doses of 15 or 30 mg once daily, for 2 to 4 weeks.

In the treatment of **gastro-oesophageal reflux disease** (p.1696) the dose is 15 to 30 mg once daily for 4 to 8 weeks; thereafter maintenance therapy can be continued with 15 or 30 mg once daily according to response. In patients unable to take oral therapy, lansoprazole may be given by intravenous infusion for the treatment of erosive oesophagitis for up to 7 days; a dose of 30 mg over 30 minutes daily is recommended.

Lansoprazole is given for the treatment of **peptic ulcer disease** (p.1702) in the UK in doses of 30 mg once daily. Treatment is continued for 2 to 4 weeks for duodenal and 4 to 8 weeks for gastric ulcer. In the USA, a dose of 15 mg daily for 4 weeks is recommended for duodenal ulcer, and 30 mg once daily is given for up to 8 weeks for gastric ulceration. When appropriate, 15 mg daily may be used as maintenance therapy for the prevention of relapse of duodenal ulcer. Lansoprazole may be combined with antibacterials in one-week **triple therapy** regimens for the eradication of *Helicobacter pylori*. Effective regimens include lansoprazole 30 mg twice daily combined with clarithromycin 500 mg twice daily and amoxicillin 1 g twice daily, or combined with clarithromycin 250 mg twice daily and metronidazole 400 mg twice daily; lansoprazole with amoxicillin and metronidazole has also been used. In patients with **NSAID-associated ulceration** a dose of 30 mg daily for 4 to 8 weeks is recommended; 15 to 30 mg daily may be used as prophylaxis for patients who require continued NSAID treatment.

In the treatment of pathological hypersecretory states such as the **Zollinger-Ellison syndrome** (p.1704) the initial dose is 60 mg once daily, adjusted as required. Doses of up to 90 mg twice daily have been used. Daily doses greater than 120 mg should be given in divided doses.

In the USA, **children** aged from 1 to 11 years may be given lansoprazole for the short-term treatment of erosive oesophagitis and symptomatic gastro-oesophageal reflux disease. Children weighing 30 kg or less should be given 15 mg once daily, and those weighing more than 30 kg are given 30 mg once daily, for up to 12 weeks. Doses of up to 30 mg twice daily have been used. In children aged from 12 to 17 years, lansoprazole 30 mg once daily for up to 8 weeks may be used for erosive oesophagitis, and 15 mg once daily for up to 8 weeks may be used for symptomatic gastro-oesophageal reflux disease. Although not licensed for children in the UK, the *BNFC* recommends comparable oral daily doses of 0.5 to 1 mg/kg in children up to 30 kg in weight, and 15 or 30 mg once daily in those over 30 kg.

Doses of lansoprazole may need to be reduced in patients with hepatic impairment (see below).

◊ General references. For general reviews of proton pump inhibitors, see Omeprazole, p.1756.

5. Croom KF, Scott LJ. Lansoprazole: in the treatment of gastro-oesophageal reflux disease in children and adolescents. *Drugs* 2005; **65:** 2129–35.

Administration. Lansoprazole *capsules* should be swallowed whole and not crushed or chewed. Lansoprazole *dispersible tablets* should be placed on the tongue and allowed to disintegrate and the resultant granules swallowed; alternatively, the tablets may be swallowed whole with a glass of water. The tablets should not be crushed or chewed. The tablets may also be dispersed in a small amount of water and given via an oral syringe, or via a nasogastric tube. Lansoprazole *granules for oral suspension* should be reconstituted in a little water and swallowed immediately. Where the suspension formulation is not available, the contents of the capsules (enteric-coated granules) can be sprinkled on a small amount of soft food (such as yogurt or apple sauce) or mixed with a little fruit juice and swallowed. For administration via a nasogastric tube, the contents of a capsule may be mixed with 40 mL of apple juice; additional apple juice may be used to flush the tube.

Administration in hepatic impairment. Exposure to lansoprazole is increased in patients with hepatic impairment. Licensed product information recommends that patients with moderate to severe liver disease should be kept under supervision, and that the daily dose should be reduced by 50%.

Liquorice

Alcaçuz; Édesgyökér; Gancao; Glycyrrhiza; Korzeń lukrecji; Lakritsijuuri; Lakritsrot; Lékořicový kořen; Licorice; Liquiritiae radix; Liquorice Root; Orozuz; Raiz de Regaliz; Regaliz; Réglisse, racine de; Saldymedžių šaknys; Süssholzwurzel.

Лакрица

Description. Liquorice is the dried rhizome and roots of *Glycyrrhiza glabra*. Those of *G. glabra* var. *typica* are known in commerce as Spanish Liquorice, those of *G. glabra* var. *glandulifera* as Russian Liquorice, and those of *G. glabra* var. *β-violacea* as Persian Liquorice.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US. Eur.* (see p.vii) also includes Liquorice Dry Extract for Flavouring Purposes. *US* also includes Powdered Licorice and Powdered Licorice Extract. *Br.* also includes Liquorice Root for use in Traditional Herbal Medicine and Processed Liquorice Root for use in Traditional Herbal Medicinal Product.

Ph. Eur. 6.2 (Liquorice Root; Liquorice BP 2008). The dried unpeeled or peeled, whole or cut root and stolons of *Glycyrrhiza glabra* and/or *G. inflata* and/or *G. uralensis*. It contains not less than 4% of glycyrrhizic acid. Protect from light.

USP 31 (Licorice). The roots, rhizomes, and stolons of *Glycyrrhiza glabra* or *G. uralensis*. It contains not less than 2.5% of glycyrrhizic acid, calculated on the dried basis. Store in a cool, dry place.

BP 2008 (Liquorice Root for use in THM). It is the dried unpeeled root and rhizome of *Glycyrrhiza uralensis*, *G. inflata*, or *G. glabra*. For use in traditional Chinese medicines. It contains not less than 2.0% of glycyrrhizic acid calculated with reference to the dried material. Protect from moisture.

BP 2008 (Processed Liquorice Root for use in THMP). Liquorice Root for use in THM which has been cleaned, softened, sliced transversely or longitudinally to form uniform pieces, and dried. It contains not less than 2.0% of glycyrrhizic acid calculated with reference to the dried material. Protect from moisture.

Adverse Effects and Precautions

Liquorice has mineralocorticoid-like actions manifesting as sodium and water retention and hypokalaemia (see below).

Deglycyrrhizinised liquorice is not usually associated with such adverse effects.

Mineralocorticoid effects. Mineralocorticoid effects have been reported after excessive or prolonged ingestion of liquorice. The liquorice may be ingested in confectionery (including liquorice-flavoured chewing gum), tea, soft drinks, herbal medicines, cough mixtures, or by chewing tobacco. The enzyme 11-β-hydroxysteroid dehydrogenase (cortisol oxidase) converts cortisol to cortisone, preventing cortisol gaining access to non-specific mineralocorticoid receptors. This enzyme is inhibited by glycyrrhetinic acid (produced by the hydrolysis of glycyrrhizic acid, a natural constituent of liquorice), resulting in increased concentrations of cortisol in the body, enhancing its physiological effects.[1-3]

Clinical manifestations include consequences of sodium retention such as hypertension,[4-10] and hypokalaemia, which can result in neuromuscular disturbances ranging from muscle weakness,[11] myoclonus,[12] and myopathy[10] to paralysis[13-15] and rhabdomyolysis.[15-17] Arrhythmias[16,18] and fatal cardiac arrest[19] have also been reported.

Increased amounts of cortisol in vascular smooth muscle may cause vasoconstriction. Vasospasm of vessels supplying the optic nerve may have caused transient visual disturbances reported after liquorice ingestion.[2]

Other reported effects of liquorice include growth retardation in a boy with Addison's disease;[20] liquorice was thought to have potentiated the effect of hydrocortisone.

Endocrine effects of liquorice have been reviewed.[21] Conflicting effects on testosterone and prolactin have been reported. Components of liquorice root (which has been tried for menopausal symptoms) have both oestrogenic and anti-oestrogenic activity, and it has reportedly caused gynaecomastia.

Individuals vary markedly in their susceptibility to liquorice-induced adverse effects.[1] Those consuming 400 mg glycyrrhetinic acid daily generally experience adverse effects, but a regular daily intake of no more than 100 mg of glycyrrhetinic acid (about 50 g of liquorice sweets) has produced adverse effects in some who appear more sensitive to its effects. Some consider a daily intake of 10 mg glycyrrhetinic acid to be a safe daily dose for adults; the amount of salt consumed needs to be considered as even a low dose of liquorice may induce sodium overload in those consuming high amounts of sodium chloride.[3]

Pregnancy. Studies in Finnish women indicated that heavy consumption of liquorice (equivalent to ≥ 500 mg/week of glycyrrhizic acid) during pregnancy was associated with an increased risk of preterm delivery.[1,2] Consumption of large amounts of liquorice was a social habit noted to occur in some northern European countries.

1. Strandberg TE, *et al.* Birth outcome in relation to licorice consumption during pregnancy. *Am J Epidemiol* 2001; **153:** 1085–8.
2. Strandberg TE, *et al.* Preterm birth and licorice consumption during pregnancy. *Am J Epidemiol* 2002; **156:** 803–5.

Uses and Administration

Liquorice is used as a flavouring and sweetening agent. It has demulcent and expectorant properties and has been used in cough preparations. It has ulcer-healing properties that may result from stimulation of mucus synthesis. It contains constituents that produce mineralocorticoid effects (see above). Liquorice may also possess some antispasmodic and laxative properties.

Deglycyrrhizinised liquorice has a reduced mineralocorticoid activity and has been used, usually with antacids, for the treatment of peptic ulcer disease (p.1702).

Loperamid oxid; Lopéramide Oxyde; Lopéramide, oxyde de; Loperamidi oxidum; Loperamidioksidi; Loperamido oksidas; Loperamidoxid; Loperamidum Oxidum; Óxido de loperamida; R-58425.

Лоперамида Оксид

$C_{29}H_{33}ClN_2O_3$ = 493.0.

CAS — 106900-12-3.

ATC — A07DA05.

ATC Vet — QA07DA05.

Pharmacopoeias. *Eur.* (see p.vii) includes the monohydrate.

Ph. Eur. 6.2 (Loperamide Oxide Monohydrate; Loperamidi Oxidum Monohydricum). A white or almost white, slightly hygroscopic, powder. Practically insoluble in water; freely soluble in alcohol and in dichloromethane. Store in airtight containers. Protect from light.

Adverse Effects and Treatment

Abdominal pain or bloating, nausea, constipation, dry mouth, dizziness, fatigue, and hypersensitivity reactions including skin rashes have been reported. Loperamide has been associated with paralytic ileus, particularly in infants and young children, and deaths have been reported. Depression of the CNS, to which children or those with hepatic impairment may be more sensitive, may be seen in overdosage; constipation and urinary retention also occur. Naloxone hydrochloride (see p.1454) has been recommended for treatment of severe overdosage.

Toxicity. Toxic megacolon has been reported[1,2] after use of loperamide. Severe effects reported in young children have included loss of consciousness[3,4] and delirium.[5] Several cases of paralytic ileus have also occurred in children,[6,7] some of which were fatal.[6]

7. Dudink J, *et al.* Ileus na gebruik van loperamide bij een kind met acute diarree. *Ned Tijdschr Geneeskd* 2003; **147:** 670–2.

Precautions

Loperamide should not be used when inhibition of peristalsis is to be avoided, in particular where ileus or constipation occur, and should be avoided in patients with abdominal distension, acute inflammatory bowel disease, or antibiotic-associated colitis. Loperamide should not be used alone in patients with dysentery.

Loperamide should be used with caution in patients with hepatic impairment because of its considerable first-pass metabolism in the liver. It should also be used with caution in young children because of a greater variability of response in this age group; it is not recommended for use in infants (see Uses and Administration, below).

Breast feeding. Loperamide is distributed into breast milk in small amounts.[1] The American Academy of Pediatrics[2] states that there have been no reports of any clinical effect on the infant associated with the use of loperamide by breast-feeding mothers, and that therefore it may be considered to be usually compatible with breast feeding.

Interactions

Loperamide may increase the gastrointestinal absorption of desmopressin (p.2186).

Antifungals. A pharmacokinetic study in 12 healthy subjects found that *itraconazole* significantly increased peak plasma concentrations and area under the concentration-time curve of loperamide, and also prolonged the half-life of loperamide. Itraconazole also inhibited metabolism of loperamide to *N*-desmethylloperamide, suggesting that metabolism of loperamide in humans concurs with *in-vitro* data (see Metabolism, below). Use of itraconazole with gemfibrozil (see Cardiovascular Drugs, below) synergistically increased exposure to loperamide.[1]

1. Niemi M, *et al.* Itraconazole, gemfibrozil and their combination markedly raise the plasma concentrations of loperamide. *Eur J Clin Pharmacol* 2006; **62:** 463–72.

Antivirals. In a single-dose study,[1] oral *ritonavir* significantly increased the bioavailability of loperamide, possibly through inhibition of the cytochrome P450 isoenzyme CYP3A4, and not necessarily as originally supposed through P-glycoprotein inhibition. No serious adverse effects occurred. Licensed information for one UK preparation of loperamide (*Imodium; Janssen-Cilag, UK*) states that the clinical relevance of the pharmacokinetic interaction with P-glycoprotein inhibitors such as ritonavir is unknown.

For the effect of loperamide on *saquinavir*, and the corresponding effect of the antiviral on loperamide concentrations, see Gastrointestinal Drugs, under Interactions of Indinavir, p.884.

1. Tayrouz Y, *et al.* Ritonavir increases loperamide plasma concentrations without evidence for P-glycoprotein involvement. *Clin Pharmacol Ther* 2001; **70:** 405–14.

Cardiovascular drugs. A pharmacokinetic study in 12 healthy subjects found that *gemfibrozil* significantly increased peak plasma concentrations and area under the concentration-time curve of loperamide, and also prolonged the half-life of loperamide. Gemfibrozil also inhibited metabolism of loperamide to *N*-desmethylloperamide, suggesting that metabolism of loperamide in humans concurs with *in-vitro* data (see Metabolism, below). Use of gemfibrozil with itraconazole (see Antifungals, above) synergistically increased exposure to loperamide.[1]

1. Niemi M, *et al.* Itraconazole, gemfibrozil and their combination markedly raise the plasma concentrations of loperamide. *Eur J Clin Pharmacol* 2006; **62:** 463–72.

Co-trimoxazole. Use with co-trimoxazole increases the bioavailability of loperamide,[1] apparently by inhibiting its first-pass metabolism.

1. Kamali F, Huang ML. Increased systemic availability of loperamide after oral administration of loperamide and loperamide oxide with cotrimoxazole. *Br J Clin Pharmacol* 1996; **41:** 125–8.

Quinidine. A small study[1] found that giving quinidine with loperamide caused respiratory depression in 8 healthy subjects; when given with placebo, loperamide produced no respiratory depression. The authors supposed that inhibition of P-glycoprotein by quinidine had increased entry of loperamide into the CNS.

1. Sadeque AJM, *et al.* Increased drug delivery to the brain by P-glycoprotein inhibition. *Clin Pharmacol Ther* 2000; **68:** 231–7.

Pharmacokinetics

About 40% of a dose of loperamide is reported to be absorbed from the gastrointestinal tract to undergo first-pass metabolism in the liver and excretion in the faeces via the bile as inactive conjugate; there is slight urinary excretion. Little intact drug reaches the systemic circulation. The elimination half-life is reported to be about 10 hours.

Metabolism. Loperamide is metabolised to desmethylloperamide through *N*-demethylation. An *in-vitro* study established that this occurs mainly via cytochrome P450 isoenzymes CYP2C8 and CYP3A4; CYP2B6 and CYP2D6 also play a role. Loperamide is also a substrate of P-glycoprotein.[1]

1. Kim K-A, *et al.* Identification of cytochrome P450 isoforms involved in the metabolism of loperamide in human liver microsomes. *Eur J Clin Pharmacol* 2004; **60:** 575–81.

Uses and Administration

Loperamide is a synthetic derivative of pethidine that inhibits gut motility and may also reduce gastrointestinal secretions. It is given orally as an antidiarrhoeal drug as an adjunct in the management of acute and chronic diarrhoeas and may also be used in the management of colostomies or ileostomies to reduce the volume of discharge.

In **acute diarrhoea** the usual initial dose for adults is loperamide hydrochloride 4 mg followed by 2 mg after each loose stool to a maximum of 16 mg daily; the usual daily dose is 6 to 8 mg. In the UK, it is not licensed for children under 4 years of age. Suggested doses for older children are: 4 to 8 years, 1 mg three or four times daily for up to 3 days; 9 to 12 years, 2 mg four times daily for up to 5 days. In the USA, loperamide is not recommended for children under the age of 2 years and an initial dose of 1 mg three times daily is suggested for children aged 2 to 5 years. (For restrictions on the use of loperamide in children and the view that antidiarrhoeal drugs should not be used at all in children, see Diarrhoea, below.)

In **chronic diarrhoea** the usual initial dose for adults is 4 to 8 mg daily in divided doses subsequently adjusted as necessary; doses of 16 mg daily should not be exceeded. If no improvement has been seen after treatment with 16 mg daily for at least 10 days, further use is unlikely to be of benefit. Although not licensed for use in children for chronic diarrhoea, in the UK the *BNFC* allows for the following oral doses of loperamide hydrochloride:

- 1 month to 1 year: 100 to 200 micrograms/kg twice daily, given 30 minutes before feeds; up to a maximum of 2 mg/kg daily in divided doses may be required
- 1 to 12 years: 100 to 200 micrograms/kg (maximum dose 2 mg) three to four times daily; up to 1.25 mg/kg daily in divided doses may be required, to a maximum of 16 mg daily
- 12 to 18 years: 2 to 4 mg two to four times daily, to a maximum of 16 mg daily

Loperamide is also given as the prodrug, **loperamide oxide**, which is converted to loperamide in the gastrointestinal tract. It has been given for acute diarrhoea in doses of 2 to 4 mg initially followed by 1 mg after each loose stool, to a maximum of 8 mg daily.

Diarrhoea. The mainstay of treatment for acute diarrhoea (p.1694) is rehydration therapy. Antidiarrhoeals may have a role for symptomatic relief in adults with acute diarrhoea, and loperamide is often chosen in such circumstances,[1] but WHO does not recommend the use of *any* antidiarrhoeal drug in children with diarrhoea. Similarly, in the UK the *BNFC* considers that antimotility drugs are not to be recommended for acute diarrhoea in children under 12 years of age. There have been problems regarding the use of antidiarrhoeals such as loperamide in young children in developing countries. Manufacturers have considered that a lower age limit is acceptable in those countries than is recommended in the UK or USA; even that lower limit is not always observed in practice and there have been reports of serious toxicity in very young children.[2] In response to such reports the manufacturers withdrew concentrated drops of loperamide worldwide and the syrup from countries where the WHO had a programme for control of diarrhoeal diseases,[3] but tablets and capsules remain available. In some countries the use of antidiarrhoeals is now restricted by law.

In the UK, NICE states that loperamide is the antidiarrhoeal of first choice in adults with faecal incontinence;[4] it can be used long-term in doses from 500 micrograms to 16 mg daily as needed. Loperamide should be started at a very low dose which can be increased as needed, and then adjusted in response to stool consistency. It should not be given to those with hard or infrequent stools, those with acute diarrhoea of unknown cause, or with acute ulcerative colitis. Patients who are unable to tolerate loperamide may be offered codeine phosphate (p.37) or co-phenotrope (see Diphenoxylate Hydrochloride, p.1724).

For mention of the use of loperamide in the management of diarrhoea caused by chemotherapy, see p.640.

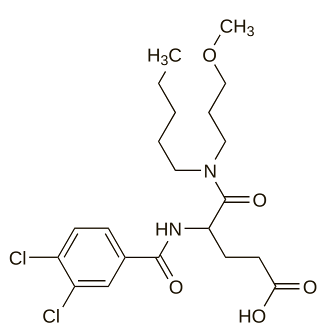
Loxiglumide *(rINN)*

CR-1505; CR-2017 (dexloxiglumide); Loxiglumida; Loxiglumidum. (±)-4-(3,4-Dichlorobenzamido)-*N*-(3-methoxypropyl)-*N*-pentylglutaramic acid.

Локсиглумид

$C_{21}H_{30}Cl_2N_2O_5$ = 461.4.

CAS — 107097-80-3 (loxiglumide); 119817-90-2 (dexloxiglumide).



Profile

Loxiglumide is a specific cholecystokinin antagonist related to proglumide (see p.1764), and has been investigated in biliary and gastrointestinal dyskinesias, constipation and irritable bowel syndrome, and pancreatitis.

The *R*-isomer of loxiglumide, dexloxiglumide is also under investigation for constipation-predominant irritable bowel syndrome.

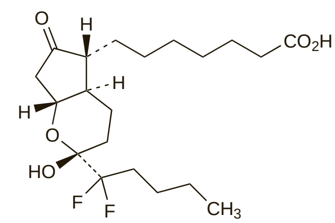
Lubiprostone *(USAN, rINN)*

Lubiprostona; Lubiprostonum; RU-0211; SPI-0211. (−)-7-[(2*R*,4a*R*,5*R*,7a*R*)-2-(1,1-Difluoropentyl)-2-hydroxy-6-oxooctahydrocyclopenta[*b*]pyran-5-yl]heptanoic acid.

Лубипростон

$C_{20}H_{32}F_2O_5$ = 390.5.

CAS — 136790-76-6; 333963-40-9.



Adverse Effects and Precautions

The most common adverse effect of lubiprostone is nausea, which is dose-dependent and may be severe in some patients. Symptoms can be reduced by taking lubiprostone with food. Diarrhoea also occurs commonly, and other gastrointestinal effects include abdominal distension and pain, flatulence, and vomiting. Other reported adverse effects include headache, dizziness, fatigue, dyspnoea, and peripheral oedema. Chest discomfort, back pain, and arthralgia can occur.

Lubiprostone is contra-indicated in patients with a history of mechanical gastrointestinal obstruction.

Pharmacokinetics

A negligible amount of lubiprostone is absorbed systemically after an oral dose. It is rapidly and extensively metabolised by carbonyl reductase, probably in the stomach and jejunum.

Uses and Administration

Lubiprostone is a chloride-channel activator that acts locally in the gut to increase intestinal fluid secretion, which increases motility. It is used in the treatment of chronic idiopathic constipation (p.1693) in a dose of 24 micrograms twice daily, taken orally with food. It is also under investigation in the treatment of constipation-predominant irritable bowel syndrome.

Proprietary Preparations (details are given in Part 3)
USA: Amitiza.

Magaldrate *(BAN, USAN, rINN)*

Aluminum Magnesium Hydroxide Sulfate; AY-5710; Magaldraatti; Magaldrát; Magaldrat; Magaldratas; Magaldrato; Magaldratum.

Магальдрат

$Al_5Mg_{10}(OH)_{31}(SO_4)_2,xH_2O$ = 1097.3 (anhydrous).

CAS — 74978-16-8.
ATC — A02AD02.
ATC Vet — QA02AD02.

NOTE. Magaldrate was formerly described as Aluminium Magnesium Hydroxide ($AlMg_2(OH)_7$ monohydrate, *CAS—1317-26-6*).

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Magaldrate). A combination of aluminium and magnesium hydroxides (see p.1706 and p.1743 respectively) and sulfates. It contains the equivalent of 90 to 105% of $Al_5Mg_{10}(OH)_{31}(SO_4)_2$, calculated with reference to the dried substance. A white or almost white crystalline powder. Practically insoluble in water and in alcohol; soluble in dilute mineral acids. It loses between 10 and 20% of its weight on drying at 200° for 4 hours.

USP 31 (Magaldrate). A combination of aluminium and magnesium hydroxides and sulfates. It contains the equivalent of 90 to

105% of $Al_5Mg_{10}(OH)_{31}(SO_4)_2$, calculated on the dried basis. A white odourless crystalline powder. Insoluble in water and in alcohol; soluble in dilute solutions of mineral acids. It loses between 10 and 20% of its weight on drying at 200° for 4 hours.

Profile

Magaldrate is an antacid (see p.1692) that is given in oral doses of up to about 2 g.

Preparations

BP 2008: Magaldrate Oral Suspension;
USP 31: Magaldrate and Simethicone Oral Suspension; Magaldrate and Simethicone Tablets; Magaldrate Oral Suspension; Magaldrate Tablets.

Proprietary Preparations (details are given in Part 3)

Magnesium Carbonate

Bázisos magnézium-karbonát; E504; Magnesii Carbonas; Magnesii subcarbonas; Magnesio, carbonato de; Magnésium, carbonate de; Magnesiumsubkarbonaatti; Magnesiumsubkarbonat; Magnezu węglan; Magnezyum Karbonate; Magnio subkarbonatas; Uhličitan hořečnatý zásaditý.

Магния Карбонат

CAS — 546-93-0 (anhydrous magnesium carbonate); 23389-33-5 (hydrated normal magnesium carbonate); 39409-82-0 (hydrated basic magnesium carbonate).
ATC — A02AA01; A06AD01.
ATC Vet — QA02AA01; QA06AD01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn, US*, and *Viet.* Some pharmacopoeias include a single monograph that permits both the light and heavy varieties while some have 2 separate monographs for the 2 varieties.
Ph. Eur. 6.2 (Magnesium Carbonate, Heavy; Magnesii Subcarbonas Ponderosus). A hydrated basic magnesium carbonate containing the equivalent of 40 to 45% of MgO. A white or almost white powder. 15 g has an apparent volume before settling of not more than 60 mL. Practically insoluble in water; dissolves in dilute acids with strong effervescence.
Ph. Eur. 6.2 (Magnesium Carbonate, Light; Magnesii Subcarbonas Levis). A hydrated basic magnesium carbonate containing the equivalent of 40 to 45% of MgO. A white or almost white powder. 15 g has an apparent volume before settling of at least 100 mL. Practically insoluble in water; dissolves in dilute acids with strong effervescence.
USP 31 (Magnesium Carbonate). A basic hydrated magnesium carbonate or a normal hydrated magnesium carbonate containing the equivalent of 40.0 to 43.5% of MgO. It is an odourless, bulky white powder or light, white, friable masses. Practically insoluble in water; insoluble in alcohol; dissolves in dilute acids with effervescence.

Profile

Magnesium carbonate is an antacid with general properties similar to those of magnesium hydroxide (below) that is given in oral doses of up to about 500 mg. When given orally, it reacts with gastric acid to form soluble magnesium chloride and carbon dioxide in the stomach; the carbon dioxide may cause flatulence and eructation. Magnesium carbonate is often given with aluminium-containing antacids such as aluminium hydroxide, which counteract its laxative effect.

Magnesium carbonate may be used as a magnesium supplement. It is also used as a food additive.

Preparations

BP 2008: Aromatic Magnesium Carbonate Mixture; Compound Magnesium Trisilicate Oral Powder; Kaolin Mixture; Magnesium Sulphate Mixture; Magnesium Trisilicate Mixture;
USP 31: Alumina and Magnesium Carbonate Oral Suspension; Alumina and Magnesium Carbonate Tablets; Alumina, Magnesium Carbonate, and Magnesium Oxide Tablets; Calcium and Magnesium Carbonates Oral Suspension; Calcium and Magnesium Carbonates Tablets; Magnesium Carbonate and Citric Acid for Oral Solution; Magnesium Carbonate and Sodium Bicarbonate for Oral Suspension; Magnesium Carbonate, Citric Acid, and Potassium Citrate for Oral Solution; Magnesium Citrate Oral Solution.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: numerous preparations are listed in Part 3.

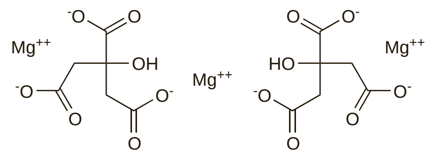
Used as an adjunct in: ***Arg.:*** Bufferin†; Dristan Analgesico†; Dristan Compuesto; ***Braz.:*** Bufferin; Somalgin; ***Canad.:*** Aspirin with Stomach Guard; Bufferin; Tri-Buffered ASA; ***Ital.:*** Bufferin†; ***USA:*** Adprin-B; Bufferin; Buffex; Extra Strength Bayer Plus.

Magnesium Citrate

Magnesii citras; Magnesio, citrato de; Magnésium, citrate de.

Магний Цитрат

$C_{12}H_{10}Mg_3O_{14}$ = 451.1.
CAS — 3344-18-1.
ATC — A06AD19; A12CC04; B05CB03.
ATC Vet — QA06AD19; QA12CC04; QB05CB03.



Pharmacopoeias. In *Eur.* (see p.vii) and *US*.
Ph. Eur. 6.2 (Magnesium Citrate, Anhydrous). A white or almost white, fine, slightly hygroscopic powder. Soluble in water; practically insoluble in alcohol. It dissolves in dilute hydrochloric acid. Store in non-metallic, airtight containers.
USP 31 (Magnesium Citrate). A 5% suspension in water has a pH of 5.0 to 9.0. Store in airtight containers.

Profile

Magnesium citrate is an osmotic laxative (p.1693) used as a bowel evacuant before investigational procedures or surgery of the colon. Dosages have ranged from about 11 to 25 g of magnesium citrate. In the UK, an aqueous solution containing magnesium citrate is prepared from a sachet (*Citramag*) containing about 11.6 g of magnesium carbonate and about 17.8 g of anhydrous citric acid by mixing with 200 mL of hot water. After the solution has cooled, one dose (the contents of one sachet) is taken by mouth at 8 a.m. the day before the procedure, and a second dose between 2 and 4 p.m. For doses in children, see below. A high fluid intake and low residue diet are needed with such bowel preparations. Magnesium citrate is also used with sodium picosulfate, p.1771.

Magnesium citrate is given as a magnesium supplement in doses of up to about 1.9 g daily by mouth.

For the general properties of magnesium salts, see p.1678.

Administration in children. The *BNFC* recommends the following oral doses of magnesium citrate (*Citramag*) for use as a bowel cleanser in children, to be taken on the day before the procedure:

- 5 to 10 years: ⁄ of a sachet at 8 a.m. and ⁄ of a sachet between 2 and 4 p.m.
- 10 to 18 years: ⁄ to 1 sachet at 8 a.m. and ⁄ to 1 sachet between 2 and 4 p.m.

For reconstitution directions, see above.

Migraine. For mention of the use of magnesium supplementation, including magnesium citrate, for the prophylaxis of migraine, see p.1681.

Preparations

USP 31: Magnesium Citrate for Oral Solution.

Proprietary Preparations (details are given in Part 3)

CAS — 1309-42-8.
ATC — A02AA04; G04BX01.
ATC Vet — QA02AA04; QG04BX01.

NOTE. Compounded preparations of magnesium hydroxide may be represented by the following names:

- Co-magaldrox *x/y* (*BAN*)—where *x* and *y* are the strengths in milligrams of magnesium hydroxide and aluminium hydroxide respectively.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *US*, and *Viet.*
Ph. Eur. 6.2 (Magnesium Hydroxide). A fine white or almost white amorphous powder. Practically insoluble in water; dissolves in dilute acids. A solution in water is alkaline to phenolphthalein.
USP 31 (Magnesium Hydroxide). A bulky white powder. Practically insoluble in water, in alcohol, in chloroform, and in ether; soluble in dilute acids. Store in airtight containers.

Adverse Effects, Treatment, and Precautions

As for magnesium salts in general, see p.1679. Magnesium hydroxide may cause diarrhoea, an effect that is dose-dependent. Hypermagnesaemia may occur, usually in patients with renal impairment.

Hypermagnesaemia. There have been reports of hypermagnesaemia in infants given magnesium-containing antacids,[1-3] and in an adult patient with normal renal function but bowel obstruction.[4]

1. Brand JM, Greer FR. Hypermagnesemia and intestinal perforation following antacid administration in a premature infant. *Pediatrics* 1990; **85:** 121–4.

4. Laughlin SA, McKinney PE. Antacid-induced hypermagnesemia in a patient with normal renal function and bowel obstruction. *Ann Pharmacother* 1998; **32:** 312–15.

Interactions

As outlined on p.1692, antacids, including magnesium salts, interact with many other drugs both by alterations in gastric pH and emptying, and by formation of complexes that are not absorbed. Interactions can be minimised by giving the antacid and any other medications 2 to 3 hours apart.

Pharmacokinetics

Magnesium hydroxide, given orally, reacts relatively rapidly with hydrochloric acid in the stomach to form magnesium chloride and water. About 30% of the magnesium ions are absorbed from the small intestine, as described for Magnesium Salts, p.1680.

Uses and Administration

Magnesium hydroxide is an antacid (see p.1692) that is given in oral doses of up to about 1 g. It is often given with aluminium-containing antacids such as aluminium hydroxide which counteract its laxative effect.

Magnesium hydroxide is also given as an osmotic laxative (p.1693) in oral doses of about 2 to 5 g.

Magnesium hydroxide has also been used as a food additive and as a magnesium supplement in deficiency states.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.* Some pharmacopoeias include a single monograph that permits both the light and heavy varieties while some have 2 separate monographs for the 2 varieties.

Ph. Eur. 6.2 (Magnesium Oxide, Heavy; Magnesii Oxidum Ponderosum). A fine, white or almost white powder. 15 g has an apparent volume before settling of not more than 60 mL. Practically insoluble in water; dissolves in dilute acids with at most slight effervescence.

Ph. Eur. 6.2 (Magnesium Oxide, Light; Magnesii Oxidum Leve). A fine, white or almost white, amorphous powder. 15 g has an apparent volume before settling of at least 100 mL. Practically insoluble in water; dissolves in dilute acids with at most slight effervescence.

USP 31 (Magnesium Oxide). A very bulky, white powder, or a relatively dense, white powder, or a granulated powder. Practically insoluble in water; insoluble in alcohol; soluble in dilute acids. Store in airtight containers.

Profile

Magnesium oxide is an antacid with general properties similar to those of magnesium hydroxide (above). It is given in usual oral doses of about 400 mg. It is often given with aluminium-containing antacids such as aluminium hydroxide, which counteract its laxative effect.

Magnesium oxide has been used for its osmotic laxative properties in bowel preparation; oral doses of 3.5 g are given for this purpose, combined with bisacodyl or sodium picosulfate.

Magnesium oxide is also used as a magnesium supplement in deficiency states in oral doses of up to 800 mg (20 mmol) daily. It is also used as a food additive.

Preparations

USP 31: Alumina, Magnesium Carbonate, and Magnesium Oxide Tablets; Aromatic Cascara Fluidextract; Aspirin, Alumina, and Magnesium Oxide Tablets; Citric Acid, Magnesium Oxide, and Sodium Carbonate Irrigation; Magnesium Oxide Capsules; Magnesium Oxide Tablets.

Magnesium Trisilicate

E553(a); Magnesii trisilicas; Magnesio, trisilicato de; Magnésium, trisilicate de; Magnesiumtrisilikaatti; Magnesiumtrisilikat; Magnézium-triszilikát; Magnezyum Trisilikat; Magnio trisilikatas; Trikřemičitan hořečnatý.

Магния Трисиликат

CAS — 14987-04-3 (anhydrous magnesium trisilicate); 39365-87-2 (magnesium trisilicate hydrate).

Description. Magnesium trisilicate is a hydrated magnesium silicate. The code E553(a) has been applied to both magnesium silicate and to magnesium trisilicate.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *US,* and *Viet.*

Ph. Eur. 6.2 (Magnesium Trisilicate). It has a variable composition corresponding approximately to the formula $Mg_2Si_3O_8,xH_2O$ containing not less than 29% of magnesium oxide and not less than the equivalent of 65% of silicon dioxide, both calculated with reference to the ignited substance. A white or almost white powder. Practically insoluble in water and in alcohol.

USP 31 (Magnesium Trisilicate). A compound of magnesium oxide and silicon dioxide with varying proportions of water. It contains not less than 20% of magnesium oxide and not less than 45% of silicon dioxide. A fine, white, odourless, powder, free from grittiness. Insoluble in water and in alcohol. It is readily decomposed by mineral acids.

Profile

Magnesium trisilicate is a hydrated magnesium silicate. It is an antacid with general properties similar to those of magnesium hydroxide (p.1743). It may be given in typical oral doses of up to about 500 mg as required, although higher doses have been given.. When given orally it reacts more slowly with hydrochloric acid in the stomach than magnesium hydroxide. Magnesium trisilicate is often given with aluminium-containing antacids such as aluminium hydroxide, which counteract its laxative effect.

Magnesium trisilicate is also used as a food additive and as a pharmaceutical excipient.

Effects on the kidneys. The formation of renal calculi containing silica is unusual, but has been reported in a small number of patients. In most of these cases, stone formation was attributed to the prolonged, and sometimes excessive, intake of antacids that contained magnesium trisilicate.[1,2]

1. Haddad FS, Kouyoumdjian A. Silica stones in humans. *Urol Int* 1986; **41:** 70–6.
2. Lee M-H, *et al.* Silica stone—development due to long time oral trisilicate intake. *Scand J Urol Nephrol* 1993; **27:** 267–9.

Preparations

BP 2008: Compound Magnesium Trisilicate Oral Powder; Compound Magnesium Trisilicate Tablets; Magnesium Trisilicate Mixture;
USP 31: Alumina and Magnesium Trisilicate Oral Suspension; Alumina and Magnesium Trisilicate Tablets; Magnesium Trisilicate Tablets.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: numerous preparations are listed in Part 3.

Used as an adjunct in: ***Swed.:*** Deltison.

Manna

Maná; Manne en Larmes.

Манна

Profile

Manna is the dried exudation from the bark of the European flowering ash, *Fraxinus ornus* (Oleaceae), containing about 40 to 60% of mannitol (p.1330). It has been used as an osmotic laxative.

Preparations

Mebeverine Hydrochloride *(BANM, USAN, rINNM)*

CSAG-144; Hidrocloruro de mebeverina; Mébévérine, chlorhydrate de; Mebeverini hydrochloridum. 4-[Ethyl(4-methoxy-α-methylphenethyl)amino]butyl veratrate hydrochloride.

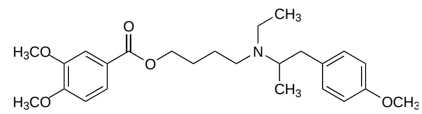
Мебеверина Гидрохлорид

$C_{25}H_{35}NO_5,HCl$ = 466.0.

CAS — 3625-06-7 (mebeverine); 2753-45-9 (mebeverine hydrochloride).

ATC — A03AA04.

ATC Vet — QA03AA04.



(mebeverine)

Pharmacopoeias. In *Br.*

BP 2008 (Mebeverine Hydrochloride). A white or almost white crystalline powder. Very soluble in water; freely soluble in alcohol; practically insoluble in ether. A 2% solution in water has a pH of 4.5 to 6.5. Store in airtight containers at a temperature not exceeding 30°. Protect from light.

Adverse Effects and Precautions

Although adverse effects appear rare, gastrointestinal disturbances, dizziness, headache, insomnia, anorexia, and decreased heart rate have been reported in patients receiving mebeverine. Cases of hypersensitivity, including erythematous rash, urticaria, and angioedema, have also been reported. Mebeverine should be avoided in patients with paralytic ileus. Based on theoretical concerns, it should be used with care in patients with marked hepatic or renal impairment, and those with cardiac disorders such as heart block.

Cystic fibrosis. A 24-year-old man with cystic fibrosis, given mebeverine hydrochloride for lower abdominal pain and constipation, was found to have a perforated stercoral ulcer with generalised peritonitis.[1] It was suggested that mebeverine produced colonic stasis, which predisposed the patient to ulceration,[1] but the manufacturers[2] considered that the development of constipation and distal intestinal syndrome (meconium ileus equivalent) in this patient precipitated the development of stercoral ulceration. It was recommended[1] that antispasmodics such as mebeverine should not be used for the symptomatic treatment of distal intestinal syndrome in cystic fibrosis.

1. Hassan W, Keaney N. Mebeverine-induced perforated colon in distal intestinal syndrome of cystic fibrosis. *Lancet* 1990; **335:** 1225.
2. Whitehead AM. Perforation of colon in distal intestinal syndrome of cystic fibrosis. *Lancet* 1990; **336:** 446.

Porphyria. Mebeverine hydrochloride is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *in-vitro* systems.

Pharmacokinetics

Mebeverine is rapidly absorbed after oral doses with peak plasma concentrations occurring in 1 to 3 hours. It is 75% bound to albumin in plasma. Mebeverine is completely metabolised by hydrolysis to veratric acid and mebeverine alcohol, the latter of which may then be conjugated. The metabolites are excreted in the urine.

Uses and Administration

Mebeverine hydrochloride is an antispasmodic with a direct action on the smooth muscle of the gastrointestinal tract. It is used in conditions such as irritable bowel syndrome (p.1699) in a usual oral dose of 135 mg three times daily before meals; 100 mg three times daily has also been used. A modified-release preparation is also available, taken as 200 mg twice daily. The embonate is also used for oral liquid preparations in a dose equivalent to 150 mg of the hydrochloride three times daily. The *BNFC* suggests that the following hydrochloride-equivalent doses may be given three times daily, based on age:

- 25 mg for those aged 3 to 4 years
- 50 mg for those 4 to 8 years
- 100 mg for those 8 to 10 years
- 135 to 150 mg for those over 10 years

Preparations

Mesalazine *(BAN, rINN)*

5-Aminosalicylic Acid; 5-ASA; Fisalamine; Mesalamine *(USAN)*; Mesalatsiini; Mesalazin; Mesalazina; Mesalazinas; Mésalazine; Mesalazinum. 5-Amino-2-salicylic acid.

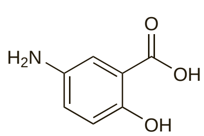
Месалазин

$C_7H_7NO_3$ = 153.1.

CAS — 89-57-6.

ATC — A07EC02.

ATC Vet — QA07EC02.



NOTE. Distinguish from 4-aminosalicylic acid (Aminosalicylic Acid, p.201) which is used in the treatment of tuberculosis.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Mesalazine). An almost white or light grey or light pink powder or crystals. Very slightly soluble in water; practically insoluble in alcohol. It dissolves in dilute solutions of alkali hydroxides and in dilute hydrochloric acid. Store in airtight containers. Protect from light.

USP 31 (Mesalamine). Light tan to pink needle-shaped crystals, odourless or with a slight characteristic odour. The colour may darken on exposure to air. Slightly soluble in water; very slightly soluble in dehydrated alcohol, in acetone, and in methyl alcohol; practically insoluble in butyl alcohol, in chloroform, in dichloromethane, in ether, in ethyl acetate, in *n*-hexane, and in propyl alcohol; soluble in dilute hydrochloric acid and in dilute alkali hydroxides. A 2.5% suspension in water has a pH of 3.5 to 4.5. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Mesalazine may cause headache and gastrointestinal disturbances, such as nausea, diarrhoea, and abdominal pain. Hypersensitivity reactions may occasionally occur. Some patients may experience exacerbation of symptoms of colitis. There are some reports of myocarditis, pericarditis, pancreatitis, interstitial nephritis, nephrotic syndrome, allergic lung reaction, increased liver enzyme values, hepatitis, lupus-like syndrome, skin reactions, alopecia, peripheral neuropathy, myalgia, and arthralgia. There have been rare reports of blood disorders including aplastic anaemia, agranulocytosis, leucopenia, neutropenia, thrombocytopenia, and methaemoglobinaemia.

Mesalazine should not be given to patients with severe renal or hepatic impairment, or salicylate hypersensitivity. It should be used with caution in the elderly, and in mild to moderate renal or hepatic impairment, active peptic ulceration, or sulfasalazine allergy.

If a blood dyscrasia is suspected treatment should be stopped immediately and a blood count performed. Patients or their carers should be told how to recognise signs of blood toxicity and should be advised to seek immediate medical attention if symptoms such as fever, sore throat, mouth ulcers, bruising, or bleeding develop. It is recommended that renal function is monitored before and during therapy (see Effects on the Kidneys, below).

◊ Many of the adverse effects associated with sulfasalazine (sulfapyridine linked to mesalazine) therapy have been attributed to the sulfapyridine moiety and most patients unable to tolerate sulfasalazine because of hypersensitivity or adverse reactions can be transferred to mesalazine without adverse effects occurring.[1-4] However, a small number of patients also have adverse effects while taking mesalazine and these are often very similar to those seen with sulfasalazine.[1-4] They may include nausea, abdominal discomfort or pain, exacerbation of diarrhoea, headache, fever, and rashes. Mesalazine is not generally associated with sulfasalazine's adverse effects on sperm (although there has been a case of reversible male infertility attributed to mesalazine—see under Sulfasalazine, p.1774). An analysis of adverse reactions reported to the UK CSM between 1991 and 1998 found no evidence of a significant difference in the frequency of serious adverse effects for mesalazine and sulfasalazine in the treatment of inflammatory bowel disease.[5] Reports of pancreatitis and interstitial nephritis (see Effects on the Kidneys, below), were more common with mesalazine. However, it has been pointed out that 80% of patients intolerant to sulfasalazine will tolerate mesalazine without problems.[6]

Mesalazine therapy should be started cautiously in patients with a history of sulfasalazine **hypersensitivity** and it should be withdrawn if signs of sensitivity develop or if there is diarrhoea or rectal bleeding. It has been suggested[2] that patients with a history of sulfasalazine hypersensitivity should be given test doses of mesalazine before starting a full course.

6. D'Haens G, van Bodegraven AA. Mesalazine is safe for the treatment of IBD. *Gut* 2004; **53:** 155.

Breast feeding. The concentrations of mesalazine in maternal plasma and breast milk in a woman taking 500 mg three times daily, were 410 and 110 nanograms/mL respectively.[1] Although it was considered that the amount of mesalazine distributed into breast milk was small and that it was safe during breast feeding,[2,3] maternal use of mesalazine 500 mg suppositories twice daily has been associated with watery diarrhoea in a breast-fed infant[2] and for this reason the American Academy of Pediatrics considers that mesalazine should be given with caution to breast-feeding mothers.[4]

Effects on the blood. Although uncommon, mesalazine-associated adverse effects on the blood have been reported, including thrombocytopenia,[1,2] neutropenia,[3] severe aplastic anaemia,[4,5] and pancytopenia.[6] In July 1995 the UK CSM stated that it had been notified of 49 haematological reactions suspected of being associated with mesalazine,[7] including 5 reports of aplastic anaemia, 1 of agranulocytosis, 11 of leucopenia, and 17 of thrombocytopenia. There had been 3 fatalities. They recommended a blood count and immediate withdrawal of the drug if a dyscrasia was suspected. Intensive immunosuppressive treatment has been used in the management of mesalazine-associated aplastic anaemia.[5,8]

Effects on the cardiovascular system. Myocarditis associated with chest pain and ECG abnormalities has been reported[1,2] in 2 patients taking mesalazine; 1 patient died in cardiogenic shock.[2] It has been suggested that mesalazine or sulfasalazine should be replaced by glucocorticoids if cardiac symptoms arise during treatment.[2] Pericarditis[3,4] with fever, rash, dyspnoea, pleural and pericardial effusions, and arthritis, has been described, and is considered to constitute a drug-induced lupus-like syndrome. Constrictive pericarditis with an absence of other lupus-like symptoms developed in a patient taking mesalazine for inflammatory bowel disease.[5] Based on reported cases of mesalazine-induced pericarditis, symptoms of this potentially life-threatening adverse effect have tended to arise 2 to 4 weeks after starting mesalazine, although symptom onset may be delayed by concurrent corticosteroid treatment.[6] Mesalazine cardiotoxicity presenting as an acute coronary syndrome, without myocarditis or pericarditis, has also been reported.[7]

Effects on fertility. For a report of reversible male infertility occurring with mesalazine, see under Sulfasalazine, p.1774.

Effects on the hair. For a report of accelerated loss of scalp hair in 2 patients receiving mesalazine enemas, see under Sulfasalazine, p.1774.

Effects on the kidneys. Between February 1988 and December 1990 the UK CSM[1] received 9 reports of serious nephrotoxic reactions associated with the use of *Asacol*, a modified-release mesalazine preparation. The reactions included 4 cases of interstitial nephritis, 3 of severe renal failure, and 2 cases of nephrotic syndrome. A subsequent case report[2] indicated that by September 1998 the number of such reports for mesalazine totalled 104, including 35 cases of interstitial nephritis. The authors considered that monitoring of renal function was required in patients receiving mesalazine. A protocol for such monitoring was subsequently suggested,[3] and a similar protocol has been adopted in UK licensing information for mesalazine, with serum creatinine being estimated:

- before treatment
- every 3 months for the first year
- every 6 months for the next 4 years
- annually thereafter

The nephrotic syndrome[4] and interstitial nephritis[5] have also been reported with sulfasalazine, and interstitial nephritis with olsalazine (see p.1752). A large UK epidemiologic study found no difference in risk of renal disease between mesalazine and sulfasalazine. The study also concluded that the risk of renal disease associated with mesalazine and related compounds is low and may be partly attributable to the underlying disease.[6] Overall nephrotoxicity has been estimated to occur in about 1 in 4000 UK patients per year taking aminosalicylate-based therapy.[7]

7. Muller AF, *et al.* Experience of 5-aminosalicylate nephrotoxicity in the United Kingdom. *Aliment Pharmacol Ther* 2005; **21:** 1217–24.

Effects on the liver. A case of chronic hepatitis and liver fibrosis has been reported after prolonged use of mesalazine.[1] The authors considered that mesalazine should be stopped when liver dysfunction occurred.

1. Deltenre P, *et al.* Mesalazine (5-aminosalicylic acid) induced chronic hepatitis. *Gut* 1999; **44:** 886–8.

Effects on the nervous system. Peripheral neuropathy,[1] mainly affecting the legs, has occurred during mesalazine treatment. The symptoms resolved on stopping the drug. Mononeuritis multiplex was part of the presentation of an eosinophilic reaction attributed to mesalazine in an asthmatic patient;[2] Churg-Strauss syndrome developed after withdrawal of mesalazine, but the patient subsequently recovered without sequelae.

2. Morice AH, *et al.* Mesalazine activation of eosinophil. *Lancet* 1997; **350:** 1105.

Effects on the pancreas. Pancreatitis has been reported as an adverse effect of mesalazine.[1-4] In 2 patients,[1,2] with abdominal pain and raised amylase activity, this reaction to mesalazine was confirmed by rechallenge and symptoms resolved on mesalazine withdrawal. By February 1994 the UK CSM had received 15 reports[3] of pancreatitis associated with mesalazine therapy. However, a case control study suggested that inflammatory bowel disease, rather than the use of mesalazine, may be associated with an increased risk of acute pancreatitis (see under Sulfasalazine, p.1774)

4. Adachi E, *et al.* Acute pancreatitis secondary to 5-aminosalicylic acid therapy in a patient with ulcerative colitis. *Int J Pancreatol* 1999; **25:** 217–21.

Effects on the respiratory system. Pulmonary complications have been rarely reported with mesalazine. There have though been cases of interstitial lung disease, with features of hypersensitivity pneumonia.[1] Symptoms have included dyspnoea, cough, fever, and pleuritic chest pain, with the onset of symptoms varying from a few days to several years after starting mesalazine therapy. Although pulmonary complications can also be associated with inflammatory bowel disease itself, there has been a report[2] of eosinophilic pleural effusion in a patient who was given mesalazine in the absence of an established diagnosis of inflammatory bowel disease.

Pulmonary complications have also been reported with sulfasalazine (p.1774), and pulmonary symptoms may also manifest as part of a broader lupus-like syndrome (see Effects on the Cardiovascular System, above).

2. Trisolini R, *et al.* Eosinophilic pleural effusion due to mesalamine: report of a rare occurrence. *Sarcoidosis Vasc Diffuse Lung Dis* 2000; **17:** 288–91.

Lupus. A lupus-like syndrome has been reported in 4 patients receiving mesalazine who developed antinuclear antibody (ANA)-positivity with at least one clinical feature of lupus, such as arthropathy, skin rashes, or acute inflammation unrelated to the underlying condition.[1] In all 4 cases symptoms resolved upon stopping mesalazine. For similar reports, see Effects on the Cardiovascular System, above.

1. Kirkpatrick AW, *et al.* Lupus-like syndrome caused by 5-aminosalicylic acid in patients with inflammatory bowel disease. *Can J Gastroenterol* 1999; **13:** 159–62.

Pregnancy. Renal insufficiency in a neonate whose mother received mesalazine 2 to 4 g daily by mouth during the second trimester of pregnancy was suggested to be due to the drug,[1] although the proposed mechanism, inhibition of prostaglandin synthesis in the neonatal kidney, has been questioned.[2] A subsequent case-control study[3] found that use of oral mesalazine in 165 pregnant women with inflammatory bowel disease was not associated with a greater incidence of malformations. However, women treated with mesalazine were more likely to have preterm deliveries and newborns with decreased birth-weights, although the disease may have been a factor in this finding. A commentator on this study,[4] considered that active inflammatory bowel disease was a greater risk to pregnancy than drug treatment. In a further cohort of 123 pregnancies,[5] oral mesalazine at doses of 3 g daily or less did not increase the risk of fetal malformations or affect pregnancy outcome. The researchers concluded that further information was required on doses higher than 3 g daily. In another study,[6] all of 19 pregnancies in women receiving rectal mesalazine were full-term with no fetal abnormalities. A Danish cohort study[7] found an increased risk of still-birth and preterm birth in women who had been prescribed mesalazine or olsalazine during pregnancy, but no significant increased risk of malformations. The risk of still-birth was greatest in women with ulcerative colitis who were prescribed corticosteroids and either mesalazine or olsalazine, and the risk of preterm birth was greatest in women with ulcerative colitis who were prescribed either mesalazine or olsalazine alone. The authors acknowledged that it was difficult to distinguish between the increase in risk due to disease state, and the increase in risk due to medication.[7] For a discussion of sulfasalazine in pregnancy, see p.1774.

Interactions

Preparations formulated to release mesalazine in the colon should not be given with drugs, such as lactulose, that lower colonic pH as they may prevent the release of mesalazine (but see Gastrointestinal Drugs below).

Anticoagulants. For reference to a case of mesalazine reducing the effect of *warfarin*, see Gastrointestinal Drugs, p.1430.

Antineoplastics. For mention of 5-aminosalicylates such as mesalazine inhibiting the metabolism of thiopurine antineoplastics, and increasing their toxicity, see Mercaptopurine, p.744.

Gastrointestinal drugs. Although it has been suggested that *lactulose* could delay the intestinal release of mesalazine from modified-release preparations, a study found no evidence that lactulose influenced the release or disposition of mesalazine.[1] Similarly, *omeprazole* did not appear to increase the likelihood of premature mesalazine release.

1. Hussain FN, *et al.* Mesalazine release from a pH dependent formulation: effects of omeprazole and lactulose co-administration. *Br J Clin Pharmacol* 1998; **46:** 173–5.

Pharmacokinetics

If given orally as conventional formulations, mesalazine would be extensively absorbed from the upper gastrointestinal tract, with little of the drug reaching the colon. Oral preparations are therefore generally formulated to release the drug in the terminal ileum and colon, where it is thought to exert a mainly local action. The specific release characteristics differ somewhat between formulations and this, together with interindividual variation, makes comparison of pharmacokinetic data between studies difficult. Even with modified-release preparations some 30 to 50% of an oral dose is thought to be lost to absorption in healthy subjects. Absorption from rectal dosage forms has also varied widely, with factors such as the dose, the formulation, and the pH also playing a role, but mean absorption of around 10 to 30% of a rectal dose has been reported.

The absorbed portion of mesalazine is almost completely acetylated in the gut wall and in the liver to acetyl-5-aminosalicylic acid. The rate of acetylation, and hence the concentration of parent drug and metabolite in the systemic circulation, may be dose dependent and subject to saturation. The acetylated metabolite is excreted mainly in urine by tubular secretion, with traces of the parent compound.

The plasma half-life of mesalazine is reported to be about 40 minutes and it is 40 to 50% bound to plasma proteins; the acetylated metabolite has a plasma half-life of 70 minutes and is about 80% bound to plasma proteins.

Only negligible quantities of mesalazine cross the placenta. Amounts distributed into breast milk are very small.

Uses and Administration

Mesalazine is an anti-inflammatory drug structurally related to the salicylates and active in inflammatory bowel disease (p.1697); it is considered to be the active moiety of sulfasalazine (p.1773). Mesalazine is thought to act locally on the inflamed intestinal tissue, rather than systemically. Although its precise mechanism of action is uncertain, it may be due to inhibition of prostaglandin and leukotriene synthesis in the gastrointestinal mucosa.

Mesalazine is given orally or rectally in the treatment of *acute attacks* of mild to moderate ulcerative colitis, or the *maintenance of remission* of ulcerative colitis. Some products are also used for the *maintenance of remission* of Crohn's ileo-colitis.

There are several differently formulated oral preparations of mesalazine available, and dosage recommendations vary. Recommended doses for some UK preparations are as follows:

- *Asacol 400 mg* tablets (*Procter and Gamble, UK*), *Ipocol* tablets (*Sandoz, UK*), *Mesren* tablets (*IVAX, UK*): acute attack, initially 2.4 g daily in divided doses; maintenance of remission, 1.2 to 2.4 g daily in divided doses. The *BNFC* includes similar doses for children aged 12 to 18 years
- *Asacol 800 mg* tablets (*Procter and Gamble, UK*): mild acute exacerbations, 2.4 g daily in divided doses; moderate acute exacerbations, 4.8 g daily in divided doses; maintenance of remission, up to 2.4 g daily in divided doses
- *Mezavant* tablets (*Shire, UK*): acute attack, initially 2.4 to 4.8 g once daily; maintenance of remission, 2.4 g once daily
- *Pentasa* tablets (*Ferring, UK*): acute attack, initially up to 4 g daily in 2 or 3 divided doses; maintenance of remission, adjusted individually from an initial dose of 1.5 g daily in 2 or 3 divided doses. The *BNFC* includes the same doses for children aged 15 to 18 years. For children aged 5 to 15 years: acute attack, 15 to 20 mg/kg (maximum 1 g) 3 times daily; maintenance of remission, 10 mg/kg (maximum 500 mg) 2 or 3 times daily
- *Pentasa* granules (*Ferring, UK*): acute attack, initially, up to 4 g daily in 2 to 4 divided doses; maintenance of remission, 2 g daily in 2 divided doses. The *BNFC* includes the same dose for acute attack in children aged 12 to 18 years, and 0.5 to 1 g twice daily for maintenance of remission. For children aged 5 to 12 years: acute attack, 15 to 20 mg/kg (maximum 1 g) 3 times daily; maintenance of remission, 10 mg/kg (maximum 500 mg) 2 or 3 times daily
- *Salofalk* tablets (*Falk, UK*): acute attack, initially 1.5 g daily in 3 divided doses; maintenance of remission, 0.75 to 1.5 g daily in divided doses. The *BNFC* includes the same dose for acute attack in children aged 12 to 18 years, and 250 to 500 mg given 2 or 3 times daily for maintenance of remission
- *Salofalk* granules (*Falk, UK*): acute attack, initially 1.5 to 3 g daily, either once daily, or in 3 divided doses; maintenance of remission, 1.5 g daily in 3 divided doses. The *BNFC* includes similar doses for children aged 12 to 18 years. For children aged 6 to 12 years: acute attack, 10 to 15 mg/kg (maximum 1 g) 3 times daily; maintenance of remission, 7.5 to 15 mg/kg (maximum 500 mg) twice daily (or 250 mg given 3 times daily for those weighing less than 40 kg)

Mesalazine may be given rectally, particularly when disease affects the sigmoid colon and rectum. Various formulations are available and the dose is usually given at night, but preparations do vary. Recommended doses for some UK preparations are as follows (the *BNFC* also suggests that these doses are suitable for children aged 12 to 18 years):

- *Asacol* suppositories (*Procter and Gamble, UK*): 0.75 to 1.5 g daily in divided doses
- *Asacol* foam enema (*Procter and Gamble, UK*): 1 g daily for disease affecting the rectosigmoid region; 2 g daily for disease involving the descending colon
- *Pentasa* suppositories and suspension enema (*Ferring, UK*): 1 g daily
- *Salofalk* suppositories (*Falk, UK*): 0.5 to 1 g given 2 or 3 times daily
- *Salofalk* foam enema and suspension enema (*Falk, UK*): 2 g daily

Similar preparations are available in other countries, and in the USA a suspension enema containing 4 g of mesalazine has been used.

Administration. Because the release characteristics of different formulations of mesalazine vary, they should not be regarded as interchangeable.[1] This applies even to those formulations where the dosage is apparently similar.[2] However, a study established that an oral once-daily regimen was bioequivalent to a twice-daily regimen of the same product (*Pentasa (Ferring, France)*).[3]

Diverticular disease. In a study involving 218 patients with a history of recurrent attacks of acute diverticulitis (p.1695), half were assigned to treatment with oral rifaximin 400 mg twice daily for 7 days, and half received rifaximin plus a modified-release formulation of mesalazine 800 mg three times daily, again for 7 days. Courses were then repeated, with rifaximin at the same dose and mesalazine at 800 mg twice daily, for 7 days in each month, and patients followed for 12 months. The combination of rifaximin and mesalazine was significantly more effective in reducing symptomatic episodes and normalisation of bowel habit than rifaximin alone: 89 of 107 patients given the combination were symptom-free at 12 months, compared with 44 of 105 given just the antibacterial.[1] Similarly, the same group found that in patients with uncomplicated diverticular disease given 10 days of treatment with rifaximin and mesalazine (*Pentacol; Sofar, Ital.*) in the doses above, followed by mesalazine 1.6 g daily for 8 weeks, 70 of 86 completing the study were completely asymptomatic, suggesting that daily mesalazine alone was an effective maintenance therapy, although longer-term studies were needed.[2] Mesalazine has also been investigated in combination with a probiotic preparation of lactic-acid-producing organisms.[3]

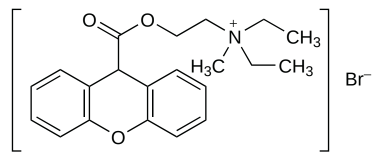
$C_{21}H_{26}BrNO_3$ = 420.3.
CAS — 5818-17-7 (methanthelinium); 53-46-3 (methanthelinium bromide).
ATC — A03AB07.
ATC Vet — QA03AB07.



Profile

Methanthelinium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used as an adjunct in the treatment of peptic ulcer disease, in gastrointestinal disorders associated with smooth muscle spasm, and in the management of urinary incontinence. A usual oral dose in gastrointestinal disorders is 50 mg three times daily.

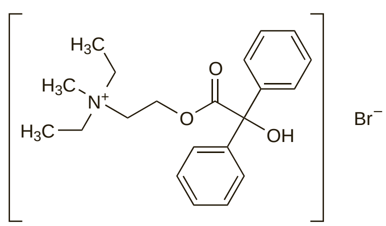
Метилбенактизия Бромид

$C_{21}H_{28}BrNO_3$ = 422.4.
CAS — 3166-62-9.



Pharmacopoeias. In *Jpn.*

Profile

Methylbenactyzium bromide, a derivative of benactyzine (p.383), is an antimuscarinic with effects similar to those of atropine (p.1219). It has been given orally for the treatment of gastrointestinal spasm and nocturnal enuresis.

Preparations

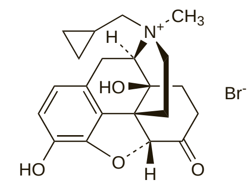
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austria:*** Anxiolit plus.

Methylnaltrexone Bromide *(USAN, rINN)*

Bromure de Méthylnaltrexone; Bromuro de Metilnaltrexona; Methylnaltrexonii Bromidum; MRZ-2663BR; Naltrexone Methobromide. (17*RS*)-17-(Cyclopropylmethyl)-4,5α-epoxy-3,14-dihydroxy-17-methyl-6-oxomorphinanium bromide.

Метилнальтрексон Бромид

$C_{21}H_{26}BrNO_4$ = 436.3.
CAS — 83387-25-1 (methylnaltrexone); 73232-52-7 (methylnaltrexone bromide).



and epimer at N+

Profile

Methylnaltrexone bromide is a selective peripherally acting antagonist of opioid μ-receptors that is used for the treatment of opioid-induced constipation in patients receiving palliative care for advanced illness, when response to usual laxative therapy is insufficient. It is also being studied for treatment of opioid-induced urinary retention and postoperative ileus.

For the treatment of opioid-induced constipation methylnaltrexone bromide may be given once every 48 hours by subcutaneous injection in the following doses according to body-weight: patients less than 38 kg in weight, 150 micrograms/kg; 38 to 62 kg, 8 mg; 62 to 114 kg, 12 mg; more than 114 kg, 150 micrograms/kg.

Метоклопрамида Гидрохлорид

$C_{14}H_{22}ClN_3O_2,HCl,H_2O$ = 354.3.
CAS — 7232-21-5 (anhydrous metoclopramide hydrochloride); 54143-57-6 (metoclopramide hydrochloride monohydrate); 2576-84-3 (anhydrous metoclopramide dihydrochloride).
ATC — A03FA01.
ATC Vet — QA03FA01.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Metoclopramide Hydrochloride). A white or almost white, crystalline powder or crystals. Very soluble in water; freely soluble in alcohol; sparingly soluble in dichloromethane. A 10% solution in water has a pH of 4.5 to 6.0. Protect from light.

USP 31 (Metoclopramide Hydrochloride). A white or practically white, odourless or practically odourless, crystalline powder.

Very soluble in water; freely soluble in alcohol; sparingly soluble in chloroform; practically insoluble in ether. Store in airtight containers. Protect from light.

Incompatibility. Proprietary preparations of metoclopramide hydrochloride are stated to be incompatible with cephalothin sodium, chloramphenicol sodium, and sodium bicarbonate.

Cisplatin, cyclophosphamide, doxorubicin hydrochloride, morphine hydrochloride, or diamorphine hydrochloride are stated to be compatible with metoclopramide hydrochloride but compatibility is dependent upon factors such as the particular formulation, drug concentration, and temperature.

Adverse Effects

Metoclopramide is a dopamine antagonist and may cause extrapyramidal symptoms (usually acute dystonic reactions); these are more common in children and young adults, and at daily doses above 500 micrograms/kg. Parkinsonism and tardive dyskinesia have occasionally occurred, usually during prolonged treatment in elderly patients, and especially in elderly women.

Other adverse effects include restlessness, drowsiness, anxiety, and diarrhoea. Hypotension, hypertension, dizziness, headache, and depression may occur and there are isolated reports of blood disorders, hypersensitivity reactions (rash, bronchospasm), and neuroleptic malignant syndrome. Disorders of cardiac conduction have been reported with intravenous metoclopramide.

Metoclopramide stimulates prolactin secretion and may cause galactorrhoea or related disorders. Transient increases in plasma-aldosterone concentrations have been reported.

Effects on the blood. Agranulocytosis was associated with use of metoclopramide on 2 separate occasions.[1] Both episodes resolved within 2 to 3 weeks of withdrawing metoclopramide. Methaemoglobinaemia[2-4] and sulfhaemoglobinaemia[5,6] have also been reported. Methaemoglobinaemia (p.1451) may be treated with methylthioninium chloride. In one case,[3] the patient died despite treatment with this drug; blood samples taken before death were found to be haemolysed, and assays showed deficiency in G6PD activity (for the view that methylthioninium chloride should not be used in G6PD-deficient patients, see Uses of Methylthioninium Chloride, p.1451).

Effects on the endocrine system. *ALDOSTERONISM.* Metoclopramide has been reported to increase plasma-aldosterone concentrations in healthy individuals[1] and in patients with liver cirrhosis and ascites associated with secondary hyperaldosteronism.[2] Increased plasma aldosterone after metoclopramide use has also been associated with the development of oedema in a patient with congestive heart failure.[3] The metoclopramide-induced aldosterone response was blunted by giving neostigmine beforehand.[1]

3. Zumoff B. Metoclopramide and edema. *Ann Intern Med* 1983; **98:** 557.

HYPERPROLACTINAEMIA. Hyperprolactinaemia, galactorrhoea, and pituitary adenoma occurred in a 49-year-old woman with reflux oesophagitis who had received metoclopramide for 3 months.[1] Her plasma-prolactin concentrations fell to normal and her symptoms resolved over 4 months after withdrawal of metoclopramide. The pituitary tumour was considered to be incidental to, and not caused by, metoclopramide therapy. A 21-year-old female developed mastodynia, galactorrhoea, and hyperprolactinaemia after 2 days of treatment with metoclopramide;[2] she had previously taken domperidone intermittently without any problems. Her symptoms resolved rapidly on stopping therapy.

Effects on mental state. There are isolated reports of dose-related delirium, depression, and uncontrollable crying in patients treated with metoclopramide in doses of 40 to 80 mg daily.[1-3] Symptoms resolved on reducing the dose or withdrawing metoclopramide, and tolerance could be achieved by gradually increasing the dose. In another report,[4] a patient developed acute akathisia (see Extrapyramidal Effects below) shortly after starting metoclopramide 10 mg four times daily; this was accompanied by restlessness, anxiety, and irritability. Despite stopping the drug after 2 days, and treatment with paroxetine and lorazepam, the patient started to experience panic attacks, which increased in frequency and severity; he also developed agoraphobia. Two months after taking metoclopramide he was diagnosed with major depressive disorder, which included intermittent suicidal ideation. Following aggressive therapy and hospitalisation, his symptoms gradually resolved.

Insomnia, with or without daytime drowsiness, has also been reported in patients taking metoclopramide 40 mg daily.[5]

Hypersensitivity psychosis has also been reported, shortly after stopping metoclopramide.[6] Symptoms included hallucinations, delusional experiences, anxiety, restlessness, and sleep disturbances; improvement and gradual resolution were noted after treatment with risperidone.

Extrapyramidal effects. The Adverse Reactions Register of the UK CSM for the years 1967 to 82 contained 479 reports of extrapyramidal reactions in which metoclopramide was the suspected drug: 455 were for dystonic-dyskinetic reactions, 20 for parkinsonism, and 4 for tardive dyskinesia.[1]

Acute **dystonic-dyskinetic** reactions occur most commonly in children and young adults[1-3] and about 70% of reactions are in females;[1,3] many are associated with doses above those recommended by the manufacturers.[1,3,4] Symptoms reported include oculogyric crisis,[4,5] opisthotonus,[6] torticollis,[5,7] trismus,[5,7] a tetanus-like reaction,[8] and blue coloration of the tongue;[6] akathisia after the use of metoclopramide alone,[9] or with droperidol[10] or haloperidol[9] has been reported (see also Effects on Mental State, above). The effects usually occur within 72 hours of starting treatment[1] but have been reported within 30 minutes of receiving metoclopramide.[4] They can occur in patients who have previously taken metoclopramide without complications[5,8,10] and may be precipitated by other drugs. Although generally self-limiting, deaths have occurred.[1,5] The reactions are readily reversed by an antihistamine such as diphenhydramine,[7] or an antimuscarinic such as benzatropine;[4,6] prophylactic use of diphenhydramine has been suggested for patients with a history of extrapyramidal reactions and in those less than 30 years of age.[7,8]

Metoclopramide-associated **parkinsonism** is thought to occur less commonly than the acute dystonias and is seen mainly in older patients. Symptoms usually appear several months after starting metoclopramide, but may occur within days or not for several years. Withdrawal of metoclopramide usually results in resolution of symptoms, although it may take several months.[1] A study has suggested that metoclopramide-induced parkinsonism (misdiagnosed as idiopathic Parkinson's disease) may be more common in the elderly than generally realised.[11]

Tardive dyskinesia may rarely be associated with use of metoclopramide. The reaction is usually confined to elderly patients after prolonged oral use,[12,13] but it has been reported with short-term high-dose parenteral use as an antiemetic in cancer chemotherapy,[14] and a case has been reported in an 8-year-old child treated with metoclopramide for gastro-oesophageal reflux disease in usual doses.[15] The average duration of treatment before the onset of symptoms was 14 months (range 4 to 44 months) in a report of 11 cases[13] and 26 months (range 8 to 60 months) in a report of 12 cases;[16] some patients did not experience symptoms until after withdrawal of metoclopramide. Tardive dyskinesia is potentially irreversible and its management is difficult.[16] Some patients improve after withdrawal of metoclopramide but symptoms persisting during follow-up periods of up to 3 years have been reported.[12,13] The emphasis must be on prevention, hence the recommendation that metoclopramide should not be prescribed for the long-term treatment of minor symptoms, especially in elderly patients.[16]

16. Orme ML'E, Tallis RC. Metoclopramide and tardive dyskinesia in the elderly. *BMJ* 1984; **289:** 397–8.

Hypersensitivity. A patient given intravenous metoclopramide and butylhyoscine for gastrointestinal disturbances developed pruritus, generalised urticaria, hypotension, and loss of consciousness. She was treated with intravenous fluid, antihistamines, and corticosteroids. Skin prick tests revealed a response to metoclopramide, suggesting an IgE-mediated allergic reaction.[1]

1. Kerstan A, *et al.* Anaphylaxis during treatment of nausea and vomiting: IgE-mediated metoclopramide allergy. *Ann Pharmacother* 2006; **40:** 1889–90.

Neuroleptic malignant syndrome. Neuroleptic malignant syndrome (NMS, p.972) has occurred very rarely with metoclopramide. In a report of a case with a fatal outcome, it was noted that 17 additional cases had been published in the years 1978 to 1998, three of which resulted in death.[1] A case report in a 6-month-old female with Freeman-Sheldon syndrome[2] given metoclopramide suggested that pre-existing fever and myopathy may be predisposing factors. In another case,[3] a burns patient, there was some suggestion that the patient may have been susceptible to neuroleptic hyperthermic syndromes such as NMS and malignant hyperthermia. Metoclopramide should be stopped immediately if NMS occurs, and the patient treated urgently with bromocriptine.

Precautions

Metoclopramide should not be used when stimulation of muscular contractions might adversely affect gastrointestinal conditions, as in gastrointestinal haemorrhage, obstruction, perforation, or for a few days after surgery. There have been reports of hypertensive crises in patients with phaeochromocytoma given metoclopramide, thus its use is not recommended in such patients; caution is advised in patients with hypertension.

Children, young adults, and the elderly should be treated with care as they are at increased risk of extrapyramidal reactions; in the UK, use of metoclopramide is restricted in patients under 20 years (see Administration in Children, below). Patients on prolonged therapy should be reviewed regularly. Care should also be taken when metoclopramide is given to patients with renal or hepatic impairment, epilepsy, Parkinson's disease, or a history of depression, atopy (including asthma), or porphyria.

Metoclopramide may cause drowsiness or impaired reactions; patients so affected should not drive or operate machinery.

Breast feeding. Metoclopramide is excreted into breast milk. The American Academy of Pediatrics[1] considers that the use of metoclopramide by mothers during breast feeding may be of concern, owing to its dopamine-receptor blocking activity. UK licensed product information states that problems in humans have not been reported.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 07/05/04)

Porphyria. Metoclopramide has been associated with acute attacks of porphyria and is considered to be unsafe in porphyric patients, although there is conflicting evidence of porphyrinogenicity, and indeed some have used it successfully in the management of acute attacks.[1]

1. Elder GH, *et al.* Metoclopramide and acute porphyria. *Lancet* 1997; **350:** 1104.

Interactions

Metoclopramide should be used with caution in patients taking other drugs that can also cause extrapyramidal reactions, such as the phenothiazines. Increased toxicity may occur if metoclopramide is given to patients receiving lithium, and caution is advisable with other centrally active drugs such as antiepileptics. Metoclopramide should be used with care with other drugs acting at central dopamine receptors, such as pergolide. Combining metoclopramide with CNS depressant drugs can lead to increased sedative effects. Antimuscarinics and opioid analgesics antagonise the gastrointestinal effects of metoclopramide.

The absorption of other drugs may be affected by metoclopramide; it may either diminish absorption from the stomach (as with digoxin) or enhance absorption from the small intestine (for example, with alcohol, ciclosporin, levodopa, aspirin, or paracetamol). It inhibits serum cholinesterase and may prolong neuromuscular blockade produced by suxamethonium (see p.1912) and mivacurium (p.1907). Metoclopramide may also increase prolactin blood concentrations and therefore interfere with drugs which have a hypoprolactinaemic effect such as bromocriptine (but see p.800). It has been suggested that it should not be given to patients receiving MAOIs.

Antidepressants. For reference to extrapyramidal effects and other adverse effects suggestive of serotonin syndrome in patients taking metoclopramide with SSRIs or venlafaxine, see Gastrointestinal Drugs under Interactions for Fluoxetine (p.397) and Venlafaxine (p.429) respectively.

Carbamazepine. For a report of neurotoxicity associated with the use of metoclopramide with carbamazepine, see p.475.

Hydroxyzine. Acute anxiety, rigidity, generalised tremor, opisthotonus, and hypertension developed in a 20-year-old man given metoclopramide 10 mg intravenously and hydroxyzine 100 mg intramuscularly.[1] The adverse effects occurred 30 minutes after giving hydroxyzine and it was suggested that hydroxyzine potentiated the onset of the reaction.

1. Fouilladieu JL, *et al.* Possible potentiation by hydroxyzine of metoclopramide's undesirable side effects. *Anesth Analg* 1985; **64:** 1227–8.

Pharmacokinetics

Metoclopramide is rapidly and almost completely absorbed from the gastrointestinal tract after oral doses, although conditions such as vomiting or impaired gastric motility may reduce absorption. However, it undergoes hepatic first-pass metabolism, which varies considerably between subjects, and hence absolute bioavailability and plasma concentrations are subject to wide interindividual variation. On average, the bioavailability of oral metoclopramide is about 80%, but it varies between about 30 and 100%. Peak plasma concentrations of metoclopramide occur about 1 to 2 hours after an oral dose. Bioavailability is equally variable after rectal or intranasal doses, although it may be somewhat better if the drug is given intramuscularly. Metoclopramide is weakly bound to plasma proteins (13 to 30%).

Metoclopramide is widely distributed in the body, and readily crosses the blood-brain barrier into the CNS. It also freely crosses the placenta, and has been reported to attain concentrations in fetal plasma about 60 to 70% of those in maternal plasma. Concentrations in breast milk may be higher than those in maternal plasma, particularly in the early puerperium, although concentrations decrease somewhat in the late puerperium.

Elimination of metoclopramide is biphasic, with a terminal elimination half-life of about 4 to 6 hours, although this may be prolonged in renal impairment, with consequent elevation of plasma concentrations. It is excreted in the urine, about 85% of a dose being eliminated in 72 hours, 20% as unchanged metoclopramide and the remainder as sulfate or glucuronide conjugates, or as metabolites. About 5% of a dose is excreted in faeces via the bile.

Uses and Administration

Metoclopramide hydrochloride is a substituted benzamide used for its prokinetic and antiemetic properties. It stimulates the motility of the upper gastrointestinal tract without affecting gastric, biliary, or pancreatic secretion and increases gastric peristalsis, leading to accelerated gastric emptying. Duodenal peristalsis is also increased which decreases intestinal transit time. The resting tone of the gastro-oesophageal sphincter is increased and the pyloric sphincter is relaxed. Metoclopramide possesses parasympathomimetic activity as well as being a dopamine-receptor antagonist with a direct effect on the chemoreceptor trigger zone. It may have serotonin-receptor (5-HT_3) antagonist properties.

Metoclopramide is used in disorders of decreased gastrointestinal motility (p.1694) such as gastroparesis or ileus; in gastro-oesophageal reflux disease (p.1696) and dyspepsia (p.1695); and in nausea and vomiting (p.1700) associated with various gastrointestinal disorders, with migraine, after surgery, and with cancer therapy. Metoclopramide is of no value in the prevention or treatment of motion sickness. It may be used to stimulate gastric emptying during radiographic examinations, to facilitate intubation of the small bowel, and in the management of aspiration syndromes (p.1693).

It is usually given as the hydrochloride monohydrate with doses expressed as the anhydrous hydrochloride. In the USA, the strength of preparations of the hydrochloride monohydrate is usually expressed in terms of the base. Metoclopramide hydrochloride 10.5 mg is equivalent to about 10.0 mg of the anhydrous substance, which is equivalent to about 8.9 mg of the anhydrous base.

For most purposes the total daily dose should not exceed 500 micrograms/kg; dosage reduction is recommended in renal and perhaps hepatic impairment (see Administration in Hepatic or Renal Impairment, below).

- In the UK, the recommended dose orally, intramuscularly, or by slow intravenous injection, is 10 mg (expressed as anhydrous metoclopramide hydrochloride) three times daily.
- In the USA, the recommended dose is 10 to 15 mg (expressed as the base) up to four times daily.
- Single doses of 10 to 20 mg (expressed as anhydrous base or anhydrous hydrochloride) should be considered where appropriate.

Modified-release preparations of metoclopramide are available; 15 mg (expressed as anhydrous metoclopramide hydrochloride) is given twice daily.

In the UK, the use of metoclopramide is restricted in patients under 20 years of age (see Administration in Children, below).

An intranasal formulation of metoclopramide is available in some countries.

The base, the dihydrochloride, and the glycyrrhizate have also been used.

High-dose therapy. High doses of metoclopramide have been used, often with other drugs such as dexamethasone, in the treatment of the nausea and vomiting associated with cancer chemotherapy. The loading dose of metoclopramide before cancer therapy is 2 to 4 mg/kg given as a continuous intravenous infusion over 15 to 20 minutes; it is followed by a maintenance dose of 3 to 5 mg/kg, again as a continuous intravenous infusion, given over 8 to 12 hours. Alternatively, initial doses of up to 2 mg/kg by intravenous infusion over at least 15 minutes may be given before cancer therapy and repeated every 2 or 3 hours. The total dosage by either continuous or intermittent infusion should not normally exceed 10 mg/kg in 24 hours.

Administration. ***INTRANASAL.*** References.

Administration in children. In the UK, the use of metoclopramide is restricted in patients under 20 years of age to severe intractable vomiting of known cause, chemotherapy- or radiotherapy-induced vomiting, as an aid to gastrointestinal intubation, and in premedication. Licensed oral and parenteral (intramuscular or intravenous) doses for all indications, except premedication, are:

- for those aged 15 to 19 years and weighing 60 kg and over: 10 mg three times daily
- 15 to 19 years (30 to 59 kg): 5 mg three times daily
- 9 to 14 years (30 kg and over): 5 mg three times daily
- 5 to 9 years (20 to 29 kg): 2.5 mg three times daily
- 3 to 5 years (15 to 19 kg): 2 mg two or three times daily
- 1 to 3 years (10 to 14 kg): 1 mg two or three times daily
- under 1 year (up to 10 kg): 1 mg twice daily

Where body-weight is below that specified for a given age group, the dose should reflect the weight rather than the age, so that a lower dose is chosen.

The *BNFC* gives similar doses, but specifies:

- 1 month to 1 year (up to 10 kg): 100 micrograms/kg (maximum 1 mg) twice daily
- neonate: 100 micrograms/kg every 6 to 8 hours (by mouth or intravenous injection only)

For **premedication** in diagnostic procedures, licensed doses (for use as a single dose by mouth or parenterally 5 to 10 minutes before the examination and subject to the same body-weight considerations as above) are:

- for those aged 15 to 19 years: 10 mg
- 9 to 14 years: 5 mg
- 5 to 9 years: 2.5 mg
- 3 to 5 years: 2 mg
- under 3 years: 1 mg

The *BNFC* gives similar oral doses, but specifies:

- 1 month to 3 years (up to 14 kg): 100 micrograms/kg (maximum 1 mg) by mouth

In the USA metoclopramide is licensed for use in children only to facilitate small bowel intubation in those resistant to conventional methods. A single intravenous dose, based on age, is recommended as follows:

- over 14 years: 10 mg
- 6 to 14 years: 2.5 to 5 mg
- under 6 years: 100 micrograms/kg

Administration in hepatic or renal impairment. Total clearance of metoclopramide is significantly reduced in patients with **renal impairment**[1-3] and the elimination half-life is prolonged to up to 19 hours.[2] This may be due to impaired metabolism[1,2] or to an alteration in enterohepatic circulation of metoclopramide.[1] Accumulation of metoclopramide could therefore occur in renal impairment with a possible increased risk of adverse effects. Dosage reductions of at least 50% have therefore been recommended in patients with moderate to severe renal impairment.[1,2] US licensed product information recommends this dose reduction in those patients whose creatinine clearance is below 40 mL/minute; UK information advises caution in severe or chronic renal impairment, but gives no guidance on dosage reduction.

Patients undergoing haemodialysis do not require dosage supplements since relatively little metoclopramide is cleared by this process.[2,3]

UK licensed product information recommends that the dose of metoclopramide should be reduced in patients with clinically significant **hepatic impairment**, although no recommendations on the size of the reduction are given; caution is advised in liver disease, due to loss of conjugation. The US product information notes that metoclopramide undergoes minimal hepatic metabolism and has been used safely in some patients with advanced liver disease (whose renal function was normal), and it makes no such recommendation for reduction of dose. Decreases in clearance and increases in half-life and area under the plasma concentration-time curve have been reported in patients with cirrhosis given metoclopramide.[4,5]

Blood disorders. Responses to treatment with metoclopramide have been reported in patients with Diamond-Blackfan anaemia, probably through induction of prolactin release, although the mechanism by which prolactin affects erythropoiesis is unclear.[1,2] In a pilot study, 3 out of 9 evaluable patients responded after 12 to 15 weeks of therapy; high serum ferritin, pituitary dysfunction, male sex, and younger age may have contributed to the poor response to metoclopramide in other patients.[1] In another case, response was seen by the fourth week of treatment; at the time of the report, the patient had remained asymptomatic and transfusion independent for 8 months.[2]

2. Akiyama M, *et al.* Successful treatment of Diamond-Blackfan anemia with metoclopramide. *Am J Hematol* 2005; **78:** 295–8.

Hiccup. Metoclopramide has been used in the management of intractable hiccup. For a discussion of hiccup and its management see p.976.

Lactation induction. Metoclopramide has been used[1,2] in doses of 10 mg three times daily for its dopamine antagonist properties to stimulate lactation in women who wish to breast feed and in whom mechanical stimulation of the nipple alone is inadequate, including mothers of adopted babies or babies born to surrogates.[3,4] However, pharmacological lactation induction should be viewed as adjunctive to mechanical methods and the duration of therapy should probably be limited to 7 to 14 days.[1,2] In addition, the efficacy of metoclopramide in stimulating lactation in women with preterm deliveries has been questioned by a controlled study.[5] Young women are at increased risk of extrapyramidal effects from metoclopramide—see under Adverse Effects, above. There has also been concern about the presence of the drug in breast milk. For a discussion of lactation inhibition and induction, see p.2003.

Migraine. Metoclopramide is used in the treatment of migraine (p.616) to alleviate nausea and vomiting and gastric stasis, which commonly develop as a migraine attack progresses and can lead to poor absorption of oral antimigraine preparations. It may also be given to counteract nausea and vomiting from the use of ergotamine. Metoclopramide is included in some combination analgesic preparations for the treatment of acute attacks of migraine. In a study, oral lysine aspirin with metoclopramide was as effective as oral sumatriptan in the treatment of migraine.[1] Metoclopramide with sumatriptan may be effective in patients unresponsive to a triptan alone.[2]

Parenteral metoclopramide has also been shown to be an effective treatment for acute migraine; it reduces pain, and to some extent nausea (although other antiemetics may be more effective), and a systematic review concluded that it should be considered a first-line treatment for migraine in the emergency department.[3] A later study found intravenous metoclopramide (with intermittent doses of diphenhydramine) to be comparable to subcutaneous sumatriptan in terms of pain relief at both 2 and 24 hours after treatment.[4]

1. Tfelt-Hansen P, *et al.* The effectiveness of combined oral lysine acetylsalicylate and metoclopramide compared with oral sumatriptan for migraine. *Lancet* 1995; **346:** 923–6.

Orthostatic hypotension. Metoclopramide has been tried in the management of some patients with orthostatic hypotension, as mentioned on p.1530.

Tourette's syndrome. A small, short-term study in children and adolescents with Tourette's syndrome (see Tics, p.954) or chronic tic disorders found that treatment with oral metoclopramide (up to 40 mg daily) significantly reduced tic score and severity compared with placebo.[1]

1. Nicolson R, *et al.* A randomized, double-blind, placebo-controlled trial of metoclopramide for the treatment of Tourette's disorder. *J Am Acad Child Adolesc Psychiatry* 2005; **44:** 640–6.

Variceal haemorrhage. Metoclopramide 20 mg intravenously controlled bleeding from oesophageal varices within 15 minutes in 10 of 11 patients compared with 4 of 11 patients given placebo; all patients were treated by sclerotherapy.[1] Lower oesophageal sphincter pressure is increased by metoclopramide, thus reducing blood flow to varices and achieving haemostasis; another study[2] found use of metoclopramide with intravenous glyceryl trinitrate to be more effective than glyceryl trinitrate alone in reducing intravariceal pressure.

For a discussion of variceal haemorrhage and its management, see p.2346.

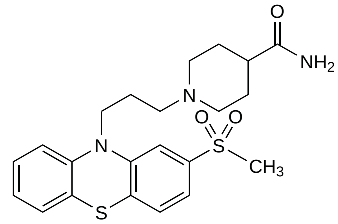
Metopimazine *(BAN, USAN, rINN)*

EXP-999; Metopimazina; Métopimazine; Metopimazinum; RP-9965. 1-[3-(2-Methylsulphonylphenothiazin-10-yl)propyl]piperidine-4-carboxamide.

Метопимазин

$C_{22}H_{27}N_3O_3S_2$ = 445.6.
CAS — 14008-44-7.
ATC — A04AD05.
ATC Vet — QA04AD05.



Pharmacopoeias. In *Fr.*

Profile

Metopimazine, a phenothiazine dopamine antagonist, is an antiemetic with general properties similar to those of chlorpromazine (p.969). It is used in the management of nausea and vomiting, including that associated with cancer chemotherapy (p.1700). It is given in usual oral doses of 15 to 30 mg daily, in 2 to 4 divided doses; similar daily doses have been given by rectum in 3 divided doses. It has also been given by injection in a dose of 10 to 20 mg daily, usually intramuscularly but occasionally by the intravenous route. Higher doses of 30 to 50 mg daily by intramuscular injection or intravenous infusion have been given for chemotherapy-induced nausea and vomiting.

Preparations

Proprietary Preparations (details are given in Part 3)

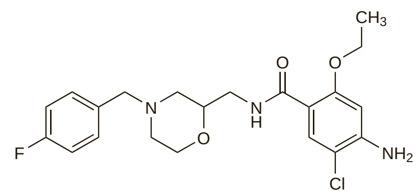
Mosapride Citrate *(rINNM)*

AS-4370; Citrato de mosaprida; Mosapride, Citrate de; Mosapridi Citras; Rimopride Citrate. (±)-4-Amino-5-chloro-2-ethoxy-*N*-{[4-(*p*-fluorobenzyl)-2-morpholinyl]methyl}benzamide citrate dihydrate.

Мозаприда Цитрат

$C_{21}H_{25}ClFN_3O_3,C_6H_8O_7,2H_2O$ = 650.0.
CAS — 112885-41-3 (mosapride); 112885-42-4 (mosapride citrate).



(mosapride)

Profile

Mosapride is a substituted benzamide used for its prokinetic properties. It is reported to be an agonist at 5-HT_4 receptors, increasing acetylcholine release and stimulating gastrointestinal motility (see also Cisapride, p.1721), as well as having 5-HT_3 antagonist properties. It is given orally as the citrate dihydrate, but doses are expressed as the anhydrous citrate, and are 5 mg three times daily before or after meals.

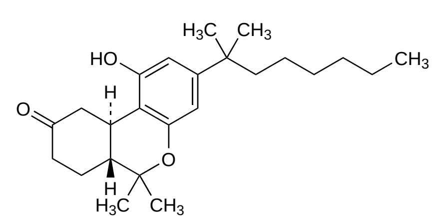
Nabilone *(BAN, USAN, rINN)* ⊗

Compound 109514; Lilly-109514; Nabilon; Nabilona; Nabiloni; Nabilonum. (±)-(6a*R*,10a*R*)-3-(1,1-Dimethylheptyl)-6a,7,8,9,10,10a-hexahydro-1-hydroxy-6,6-dimethyl-6*H*-benzo[*c*]chromen-9-one.

Набилон

$C_{24}H_{36}O_3$ = 372.5.
CAS — 51022-71-0.
ATC — A04AD11.
ATC Vet — QA04AD11.



Adverse Effects

Nabilone may produce adverse effects similar to those of cannabis (see p.2275). The most common adverse effects are drowsiness, vertigo, and dry mouth. Neurological effects have included ataxia, confusion, disorientation, dizziness, euphoria, dysphoria, hallucinations, psychosis, depression, headache, decreased concentration, blurred vision, sleep disturbances, decreased coordination, and tremors. Adverse cardiovascular reactions including hypotension, orthostatic hypotension, and tachycardia have occurred. Gastrointestinal disturbances, decreased appetite, and abdominal pain have also been reported.

Precautions

Nabilone is extensively metabolised and largely excreted in bile, and therefore is not recommended in patients with severe hepatic impairment. It should be used with caution in patients with a history of psychiatric disorders or depression, or those with hypertension or heart disease.

Because of the possibility of CNS depression, patients should be warned not to drive or operate machinery.

The possibility of dependence similar to that of cannabis should be borne in mind.

Interactions

Nabilone has been shown to have an additive CNS depressant effect when given with alcohol, codeine, diazepam, or other CNS depressants.

Pharmacokinetics

Nabilone is well absorbed from the gastrointestinal tract and is rapidly and extensively metabolised; one or more of the metabolites may be active. The major excretory pathway is the biliary system; about 65% of a dose is excreted in the faeces and about 20% in the urine. The elimination half-life of nabilone is about 2 hours, but the half-life of its combined metabolites is about 35 hours after an oral dose.

◊ References.

1. Rubin A, *et al.* Physiologic disposition of nabilone, a cannabinol derivative, in man. *Clin Pharmacol Ther* 1977; **22:** 85–91.

Uses and Administration

Nabilone, a synthetic cannabinoid with antiemetic properties, is used for the control of nausea and vomiting associated with cancer chemotherapy in patients who have failed to respond adequately to conventional antiemetics (p.1700).

The usual initial oral dose for adults is 1 mg twice daily, increased to 2 mg twice daily if necessary. The first dose should be given the evening before starting chemotherapy, and the second dose 1 to 3 hours before the first dose of antineoplastic. Nabilone may be given throughout each cycle of chemotherapy and for 48 hours after the last dose of chemotherapy, if required. The dose of nabilone should not exceed 6 mg daily, given in 3 divided doses.

2. Davis MP. Oral nabilone capsules in the treatment of chemotherapy-induced nausea and vomiting and pain. *Expert Opin Invest Drugs* 2008; **17:** 85–95.

Multiple sclerosis. There is a report of reduction in spasticity and nocturia, and improvement in mood and well-being, in a patient with multiple sclerosis (p.892) who received nabilone 1 mg every second day.[1] A subsequent small crossover study[2] in patients with chronic upper motor neurone syndrome found that oral nabilone 1 mg daily reduced spasticity-related pain in this group. There are also anecdotal reports of improvement in symptoms in patients with multiple sclerosis who took cannabis, however, a review[3] considered evidence of effectiveness to be lacking.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Nizatidine). An almost white or slightly brownish, crystalline powder. Sparingly soluble in water; soluble in methyl alcohol. A 1% solution in water has a pH of 8.5 to 10.0.

USP 31 (Nizatidine). An off-white to buff crystalline solid. Sparingly soluble in water; freely soluble in chloroform; soluble in methyl alcohol. Store in airtight containers. Protect from light.

Adverse Effects

As for Cimetidine, p.1716. Some patients taking nizatidine may experience excessive sweating and urticaria; anaemia may also occur.

Nizatidine is considered to have little or no anti-androgenic activity although there are isolated reports of gynaecomastia and impotence.

Effects on the cardiovascular system. Nizatidine has been reported to reduce heart rate in healthy subjects,[1,2] an effect that was not seen when they were pretreated with ranitidine[1] or also given the antimuscarinic pirenzepine.[2] As with other H_2-antagonists (see Cimetidine, p.1717), tachycardia, bradycardia, orthostatic hypotension and syncope have been reported rarely with rapid intravenous injection of nizatidine.

1. Mescheder A, *et al.* Changes in the effects of nizatidine and famotidine on cardiac performance after pretreatment with ranitidine. *Eur J Clin Pharmacol* 1993; **45:** 151–6.
2. Hinrichsen H, *et al.* Dose-dependent heart rate reducing effect of nizatidine, a histamine H -receptor antagonist. *Br J Clin Pharmacol* 1993; **35:** 461–6.

Effects on the endocrine system. A report of reversible impotence in a patient taking nizatidine 300 mg at night.[1]

1. Kassianos GC. Impotence and nizatidine. *Lancet* 1989; **i:** 963.

Effects on the skin. Similarly to cimetidine (p.1717), vasculitis has been reported with nizatidine.[1] Exfoliative dermatitis has also occurred.

1. Suh J-G, *et al.* Leukocytoclastic vasculitis associated with nizatidine therapy. *Am J Med* 1997; **102:** 216–17.

Precautions

As for Cimetidine, p.1718.

Interactions

Unlike cimetidine (p.1718) nizatidine does not inhibit cytochrome P450, and therefore is considered to have little effect on the metabolism of other drugs. However, like other H_2-antagonists its effects on gastric pH may affect the absorption of some other drugs.

Pharmacokinetics

Nizatidine is readily and almost completely absorbed from the gastrointestinal tract. The bioavailability of nizatidine after oral doses exceeds 70% and may be slightly increased by the presence of food. It is widely distributed and is about 35% bound to plasma proteins.

The elimination half-life of nizatidine is 1 to 2 hours and is prolonged in renal impairment. Nizatidine is partly metabolised in the liver: nizatidine *N*-2-oxide, nizatidine *S*-oxide, and *N*-2-monodesmethylnizatidine have been identified, the latter having about 60% of the activity of nizatidine.

More than 90% of a dose of nizatidine is excreted in the urine, in part by active tubular secretion, within 12 hours, about 60% as unchanged drug. Less than 6% is excreted in the faeces. Nizatidine is distributed into breast milk.

◊ References.

3. Blum RA, *et al.* Pharmacokinetics and pharmacodynamics of a novel nizatidine controlled-release formulation in healthy subjects. *J Clin Pharmacol* 2003; **43:** 74–83.

Bioavailability. The bioequivalence of 3 oral liquid formulations of nizatidine was investigated relative to a commercially available nizatidine capsule. Of the 3 liquid formulations, one was a commercially available oral syrup (15 mg/mL), and 2 others were extemporaneously prepared, one as a solution in apple juice (1.2 mg/mL) and another as a suspension in an infant formula (*Enfamil; Ross, USA*; 15 mg/mL). Nizatidine in apple juice showed markedly less bioavailability, whereas the other 2 formulations were considered to be bioequivalent to the reference capsule.[1]

1. Abdel-Rahman SM, *et al.* The bioequivalence of nizatidine (Axid) in two extemporaneously and one commercially prepared oral liquid formulations compared with capsule. *J Clin Pharmacol* 2003; **43:** 148–53.

Distribution into breast milk. About 0.1% of an oral dose of nizatidine was secreted in breast milk in a study in lactating women.[1] The milk to serum ratio varied (from 1:1 to 4.9:1) with the time of samples.

1. Obermeyer BD, *et al.* Secretion of nizatidine into human breast milk after single and multiple doses. *Clin Pharmacol Ther* 1990; **47:** 724–30.

Uses and Administration

Nizatidine is a histamine H_2-antagonist with actions and uses similar to those of cimetidine (see p.1719). It is given orally and by intravenous infusion.

In the management of benign **gastric** and **duodenal ulceration** (p.1702) a single daily oral dose of nizatidine 300 mg at night is recommended, which should be given initially for 4 weeks and may be extended to 8 weeks if necessary; alternatively 150 mg may be given twice daily in the morning and evening. Where appropriate a maintenance dose of 150 mg daily may be given at night. In patients who are unsuited to receive oral therapy nizatidine may be given on a short-term basis by continuous intravenous infusion of 10 mg/hour; alternatively 100 mg may be diluted in 50 mL of infusion fluid and be given over 15 minutes, three times daily. The total intravenous dose should not exceed 480 mg daily.

In **gastro-oesophageal reflux disease** (p.1696) an oral dose of 150 to 300 mg twice daily is recommended for up to 12 weeks. In children aged 12 years and older, a dose of 150 mg twice daily may be given for up to 8 weeks.

For the short-term symptomatic relief of **dyspepsia** a dose of 75 mg, repeated if necessary, up to a maximum of 150 mg daily may be taken by mouth for up to 14 days.

Doses of nizatidine should be reduced in patients with renal impairment (see below).

Administration in renal impairment. The dosage of nizatidine should be reduced in patients with renal impairment according to creatinine clearance (CC). Licensed product information recommends the following oral doses in renal impairment:

- CC 20 to 50 mL/minute: doses should be reduced by 50%, *or* where the standard dose would be 150 mg daily, 150 mg may be given on alternate days
- CC less than 20 mL/minute: doses should be reduced by 75%, *or* where the standard dose would be 300 mg daily, 150 mg may be given on alternate days, and where the standard dose would be 150 mg daily, 150 mg may be given every third day

(olsalazine)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Olsalazine Sodium). A yellow, fine, crystalline powder; it exhibits polymorphism. Sparingly soluble in water; soluble in dimethyl sulfoxide; very slightly soluble in methyl alcohol.

Adverse Effects and Precautions

As for Mesalazine, p.1745. The most common adverse effects associated with olsalazine sodium are diarrhoea, arthralgia, and skin rashes. Diarrhoea may be watery in some patients; it may resolve with dosage reduction but can be severe enough to require withdrawal of treatment. Diarrhoea is less likely if the drug is taken after meals. There have been a few reports of blood dyscrasias. If a blood dyscrasia is suspected treatment should be stopped immediately and a blood count performed. Patients or their carers should be told how to recognise signs of haematotoxicity and should be advised to seek immediate medical attention if symptoms such as fever, sore throat, mouth ulcers, bruising, or bleeding develop.

Incidence of adverse effects. In an open study[1] of olsalazine 1 g daily by mouth involving 160 patients with active ulcerative colitis and a history of sulfasalazine intolerance, 103 (64.4%) patients had no adverse effects; 29 patients reported only minor adverse effects: gastrointestinal disturbances in 22 patients, transient skin rash in 3, and headache, increased salivation, cough, and irritability each in one patient. The most common adverse effect was frequent loose stools which affected 25 patients, 20 of whom had to stop treatment. This adverse effect occurred early in treatment, within 10 hours of the first dose in 13 patients. Severe diarrhoea was more frequent in patients with widespread disease, but the incidence of diarrhoea did not correlate with disease severity.

A subsequent study[2] in healthy subjects has shown that olsalazine has a significant inhibitory effect on water and electrolyte absorption in the small intestine, which may account, at least in part, for the induction of diarrhoea. Patients with extensive colitis have reduced colonic absorptive function and may be less able to assimilate the increased colonic inflow volumes.

1. Sandberg-Gertzén H, *et al.* Azodisal sodium in the treatment of ulcerative colitis: a study of tolerance and relapse-prevention properties. *Gastroenterology* 1986; **90:** 1024–30.
2. Raimundo AH, *et al.* Effects of olsalazine and sulphasalazine on jejunal and ileal water and electrolyte absorption in normal human subjects. *Gut* 1991; **32:** 270–4.

Breast feeding. A study[1] involving a 39-year-old woman with Crohn's disease found that olsalazine did not appear to present a clinically significant risk to the breast-fed infant. Olsalazine was undetectable in the breast milk for 48 hours after a single oral 500-mg dose, and although small amounts of the metabolite acetylated 5-aminosalicylic acid were detected in breast milk the infant showed no adverse effects during the 3 weeks afterwards in which the mother continued taking olsalazine.

1. Miller LG, *et al.* Disposition of olsalazine and metabolites in breast milk. *J Clin Pharmacol* 1993; **33:** 703–6.

Effects on the blood. As of July 1995, the UK CSM had received 4 reports of blood dyscrasias associated with olsalazine, none of them fatal.[1] It was recommended that a blood count be performed and the drug stopped immediately if there was suspicion of a dyscrasia. See also under Mesalazine, p.1745.

Effects on the kidneys. A report of nephrotoxicity, characterised by interstitial nephritis, was associated with the use of olsalazine.[1] Symptoms resolved on stopping of the drug. See also under Mesalazine, p.1745.

1. Wilcox GM, *et al.* Nephrotoxicity associated with olsalazine. *Am J Med* 1996; **100:** 238–40.

Interactions

Antineoplastics. For mention of 5-aminosalicylates such as olsalazine inhibiting the metabolism of thiopurine antineoplastics, and increasing their toxicity, see Mercaptopurine, p.744.

Pharmacokinetics

Very little of an oral dose of olsalazine is absorbed via the upper gastrointestinal tract, and almost the entire dose reaches its site of action in the colon intact. It is broken down by the colonic bacterial flora into 2 molecules of 5-aminosalicylic acid (mesalazine). Some mesalazine is absorbed and acetylated (see p.1746) but systemic concentrations of mesalazine and its metabolite are lower than after comparable oral doses of mesalazine, perhaps because there is less release of mesalazine in the small intestine, where absorption is better. Mesalazine concentrations in the colon after a dose of olsalazine are stated to be about 1000 times greater than systemic concentrations.

The small amounts (1 to 2% of the dose or less) of intact olsalazine that are absorbed are excreted mainly in urine; the elimination half-life after an intravenous dose has been calculated at about 1 hour. Some olsalazine is metabolised by sulfate conjugation in the liver: the elimination half-life of the metabolite is reported to be about 7 days.

Uses and Administration

Olsalazine consists of two molecules of mesalazine (p.1745) linked with an azo bond. It is activated in the colon where the active mesalazine is released. It is used as the sodium salt in the management of acute mild ulcerative colitis and for the maintenance of remission (see Inflammatory Bowel Disease, p.1697). The usual initial dose of olsalazine sodium is 1 g by mouth daily in divided doses and this is gradually increased, if necessary, over one week, to a maximum dose of 3 g daily. The usual dose for the maintenance of remission is 500 mg twice daily. Doses should be taken after meals and a single dose should not exceed 1 g. Although not licensed for use in children, the *BNFC* includes a dose for children aged 2 years and over; the adult dose may be given for management of an acute attack of mild ulcerative colitis, and a dose of 250 to 500 mg twice daily may be used for maintenance.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Omeprazole Sodium). A white or almost white, hygroscopic powder. Freely soluble in water and in alcohol; very slightly soluble in dichloromethane; soluble in propylene glycol. The pH of a 2% solution in water is 10.3 to 11.3. Store in airtight containers. Protect from light.

Adverse Effects

Proton pump inhibitors are generally well tolerated, and adverse effects are relatively infrequent. The adverse effects reported most often with omeprazole and other proton pump inhibitors have been headache, diarrhoea, and skin rashes; they have sometimes been severe enough to require stopping treatment. Other effects include pruritus, dizziness, fatigue, constipation, nausea and vomiting, flatulence, abdominal pain, arthralgia and myalgia, urticaria, and dry mouth. Isolated cases of photosensitivity, bullous eruption, erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis have occurred. Hypersensitivity reactions, including fever, bronchospasm, angioedema, and anaphylaxis have been reported. Effects on the CNS include occasional insomnia, somnolence, and vertigo; reversible confusional states, agitation, depression, and hallucinations have occurred in severely ill patients. Raised liver enzymes, and isolated cases of hepatitis, jaundice, hepatic failure, and hepatic encephalopathy, have been reported. Other adverse effects reported rarely include paraesthesia, blurred vision, alopecia, stomatitis, increased sweating, taste disturbances, peripheral oedema, malaise, hyponatraemia, blood disorders (including agranulocytosis, leucopenia, and thrombocytopenia), gynaecomastia, impotence, and interstitial nephritis.

Proton pump inhibitors may increase the risk of gastrointestinal infections because of their acid suppressive effects.

Early toxicological studies identified carcinoid-like tumours of the gastric mucosa in *rats* given very high doses of omeprazole over long periods; this is reviewed in more detail under Gastrointestinal Tumours, below.

Incidence of adverse effects. Prescription-event monitoring for 16 205 patients prescribed omeprazole, 17 329 prescribed lansoprazole, and 11 541 prescribed pantoprazole indicated that adverse events were reported infrequently, with the most common being gastrointestinal disturbances and headache. The incidences of diarrhoea, the most commonly reported event, per 1000 days of exposure, were 0.18 for omeprazole, 0.39 for lansoprazole, and 0.23 for pantoprazole. Despite the inherent biases of such a cohort study, there did seem to be some evidence that lansoprazole might be associated with a somewhat greater risk of diarrhoea, particularly in the elderly.[1]

1. Martin RM, *et al.* The rates of common adverse events reported during treatment with proton pump inhibitors used in general practice in England: cohort studies. *Br J Clin Pharmacol* 2000; **50:** 366–72.

Effects on the blood. There have been rare cases of leucopenia, agranulocytosis, thrombocytopenia, and pancytopenia, with omeprazole and other proton pump inhibitors such as lansoprazole and pantoprazole.[1-3] Auto-immune haemolytic anaemia has also been reported with omeprazole.[4]

4. Butt MI, *et al.* Autoimmune haemolytic anaemia associated with use of omeprazole. *Br J Hosp Med* 2007; **68:** 108.

Effects on the cardiovascular system. Results and preliminary analyses from 2 studies raised concerns about a possible increased risk of myocardial infarction, cardiac failure, and cardiac-related sudden death in patients taking *omeprazole* or *esomeprazole* compared with patients who received surgery for gastro-oesophageal reflux disease.[1,2] However, an FDA safety review found that patients who underwent surgery tended to be younger and less likely to have a history of cardiac problems or cardiac risk factors than those treated with one of the drugs.[2] The FDA concluded that long-term use of these drugs is not likely to be associated with an increased risk of cardiac problems.[3] However, while Health Canada[4] considered that there was no evidence to support such an increased risk with long-term use of esomeprazole they were unable to make such a definitive conclusion for omeprazole.

Effects on the endocrine system. Up to December 1991, WHO had received 30 reports of impotence or gynaecomastia which might have been due to omeprazole;[1] of these reports 15 were of impotence, 13 of gynaecomastia in men, and 2 of breast enlargement in women. The Spanish Pharmacovigilance System reported 24 cases of gynaecomastia in association with use of proton pump inhibitors, including lansoprazole and rabeprazole, between January 1982 and July 2006. In most of the cases, gynaecomastia improved after stopping the drug.[2] For reference to a case-control study showing no statistical link between gynaecomastia and omeprazole, see under Cimetidine, p.1717.

Effects on the eyes. Visual disturbances associated with the use of omeprazole have included 6 cases of irreversible blindness or visual impairment in severely ill patients given the drug intravenously, and 13 cases of visual disturbances associated with oral use.[1] As a result of concern about these effects the availability of intravenous omeprazole was restricted in Germany; however, the consensus appears to be that a causal link has not been established between omeprazole and these ocular effects. Suggestions that visual (and also auditory[2]) impairment could follow drug-induced vasculitis[2-4] appear to be contentious.[1,5-7] A cohort study involving 140 128 patients receiving antisecretory therapy, 33 988 of whom received omeprazole, found no evidence that any of the drugs used was associated with a major increase in risk of vascular or inflammatory disorders of the eye;[8] however, the statistical power of this study was not high.[9]

Effects on the kidneys. Acute interstitial nephritis developed in 2 elderly patients given *omeprazole* for the treatment of gastro-oesophageal reflux disease.[1,2] When the drug was stopped, renal function improved rapidly in 1 patient, but recurred upon rechallenge,[1] while in the other renal function remained severely affected for several months.[2] It was postulated that this adverse effect might have an allergic mechanism.[2] In these cases interstitial nephritis was associated with rash and eosinophilia; however, a further 2 cases of acute interstitial nephritis associated with omeprazole therapy in elderly patients[3,4] did not exhibit these symptoms. In another report, associated rash without eosinophiluria was seen.[5]

The Australian Adverse Drug Reactions Advisory Committee (ADRAC)[6] stated in April 2003 that it had received 18 biopsy-confirmed reports of interstitial nephritis associated with the use of omeprazole. These patients had presented with symptoms including weight loss, malaise, fever, and nausea; polyuria and polydipsia occurred in one case. Most patients had raised plasma-urea and/or plasma-creatinine concentrations. ADRAC had also received 2 reports of interstitial nephritis associated with *rabeprazole*.[6] A case report (in March 2005) of 2 cases of interstitial nephritis associated with the omeprazole isomer *esomeprazole* noted that, by October 2004, the manufacturer had reported being aware of some 15 cases worldwide possibly associated with the drug, and at least 200 associated with omeprazole.[7] Acute interstitial nephritis has also been associated with the use of *pantoprazole* in an elderly woman for the treatment of gastro-oesophageal reflux disease.[8]

Effects on the liver. Raised liver enzymes have occurred with omeprazole and other proton pump inhibitors, and there have been isolated cases of hepatotoxicity. For a study suggesting a relatively low incidence of acute liver injury in patients receiving omeprazole see Cimetidine, p.1717.

References.

Effects on the musculoskeletal system. Progressive muscular weakness suggestive of *myopathy* developed in a 78-year-old patient given oral omeprazole.[1] After 4 weeks of treatment the patient required assistance in walking and rising from squatting. Weakness resolved on withdrawal of the drug, but returned on rechallenge. Acute myopathy has also been reported after a single infusion of omeprazole.[2] Analysis of the WHO adverse drug reaction database in March 2005 revealed 868 reports associating proton pump inhibitors with *myalgia*, of which 292 cases had symptoms indicative of muscle disorders including *polymyositis* and *rhabdomyolysis*.[3] Reports implicated omeprazole, pantoprazole, lansoprazole, esomeprazole, and rabeprazole, and it was suggested that myopathy was probably a class effect. The mechanism might involve induction of auto-immune antibodies.

A report of 5 cases of *arthralgia*, sometimes associated with swelling of the affected joints, in patients receiving omeprazole,[4] also noted that some reported cases of omeprazole-associated headache were accompanied by arthralgia or myalgia. In another case[5] arthralgia in a patient with a hereditary myopathy receiving omeprazole appeared to represent one aspect of a drug-induced *lupus* syndrome, being accompanied by malaise, fever, Raynaud's phenomenon, raised antinuclear antibody titres, and anticardiolipin and antihistone antibodies. Symptoms resolved on withdrawal of the drug.

A case of *eosinophilia* and myalgia related to lansoprazole treatment has been reported.[6]

There has also been a report of 2 cases of acute *gout* associated with omeprazole;[7] in one patient symptoms, which resolved on withdrawal, recurred on rechallenge. However, case control studies have failed to show an increased risk of polyarthralgia[8] or gout[9] associated with omeprazole use.

A large case-control study found an increased risk of *hip fracture* with more than 1 year of proton pump inhibitor therapy, especially with those patients on high doses.[10] The authors theorised that calcium malabsorption secondary to acid suppression may explain this association. While further studies were deemed necessary to confirm these findings, they suggested that calcium intake be emphasised in elderly patients taking proton pump inhibitors.

Effects on the nervous system. Ataxia has been reported in a patient given omeprazole;[1] symptoms resolved on stopping the drug. A patient given rabeprazole developed marked anxiety with panic attacks, episodic night terrors, confusion, and attention deficit.[2] Her symptoms resolved 2 days after stopping therapy. A month later, she was given esomeprazole, with no adverse neuropsychiatric symptoms. The authors hypothesised that rabeprazole use had resulted in significantly greater plasma gastrin concentrations than esomeprazole, which may have affected gastrin receptors in the brain.

Effects on the respiratory system. An intractable, dry, non-productive cough started abruptly in a 42-year-old non-smoker given omeprazole for gastro-oesophageal reflux disease (GORD). The cough was initially thought to be related to the GORD and treatment was continued for 4 months, without any cessation in the cough. Omeprazole was stopped, and the cough ceased abruptly, with no recurrence during a 2-year follow-up.[1]

Effects on the skin. An extensive blistering erythematous skin rash in an elderly woman given omeprazole[1] was characteristic of acute disseminated epidermal necrosis. The UK CSM had received 223 reports of cutaneous reactions to omeprazole up to August 1992, including 6 of erythema multiforme, but none of this severity. Other severe reactions that have subsequently been reported include a toxic bullous skin reaction,[2] exfoliative dermatitis,[3,4] erythema multiforme,[4] toxic erythema,[4] and dermatomyositis.[5] One patient developed exfoliative dermatitis with both omeprazole and lansoprazole.[4] The authors of this report noted that by January 1998 a total of 1296 skin reactions to omeprazole, 500 to lansoprazole, and 44 to pantoprazole, had been reported to the CSM. Most were non-specific rashes, pruritus, urticaria, erythematous rashes, and photosensitive eruptions. A lichenoid reaction that occurred in a patient taking omeprazole cleared after ceasing the drug, but recurred during treatment with both lansoprazole and pantoprazole.[6] Proton pump inhibitors, including esomeprazole, have been reported to worsen vitiligo.[7]

For a report of urticaria and angioedema possibly associated with the formulation of omeprazole see Hypersensitivity, below. For the association of rash with interstitial nephritis, see Effects on the Kidneys, above.

Fever. Fever, associated with severe myalgia and headache, was seen in a 64-year-old man on 2 occasions, several hours after taking a dose of esomeprazole.[1] Although it was suggested[2] that the patient's hyperpyrexia was due to a hypersensitivity reaction, the authors argued[3] that esomeprazole may have interfered with the hypothalamic regulatory centres of body temperature.[1,3]

Gastrointestinal tumours. Early toxicological studies in *rats* given high doses of omeprazole over 2 years identified carcinoid tumours of the gastric mucosa associated with complete block of gastric acid secretion leading to *hypergastrinaemia and hyperplasia of enterochromaffin-like cells*.[1] This has been the main issue concerning the safety of omeprazole and other proton pump inhibitors and initially led to restrictions in use and duration of treatment. A drug manufacturer, *Glaxo*, developed a new test to detect genotoxicity of antisecretory drugs which indicated that a genotoxic effect of omeprazole could not be discounted.[2] This study was heavily criticised; more established genotoxicity tests have been reported to be negative for omeprazole,[3-5] and other groups have not been able to replicate the findings with the new test.[6] The lowest doses at which *Glaxo* found[2] a genotoxic effect of omeprazole were 10 to 20 mg/kg and the clinical significance of their results was questioned.[3] Long-term studies of omeprazole in patients with Zollinger-Ellison syndrome have found no increase in fasting serum-gastrin concentrations and no evidence of gastric carcinoid tumours.[7,8] For mention of the risk of proton pump inhibitors delaying the diagnosis of gastric carcinoma, see under Precautions, below. Hypergastrinaemia can occur with both short- and long-term omeprazole therapy,[9] and may be higher in patients with *Helicobacter pylori* infection.[10,11] Patients who had *H. pylori* eradicated before long-term omeprazole treatment had lower gastrin concentrations than those who did not, since *H. pylori* eradication reduced the pretreatment gastrin concentrations.[12]

H. pylori is also a cause of *atrophic gastritis*, another risk factor for stomach cancer, and one study found that omeprazole increased the risk of atrophic gastritis in *H. pylori*-positive patients with gastro-oesophageal reflux disease.[13] However, the results of this study require confirmation since it was nonrandomised and retrospective. Nevertheless, some have suggested that it may be appropriate to eradicate *H. pylori* before long-term treatment with a proton pump inhibitor.[12,13] Conversely, there is some evidence that *H. pylori* may be protective in gastro-oesophageal reflux disease.[14]

There has been a report of *gastric polyps* developing in 3 of 8 patients after receiving omeprazole 20 or 40 mg daily for one year.[15] In a subsequent report it was noted that these omeprazole-induced fundic gland polyps had remained asymptomatic and non-malignant for up to five years after their onset.[16]

Further long-term studies of omeprazole may be needed before a realistic risk assessment can be made.

Hypersensitivity. Cases of anaphylactic reactions after treatment with omeprazole, lansoprazole, and pantoprazole, have been reported in the literature and to WHO.[1]

Urticaria, facial angioedema, and bronchospasm in a patient given omeprazole capsules did not recur when the patient was given omeprazole granules and the reaction might have been precipitated by the ingredients of the capsule shell.[2]

Infection. Oesophageal candidiasis occurred in 2 elderly patients given omeprazole but was successfully treated with antifungal therapy. It was postulated that gastric acid secretion and a degree of physiological reflux of acid into the oesophagus might normally play a protective role in preventing candidal infection.[1] A case-control study found that yeast was recovered more often from peritoneal cultures in those patients with community-acquired peritonitis who had previously used proton pump inhibitors, although the trend was non-significant.[2] The profound reduction in acid secretion produced by omeprazole may also predispose to gastrointestinal infection;[3] there is some evidence for an increased risk of community-acquired pneumonia,[3] and campylobacter infection,[4] as well as a report of recurrent salmonellal infection.[5] Data from cohort and case-control studies[6-8] suggest that gastric acid suppression by proton pump inhibitors may also be a risk factor for *Clostridium difficile*-associated diarrhoea. For evidence of an increased risk of pneumonia in primary-care patients prescribed proton pump inhibitors see p.1717.

Lupus syndrome. For a report of drug-induced lupus syndrome associated with omeprazole therapy, see Effects on the Musculoskeletal System, above.

Malabsorption. Omeprazole has been reported to result in a substantial reduction in *cyanocobalamin* (vitamin B_{12}) absorption,[1] probably related to the increase in gastric pH, and indicating a potential risk of vitamin deficiency with long-term therapy.[2] UK licensed product information recommends that severely ill children, who may have borderline body stores of cyanocobalamin, should have serum vitamin B_{12} concentrations monitored if they require long-term therapy. Omeprazole has also been reported to impair the bioavailability of dietary *vitamin C*.[3] *Fat* malabsorption, secondary to increased deconjugation of bile acids caused by bacterial overgrowth in the jejunum, has also been reported with omeprazole treatment.[4] For the suggestion that proton pump inhibitors can cause *calcium* malabsorption, see Effects on the Musculoskeletal System, above.

Precautions

Before giving omeprazole or other proton pump inhibitors to patients with gastric ulcers the possibility of malignancy should be excluded since these drugs may mask symptoms and delay diagnosis. Omeprazole and other proton pump inhibitors should be used with caution in hepatic impairment and dose adjustment may be required.

Gastric carcinoma. Proton pump inhibitors relieve dyspeptic symptoms associated with gastric carcinoma and can therefore delay its diagnosis. In addition, there is some evidence that they may also endoscopically 'heal' early gastric carcinoma so that the diagnosis is missed.[1] Consequently, some commentators recommend that proton pump inhibitors should not be prescribed for symptom control before endoscopy in patients at risk for gastric carcinoma.[2]

1. Wayman J, *et al.* The response of early gastric cancer to proton-pump inhibitors. *N Engl J Med* 1998; **338:** 1924–5.
2. Griffin SM, Raimes SA. Proton pump inhibitors may mask early gastric cancer: dyspeptic patients over 45 should undergo endoscopy before these drugs are started. *BMJ* 1998; **317:** 1606–7.

Helicobacter infection. Treatment with proton pump inhibitors may cause false-negative results in the urea breath test for *Helicobacter pylori* infection. In one study in patients with *H. pylori* infection, 4 weeks of treatment with lansoprazole 30 mg daily caused 33% of patients to have negative urea breath tests.[1] The breath test became positive again in all patients within 2 weeks of stopping lansoprazole therapy. In a similar study, 52% of patients had negative urea breath tests for *H. pylori* while receiving omeprazole 20 mg daily, and the breath test became positive again in all patients within 2 to 6 days of stopping treatment.[2] The manufacturers of the urea breath test for *H. pylori* recommend that it should not be performed for at least 2 weeks after stopping treatment with an antisecretory drug.

For a discussion of the link between proton pump inhibitors, *H. pylori*, and gastritis, see under Gastrointestinal Tumours above.

2. Connor SJ, *et al.* The effect of dosing with omeprazole on the accuracy of the C-urea breath test in Helicobacter pylori-infected subjects. *Aliment Pharmacol Ther* 1999; **13:** 1287–93.

Hepatic impairment. In patients with cirrhosis an increase in omeprazole bioavailability, and elimination half-life has been reported.[1] For dosage adjustment in hepatic impairment see Administration in Hepatic Impairment, below.

1. Andersson T, *et al.* Pharmacokinetics of [C]omeprazole in patients with liver cirrhosis. *Clin Pharmacokinet* 1993; **24:** 71–8.

Pregnancy. Proton pump inhibitors are not generally licensed for use during pregnancy (although the UK has licensed omeprazole for such use), but a meta-analysis[1] of 5 studies of exposure to proton pump inhibitors during the first trimester, involving 593 exposed infants, found the relative risk of major abnormalities associated with such exposure to be only 1.18, with a 95% confidence interval ranging from 0.72 to 1.94. Meta-analysis of exposures to omeprazole (from 4 studies only) gave a relative risk of 1.05 (95% confidence interval 0.59 to 1.85). It was concluded that exposure to proton pump inhibitors, and omeprazole in particular, did not pose an important teratogenic risk. A retrospective epidemiological study of data from the Swedish Medical Birth Registry, which identified 955 exposed infants, also found no evidence of significant risk after exposure to omeprazole during pregnancy.[2]

Interactions

Omeprazole and other proton pump inhibitors are metabolised by the cytochrome P450 system, primarily by isoenzyme CYP2C19, and to a smaller extent by CYP3A4. Inhibitors or inducers of these isoenzymes may affect exposure to omeprazole and other proton pump inhibitors. In turn, proton pump inhibitors may alter the metabolism of some drugs metabolised by these enzymes. Omeprazole may prolong the elimination of diazepam, phenytoin, and warfarin (but see below). Omeprazole and other proton pump inhibitors can reduce the absorption of drugs such as dasatinib, ketoconazole, and itraconazole, whose absorption is dependent on an acid gastric pH. With voriconazole, the plasma concentration of both drugs may be increased (for further information, see below). Other proton pump inhibitors may be similarly affected by voriconazole. Omeprazole and other proton pump inhibitors should not be used with atazanavir, as it substantially reduces exposure to atazanavir.For further information on interactions between proton pump inhibitors and HIV-protease inhibitors, see Table 1, under Antivirals, p.917.

◊ Omeprazole is metabolised primarily by the cytochrome P450 isoenzyme CYP2C19 (see Metabolism, below) and therefore may interact with diazepam (see under Gastrointestinal Drugs, p.991). Some metabolism of phenytoin (see p.500), tolbutamide, and the *R*-enantiomer of warfarin (see p.1430) also takes place by CYP2C19, but the effects seen have been minor.[1] Although some induction of CYP1A2, which metabolises caffeine and theophylline (p.1145), has been reported this does not appear to be clinically significant.[2] While some consider the effect of omeprazole on CYP3A4 activity to be insignificant,[3] others have noted an increasing body of evidence that competitive inhibition of intestinal CYP3A4 by omeprazole may affect the first-pass metabolism of a number of drugs.[4] A review concluded that, while omeprazole and possibly esomeprazole have a considerable potential for drug interactions, lansoprazole, pantoprazole and rabeprazole are associated with a lower incidence of drug interactions.[4]

For a study *in vitro* suggesting that omeprazole affected CYP3A4 metabolism of tacrolimus, see under Interactions of Tacrolimus, p.1845. For more on the effect of proton pump inhibitors on tacrolimus, see Gastrointestinal Drugs, p.1845.

For reference to the possibility of enhanced digoxin absorption with omeprazole, see p.1262. For a study suggesting that omeprazole reduces the absorption of cyanocobalamin and vitamin C, see Malabsorption, above, and for its effect on calcium absorption see p.1714. For reference to possible interactions between methotrexate and omeprazole, see p.748.

Clarithromycin. Studies in healthy subjects have indicated that use of omeprazole with clarithromycin results in an approximate 30% increase in peak plasma concentrations of omeprazole, and an increase in its mean half-life from 1.2 to 1.6 hours.[1] At the same time, plasma concentrations of clarithromycin were also modestly increased, as were local concentrations in gastric tissue and mucus.[1] Clarithromycin inhibits[2] the metabolism of omeprazole mediated by the cytochrome P450 isoenzyme CYP3A4. The interaction may contribute to the benefits of combined therapy for *Helicobacter pylori* infection.

2. Furuta T, *et al.* Effects of clarithromycin on the metabolism of omeprazole in relation to CYP2C19 genotype status in humans. *Clin Pharmacol Ther* 1999; **66:** 265–74.

Fluvoxamine. Omeprazole and other proton pump inhibitors are metabolised mainly by cytochrome P450 isoenzyme CYP2C19, which shows genetically determined polymorphism, yielding extensive metabolisers and poor metabolisers. Fluvoxamine increased exposure to omeprazole, lansoprazole, and rabeprazole in patients who were extensive metabolisers, but had no effect on pharmacokinetic parameters in poor metabolisers.[1-3] Dose reductions may need to be considered in patients treated with fluvoxamine and proton pump inhibitors.

3. Uno T, *et al.* Different effects of fluvoxamine on rabeprazole pharmacokinetics in relation to CYP2C19 genotype status. *Br J Clin Pharmacol* 2006; **61:** 309–14.

Voriconazole. When omeprazole is given with voriconazole, exposure to both drugs is increased. UK licensed product information for omeprazole states that a dose adjustment of omeprazole is not routinely indicated, unless patients have severe hepatic impairment and long-term therapy is indicated. However, UK licensed product information for voriconazole states that, while no dosage adjustment is considered necessary for voriconazole, when patients already receiving omeprazole are started on voriconazole, the dose of omeprazole should be halved. Other proton pump inhibitors may be similarly affected by voriconazole.

Pharmacokinetics

Omeprazole is rapidly but variably absorbed after oral doses. Absorption is not significantly affected by food. Omeprazole is acid-labile and the pharmacokinetics of the various formulations developed to improve oral bioavailability may vary. The absorption of omeprazole also appears to be dose-dependent; increasing the dosage above 40 mg has been reported to increase the plasma concentrations in a non-linear fashion because of saturable first-pass hepatic metabolism. In addition, bioavailability is higher after long-term use.

Bioavailability of omeprazole may be increased in elderly patients, in some ethnic groups such as Chinese, and in patients with hepatic impairment, but is not markedly affected in patients with renal impairment.

On absorption, omeprazole is almost completely metabolised in the liver, primarily by the cytochrome P450 isoenzyme CYP2C19 to form hydroxy-omeprazole, and to a small extent by CYP3A4 to form omeprazole sulfone. The metabolites are inactive, and are excreted mostly in the urine and to a lesser extent in bile. The elimination half-life from plasma is reported to be about 0.5 to 3 hours. Omeprazole is about 95% bound to plasma proteins.

Metabolism. The major enzyme involved in omeprazole metabolism is cytochrome P450 isoenzyme CYP2C19. This enzyme is polymorphically expressed, and individuals who are deficient in the enzyme are poor metabolisers of omeprazole. This occurs in about 3% of Caucasians and 15% of Chinese, Japanese, and Koreans. These individuals have markedly higher plasma concentrations of omeprazole, and they may require dosage adjustment. Some omeprazole is metabolised by CYP3A4, and some by CYP2D6 to form desmethylomeprazole.

Uses and Administration

Omeprazole is a proton pump inhibitor. It suppresses secretion of gastric acid by inhibiting the enzyme system of hydrogen/potassium adenosine triphosphatase (H^+/K^+ ATPase), the 'proton pump' of the gastric parietal cell. It is used in conditions where inhibition of gastric acid secretion may be beneficial, including aspiration syndromes (p.1693), dyspepsia (below), gastro-oesophageal reflux disease (p.1696), peptic ulcer disease (p.1702), and the Zollinger-Ellison syndrome (p.1704).

Esomeprazole (p.1729), an isomer of omeprazole, is also used.

Omeprazole may be given orally as the base or magnesium salt, or intravenously as the sodium salt. Doses are expressed in terms of the base. Omeprazole magnesium 10.32 mg and omeprazole sodium 10.64 mg are each equivalent to about 10 mg of omeprazole.

For the relief of acid-related **dyspepsia** omeprazole is given in usual doses of 10 or 20 mg daily orally for 2 to 4 weeks.

The usual dose for the treatment of **gastro-oesophageal reflux disease** is 20 mg orally once daily for 4 weeks, followed by a further 4 to 8 weeks if not fully healed. In refractory oesophagitis, a dose of 40 mg daily may be used. Maintenance therapy after healing of oesophagitis is 20 mg once daily, and for acid reflux is 10 mg daily. For dosage in children see below.

In the management of **peptic ulcer disease** a single daily dose of 20 mg orally, or 40 mg in severe cases, is given. Treatment is continued for 4 weeks for duodenal ulcer and 8 weeks for gastric ulcer. Where appropriate, a dose of 10 to 20 mg once daily may be given for maintenance.

For the eradication of *Helicobacter pylori* in peptic ulceration omeprazole may be combined with antibacterials in dual or triple therapy. Effective **triple therapy** regimens include omeprazole 20 mg twice daily or 40 mg once daily combined with: amoxicillin 500 mg and metronidazole 400 mg, both three times daily; clarithromycin 250 mg and metronidazole 400 mg (or tinidazole 500 mg) both twice daily; or with amoxicillin 1 g and clarithromycin 500 mg, both twice daily. These regimens are given for 1 week. **Dual therapy** regimens such as omeprazole 20 mg twice daily or 40 mg daily with either amoxicillin 750 mg to 1 g twice daily or clarithromycin 500 mg three times daily, are less effective and must be given for 2 weeks. Omeprazole alone may be continued for a further 4 to 8 weeks.

Doses of 20 mg daily orally are used in the treatment of **NSAID-associated ulceration**; a dose of 20 mg daily may also be used for prophylaxis in patients with a history of gastroduodenal lesions who require continued NSAID treatment.

The initial recommended dosage for patients with the **Zollinger-Ellison syndrome** is 60 mg orally once daily, adjusted as required. The majority of patients are effectively controlled by doses in the range 20 to 120 mg daily, but doses up to 120 mg three times daily have been used. Daily doses above 80 mg should be given as divided doses (usually 2).

Omeprazole is also used for the prophylaxis of **acid aspiration** during general anaesthesia, in a dose of 40 mg the evening before surgery and a further 40 mg two to six hours before the procedure.

The dose of omeprazole may need to be reduced in patients with hepatic impairment (see below).

PARENTERAL DOSAGE.

In patients who are unsuited to receive oral therapy omeprazole sodium may be given on a short-term basis by intravenous infusion, in a usual dose equivalent to 40 mg of the base over a period of 20 to 30 minutes in 100 mL of sodium chloride 0.9% or glucose 5%. It may also be given by slow intravenous injection. Higher intravenous doses have been given to patients with Zollinger-Ellison syndrome.

Administration. Omeprazole is given orally as tablets or capsules containing enteric-coated pellets or granules, which should be swallowed whole and not crushed or chewed. In children or patients with swallowing difficulties, UK licensed product information (*Losec; AstraZeneca*) states that the tablet be dispersed in water and then mixed with fruit juice (with a pH less than 5) or yogurt before swallowing without chewing. Similarly the contents of the capsules can be mixed with water, fruit juice (with a pH less than 5) or yogurt and swallowed without chewing. A mixture of omeprazole and sodium bicarbonate as a powder for oral suspension is available in some countries.

Administration in children. Licensed UK *oral* doses of omeprazole for the treatment of gastro-oesophageal reflux disease in children 1 year of age and over are determined by body-weight as follows:

- 10 to 20 kg: 10 mg once daily
- over 20 kg: 20 mg once daily

These doses may be doubled if necessary. Treatment may be given for 4 to 12 weeks.

For gastro-oesophageal reflux disease, acid-related dyspepsia, treatment of duodenal and benign gastric ulcers including NSAID-associated ulceration, prophylaxis of acid aspiration, and Zollinger-Ellison syndrome, the *BNFC* recommends an oral dose of 700 micrograms/kg once daily in neonates and children 1 month to 2 years of age. If needed, doses may be increased in neonates after 7 to 14 days, to 1.4 mg/kg once daily; some neonates may require up to 2.8 mg/kg once daily. Children's doses may be increased up to 3 mg/kg (to a maximum of 20 mg) once daily.

For *parenteral* dosage in children the *BNFC* recommends an intravenous dose of 500 micrograms/kg (to a maximum of 20 mg) once daily in children aged 1 month to 12 years; this may be increased to 2 mg/kg (to a maximum of 40 mg) once daily if needed.

For the eradication of *Helicobacter pylori* in children, the *BNFC* recommends an oral dose of omeprazole 1 to 2 mg/kg (to a maximum dose of 40 mg) once daily. This is given with antibacterial therapy under specialist supervision.

For administration of the tablets or capsules to children, see Administration, above.

Administration in hepatic impairment. Bioavailability and half-life of omeprazole can increase in patients with hepatic impairment. UK licensed product information recommends that a maximum daily oral dose of 20 mg be used in these patients; a daily intravenous dose of 10 to 20 mg is considered sufficient.

Asthma. Gastro-oesophageal reflux has been suggested as a potential exacerbating factor for asthma (p.1108), and acid suppressive therapy with omeprazole has been reported to reduce asthma symptoms in some[1] but not other[2] studies. A meta-analysis of acid suppressive therapy concluded it was not effective in improving asthma symptoms in most patients with gastro-oesophageal reflux,[3] and the link between reflux and asthma symptoms has been disputed.[4]

Dyspepsia. Although earlier UK guidelines on the use of proton pump inhibitors in dyspepsia (p.1695) suggested that they should not be used routinely in non-ulcer dyspepsia,[1] subsequent guidelines on its general management in both the UK[2] and the US[3] consider that a 1-month empirical trial in patients aged under 55 without symptoms suggestive of more serious disease is a valid first-line treatment.

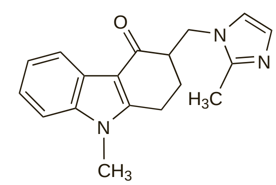
Ondansetron *(BAN, rINN)*

GR-38032; Ondansétron; Ondansetrón; Ondansetroni; Ondansetronum. (±)-1,2,3,9-Tetrahydro-9-methyl-3-(2-methylimidazol-1-ylmethyl)-carbazol-4(9*H*)-one.

Ондансетрон

$C_{18}H_{19}N_3O$ = 293.4.
CAS — 99614-02-5; 116002-70-1.
ATC — A04AA01.
ATC Vet — QA04AA01.



Pharmacopoeias. In *US.*

USP 31 (Ondansetron). A white to off-white powder. Sparingly soluble in water; very soluble in acid solutions. Store in airtight containers. Protect from light.

Ondansetron Hydrochloride *(BANM, USAN, rINNM)*

GR-38032F; Hidrocloruro de ondansetrón; Ondansétron, chlorhydrate d'; Ondansetron hydrochlorid; Ondansetronhydroklorid; Ondansetroni hydrochloridum; Ondansetronihydrokloridi; Ondansetrono hidrochloridas; Ondanstroni Hydrochloridum; Ondánszetronhidroklorid; SN-307.

Ондансетрона Гидрохлорид

$C_{18}H_{19}N_3O,HCl,2H_2O$ = 365.9.
CAS — 99614-01-4; 103639-04-9.
ATC — A04AA01.
ATC Vet — QA04AA01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Ondansetron Hydrochloride Dihydrate). A white or almost white powder. Sparingly soluble in water and in alcohol; slightly soluble in dichloromethane; soluble in methyl alcohol. Protect from light.

USP 31 (Ondansetron Hydrochloride). A white to off-white powder. Sparingly soluble in water and in alcohol; very slightly soluble in acetone, in chloroform, and in ethyl acetate; slightly soluble in dichloromethane and in isopropyl alcohol; soluble in methyl alcohol. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°. Protect from light.

Incompatibility. Ondansetron hydrochloride and dexamethasone sodium phosphate were not compatible when high concentrations were combined in polypropylene syringes.[1] Lower concentrations (up to 640 micrograms/mL of ondansetron and 400 micrograms/mL of dexamethasone phosphate) were stable in 50 mL containers of infusion fluid for 30 days under refrigeration. Compatibility has been reported for 24 hours in plastic syringes at 4° or 23° with a variety of other drugs,[2] and with several antineoplastics (cytarabine, dacarbazine, doxorubicin, etoposide, or methotrexate) in PVC infusion bags for 48 hours at room temperature.[3]

3. Stewart JT, *et al.* Stability of ondansetron hydrochloride and five antineoplastic medications. *Am J Health-Syst Pharm* 1996; **53:** 1297–1300.

Adverse Effects and Precautions

Ondansetron and other 5-HT_3 antagonists may cause headache, a sensation of flushing or warmth, hiccups, and constipation. A transient rise in liver enzymes has occasionally occurred. There have been rare reports of immediate hypersensitivity reactions, including anaphylaxis. Chest pain, arrhythmias, hypotension, tachycardia, and bradycardia have been reported rarely. Dizziness and transient visual disturbances such as blurred vision (or very rarely, transient blindness) have been reported during rapid intravenous injection. Transient ECG changes including QT interval prolongation have occurred very rarely, mainly with intravenous ondansetron. Seizures and movement disorders, including extrapyramidal reactions such as dystonia, dyskinesia, and oculogyric crisis have been reported. Rashes and urticaria have also occurred. Injection site reactions may develop, and local burning sensations are common after insertion of suppositories.

5-HT_3 antagonists should generally not be used in patients who have had a hypersensitivity reaction to a member of this drug class. They should be used with care in patients with signs of subacute intestinal obstruction or ileus. Ondansetron should be given in reduced doses to patients with moderate to severe hepatic impairment.

Effects on the cardiovascular system. Chest pain and/or cardiac arrhythmias that might have been associated with ondansetron were reported[1] in 4 patients, 2 of whom died. In 3 subsequent patients who developed severe chest or anginal pain, treatment with ondansetron was stopped.

The manufacturers (*Glaxo*) had at that time no evidence of a causal relationship between ondansetron and episodes of chest pain and cardiac abnormalities.[2] Giving ondansetron or granisetron intravenously produced no clinically important cardiovascular changes in a study in 12 healthy subjects.[3] Since then, however, myocardial ischaemia has been reported with both ondansetron[4] and dolasetron;[5] in the latter case this led to an acute myocardial infarction. Supraventricular tachycardia reported with dolasetron was attributed to an interaction with sevoflurane.[6] Another study in healthy subjects found that dolasetron mainly altered ECG parameters indicative of ventricular depolarisation, whereas ondansetron affected mainly ventricular repolarisation.[7] However, ECG changes were transient and asymptomatic. Studies of high-dose intravenous granisetron[8-10] found no significant adverse effects on pulse, blood pressure, or ECG measurements. A review[11] of the electrocardiographic and cardiovascular effects of the 5-HT_3 antagonists concluded that although this class of drugs may cause small, transient ECG changes, the clinical benefits of the drugs outweighed the small theoretical risk of any clinically significant cardiovascular events. Nonetheless, the use of dolasetron in children has been contra-indicated in the UK (see Uses and Administration, p.1726).

Effects on the eyes. Blurring followed by transient loss of vision has been reported after rapid intravenous injection of ondansetron.[1] Oculogyric crisis may occur as part of extrapyramidal reactions seen with ondansetron, see Effects on the Nervous System, below.

1. Cherian A, Maguire M. Transient blindness following intravenous ondansetron. *Anaesthesia* 2005; **60:** 938–9.

Effects on the liver. Although disturbances in liver enzyme values have been reported in patients given ondansetron, more severe symptoms of liver disorder appear to be very rare; however, there is a report of severe jaundice associated with ondansetron as an antiemetic for chemotherapy.[1] Symptoms did not recur when the patient received granisetron.

1. Verrill M, Judson I. Jaundice with ondansetron. *Lancet* 1994; **344:** 190–1.

Effects on the nervous system. Tonic-clonic movements and frothing at the mouth occurred in a patient 90 minutes after an infusion of ondansetron;[1] the patient responded to diazepam intravenously. The manufacturers had seen 10 patients who developed *seizures* during initial clinical studies, but considered that, unlike this case, all these patients had predisposing factors. Hypotension and generalised tonic-clonic seizures were reported in a patient with metastatic breast cancer given ondansetron as an intravenous bolus.[2] Although seizures might have been due to brain metastases, the authors concluded that ondansetron had been the likely cause, since the patient experienced no further problems when antiemetic therapy was changed to metoclopramide. *Extrapyramidal reactions* in patients given ondansetron as part of a chemotherapy regimen[3,4] and for postoperative nausea and vomiting[5-7] have also been reported. In one case,[7] transient multifocal encephalopathy developed. Clinical manifestations such as clonus, oculogyric crisis, and oromandibular and limb dystonia resembled those of structural brain injury, and response to diphenhydramine was poor; despite this, the patient made a full neurological recovery over the course of 12 hours.

Hypersensitivity. Anaphylactoid reactions have been reported in patients given ondansetron injections. The FDA stated in October 1993 that it had received 24 reports of such reactions,[1] mostly occurring after the first ondansetron dose of the second or third chemotherapy cycle, and characterised by urticaria, angioedema, hypotension, bronchospasm, and dyspnoea. Similar effects have been reported in a patient with no prior exposure to ondansetron.[2]

Cross-sensitivity between 5-HT_3 antagonists has been reported;[3] 2 patients who had had a mild hypersensitivity reaction to one 5-HT_3 antagonist developed a more severe reaction after exposure to another. In the first case severe acute asthma, cyanosis, and loss of consciousness developed after ondansetron in a patient who had previously experienced an asthmatic reaction after tropisetron. The second patient had developed pruritus after a tropisetron injection and urticaria after ondansetron, and subsequently developed anaphylactic shock 5 minutes after a further dose of tropisetron. It was recommended that another 5-HT_3 antagonist should not be given as a replacement to patients who developed a hypersensitivity reaction to a drug of this class.

Interactions

Ondansetron does not appear to induce or inhibit the cytochrome P450 isoenzyme system, but it is itself metabolised by multiple hepatic isoenzymes, including CYP3A4, CYP2D6, and CYP1A2. US licensed product information states that inducers or inhibitors of these isoenzymes may change the clearance and half-life of ondansetron, but that on the basis of available data, no dose adjustments are recommended. UK licensed product information states that enzyme inhibition of one isoenzyme is usually compensated for by other enzymes and should result in little or no significant change in overall ondansetron clearance or dose requirement. Potent inducers of CYP3A4, such as phenytoin, carbamazepine, and rifampicin, have been reported to increase ondansetron clearance and reduce ondansetron plasma concentrations.

Because of the reports of transient ECG changes in some patients taking 5-HT_3 antagonists (see above), there is a theoretical need for caution if given with other drugs that prolong QT-interval; however, clinical evidence of a significant interaction seems to be mostly lacking.

Analgesics. For evidence of reduced analgesic efficacy of *tramadol* in patients also given 5-HT_3-receptor antagonists, such as ondansetron, see p.131.

Antibacterials. *Rifampicin* pretreatment reduced the area under the plasma concentration-time curve of oral ondansetron by 65% and of intravenous ondansetron by 48% in healthy subjects.[1] Use of rifampicin, or other potent inducers of cytochrome P450 isoenzyme CYP3A4, with ondansetron may reduce antiemetic efficacy.

1. Villikka K, *et al.* The effect of rifampin on the pharmacokinetics of oral and intravenous ondansetron. *Clin Pharmacol Ther* 1999; **65:** 377–81.

Antineoplastics. For mention of retrospective studies suggesting a change of pharmacokinetic parameters of high-dose cyclophosphamide and cisplatin when given with an ondansetron-containing antiemetic regimen, see Gastrointestinal Drugs, p.703.

Pharmacokinetics

Peak plasma concentrations of ondansetron occur about 1.5 hours after an oral dose of 8 mg, and about 6 hours after a rectal dose. The absolute bioavailability is about 60%, mainly because of hepatic first-pass metabolism. In elderly subjects, bioavailability may be somewhat higher (65%) and clearance lower, presumably due to reduced hepatic first-pass metabolism.

Ondansetron is extensively distributed in the body; about 70 to 75% of the drug in plasma is protein bound. It is metabolised in the liver through multiple enzymatic pathways; ondansetron is a substrate for cytochrome P450 isoenzymes, primarily CYP3A4, but also CYP1A2 and CYP2D6. Less than 5% of a dose is excreted unchanged in the urine.

The terminal elimination half-life is about 3 hours after oral or parenteral doses, and about 6 hours after rectal use. The terminal elimination half-life is prolonged to about 5 hours in the elderly and in those with renal impairment. These differences are not considered sufficient to warrant dosage adjustment. However, in patients with severe hepatic impairment, bioavailability may approach 100% and clearance is markedly reduced, with elimination half-lives of 15 to 32 hours; dosage restriction is advisable (see Administration in Hepatic Impairment, below). In general, children have a higher clearance than adults, although age-related reductions in clearance have also been reported, with younger children having lower clearances. Use of weight-based doses compensates for these changes and normalises exposure in paediatric patients.

Uses and Administration

Ondansetron is a 5-HT_3 antagonist (5-HT_3-receptor antagonist) with antiemetic activity. It is used in the management of **nausea and vomiting** induced by cytotoxic chemotherapy and radiotherapy. It is also used for the prevention and treatment of postoperative nausea and vomiting. For the management of nausea and vomiting, and the important role of 5-HT_3 antagonists, see p.1700.

Ondansetron is given by intramuscular or slow intravenous injection or infusion as the hydrochloride, by mouth as the hydrochloride or base, or rectally as the base. Doses are expressed in terms of the base. Ondansetron hydrochloride 4.99 mg is equivalent to about 4 mg of ondansetron base.

Numerous dosing schedules of ondansetron have been used; some typical examples are cited below.

For *highly emetogenic* **chemotherapy** the following dose schedules appear to be equally effective in *preventing* acute emesis:

- a single dose of 8 mg by slow intravenous or intramuscular injection immediately before treatment

or

- 8 mg by slow intravenous or intramuscular injection immediately before treatment, either followed by a continuous intravenous infusion of 1 mg/hour for up to 24 hours, or by a further two doses of 8 mg two to four hours apart

or

- a single dose of 32 mg given by intravenous infusion over at least 15 minutes immediately before treatment

or

- 150 micrograms/kg by intravenous infusion over 15 minutes, beginning 30 minutes before chemotherapy, and repeated 4 and 8 hours after the first dose

or

- a 16-mg suppository rectally, given 1 to 2 hours before treatment

or

- a single oral dose of 24 mg taken 30 minutes before the start of single-day chemotherapy

The efficacy of ondansetron in highly emetogenic chemotherapy may be enhanced by giving intravenous dexamethasone sodium phosphate 20 mg before chemotherapy.

Similar regimens to those given above are used for preventing acute emesis with *less emetogenic chemotherapy* and/or **radiotherapy** and also include:

- 8 mg can be given orally up to 2 hours before treatment followed by 8 mg 8 to 12 hours later

To protect against delayed emesis these regimens are followed by oral ondansetron 8 mg twice daily, or 16 mg rectally once daily, for up to 5 days after the end of a course of chemotherapy.

For children the licensed dose in the UK is 5 mg/m^2 intravenously immediately before chemotherapy, followed by 4 mg orally 12 hours later. A dose of 4 mg orally twice daily may be continued for up to 5 days after the end of chemotherapy. The *BNFC* allows (in children aged 1 to 12 years) for 5 mg/m^2 intravenously before chemotherapy (up to a maximum single dose of 8 mg), which can be repeated every 8 to 12 hours during chemotherapy and for at least 24 hours afterwards; alternatively oral doses of 4 mg can be given every 8 to 12 hours for up to 5 days after intravenous use. In the USA a licensed regimen in children over 6 months of age is 150 micrograms/kg by intravenous infusion 30 minutes before chemotherapy, repeated 4 and 8 hours after the first dose. Alternatively, for children aged 4 to 11 years, an oral dose of 4 mg may be given 30 minutes before the start of chemotherapy, with subsequent 4-mg doses given 4 and 8 hours thereafter. An oral dose of 4 mg three times daily may be given for 1 to 2 days after the end of chemotherapy.

To *prevent* **postoperative nausea and vomiting** adults may be given:

- 16 mg orally an hour before anaesthesia

or

- 8 mg orally an hour before anaesthesia followed by 2 further doses of 8 mg at 8-hour intervals

or

- a single dose of 4 mg by intramuscular or slow intravenous injection at induction of anaesthesia

For the *treatment* of postoperative nausea and vomiting a single 4-mg dose by intramuscular or slow intravenous injection is recommended.

In the UK, children aged 2 years and over may be given 100 micrograms/kg by slow intravenous injection, up to a maximum dose of 4 mg, both for the prevention and treatment of postoperative nausea and vomiting; in the USA this dose is licensed from 1 month of age.

In patients with moderate or severe *hepatic impairment* it is recommended that the total daily dose of ondansetron should not exceed 8 mg (see below).

Administration. Ondansetron has been successfully used by continuous *subcutaneous* infusion to control intractable nausea and vomiting.[1] Despite concern about the low pH of ondansetron injection there was no problem with the skin at the infusion site. An *oral* protocol for chemotherapy-induced emesis in children has been described;[2] efficacy was similar to intravenous use.

Administration in hepatic impairment. Licensed drug information recommends that the dose of ondansetron should not exceed 8 mg daily in patients with moderate or severe hepatic impairment. When this dose was given intravenously to patients with hepatic impairment, those with severe impairment showed an increase in the area under the plasma concentration/time curve and in the terminal plasma half-life, and a decrease in plasma clearance.[1] The authors of this study, some of whom worked for the manufacturers (*Glaxo*), considered that ondansetron should be restricted to once daily dosage in severe hepatic impairment.

Bulimia nervosa. A combination of counselling, support, psychotherapy, and antidepressants is the usual treatment of bulimia nervosa. Preliminary reports have indicated that ondansetron may be of benefit in the treatment of this disorder.[1,2]

Fatigue. Preliminary results indicated that treatment with 5-HT_3 antagonists such as ondansetron and tropisetron may be of benefit in patients with chronic fatigue.[1] Ondansetron 4 mg twice daily by mouth was reported[2] to resolve fatigue in a woman with chronic hepatitis C. In a randomised study in 36 patients with chronic hepatitis C, this dose of ondansetron given for 1 month significantly improved fatigue scores at day 15 and day 60 (beyond the treatment period) when compared with placebo.[3] The authors noted that patient awareness that constipation was a possible effect of active treatment may have potentially unblinded the study. Further confirmation by larger studies is needed.

Pain. Preliminary results from a small crossover study[1] indicated that oral ondansetron was more effective than paracetamol in relieving the pain of fibromyalgia, a chronic disorder that responds poorly to conventional analgesics. A single bolus of ondansetron given to patients with chronic neuropathic pain significantly reduced pain scores 2 hours after injection in a placebo-controlled study;[2] this effect may be due to an action on 5-HT_3 receptors in the spinal cord.

Other 5-HT_3 antagonists such as granisetron[3-5] and tropisetron[6-8] have also been investigated in various painful syndromes.

Pruritus. There are several case reports[1,2] of cholestatic pruritus (p.1582) responding to intravenous or oral ondansetron, including one in pregnancy.[3] However, results from controlled studies[4-6] have been mixed. It is similarly unclear if ondansetron is of benefit in pruritus due to renal failure,[7-9] and results have been conflicting from controlled studies evaluating its use in opioid-induced pruritus.[10-15] There are reports of ondansetron ameliorating the pruritus associated with some skin disorders.[16] Other 5-HT_3 antagonists such as tropisetron[9] and dolasetron[14] have also been investigated.

Psychiatric disorders. Ondansetron has been tried experimentally in a number of psychiatric disorders including schizophrenia,[1-3] and psychosis in patients with parkinsonism,[4] and may be of value in moderating tardive dyskinesia.[5] A reduction in tic severity in Tourette's syndrome (p.954) has been reported,[6] and preliminary results have suggested benefit in obsessive-compulsive disorder,[7] and bulimia nervosa (see above). It is also reported to be under investigation in the management of panic attacks (p.952). For the more conventional management of schizophrenia, parkinsonism, and obsessive-compulsive disorder see p.955, p.791, and p.952, respectively.

Substance dependence. Ondansetron is being studied in the management of alcohol dependence (p.1626). However, in one study[1] a significant reduction in alcohol consumption was found only in lighter drinkers after subgroup analysis. Another study[2] found a reduction in alcohol consumption by patients with early-onset alcoholism (onset before age 25) who took ondansetron compared with placebo. No such effect was seen, however, in patients with late-onset alcoholism. Further study found that ondansetron also effectively ameliorated mood disturbances including symptoms of depression, anxiety, and hostility, in early-onset alcoholics.[3] Self-reported alcohol consumption also reduced in adolescents (between ages 14 and 20) with alcohol dependence who were given ondansetron in an open study.[4]

Oxyphencyclimine Hydrochloride *(BANM, rINNM)*

Hidrocloruro de oxifenciclimina; Oksifensiklimin Hidroklorür; Oxyphencyclimine, Chlorhydrate d'; Oxyphencyclimini Hydrochloridum. 1,4,5,6-Tetrahydro-1-methylpyrimidin-2-ylmethyl α-cyclohexylmandelate hydrochloride.

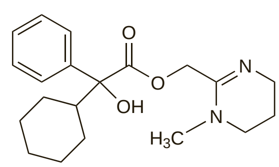
Оксифенциклимина Гидрохлорид

$C_{20}H_{28}N_2O_3$,HCl = 380.9.

CAS — 125-53-1 (oxyphencyclimine); 125-52-0 (oxyphencyclimine hydrochloride).

ATC — A03AA01.

ATC Vet — QA03AA01.



(oxyphencyclimine)

Profile

Oxyphencyclimine hydrochloride is a tertiary amine antimuscarinic with effects similar to those of atropine (p.1219). It has been used as an adjunct in the treatment of peptic ulcer disease and for the relief of smooth muscle spasms in gastrointestinal disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Hong Kong: Daricon; ***Thai.:*** Daricon†; Med-Spastic†; Oxyno; Proclimine.

Multi-ingredient: ***Hong Kong:*** Rudd-U†; ***Turk.:*** Spazmo-Valibrin.

Oxyphenonium Bromide *(BAN, rINN)*

Bromuro de oxifenonio; Oksyfenoniowy bromek; Oxphenonii Bromidum; Oxyphenonii Bromidum; Oxyphenonium Bromatum; Oxyphénonium, Bromure d'. 2-(α-Cyclohexylmandeloyloxy)ethyldiethylmethylammonium bromide.

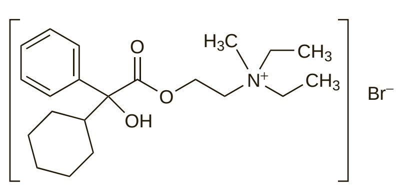
Оксифенония Бромид

$C_{21}H_{34}BrNO_3$ = 428.4.

CAS — 14214-84-7 (oxyphenonium); 50-10-2 (oxyphenonium bromide).

ATC — A03AB03.

ATC Vet — QA03AB03.



Pharmacopoeias. In *Pol.*

Profile

Oxyphenonium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been given orally to relieve visceral spasms.

Preparations

Proprietary Preparations (details are given in Part 3)

India: Antrenyl; ***Pol.:*** Spasmophen; ***S.Afr.:*** Spastrex†.

Multi-ingredient: ***Cz.:*** Endiform†.

Palonosetron Hydrochloride

(USAN, rINNM)

Hidrocloruro de palonosetrón; Palonosétron, Chlorhydrate de; Palonosetroni Hydrochloridum; RS-25259-197. (3a*S*)-2,3,3a,4,5,6-Hexahydro-2-[(3*S*)-3-quinuclidinyl]-1*H*-benz[*de*]isoquinolin-1-one hydrochloride.

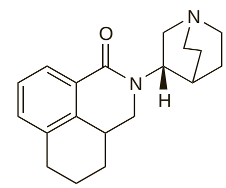
Палоносетрона Гидрохлорид

$C_{19}H_{24}N_2O$,HCl = 332.9.

CAS — 135729-56-5 (palonosetron); 135729-55-4 (palonosetron hydrochloride); 135729-62-3 (palonosetron hydrochloride).

ATC — A04AA05.

ATC Vet — QA04AA05.



(palonosetron)

Stability. The stability of palonosetron hydrochloride at concentrations of 5 and 30 micrograms/mL was assessed in polyvinyl chloride bags of the following 4 infusion solutions: glucose 5%, sodium chloride 0.9%, glucose 5% in sodium chloride 0.45%, and glucose 5% in lactated Ringer's solution. All solutions were considered to be physically and chemically stable for at least 48 hours at room temperature exposed to light, and for 14 days under refrigeration.[1]

Palonosetron 50 micrograms/mL was found to be physically and chemically stable during simulated Y-site administration with the following drugs: fentanyl citrate 50 micrograms/mL, hydromorphone hydrochloride 500 micrograms/mL, morphine sulfate 15 mg/mL, pethidine hydrochloride 10 mg/mL, and sufentanil citrate (12.5 micrograms/mL of sufentanil).[2]

1. Trissel LA, Xu QA. Physical and chemical stability of palonosetron HCl in 4 infusion solutions. *Ann Pharmacother* 2004; **38:** 1608–11.
2. Trissel LA, *et al.* Physical and chemical stability of palonosetron hydrochloride with five opiate agonists during simulated Y-site administration. *Am J Health-Syst Pharm* 2007; **64:** 1209–13.

Adverse Effects and Precautions

As for Ondansetron, p.1757, although no dosage reduction is considered necessary in hepatic impairment. Diarrhoea, fatigue, and abdominal pain may also occur. Patients with a history of constipation or signs of subacute intestinal obstruction should be monitored if given palonosetron.

Effects on the cardiovascular system. For a discussion of the effects of 5-HT_3 antagonists on the cardiovascular system, see under Ondansetron, p.1757.

Interactions

As for Ondansetron, p.1757.

Pharmacokinetics

Palonosetron has a volume of distribution of around 7 to 8 litres/kg; plasma protein binding is about 62%. About 50% of a dose is metabolised in the liver by cytochrome P450 isoenzymes (notably CYP2D6, but also CYP3A4 and CYP1A2). About 80% of a dose is recovered in the urine within 144 hours, as palonosetron and its metabolites. The mean elimination half-life is reported to be about 40 hours.

◊ References.

2. Shah A, *et al.* Pharmacokinetic evaluation and safety profile of a 15-minute versus 30-second infusion of palonosetron in healthy subjects. *J Clin Pharmacol* 2006; **46:** 1139–45.

Uses and Administration

Palonosetron is a 5-HT_3 antagonist used in the prevention of nausea and vomiting induced by cytotoxic chemotherapy and for the prevention of postoperative nausea and vomiting. Palonosetron is given as the hydrochloride but doses are expressed in terms of the base; 280.8 micrograms of palonosetron hydrochloride is equivalent to about 250 micrograms of palonosetron.

For the prevention of acute and delayed **nausea and vomiting** associated with initial and repeat courses of moderately or highly emetogenic cancer **chemotherapy**, a dose of 250 micrograms is given intravenously over 30 seconds about 30 minutes before chemotherapy. Repeated dosing within 7 days is not recommended.

For the prevention of **postoperative** nausea and vomiting, for up to 24 hours after surgery, a single dose of 75 micrograms is given intravenously over 10 seconds immediately before the induction of anaesthesia. Efficacy beyond 24 hours has not been demonstrated.

ATC Vet — QA02BC02.

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).
Ph. Eur. 6.2 (Pantoprazole Sodium Sesquihydrate). A white or almost white powder. Freely soluble in water and in alcohol; practically insoluble in hexane. Protect from light.

Stability. A suspension of pantoprazole 2 mg/mL in sterile water and sodium bicarbonate was deemed to be physically and chemically stable[1] in amber polyethylene terephthalate bottles for 62 days at 2° to 8°.

1. Dentinger PJ, *et al.* Stability of pantoprazole in an extemporaneously compounded oral liquid. *Am J Health-Syst Pharm* 2002; **59:** 953–6.

Adverse Effects and Precautions

As for Omeprazole, p.1753. Dosage may need to be reduced in severe hepatic impairment; liver function should be monitored regularly, and therapy stopped if liver enzymes are elevated.

Incidence of adverse effects. In a postmarketing surveillance study of the 6-month period after the launch of pantoprazole in England (UK), the adverse effects reported most frequently were diarrhoea, nausea, and headache. Other effects included malaise or lassitude, rash, other gastrointestinal disturbances, myalgia, and oedema.[1]

1. Wilton LV, *et al.* The pharmacovigilance of pantoprazole: the results of postmarketing surveillance on 11 541 patients in England. *Drug Safety* 2003; **26:** 121–32.

Effects on the blood. For a report of thrombocytopenia with pantoprazole, see under Omeprazole, p.1753.

Effects on the kidneys. For reports of interstitial nephritis associated with pantoprazole see p.1753.

Effects on the skin. For mention of skin reactions to pantoprazole, see p.1754.

Interactions

As for Omeprazole, p.1755.

◊ For reference to a lack of effect of pantoprazole on diazepam, see Gastrointestinal Drugs, p.991, and for a lack of effect on theophylline, see p.1145. Licensed product information states that there are reports of increased prothrombin time in patients taking pantoprazole and warfarin, but for reports suggesting a lack of effect on warfarin, see p.1430. For a report of severe generalised myalgia and bone pain attributed to the use of methotrexate with pantoprazole, see Gastrointestinal Drugs, p.748.

Pharmacokinetics

Pantoprazole is rapidly absorbed and peak plasma-pantoprazole concentrations are achieved about 2 to 2.5 hours after an oral dose. The oral bioavailability is about 77% with the enteric-coated tablet formulation, and does not vary after single or multiple doses. Pantoprazole is about 98% bound to plasma proteins. It is extensively metabolised in the liver, primarily by the cytochrome P450 isoenzyme CYP2C19, to desmethylpantoprazole; small amounts are also metabolised by CYP3A4, CYP2D6, and CYP2C9. Metabolites are excreted mainly (about 80%) in the urine, with the remainder being excreted in faeces via the bile. The terminal elimination half-life is about 1 hour, and is prolonged in hepatic impairment; the half-life in patients with cirrhosis was 3 to 6 hours. Although the elimination half-life has been reported to be 3.5 to 10 hours in slow metabolisers (see also Metabolism under Omeprazole, p.1755), minimal accumulation occurs with once-daily dosing.

◊ References.

1. Pue MA, *et al.* Pharmacokinetics of pantoprazole following single intravenous and oral administration to healthy male subjects. *Eur J Clin Pharmacol* 1993; **44:** 575–8.

Bioavailability. A suspension of pantoprazole in sodium bicarbonate solution was rapidly absorbed, and peak plasma concentrations were comparable to that of the tablet. However, bioavailability of the suspension was about 25% lower than that of the tablet; the amount of sodium bicarbonate used may affect the bioavailability.[1]

1. Ferron GM, *et al.* Oral bioavailability of pantoprazole suspended in sodium bicarbonate solution. *Am J Health-Syst Pharm* 2003; **60:** 1324–9.

Uses and Administration

Pantoprazole is a proton pump inhibitor with actions and uses similar to those of omeprazole (p.1755). It is given as the sodium salt but doses are expressed in terms of the base. Pantoprazole sodium 11.28 mg is equivalent to about 10 mg of pantoprazole. Once-daily doses should be given in the morning.

In the treatment of **gastro-oesophageal reflux disease** (p.1696), the usual oral dose is 20 to 40 mg once daily for 4 weeks, increased to 8 weeks if necessary; in the USA, up to 16 weeks of therapy is permitted for healing of erosive oesophagitis. For maintenance therapy, treatment can be continued with 20 to 40 mg daily. Alternatively, for recurring symptoms, an on-demand regimen of 20 mg daily may be given.

The usual dose for the treatment of **peptic ulcer disease** (p.1702) is 40 mg once daily. Treatment is usually given for 2 to 4 weeks for duodenal ulceration, or 4 to 8 weeks for benign gastric ulceration. For the eradication of *Helicobacter pylori* pantoprazole may be combined with two antibacterials in a 1-week **triple therapy** regimen. Effective regimens include pantoprazole 40 mg twice daily combined with clarithromycin 500 mg twice daily and amoxicillin 1 g twice daily, or combined with clarithromycin 250 mg twice daily and metronidazole 400 mg twice daily.

Patients who require prophylaxis for **NSAID-associated ulceration** may take 20 mg daily.

In the treatment of pathological hypersecretory states such as the **Zollinger-Ellison syndrome** (p.1704), the initial dose is 80 mg daily, adjusted as required. Doses of up to 240 mg daily have been used. Daily doses greater than 80 mg should be given in 2 divided doses.

PARENTERAL DOSAGE.

Pantoprazole may also be given intravenously, as the sodium salt, over 2 to 15 minutes, either as a slow injection or a short-term infusion. For peptic ulceration or gastro-oesophageal reflux disease, the recommended dose is 40 mg daily. A dose of 80 mg once or twice daily may be used for Zollinger-Ellison syndrome; up to 240 mg daily may be given in divided doses. Patients should be switched to oral therapy as soon as possible.

Doses of pantoprazole may need to be reduced in patients with hepatic impairment (see below).

◊ Reviews.

1. Anonymous. Pantoprazole—a third proton pump inhibitor. *Drug Ther Bull* 1997; **35:** 93–4.
2. Poole P. Pantoprazole. *Am J Health-Syst Pharm* 2001; **58:** 999–1008.
3. Cheer SM, *et al.* Pantoprazole: an update of its pharmacological properties and therapeutic use in the management of acid-related disorders. *Drugs* 2003; **63:** 101–32.
4. Gisbert JP, *et al.* Pantoprazole based therapies in Helicobacter pylori eradication: a systematic review and meta-analysis. *Eur J Gastroenterol Hepatol* 2004; **16:** 89–99.
5. Lehmann FS, Beglinger C. Role of pantoprazole in the treatment of gastro-oesophageal reflux disease. *Expert Opin Pharmacother* 2005; **6:** 93–104.

Administration. The safety and tolerability profiles of intravenous pantoprazole given in 10 mL of sodium chloride 0.9% over 2 minutes were similar to those given over 15 minutes in 100 mL.[1]

1. Micalizzi M, *et al.* Comparative tolerability of 2- and 15-minute intravenous infusions of pantoprazole. *Am J Health-Syst Pharm* 2007; **64:** 1822–6.

Administration in hepatic impairment. Dosage of pantoprazole may need to be reduced in severe hepatic impairment, or doses given only on alternate days. A maximum dose of 20 mg daily orally or intravenously, or 40 mg orally on alternate days, has been suggested. Doses above 40 mg daily have not been studied in patients with hepatic impairment. Liver enzymes should be monitored during therapy, and pantoprazole should be stopped if elevations occur.

Administration in renal impairment. Most studies have not found the pharmacokinetics of pantoprazole to be altered in patients with renal impairment[1] and licensed drug information in the UK and US generally does not recommend dosage adjustment in this group; however some UK sources, including the *BNF*, suggest that a maximum dose of 40 mg daily should be observed.

Масло Мяты Перечной

CAS — 8006-90-4.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Peppermint Oil). It is obtained by steam distillation from the fresh overground parts of the flowering plant of *Mentha × piperita*. It contains 30.0 to 55.0% menthol, 14.0 to 32.0% menthone, and 2.8 to 10.0% menthyl acetate, 3.5 to 14.0% cineole, 1.5 to 10.0% isomenthone, 1.0 to 9.0% menthofuran, 1.0 to 5.0% limonene, not more than 4.0% pulegone, and not more than 1.0% carvone; the ratio of eucalyptol content to limonene content is greater than two.

It is a colourless, pale yellow, or pale greenish-yellow liquid with a characteristic odour and taste followed by a sensation of cold. Miscible with alcohol and with dichloromethane. Store in well-filled, airtight containers. Protect from light and heat.

USNF 26 (Peppermint Oil). The volatile oil distilled with steam from the fresh overground parts of the flowering plant *Mentha piperita* (Labiatae), rectified by distillation, and neither partially nor wholly dementholised. It yields not less than 5% of esters calculated as menthyl acetate and not less than 50% of total menthol, free and as esters.

It is a colourless or pale yellow liquid with a strong, penetrating, characteristic odour and a pungent taste, followed by a sensation of cold when air is drawn into the mouth. Soluble 1 in 3 of alcohol (70%) with not more than slight opalescence. Store in airtight containers at a temperature not exceeding 40°.

Storage. The Pharmaceutical Society of Great Britain's Department of Pharmaceutical Sciences found that PVC bottles softened and distorted fairly rapidly in the presence of peppermint oil, which should not be stored or dispensed in such bottles.[1]

1. Department of Pharmaceutical Sciences of the Pharmaceutical Society of Great Britain. Plastic medicine bottles of rigid PVC. *Pharm J* 1973; **210:** 100.

Adverse Effects and Precautions

Peppermint oil can be irritant and may rarely cause hypersensitivity reactions. Reported reactions include erythematous skin rash, headache, bradycardia, muscle tremor, and ataxia. Heartburn has also been reported.

Effects on the cardiovascular system. Idiopathic atrial fibrillation occurred in 2 patients addicted to 'peppermints'. Normal rhythm was restored when peppermint-sucking ceased.[1]

1. Thomas JG. Peppermint fibrillation. *Lancet* 1962; **i:** 222.

Hypersensitivity. Exacerbation of asthma, with wheezing and dyspnoea, was associated with the use of paste-based toothpastes containing peppermint or wintergreen as a flavouring.[1]

1. Spurlock BW, Dailey TM. Shortness of (fresh) breath—toothpaste-induced bronchospasm. *N Engl J Med* 1990; **323:** 1845–6.

Interactions

Adverse effects may be more likely if peppermint oil is taken with alcohol. Enteric-coated capsules containing peppermint oil should not be taken immediately after food or with antacids. There is some evidence that peppermint oil can inhibit the cytochrome P450 isoenzyme CYP3A4, and may affect the clearance of drugs whose metabolism is mediated by this enzyme.

◊ References.

1. Dresser GK, *et al.* Evaluation of peppermint oil and ascorbyl palmitate as inhibitors of cytochrome P4503A4 activity in vitro and in vivo. *Clin Pharmacol Ther* 2002; **72:** 247–55.

Uses and Administration

Peppermint oil is an aromatic carminative that relaxes gastrointestinal smooth muscle and relieves flatulence and colic. Enteric-coated capsules containing peppermint oil are used for the relief of symptoms of the irritable bowel syndrome or gastrointestinal spasm secondary to other disorders. Usual oral doses in adults and adolescents from the age of 15 years are 0.2 mL three times daily, (increased to 0.4 mL three times daily if necessary) for up to 2 to 3 months. The capsules should be taken half to one hour before food and swallowed whole, not chewed.

Peppermint oil is used as a flavour and with other volatile agents in preparations for respiratory-tract disorders. It is also used in aromatherapy.

Peppermint leaf, the source of the oil, has also been used for its carminative and flavouring properties.

Gastrointestinal disorders. Menthol (p.2340), the major constituent of peppermint oil, has properties similar to those of calcium-channel blockers on smooth muscle such as that in the human gut.[1] Reviews[2,3] of the use of peppermint oil in irritable bowel syndrome (p.1699) concluded that there was some evidence of its benefit.

The relaxant effect of peppermint oil on the gastrointestinal tract has been used to reduce spasm during endoscopy by giving solubilised peppermint oil directly into the lumen, through the accessory channel of the endoscope. It has been described as effective during colonoscopy[4] and may be more effective than intramuscular hyoscine butylbromide during upper gastrointestinal endoscopy.[5] Addition of peppermint oil to barium enema has also been tried and appears to reduce spasm[6,7] and the need for intravenous antispasmodics.[6]

USP 31: Peppermint Spirit.

Proprietary Preparations (details are given in Part 3)

Austral.: Mintec; ***Austria:*** Colpermin; ***Cz.:*** China-Oel†; Colpermin; Gallentee†; Ki-Min-To†; Mata Pieporna†; Matovy; Nat Maty Peprne; ***Fr.:*** Localbiotal; ***Ger.:*** Chiana†; China-Oel†; Euminz; Inspirol Heilpflanzenol; Medacalm; Mentacur†; spasmo gallo sanol N; Wildkrauterol special K; ***Gr.:*** Colpermin; ***Hong Kong:*** Colpermin; ***Irl.:*** Colpermin; ***Israel:*** China Oel; Colpermin; Po Sum On Medicated Oil; ***Ital.:*** Carmint; Mintoil; ***Mex.:*** Colpermin†; ***NZ:*** Mintec; ***Port.:*** Colominte; ***S.Afr.:*** Pepermentdruppels; ***Singapore:*** Colpermin; ***Switz.:*** Chiana-Oel; Colpermin; ***Thai.:*** Colpermin; ***Turk.:*** China Oel; Colpermin; ***UK:*** Colpermin; Equilon Herbal; Mintec; Obbekjaers.

Multi-ingredient: numerous preparations are listed in Part 3.

Phenamazide Hydrochloride

Fenamazida, hidrocloruro de; Phenamacide Hydrochloride. (±)-α-Aminobenzeneacetic acid 3-methylbutyl ester hydrochloride.

$C_{13}H_{19}NO_2,HCl$ = 257.8.

CAS — 84580-27-8 (phenamazide); 31031-74-0 (phenamazide hydrochloride).

Profile

Phenamazide is an antimuscarinic with actions similar to those of atropine (p.1219). It has been used as the hydrochloride in the treatment of visceral spasms.

Preparations

Proprietary Preparations (details are given in Part 3)

Ger.: Aklonin†.

Phenolphthalein (BAN, rINN)

Dihydroxyphthalophenone; Fenolftalein; Fenolftaleína; Fenolftaleinas; Fenoliftaleiini; Fenoloftaleina; Phénolphtaléine; Phenolphtaleinum; Phenolphthaleinum. 3,3-Bis(4-hydroxyphenyl)-phthalide.

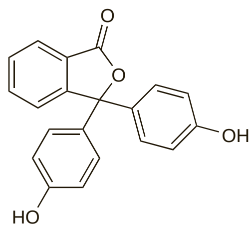
Фенолфталеин

$C_{20}H_{14}O_4$ = 318.3.

CAS — 77-09-8.

ATC — A06AB04.

ATC Vet — QA06AB04.



Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).

Ph. Eur. 6.2 (Phenolphthalein). A white or almost white powder. Practically insoluble in water; soluble in alcohol. Protect from light.

Adverse Effects and Precautions

As for Bisacodyl, p.1710. Hypersensitivity reactions, usually as skin rashes or eruptions, have occurred with phenolphthalein. Phenolphthalein may cause pink discoloration of alkaline urine.

Tumours have occurred in *rats* and *mice* given very high doses of phenolphthalein; there does not appear to be evidence of carcinogenicity in humans, but phenolphthalein-containing products have been withdrawn in many countries because of concerns about long-term safety.

Effects on the skin. Reports of skin reactions associated with phenolphthalein include fixed drug eruptions,[1,2] erythema multiforme reactions,[1,3] and toxic epidermal necrolysis.[4,5]

1. Baer RL, Harris H. Types of cutaneous reactions to drugs. *JAMA* 1967; **202:** 710–13.
2. Savin JA. Current causes of fixed drug eruptions. *Br J Dermatol* 1970; **83:** 546–9.
3. Shelley WB, *et al.* Demonstration of intercellular immunofluorescence and epidermal hysteresis in bullous fixed drug eruption due to phenolphthalein. *Br J Dermatol* 1972; **86:** 118–25.
4. Kar PK, *et al.* Toxic epidermal necrolysis in a patient induced by phenolphthalein. *J Indian Med Assoc* 1986; **84:** 189–93.
5. Artymowicz RJ, *et al.* Phenolphthalein-induced toxic epidermal necrolysis. *Ann Pharmacother* 1997; **31:** 1157–9.

Overdosage. The most likely consequence of phenolphthalein overdosage is excessive purgation, which may require fluid and electrolyte replacement. However, a possible association with acute pancreatitis occurred in a 34-year-old man who inadvertently ingested phenolphthalein 2 g. There was complete recovery with no sequelae from the pancreatitis.[1] Widespread organ failure with disseminated intravascular coagulation, massive liver damage, pulmonary oedema, renal failure, and myocardial damage in a second patient[2] were attributed to self-poisoning with an unknown quantity of phenolphthalein-containing laxative, although the diagnosis was problematic. The patient died despite intensive support.

1. Lambrianides AL, Rosin RD. Acute pancreatitis complicating excessive intake of phenolphthalein. *Postgrad Med J* 1984; **60:** 491–2.
2. Sidhu PS, *et al.* Fatal phenolphthalein poisoning with fulminant hepatic failure and disseminated intravascular coagulation. *Hum Toxicol* 1989; **8:** 381–4.

Pharmacokinetics

Up to 15% of phenolphthalein given orally is subsequently excreted in the urine. Enterohepatic circulation occurs and the glucuronide is excreted in the bile. Elimination may take several days.

Uses and Administration

Phenolphthalein is a diphenylmethane stimulant laxative that has been used for the treatment of constipation (p.1693) and for bowel evacuation before investigational procedures or surgery. It has been withdrawn in many countries because of concern over its carcinogenic potential after reports of tumours in *rodents.*

It has been given in pills or tablets, and as an emulsion with liquid paraffin. Yellow phenolphthalein, an impure form, has been used similarly.

Preparations

Proprietary Preparations (details are given in Part 3)

Pipenzolate Bromide (BAN, rINN)

Bromuro de pipenzolato; Pipenzolat Bromür; Pipenzolate, Bromure de; Pipenzolate Methylbromide; Pipenzolati Bromidum. 3-Benziloyloxy-1-ethyl-1-methylpiperidinium bromide.

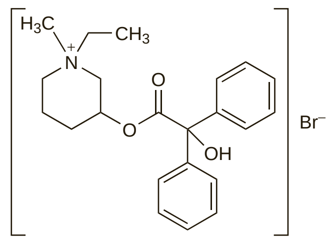
Пипензолата Бромид

$C_{22}H_{28}BrNO_3$ = 434.4.

CAS — 13473-38-6 (pipenzolate); 125-51-9 (pipenzolate bromide).

ATC — A03AB14.

ATC Vet — QA03AB14.



Profile

Pipenzolate bromide is a quaternary ammonium antimuscarinic with peripheral actions similar to those of atropine (p.1219). It has been used as an adjunct in the treatment of gastrointestinal disorders characterised by smooth muscle spasm.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Ila-med m; ***Mex.:*** Expal; Pipzen; ***Turk.:*** Piptalin.

Piperidolate Hydrochloride (BANM, rINNM)

Hidrocloruro de piperidolato; Pipéridolate, Chlorhydrate de; Piperidolati Hydrochloridum. 1-Ethyl-3-piperidyl diphenylacetate hydrochloride.

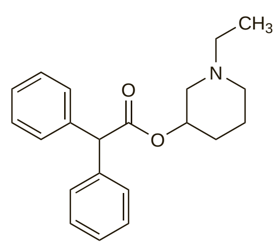
Пиперидолата Гидрохлорид

$C_{21}H_{25}NO_2,HCl$ = 359.9.

CAS — 82-98-4 (piperidolate); 129-77-1 (piperidolate hydrochloride).

ATC — A03AA30.

ATC Vet — QA03AA30.



(piperidolate)

Profile

Piperidolate hydrochloride is a tertiary amine antimuscarinic with effects similar to those of atropine (p.1219). It has been given in the symptomatic treatment of smooth muscle spasm associated with gastrointestinal disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Mex.: Dactil OB.

Multi-ingredient: ***Braz.:*** Dactil OB.

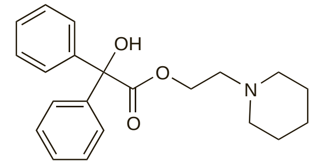
Pipethanate Ethobromide (rINNM)

Ethylpipethanate Bromide; Etobromuro de pipetanato; Piperilate Ethobromide; Pipéthanate, Ethobromure de; Pipethanati Ethobromidum. 1-(2-Benziloyloxyethyl)-1-ethylpiperidinium bromide.

Пипетаната Этобромид

$C_{23}H_{30}BrNO_3$ = 448.4.

CAS — 4546-39-8 (pipethanate); 23182-46-9 (pipethanate ethobromide).



(pipethanate)

Profile

Pipethanate ethobromide is an antimuscarinic with actions similar to those of atropine (p.1219). It has been used in the symptomatic treatment of visceral spasms in oral doses of up to 160 mg daily in divided doses. Pipethanate ethobromide has also been given intramuscularly or intravenously in doses of 10 to 20 mg daily and rectally in doses of 60 or 120 mg daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Chile: Nospasmin; ***Ital.:*** Spasmodil; ***Jpn:*** Panpurol†.

Multi-ingredient: ***Chile:*** Nospasmin Compuesto.

Pirenzepine Hydrochloride (BANM, USAN, rINNM)

Hidrocloruro de pirenzepina; LS-519 (pirenzepine); LS-519-Cl2; Pirentsepiinidihydrokloridimonohydraatti; Pirenzepin-dihidrokloridmonohidrát; Pirenzepin-dihydrochlorid monohydrát; Pirenzepindihydrokloridmonohydrat; Pirenzépine, Chlorhydrate de; Pirenzépine (dichlorhydrate de) monohydraté; Pirenzepini dihydrochloridum monohydricum; Pirenzepini Hydrochloridum; Pirenzepino dihidrochloridas monohidratas. 5,11-Dihydro-11-(4-methylpiperazin-1-ylacetyl)pyrido[2,3-*b*][1,4]benzodiazepin-6-one dihydrochloride monohydrate.

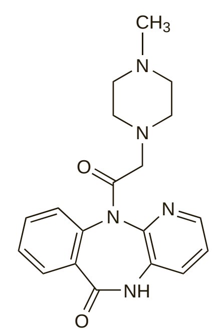
Пирензепина Гидрохлорид

$C_{19}H_{21}N_5O_2,2HCl,H_2O$ = 442.3.

CAS — 28797-61-7 (pirenzepine); 29868-97-1 (pirenzepine hydrochloride).

ATC — A02BX03.

ATC Vet — QA02BX03.



(pirenzepine)

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.*

Ph. Eur. 6.2 (Pirenzepine Dihydrochloride Monohydrate; Pirenzepine Hydrochloride BP 2008). A white or yellowish crystalline powder. Freely soluble in water; very slightly soluble in dehydrated alcohol; practically insoluble in dichloromethane; slightly soluble in methyl alcohol. A 10% solution in water has a pH of 1.0 to 2.0. Protect from light.

Adverse Effects and Precautions

Dry mouth and blurred vision have been reported but the risk of antimuscarinic effects (see Atropine Sulfate, p.1219) may be reduced. Pirenzepine should be used with caution in patients with renal impairment, particularly those with end-stage renal failure.

Effects on the blood. Thrombocytopenia in one patient and agranulocytosis in another was probably associated with the use of pirenzepine.[1]

1. Stricker BHC, *et al.* Blood disorders associated with pirenzepine. *BMJ* 1986; **293:** 1074.

Interactions

As for antimuscarinics in general (see Atropine Sulfate, p.1220).

Pharmacokinetics

Pirenzepine is absorbed from the gastrointestinal tract but the bioavailability is reported to be only about 20 to 30%, and is decreased to about 10 to 20% when taken with food. Very little pirenzepine is metabolised. About 10% of an oral dose is excreted unchanged in the urine, the remainder being excreted in the faeces.

Pirenzepine has an elimination half-life of about 12 hours and is about 12% bound to plasma proteins. Diffusion across the blood-brain barrier is poor and only minimal amounts are present in breast milk.

Renal impairment. The renal clearance and total plasma clearance of pirenzepine may be significantly reduced in patients with renal impairment,[1,2] with clearance decreasing proportionately with the degree of renal impairment. The half-life of pirenzepine is increased with reported values ranging from 14 to 20 hours.[1-3] Plasma concentrations of pirenzepine may be reduced by up to about 50% during haemodialysis.[2,3]

1. Krakamp B, *et al.* Steady-state intravenous pharmacokinetics of pirenzepine in patients with hepatic insufficiency and combined renal- and hepatic insufficiency. *Eur J Clin Pharmacol* 1989; **36:** 71–3.
2. Krakamp B, *et al.* Steady-state intravenous pharmacokinetics of pirenzepine in patients with differing degrees of renal dysfunction. *Eur J Clin Pharmacol* 1989; **36:** 75–8.
3. MacGregor T, *et al.* Oral pharmacokinetics of pirenzepine in patients with chronic renal insufficiency, failure, and maintenance haemodialysis. *Eur J Clin Pharmacol* 1990; **38:** 405–6.

Uses and Administration

Pirenzepine is a selective M_1 tertiary amine antimuscarinic that displays a preferential action on the gastric mucosa thus causing a reduction in the secretion of gastric acid; it also reduces the secretion of pepsin. At therapeutic doses it has few other antimuscarinic actions.

Pirenzepine hydrochloride has been used in the management of peptic ulcer disease (p.1702) in a usual oral dose of 50 mg two or three times daily for 4 to 6 weeks. It has also been given by slow intravenous injection in doses of up to 60 mg daily.

Myopia. Pirenzepine ophthalmic gel has been investigated[1-3] in children for its potential in slowing the progression of myopia. In a study[3] involving 353 children with myopia, pirenzepine 2% gel given once or twice daily into the lower eyelid for 1 year was associated with reduced progression: at 12 months myopia had progressed by a mean of 0.7 and 0.47 dioptres in children assigned to once and twice daily dosage respectively, compared with 0.84 dioptres in those given placebo. The gel was generally well tolerated, the most frequent adverse effects being development of papillae or follicles, or abnormalities of accommodation such as mydriasis or cycloplegia. Of 55 patients who failed to complete the study, 31 did so as a result of adverse effects.

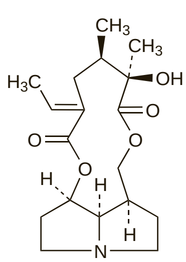
Platyphylline Acid Tartrate

Platyphylline Bitartrate; Platyphyllini Hydrotartras. 1,2-Dihydro-12-hydroxysenecionan-11,16-dione hydrogen tartrate.

Платифиллина Битартрат

$C_{18}H_{27}NO_5,C_4H_6O_6$ = 487.5.

CAS — 480-78-4 (platyphylline); 1257-59-6 (platyphylline acid tartrate).



(platyphylline)

Profile

Platyphylline acid tartrate is a pyrrolizidine alkaloid occurring in *Senecio platyphyllus* and other *Senecio* spp. It has antimuscarinic actions and has been given with papaverine in antispasmodic preparations.

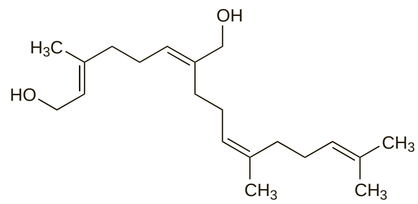
Plaunotol (rINN)

CS-684; Plaunotolum. (2*Z*,6*E*)-2-[(3*E*)-4,8-Dimethyl-3,7-nonadienyl]-6-methyl-2,6-octadiene-1,8-diol.

Плаунотол

$C_{20}H_{34}O_2$ = 306.5.

CAS — 64218-02-6.



Profile

Plaunotol is a complex aliphatic alcohol extracted from the Thai medicinal plant plau-noi (*Croton sublyratus* (Euphorbiaceae)). It is reported to possess cytoprotective properties and has been used in the treatment of gastritis and peptic ulcer disease in an oral dose of 80 mg three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)

Jpn: Kelnac; ***Thai.:*** Kelnac.

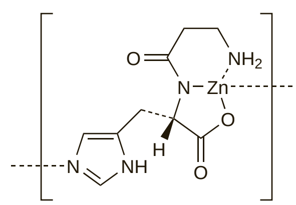
Polaprezinc (rINN)

Polaprézinc; Polaprezincum; Z-103; Zinc-L-carnosine. *catena*-Poly{zinc-μ-[β-alanyl-L-histidinato(2-)-*N*,*N*[N],*O*:*N*[τ]]}.

Полапрезинк

$(C_9H_{12}N_4O_3Zn)_n$.

CAS — 107667-60-7.



Profile

Polaprezinc is a cytoprotective agent used in the treatment of peptic ulcer disease.

Poldine Metilsulfate (BAN, pINN)

IS-499; McN-R-726-47; Metilsulfato de poldina; Poldine Methosulphate; Poldine Methylsulfate *(USAN)*; Poldine Methylsulphate; Poldine, Métilsulfate de; Poldini Metilsulfas. (*RS*)-2-Benziloyloxymethyl-1,1-dimethylpyrrolidinium methylsulphate.

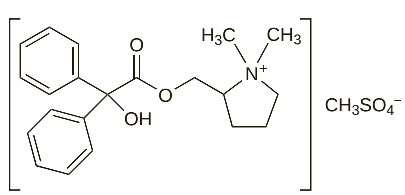
Польдина Метилсульфат

$C_{21}H_{26}NO_3,CH_3O_4S$ = 451.5.

CAS — 596-50-9 (poldine); 545-80-2 (poldine metilsulfate).

ATC — A03AB11.

ATC Vet — QA03AB11.



Pharmacopoeias. In *Br.*

BP 2008 (Poldine Metilsulfate). A white odourless or almost odourless crystalline powder. Freely soluble in water; soluble in alcohol; slightly soluble in chloroform. A 1% solution in water has a pH of 5.0 to 7.0.

Profile

Poldine metilsulfate is a quaternary ammonium antimuscarinic with peripheral actions similar to those of atropine (p.1219) and has been used in the management of gastrointestinal disorders, including peptic ulcer disease.

Preparations

BP 2008: Poldine Tablets.

Polycarbophil (BAN, rINN)

Policarbofilo; Polycarbophile; Polycarbophilum.

Поликарбофил

CAS — 9003-97-8.

Pharmacopoeias. In *US.*

USP 31 (Polycarbophil). It is polyacrylic acid cross-linked with divinyl glycol. White to creamy-white granules, with a characteristic, ester-like odour. Swells in water to a range of volumes, depending primarily on the pH. Insoluble in water, in common organic solvents, and in dilute acids and alkalis. A 1% mixture in water has a pH of not more than 4.0. Store in airtight containers.

Polycarbophil Calcium (BANM, rINNM)

AHR-3260B; Calcii Polycarbophilum; Calcium Polycarbophil *(USAN)*; Policarbofilo cálcico; Polycarbophile Calcique; Polycarbophilum Calcii; Polykarbofiilikalsium; Polykarbofilkalcium; Polykarbophilum Calcicum; WI-140.

Кальций Поликарбофил

CAS — 126040-58-2.

ATC — A06AC08.

ATC Vet — QA06AC08.

Pharmacopoeias. In *US.*

USP 31 (Calcium Polycarbophil). A white to creamy-white powder. Insoluble in water, in common organic solvents, and in dilute acids and alkalis. It loses not more than 10% of its weight on drying and contains not less than 18% and not more than 22% of calcium, calculated on the dried basis. Store in airtight containers.

Adverse Effects and Precautions

As for Ispaghula, p.1737. Polycarbophil calcium releases calcium ions in the gastrointestinal tract and should be avoided by patients who must restrict their calcium intake.

There is a risk of intestinal or oesophageal obstruction and faecal impaction, especially if such bulk laxatives are swallowed dry. Therefore, they should always be taken with sufficient fluid and should not be taken immediately before going to bed. They should be avoided by patients who have difficulty swallowing.

Interactions

The calcium component of polycarbophil calcium may produce interactions typical of calcium salts (p.1677), such as reducing the absorption of tetracyclines from the gastrointestinal tract; it should not be taken within 2 hours of the antibacterial. Polycarbophil calcium has also been reported to decrease the absorption of ciprofloxacin and mycophenolate mofetil.

Uses and Administration

Polycarbophil calcium has similar properties to ispaghula (p.1737) and is used as a bulk laxative and for adjusting faecal consistency. After ingestion calcium ions are replaced by hydrogen ions from gastric acid and the resultant polycarbophil exerts a hydrophilic effect in the intestines.

It is given orally in a usual dose equivalent to 1 g of polycarbophil up to four times daily, as necessary. Doses should be taken with at least 250 mL of water.

Polycarbophil is used topically as a vaginal moisturiser and as an ocular lubricant.

Potassium Acid Tartrate

E336; Hydrogenvinan draselný; Kalii hydrogenotartras; Kaliovandenilio tartratas; Kalium Hydrotartaricum; Kálium-hidrogéntartarát; Kaliumvätetartrat; Kaliumvetytartraatti; Potassium Bitartrate (USAN); Potassium Hydrogen Tartrate; Potassium, hydrogénotartrate de; Potasu wodorowinian; Purified Cream of Tartar; Tartarus Depuratus; Tartrato ácido de potasio; Weinstein.

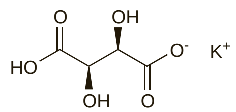
Кислый Виннокислый Калий

$C_4H_5KO_6$ = 188.2.

CAS — 868-14-4.

ATC — A12BA03.

ATC Vet — QA12BA03.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Potassium Hydrogen Tartrate). A white or almost white, crystalline powder or colourless crystals. Slightly soluble in water; practically insoluble in alcohol. It dissolves in dilute solutions of mineral acids and alkali hydroxides.

USP 31 (Potassium Bitartrate). Colourless or slightly opaque crystals or a white, crystalline powder. Slightly soluble in water; soluble in boiling water; very slightly soluble in alcohol. A saturated solution is acid to litmus. Store in airtight containers.

Profile

Potassium acid tartrate is given with sodium bicarbonate as a suppository for the treatment of constipation (p.1693) and for bowel evacuation before investigational procedures or surgery. Carbon dioxide gas is produced in the rectum, which stimulates defaecation within 5 to 30 minutes.

Potassium acid tartrate is used as a food additive and pharmaceutical aid.

Potassium acid tartrate has been used as an ingredient of preparations for potassium supplementation, although other potassium salts are usually preferred. For the general properties of potassium salts, see p.1684.

(anhydrous sodium potassium tartrate)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Potassium Sodium Tartrate Tetrahydrate). A white or almost white, crystalline powder or colourless transparent crystals. Very soluble in water; practically insoluble in alcohol.

USP 31 (Potassium Sodium Tartrate). Colourless crystals or a white, crystalline powder, with a cooling, saline taste. It effloresces slightly in warm dry air, the crystals often being coated with a white powder. Soluble 1 in 1 of water; practically insoluble in alcohol. Store in airtight containers.

Profile

Potassium sodium tartrate has been used as an osmotic laxative (p.1693). It is also used as a food additive.

For the general properties of potassium salts, see p.1684, and of sodium salts, see p.1686.

Prifinium Bromide (rINN)

Bromuro de prifinio; PDB; Prifinii Bromidum; Prifinium, Bromure de; Pyrodifenium Bromide. 3-Diphenylmethylene-1,1-diethyl-2-methylpyrrolidinium bromide.

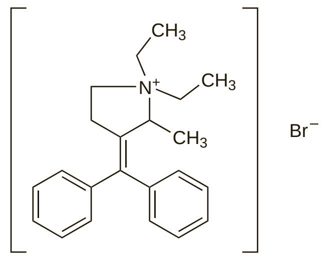
Прифиния Бромид

$C_{22}H_{28}BrN$ = 386.4.

CAS — 10236-81-4 (prifinium); 4630-95-9 (prifinium bromide).

ATC — A03AB18.

ATC Vet — QA03AB18.



Profile

Prifinium bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It is structurally related to diphemanil metilsulfate (p.2295).

Prifinium bromide is used to relieve smooth muscle spasms. Oral doses usually range from 90 to 180 mg daily in 3 divided doses. It has also been given rectally in a dose of 60 mg three or four times daily, or by subcutaneous, intramuscular, or intravenous injection in a dose of 15 mg given 2 to 4 times daily.

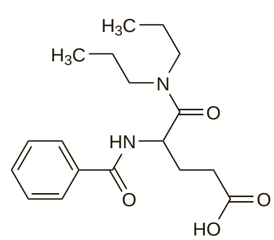
ATC Vet — QA02BX06.



Pharmacopoeias. In *Chin.* and *Jpn.*

Profile

Proglumide is a cholecystokinin antagonist with an inhibitory effect on gastric secretion. It has been used in the treatment of peptic ulcer disease (p.1702) and other gastrointestinal disorders in usual doses of 400 mg two to four times daily by mouth before meals; up to 800 mg three times daily may be given. It has also been given by intramuscular or intravenous injection in a dose of 400 to 800 mg daily.

Propantheline Bromide (BAN, rINN)

Bromuro de propantelina; Propanteliinibromidi; Propantelin Bromür; Propantelinbromid; Propantelin-bromid; Propantelino bromidas; Propanthéline, bromure de; Propanthelini bromidum; Propanthelinii Bromidum; Propanthelinium-bromid. Di-isopropylmethyl[2-(xanthen-9-ylcarbonyloxy)ethyl]ammonium bromide.

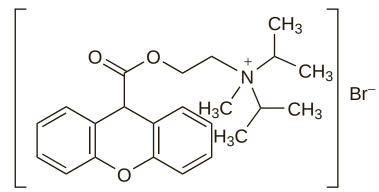
Пропантелина Бромид

$C_{23}H_{30}BrNO_3$ = 448.4.

CAS — 298-50-0 (propantheline); 50-34-0 (propantheline bromide).

ATC — A03AB05.

ATC Vet — QA03AB05.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Propantheline Bromide). A white or yellowish-white, slightly hygroscopic powder. Very soluble in water, in alcohol, and in dichloromethane. Store in airtight containers.

USP 31 (Propantheline Bromide). White or practically white, odourless, crystals. Very soluble in water, in alcohol, and in chloroform; practically insoluble in ether and in benzene.

Adverse Effects, Treatment, and Precautions

As for Atropine Sulfate, p.1219. Contact dermatitis has been reported after topical application of propantheline bromide.

Buccal and oesophageal ulceration. Severe buccal mucosal ulceration has been reported[1] in a 95-year-old woman as a result of retaining emepronium bromide tablets in her mouth, and recurred on giving propantheline bromide tablets.

1. Huston GJ, *et al.* Anticholinergic drugs, buccal ulceration and mucosal potential difference. *Postgrad Med J* 1978; **54:** 331–2.

Interactions

As for antimuscarinics in general (see Atropine Sulfate, p.1220).

Pharmacokinetics

Propantheline bromide is incompletely absorbed from the gastrointestinal tract and bioavailability is reported to be reduced by food; it is extensively metabolised in the small intestine before absorption. The plasma elimination half-life after a single oral dose has been reported to be about 2 to 3 hours. Propantheline is eliminated mainly in the urine as metabolites and less than 10% as unchanged drug. The duration of action is about 6 hours.

Uses and Administration

Propantheline bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been used as an antispasmodic (p.1692) for conditions associated with gastrointestinal spasm, and as an adjunct in the treatment of peptic ulcer disease (p.1702). The usual initial oral dose is 15 mg three times daily, 30 to 60 minutes before meals, and 30 mg at bedtime; doses of up to 120 mg daily may be needed in some patients. In elderly patients, doses of 7.5 mg three times daily may be sufficient. Doses of 300 micrograms/kg (to a maximum of 15 mg) given 3 or 4 times daily have been used for the relief of gastrointestinal spasm in children aged 1 month to 12 years; older children may be given the adult dose.

Propantheline bromide has been used in the treatment of adult enuresis or urinary incontinence, and in hyperhidrosis (see below), in doses similar to those given above.

Hyperhidrosis. Some antimuscarinics, including propantheline, have been applied topically in the treatment of hyperhidrosis (p.1580). Adverse effects of antimuscarinics given by mouth generally preclude their use by this route, although oral propantheline was used successfully to control excessive sweating in 2 patients with spinal cord injuries,[1] and it is sometimes used in palliative care to control night sweats. The *BNF* notes that propantheline may be used for gustatory sweating in patients with diabetic neuropathy.

1. Canaday BR, Stanford RH. Propantheline bromide in the management of hyperhidrosis associated with spinal cord injury. *Ann Pharmacother* 1995; **29:** 489–92.

Urinary incontinence. In the UK, guidelines issued by NICE suggest that propantheline should not be recommended for the treatment of urinary incontinence (p.2180) or overactive bladder in women; other antimuscarinics are preferred.[1]

1. National Institute for Health and Clinical Excellence. Urinary incontinence: the management of urinary incontinence in women (issued October 2006). Available at: http://www.nice.org.uk/nicemedia/pdf/CG40fullguideline.pdf (accessed 03/07/08)

Rabeprazole Sodium *(BANM, USAN, rINNM)*

E-3810; LY-307640; Natrii Rabeprazolum; Rabeprazol sódico; Rabeprazol Sodyum; Rabéprazole sodique; Rabeprazolum natricum; Sodium Pariprazole. 2-({[4-(3-Methoxypropoxy)-3-methyl-2-pyridyl]methyl}sulfinyl)-1*H*-benzimidazole sodium.

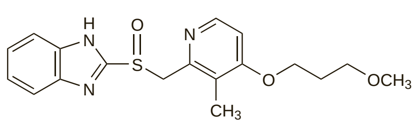
Натрий Рабепразол

$C_{18}H_{20}N_3NaO_3S$ = 381.4.

CAS — 117976-89-3 (rabeprazole); 117976-90-6 (rabeprazole sodium).

ATC — A02BC04.

ATC Vet — QA02BC04.



(rabeprazole)

Adverse Effects and Precautions

As for Omeprazole, p.1753.

Effects on the endocrine system. For cases of gynaecomastia associated with rabeprazole see p.1753.

Effects on the kidneys. For reports of interstitial nephritis associated with rabeprazole see p.1753.

Effects on the nervous system. For a report of neuropsychiatric symptoms associated with rabeprazole, see under Omeprazole, p.1754.

Interactions

As for Omeprazole (p.1755) but clinically significant interactions with diazepam, phenytoin, theophylline, or warfarin have not been found in healthy subjects.

Pharmacokinetics

Rabeprazole is rapidly absorbed and peak plasma concentrations are reached about 3.5 hours after an oral dose. The oral bioavailability is about 52% with the enteric-coated tablet formulation, because of first-pass metabolism, and does not appear to vary after single or repeated doses. Rabeprazole is about 97% bound to plasma proteins. It is extensively metabolised in the liver by cytochrome P450 isoenzymes CYP2C19 and CYP3A4 to the thioether, thioether carboxylic acid, sulfone, and desmethylthioether. Metabolites are excreted principally in the urine (about 90%) with the remainder in the faeces. The plasma half-life is about 1 hour, increased two to threefold in hepatic impairment, 1.6 times in CYP2C19 slow metabolisers (see also Metabolism under Omeprazole, p.1755), and by 30% in the elderly.

◊ References.

2. Keane WF, *et al.* Rabeprazole: pharmacokinetics and tolerability in patients with stable, end-stage renal failure. *J Clin Pharmacol* 1999; **39:** 927–33.

Uses and Administration

Rabeprazole is a proton pump inhibitor with actions and uses similar to those of omeprazole (p.1755). It is given orally as rabeprazole sodium in the form of enteric-coated tablets. It is normally taken in the morning.

In the treatment of severe (erosive or ulcerative) **gastro-oesophageal reflux disease** (p.1696), the usual dose of rabeprazole sodium is 20 mg once daily for 4 to 8 weeks; in the USA, a further 8-week course is permitted for healing of erosive oesophagitis. Thereafter, maintenance therapy can be continued with 10 or 20 mg daily depending on the response. For symptomatic disease without erosive or ulcerative oesophagitis a dose of 10 or 20 mg may be given once daily for 4 weeks; in the USA, a further 4-week course is permitted. Once symptoms have resolved, a dose of 10 mg once daily may be given as necessary.

For the treatment of active **peptic ulcer disease** (p.1702), 20 mg daily is given for 4 to 8 weeks for duodenal ulcer and 6 to 12 weeks for gastric ulcer. For the eradication of *Helicobacter pylori* rabeprazole sodium may be combined with two antibacterials in a 1-week **triple therapy** regimen. Effective regimens include 20 mg twice daily combined with clarithromycin 500 mg twice daily and amoxicillin 1 g twice daily, or combined with clarithromycin 250 mg twice daily and metronidazole 400 mg twice daily.

For **Zollinger-Ellison syndrome** (p.1704), the starting dose is 60 mg once daily, adjusted according to response. Doses up to 120 mg daily have been given; when the daily dose is more than 100 mg it should be given in 2 divided doses.

Racecadotril *(rINN)*

Acetorphan; Racécadotril; Racecadotrilo; Racecadotrilum. (±)-*N*-{2-[(Acetylthio)methyl]-1-oxo-3-phenylpropyl}glycine phenylmethyl ester; *N*-[(*R,S*)-3-acetylthio-2-benzylpropanoyl]glycine benzyl ester; (±)-*N*-[α-(Mercaptomethyl)hydrocinnamoyl]glycine benzyl ester acetate.

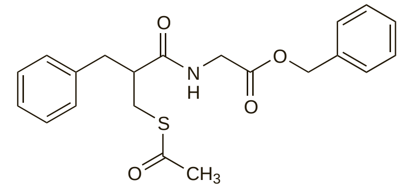
Рацекадотрил

$C_{21}H_{23}NO_4S$ = 385.5.

CAS — 81110-73-8.

ATC — A07XA04.

ATC Vet — QA07XA04.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Racecadotril). A white or almost white powder. Practically insoluble in water; freely soluble in methyl alcohol and in dichloromethane.

Profile

Racecadotril is an enkephalinase inhibitor that inhibits the breakdown of endogenous opioids, thus reducing intestinal secretions. It is given orally in doses of 100 mg three times daily before meals for up to 7 days for the symptomatic management of acute diarrhoea (p.1694).

The *S*-form of racecadotril (sinorphan, ecadotril—see Natriuretic Peptides, p.1347) has been investigated for hypertension and heart failure.

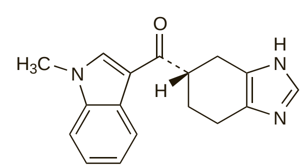
CAS — 132036-88-5 (ramosetron); 132907-72-3 (ramosetron hydrochloride).



(ramosetron)

Profile

Ramosetron is a 5-HT_3 antagonist with general properties similar to those of ondansetron (p.1756). Ramosetron hydrochloride is given for its antiemetic properties in the management of nausea and vomiting induced by cancer chemotherapy in usual doses of 300 micrograms once daily intravenously, or 100 micrograms once daily by mouth. Ramosetron is also under investigation in the management of diarrhoea-predominant irritable bowel syndrome.

Carcinogenicity. For a discussion of the possible association between histamine H_2-antagonists and cancer, including mention of a study with ranitidine, see Cimetidine, p.1717.

Effects on the blood. For a discussion of the adverse haematological effects of H_2-antagonists, see Cimetidine, p.1717.

Effects on the cardiovascular system. Similarly to cimetidine (p.1717), bradycardia,[1,2] AV block,[2] and cardiac arrest[3] have been reported rarely during ranitidine therapy. A positive inotropic effect, without significant changes in heart rate or blood pressure, has also been reported in healthy subjects[4] and pretreatment with ranitidine has blocked the cardiac depressant effects seen in some subjects given famotidine or nizatidine.[5] Although studies in critically ill patients[6] and healthy subjects[7,8] have found no adverse haemodynamic effects associated with ranitidine, it is likely that a small proportion of patients are more susceptible to the cardiovascular effects of ranitidine. Caution is recommended when ranitidine is given intravenously, particularly in patients with cardiovascular disease.

8. Hilleman DE, *et al.* Impact of chronic oral H -antagonist therapy on left ventricular systolic function and exercise capacity. *J Clin Pharmacol* 1992; **32:** 1033–7.

Effects on the endocrine system. Unlike cimetidine (p.1717), ranitidine does not bind to androgen receptors and has little, if any, anti-androgenic effect. Studies in men taking ranitidine for the management of duodenal ulcer[1,2] reported no significant changes in the plasma concentrations of testosterone, luteinising hormone, follicle-stimulating hormone, or prolactin after up to 2 years of treatment; no significant changes in sperm concentration, motility, or morphology were noted.[1] There have been isolated reports of gynaecomastia,[3] loss of libido,[4] and impotence[5] associated with ranitidine, but in 9 patients with cimetidine-induced breast changes and impotence, transfer to ranitidine resulted in resolution of these symptoms.[6]

3. Liberopoulos EN, *et al.* Possible ranitidine-induced cholestatic jaundice. *Ann Pharmacother* 2002; **36:** 172.

Effects on the nervous system. Ranitidine has been associated with adverse neurological effects including confusion,[1-8] loss of colour vision,[4] aggressiveness,[2,4,6] lethargy,[8] somnolence,[8] disorientation,[8] depression,[8] hallucinations,[1,7-9] and severe headache.[10] As with cimetidine (p.1717) these reactions occur mainly in the elderly, the severely ill, or patients with renal or hepatic impairment. Single-dose studies in young healthy subjects have found no adverse changes in performance, CNS function, or subjective assessment of mood after oral doses of ranitidine 150 or 300 mg.[11]

Precautions

As for Cimetidine, p.1718.

Helicobacter pylori testing. For reference to the effect of ranitidine on the urea breath test for *Helicobacter pylori*, see p.1718.

Hepatic impairment. Sixteen of 27 patients with cirrhosis of the liver and indications for treatment with an H_2-antagonist (peptic ulcer, gastritis, or reflux oesophagitis) failed to respond to ranitidine 300 mg compared with 6 failures from 32 patients without cirrhosis. Famotidine 40 mg was given to 10 of the cirrhotic nonresponders and 8 still had no response; 7 of these patients were given cimetidine 800 mg and only 1 responded. In the control group, all 3 patients given famotidine did not respond and only 1 responded when given cimetidine. It was concluded that the incidence of non-response to H_2-antagonists is increased in patients with liver cirrhosis but no explanation could be given for this effect.[1] Interestingly there is an earlier report of patients with cirrhosis demonstrating increased bioavailability and decreased clearance of ranitidine.[2]

1. Walker S, *et al.* Frequent non-response to histamine H -receptor antagonists in cirrhotics. *Gut* 1989; **30:** 1105–9.
2. Young CJ, *et al.* Effects of cirrhosis and ageing on the elimination and bioavailability of ranitidine. *Gut* 1982; **23:** 819–23.

Porphyria. Ranitidine is considered to be unsafe in patients with porphyria although there is conflicting experimental evidence of porphyrinogenicity.

Renal impairment. For evidence of reduced clearance of ranitidine in patients with renal impairment see Administration in Renal Impairment, below.

Interactions

Unlike cimetidine (p.1718), ranitidine does not seem to affect cytochrome P450 to any great extent, and therefore is considered to have little effect on the metabolism of other drugs. However, as with other H_2-antagonists, its effects on gastric pH may alter the absorption of some other drugs.

◊ A review comparing the drug interactions of ranitidine with those of cimetidine.[1]

1. Smith SR, Kendall MJ. Ranitidine versus cimetidine: a comparison of their potential to cause clinically important drug interactions. *Clin Pharmacokinet* 1988; **15:** 44–56.

Cisapride. Peak plasma concentrations of ranitidine were achieved more rapidly in 12 healthy subjects who also took cisapride.[1] The clinical significance is questionable and such combinations have been used clinically, although the use of cisapride is now restricted in most countries.

1. Rowbotham DJ, *et al.* Effect of single doses of cisapride and ranitidine administered simultaneously on plasma concentrations of cisapride and ranitidine. *Br J Anaesth* 1991; **67:** 302–305.

Pharmacokinetics

Ranitidine is readily absorbed from the gastrointestinal tract with peak concentrations in plasma occurring about 2 to 3 hours after oral doses. Food does not significantly impair absorption. The bioavailability of ranitidine after oral doses is about 50%. Ranitidine is rapidly absorbed on intramuscular injection, with peak plasma concentrations occurring in about 15 minutes. It is weakly bound, about 15%, to plasma proteins.

The elimination half-life is about 2 to 3 hours and is increased in renal impairment. A small proportion of ranitidine is metabolised in the liver to the *N*-oxide, the *S*-oxide, and desmethylranitidine; the *N*-oxide is the major metabolite but accounts for only about 4 to 6% of a dose. About 30% of an oral dose and 70% of an intravenous dose is excreted unchanged in the urine in

24 hours, primarily by active tubular secretion; there is some excretion in the faeces. Ranitidine crosses the placental barrier and is distributed into breast milk.

Distribution into breast milk. A study in a mother given multiple doses of ranitidine showed higher concentrations in breast milk than in serum; the minimum milk concentration occurred between 1 and 2 hours after a dose and the highest concentration was towards the end of the 12-hour dosing interval.[1] The amount that would be ingested by the infant could not be reliably estimated because of the variable milk to serum ratio.

1. Kearns GL, *et al*. Appearance of ranitidine in breast milk following multiple dosing. *Clin Pharm* 1985; **4:** 322–4.

Enterohepatic recycling. Some individuals have a second peak in the plasma concentration of ranitidine, which could be due to enterohepatic recirculation. However, only 0.7 to 2.6% and 0.3 to 1.0% of a dose of ranitidine was excreted into the bile of 3 patients in 24 hours after 50 mg given intravenously or 300 mg by mouth respectively, indicating that significant recirculation did not occur.[1]

1. Klotz U, Walker S. Biliary excretion of H -receptor antagonists. *Eur J Clin Pharmacol* 1990; **39:** 91–2.

Neonates. Renal function is limited in the first month of life, and reduced clearance of ranitidine would be expected. Blood samples taken from 27 full-term neonates given a single intravenous dose of ranitidine 2.4 mg/kg revealed the following pharmacokinetic data: elimination half-life, 3.45 hours; total volume of distribution, 1.52 litres/kg; total plasma clearance, 5.02 mL/kg per minute.[1] None of the infants had renal or hepatic impairment. In another study,[2] an elimination half-life of 6.61 hours was found in 13 full-term neonates given ranitidine 2 mg/kg. See also Administration in Children, below.

1. Fontana M, *et al.* Ranitidine pharmacokinetics in newborn infants. *Arch Dis Child* 1993; **68:** 602–3.
2. Wells TG, *et al.* Pharmacokinetics and pharmacodynamics of ranitidine in neonates treated with extracorporeal membrane oxygenation. *J Clin Pharmacol* 1998; **38:** 402–7.

Uses and Administration

Ranitidine is a histamine H_2-antagonist with actions and uses similar to those of cimetidine (p.1719).

Ranitidine may be given orally or parenterally by the intravenous or intramuscular routes. Although most preparations contain ranitidine hydrochloride, strengths and doses are expressed in terms of the base. Ranitidine hydrochloride 111.6 mg is equivalent to about 100 mg of ranitidine.

In the management of benign **gastric** and **duodenal ulceration** (p.1702) a single daily oral dose of 300 mg at bedtime or 150 mg twice daily (in the morning and at bedtime) is given initially for at least 4 weeks. A dose of 300 mg twice daily may also be used in duodenal ulcer. Where appropriate a maintenance dose of 150 mg daily may be given at bedtime. Ranitidine 150 mg twice daily may be given during therapy with NSAIDs for prophylaxis against duodenal ulceration. A suggested dose for the treatment of peptic ulcer in children is 2 to 4 mg/kg twice daily to a maximum of 300 mg in 24 hours; a maintenance dose of 2 to 4 mg/kg once daily may be used, to a maximum of 150 mg daily.

For duodenal ulcer associated with *Helicobacter pylori* infection, ranitidine in a usual oral dose of 300 mg once daily or 150 mg twice daily may be given as part of triple therapy with amoxicillin 750 mg and metronidazole 500 mg, both three times daily, for 2 weeks. Therapy with ranitidine should then be continued for a further 2 weeks.

In **gastro-oesophageal reflux disease** (p.1696) the oral dose is 150 mg twice daily or 300 mg at bedtime for up to 8 weeks or, if required, 12 weeks. This may be increased to 150 mg four times daily for up to 12 weeks in severe cases. In the maintenance of healing erosive oesophagitis, a dose of 150 mg twice daily may be used. Although there is limited data on the use of ranitidine for gastro-oesophageal reflux disease and erosive oesophagitis in children, a dose of 5 to 10 mg/kg daily, usually given in 2 divided doses, has been used. In pathological hypersecretory conditions, such as the **Zollinger-Ellison syndrome**, (p.1704) the initial oral dose is usually 150 mg twice or three times daily and may be increased if necessary; doses of up to 6 g daily have been used. Alternatively, an intravenous infusion may be given, initially at a rate of 1 mg/kg per hour; the rate may be increased by increments of 500 micrograms/kg per hour, beginning after 4 hours, if required.

For the management of patients at risk from **stress ulceration** of the upper gastrointestinal tract, parenteral therapy may be given as a slow intravenous injection of a 50-mg priming dose followed by a continuous intravenous infusion of 125 to 250 micrograms/kg per hour. Oral doses of 150 mg twice daily may be given once oral feeding is resumed.

In patients at risk of developing the **acid aspiration syndrome** (p.1693) during general anaesthesia, an oral dose of 150 mg may be given 2 hours before the induction of anaesthesia and preferably also 150 mg the previous evening. Alternatively, a dose of 50 mg may be given by intramuscular or slow intravenous injection 45 to 60 minutes before the induction of anaesthesia. In obstetric patients, at the start of labour an oral dose of 150 mg may be given and may be repeated at intervals of 6 hours if required.

In patients with chronic episodic **dyspepsia** (p.1695), a dose of 150 mg twice daily orally for up to 6 weeks may be given. For the short-term symptomatic relief of dyspepsia a dose of 75 mg, repeated if necessary up to a maximum of 4 doses daily, may be taken. Treatment should be restricted to a maximum of 2 weeks of continuous use at one time.

PARENTERAL DOSAGE.

The usual dose of ranitidine by intramuscular or intravenous injection is 50 mg, which may be repeated every 6 to 8 hours; the intravenous injection should be given slowly over not less than 2 minutes and should be diluted to contain 50 mg in 20 mL. For an intermittent intravenous infusion the recommended dose in the UK is 25 mg/hour given for 2 hours which may be repeated every 6 to 8 hours. A rate of 6.25 mg/hour has been suggested for continuous intravenous infusion although higher rates may be used for conditions such as Zollinger-Ellison syndrome or in patients at risk from stress ulceration (see above).

DOSAGE IN RENAL IMPAIRMENT.

For dosage in renal impairment, see below.

Administration in children. The disposition of ranitidine in children is not significantly different from that in young adults and an oral dose of 2 mg/kg (about equal to an adult dose of 150 mg) has been used for the prevention of acid aspiration in children undergoing surgery.[1] A study in premature infants being treated with dexamethasone for bronchopulmonary dysplasia found that infusion of ranitidine 62.5 micrograms/kg per hour was sufficient to raise and maintain gastric pH above 4 to help protect against gastrointestinal bleeding and perforation.[2] Another study found 500 micrograms/kg twice daily to be sufficient for preterm infants, but that 1.5 mg/kg three times daily was needed for full-term infants.[3] A minimum dosage of 3 mg/kg daily was suggested for stress ulcer prophylaxis in older infants and children.[4]

1. Christensen S, *et al.* Effects of ranitidine and metoclopramide on gastric fluid pH and volume in children. *Br J Anaesth* 1990; **65:** 456–60.
2. Kelly EJ, *et al.* The effect of intravenous ranitidine on the intragastric pH of preterm infants receiving dexamethasone. *Arch Dis Child* 1993; **69:** 37–9.
3. Kuusela A-L. Long term gastric pH monitoring for determining optimal dose of ranitidine for critically ill preterm and term neonates. *Arch Dis Child Fetal Neonatal Ed* 1998; **78:** F151–F153.
4. Harrison AM, *et al.* Gastric pH control in critically ill children receiving intravenous ranitidine. *Crit Care Med* 1998; **26:** 1433–6.

Administration in renal impairment. A study in patients with varying degrees of renal impairment[1] found that the mean terminal half-life of ranitidine was increased from 2.09 hours in subjects with normal renal function to between 4.23 and 8.45 hours in patients with renal impairment, the degree of prolongation being proportional to the degree of impairment as measured by glomerular filtration rate. As a result of these findings it was recommended that the dose of ranitidine should be halved in patients with a glomerular filtration rate of 20 mL/minute or less. Licensed drug information therefore recommends that dosage of ranitidine be reduced in patients with severe renal impairment.

For patients with a creatinine clearance of less than 50 mL/minute, an *oral* dose of 150 mg daily is recommended, which may be cautiously increased to 150 mg every 12 hours if needed.

For *intravenous* use, licensed recommendations vary between countries. In the UK, individual doses may be reduced to 25 mg, while the frequency is adjusted in the USA to give a recommended usual dose of 50 mg every 18 to 24 hours, which may be cautiously increased to every 12 hours or more often if necessary.

Ranitidine 150 mg daily provided adequate serum concentrations without excessive accumulation in 20 patients undergoing regular haemodialysis.[2] The serum-ranitidine concentrations fell by about 50% during a 4-hour haemodialysis session but less than 3% of the dose was removed and supplemental doses after dialysis were considered unnecessary.

2. Comstock TJ, *et al.* Ranitidine accumulation in patients undergoing chronic hemodialysis. *J Clin Pharmacol* 1988; **28:** 1081–5.

Cystic fibrosis. A comparative study involving 29 patients with cystic fibrosis (p.166) found that ranitidine was more effective than cisapride in improving dyspeptic symptoms and gastric emptying and distension.[1] Antisecretory drugs are also used in this condition to decrease the inactivation of oral pancreatic enzyme therapy.

1. Cucchiara S, *et al.* Ultrasound measurement of gastric emptying time in patients with cystic fibrosis and effect of ranitidine on delayed gastric emptying. *J Pediatr* 1996; **128:** 485–8.

Immunomodulation. Like cimetidine (see p.1719), ranitidine has been proposed to have immunoregulatory effects. However, ranitidine 300 mg twice daily had no effect on absolute CD4 cell counts or plasma HIV RNA in patients with HIV infection in a placebo-controlled study.[1] Similarly, ranitidine had no significant benefit in patients with gastric cancer (see Malignant Neoplasms, p.1719).

1. Bartlett JA, *et al.* A placebo-controlled trial of ranitidine in patients with early human immunodeficiency virus infection. *J Infect Dis* 1998; **177:** 231–4.

Skin disorders. As with cimetidine (p.1720), ranitidine has been tried in various skin disorders. Ranitidine 300 mg twice daily by mouth has been reported to be of benefit as an adjuvant to local treatment with corticosteroids and a moisturising ointment in patients with *atopic dermatitis*.[1] There are reports of improvements in *psoriasis* after use of ranitidine,[2-4] although this is a field that is notoriously difficult to evaluate because of the chronic relapsing and remitting nature of the disease, and others have failed to show benefit.[5]

Ranitidine Bismuth Citrate *(BAN, USAN)*

A complex of ranitidine and bismuth citrate; GR-122311X; Ranitidin Bizmut Sitrat; Ranitidin Bizmutreks; Ranitidina y bismuto, citrato de; Ranitidine Bismutrex. *N*-[2-({5-[(Dimethylamino)methyl]furfuryl}thio)-ethyl]-*N*′-methyl-2-nitro-1,1-ethenediamine, compound with bismuth(3+) citrate (1:1).

Ранитидин Висмут Цитрат

$C_{13}H_{22}N_4O_3S,C_6H_5BiO_7$ = 712.5.
CAS — 128345-62-0.
ATC — A02BA07.
ATC Vet — QA02BA07.

Adverse Effects and Precautions

Ranitidine bismuth citrate would be expected to combine the adverse effects of both bismuth compounds (p.1711) and ranitidine (p.1766). Blackening of the tongue and faeces is common, and gastrointestinal disturbances, headache, mild anaemia, and altered liver enzyme values have been reported. Rarely, hypersensitivity reactions (including anaphylaxis), have occurred.

Ranitidine bismuth citrate should not be given to patients with moderate to severe renal impairment. It is not suitable for long-term or maintenance therapy because of the risk of bismuth accumulation. As with other antisecretory drugs, the possibility of malignancy should be considered when giving ranitidine bismuth citrate to patients with gastric ulcers since the drug may mask symptoms and delay diagnosis.

Interactions

Ranitidine bismuth citrate would be expected to have the interactions of bismuth compounds (p.1712), and ranitidine (p.1766).

Pharmacokinetics

After oral doses, ranitidine bismuth citrate dissociates into its ranitidine and bismuth components in the stomach. For the pharmacokinetics of ranitidine, see p.1766, and for those of bismuth, see p.1712.

◊ References.

Uses and Administration

Ranitidine bismuth citrate is a complex of ranitidine with bismuth and citrate, which releases ranitidine and bismuth in the gastrointestinal tract and therefore possesses both the actions of the bismuth compounds (p.1712) and of ranitidine (p.1767). It has been used in the management of peptic ulcer disease (p.1702), and may be given with antibacterials for the eradication of *Helicobacter pylori* infection and the prevention of relapse of peptic ulcer disease.

Doses are 400 mg twice daily orally; treatment has usually been given for 4 to 8 weeks for duodenal ulceration and for 8 weeks for benign gastric ulceration. Ranitidine bismuth citrate should not be used for treatment, and a maximum of 16 weeks of treatment (two 8-week courses or four 4-week courses) may be given in a 12-month period. For duodenal ulceration where *H. pylori* infection is present, ranitidine bismuth citrate has been given as part of a 7-day triple therapy regimen, typically combined with any two of clarithromycin 500 mg twice daily, amoxicillin 1 g twice daily, or metronidazole 400 mg twice daily. Alternatively, a 14-day dual therapy regimen of ranitidine bismuth citrate combined with clarithromycin 500 mg two or three times daily has been used. In both regimens ranitidine bismuth citrate alone may be continued to a total of 28 days.

and enantiomer

Profile

Rebamipide is stated to possess cytoprotective properties and is used in the treatment of peptic ulcer disease (p.1702) and gastritis in usual oral doses of 100 mg three times daily. It has also been used rectally for the treatment of intestinal inflammation. Rebamipide eye drops are under investigation in the treatment of dry eye.

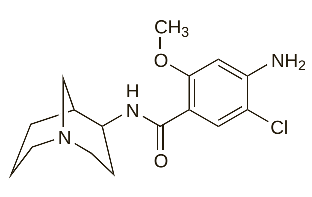
Renzapride *(BAN, rINN)*

ATL-1251; BRL-24924A; Renzaprida; Renzapridum. (±)-*endo*-4-Amino-*N*-(1-azabicyclo[3.3.1]non-4-yl)-5-chloro-*o*-anisamide.

Рензаприд

$C_{16}H_{22}ClN_3O_2$ = 323.8.
CAS — 88721-77-1; 112727-80-7.



Profile

Renzapride is a substituted benzamide with prokinetic actions on gastrointestinal motility. It also has $5-HT_4$ agonist and $5-HT_3$ antagonist activity. It is under investigation for the management of gastrointestinal disorders including irritable bowel syndrome.

◊ References.

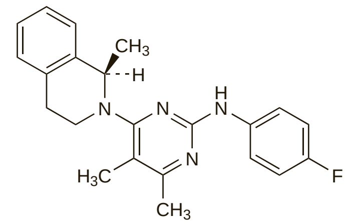
Revaprazan *(rINN)*

Révaprazan; Revaprazán; Revaprazanum. *N*-(4-Fluorophenyl)-4,5-dimethyl-6-[(1*RS*)-1-methyl-3,4-dihydroisoquinolin-2(1*H*)-yl]pyrimidin-2-amine.

Ревапразан

$C_{22}H_{23}FN_4$ = 362.4.
CAS — 199463-33-7.



Revaprazan Hydrochloride *(USAN, rINNM)*

Hidrocloruro de revaprazán; Révaprazan, Chlorhydrate de; Revaprazani Hydrochloridum; YH-1238; YH-1885. *N*-(4-Fluorophenyl)-5,6-dimethyl-4-[(1*RS*)-1-methyl-3,4-dihydroisoquinolin-2(1*H*)-yl]pyrimidin-2-amine hydrochloride.

Ревапразана Гидрохлорид

$C_{22}H_{23}FN_4,HCl$ = 398.9.
CAS — 178307-42-1.

Profile

Revaprazan is a proton pump inhibitor that is under investigation for the management of gastric and duodenal ulceration, functional dyspepsia, and gastro-oesophageal reflux disease.

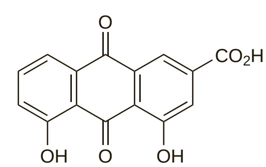
Rhubarb

Chinese Rhubarb; Korzeń rzewienia; Rabarbaro; Rabarbarų šaknys; Rabarberrot; Raparperinjuuri; Ravent; Rebarbara-gyökértörzs; Reveňový kořen; Rhabarber; Rhei radix; Rhei Rhizoma; Rheum; Rhubarb Rhizome; Rhubarbe; Ruibarbo.

Ревень Аптечный



(rhein)

Description. Indian rhubarb (Himalayan rhubarb) consists of the dried rhizome and roots of *Rheum emodi*, *R. webbianum*, or some other related species of *Rheum*.
Rhapontic rhubarb (Chinese rhapontica) consists of the dried rhizomes of *R. rhaponticum*. It may occur as an adulterant of rhubarb, and pharmacopoeias specify a test to confirm its absence. Garden rhubarb, of which the leaf-stalks are used as food, is derived from *R. rhaponticum*.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn. Chin.* and *Jpn* also permit *Rheum tanguticum*, and *Jpn* also permits *R. coreanum*.
Ph. Eur. 6.2 (Rhubarb). The whole or cut, dried underground parts of *Rheum palmatum* or of *R. officinale* or of hybrids of these two species or of a mixture. The underground parts are often divided; the stem and most of the bark with the rootlets are removed. It contains not less than 2.2% of hydroxyanthracene derivatives, expressed as rhein ($C_{15}H_8O_6$ = 284.2), calculated with reference to the dried drug. Protect from light.

Adverse Effects and Precautions

As for Senna, p.1769.

Uses and Administration

Rhubarb is an anthraquinone stimulant laxative used similarly to senna (p.1770). It also exerts an astringent action due to the presence of gallic acid derivatives and tannins.

Homoeopathy. Rhubarb has been used in homoeopathic medicines under the following names: Rheum; Rhei radix; Rheum palmatum.

Preparations

BP 2008: Compound Rhubarb Tincture.

Proprietary Preparations (details are given in Part 3)

Roxatidine Acetate Hydrochloride

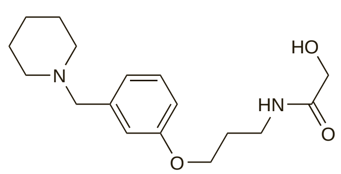
(BANM, USAN, rINNM)

Hidrocloruro de acetato de roxatidina; Hoe-760; Hoe-062 (roxatidine); Pifatidine Hydrochloride; Roxatidine, Acétate Chlorhydrique de; Roxatidini Acetati Hydrochloridum; TZU-0460. *N*-{3-[(α-Piperidino-*m*-tolyl)oxy]propyl}glycolamide acetate monohydrochloride.

Роксатидина Ацетат Гидрохлорид

$C_{17}H_{26}N_2O_3,C_2H_2O,HCl = 384.9.$

CAS — 78273-80-0 (roxatidine); 97900-88-4 (roxatidine hydrochloride); 78628-28-1 (roxatidine acetate); 93793-83-0 (roxatidine acetate hydrochloride).
ATC — A02BA06.
ATC Vet — QA02BA06.



(roxatidine)

Pharmacopoeias. In *Jpn.*

Stability. The stability of roxatidine acetate hydrochloride in parenteral nutrition solutions was influenced by storage temperature and amino acid content and composition.[1]

1. Oh J, *et al.* Stability of roxatidine acetate in parenteral nutrient solutions containing different amino acid formulations. *Am J Health-Syst Pharm* 2005; **62:** 289–91.

Adverse Effects and Precautions

As for Cimetidine, p.1716.

Interactions

Unlike cimetidine (p.1718) roxatidine does not appear to affect cytochrome P450, and therefore is considered to have little effect on the metabolism of other drugs. However, like other H_2-antagonists its effects on gastric pH may alter the absorption of some other drugs.

Pharmacokinetics

Roxatidine acetate hydrochloride is rapidly and almost completely absorbed from the gastrointestinal tract with peak concentrations in plasma occurring about 1 to 3 hours after doses by mouth. It is rapidly hydrolysed to the active desacetyl metabolite, roxatidine, by esterases in the liver, small intestine, and serum.

Over 90% of a dose is excreted in the urine as roxatidine and other metabolites. The elimination half-life of roxatidine is about 6 hours and is prolonged in renal impairment.

Small amounts of roxatidine have been reported to be distributed into breast milk.

Uses and Administration

Roxatidine acetate hydrochloride is an H_2-antagonist with actions and uses similar to those of cimetidine (p.1719).

In the management of peptic ulcer disease the oral dose is 150 mg at bedtime or 75 mg twice daily for 4 to 6 weeks. Where appropriate a maintenance dose of 75 mg at bedtime may be given to prevent the recurrence of ulcers. In gastro-oesophageal reflux disease the recommended dose is 150 mg at bedtime or 75 mg twice daily for 6 to 8 weeks. Gastritis has been managed with 75 mg once daily in the evening, and a dose of 75 mg twice daily has been used for Zollinger-Ellison syndrome.

When used as a pre-anaesthetic medication, an oral dose of roxatidine acetate hydrochloride 75 mg is given in the evening on the day before surgery and repeated 2 hours before the induction of anaesthesia; alternatively a single dose of 150 mg may be given the night before surgery.

Roxatidine acetate hydrochloride may also be given intravenously for the treatment of upper gastrointestinal tract haemorrhage in a dose of 75 mg twice daily by slow intravenous injection or by intravenous infusion.

For dosage in renal impairment, see below.

◊ Reviews.

1. Murdoch D. Roxatidine acetate: a review of its pharmacodynamic and pharmacokinetic properties, and its therapeutic potential in peptic ulcer disease and related disorders. *Drugs* 1991; **42:** 240–60.

Administration in renal impairment. The dosage of roxatidine acetate hydrochloride should be reduced in patients with renal impairment. Suggested oral doses, based on creatinine clearance (CC), for patients on acute therapy are:

- CC 20 to 50 mL/minute: 75 mg at bedtime
- CC less than 20 mL/minute: 75 mg every 2 days

However, results in 6 patients with chronic renal failure and CC less than 20 mL/minute indicated that giving the recommended dose of roxatidine acetate hydrochloride, 75 mg every other day, was inadequate to maintain gastric pH above 4 for more than 6 hours. Subsequent study in 8 patients showed that a dose of 75 mg daily was well tolerated and effective.[1]

Senna

Alexandriai szenna termés (senna pods, Alexandrian); Listek senesu (senna leaf); Plod kasie ostrolisté (senna pods, Alexandrian); Plod kasie úzkolisté (senna pods, Tinnevelly); Sen; Séné de Khartoum ou d'Alexandrie, fruit de (senna pods, Alexandrian); Séné de l'Inde ou de Tinnevelly, fruit de (senna pods, Tinnevelly); Séné, feuille de (senna leaf); Sennabalja, alexandrinsk (senna pods, Alexandrian); Sennabalja, Tinnevelley- (senna pods, Tinnevelley); Sennae folium (senna leaf); Sennae fructus acutifoliae (senna pods, Alexandrian); Sennae fructus angustifoliae (senna pods, Tinnevelly); Sennanpalko, Aleksandrian (senna pods, Alexandrian); Sennanpalko, Tinnevelleyn (senna pods, Tinnevelley); Sennový list (senna leaf); Senų lapai (senna leaf); Senų vaisiai (senna pods, Alexandrian); Siauralapių senų vaisiai (senna pods, Tinnevelly); Sinameki; Szennalevél (senna leaf); Tinevelly szenna termés (senna pods, Tinnevelly).

Кассия Остролистная (Alexandrian senna); Сенна Остролистная (Alexandrian senna); Александрийский Лист (Alexandrian senna leaf)

CAS — 8013-11-4.
ATC — A06AB06.
ATC Vet — QA06AB06.

Description. Senna obtained commercially from *Cassia senna* (*C. acutifolia*) (Leguminosae) is known as Alexandrian senna or Khartoum senna and that from *Cassia angustifolia* (Leguminosae) as Tinnevelly senna.

Pharmacopoeias. Senna fruit, from Alexandrian and Tinnevelly senna is included in *Eur.* (see p.vii), *Int.*, and *US.* Senna leaf, from Alexandrian or Tinnevelly senna or both, is included in *Chin.*, *Eur.*, *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Senna Pods, Alexandrian; Sennae Fructus Acutifoliae; Alexandrian Senna Fruit BP 2008). The dried fruit of *Cassia senna* (*Cassia acutifolia*) containing not less than 3.4% of hydroxyanthracene glycosides, calculated as sennoside B ($C_{42}H_{38}O_{20}$ = 862.7) with reference to the dried drug. Protect from light and moisture.

Ph. Eur. 6.2 (Senna Pods, Tinnevelly; Sennae Fructus Angustifoliae; Tinnevelly Senna Fruit BP 2008). The dried fruit of *Cassia angustifolia* containing not less than 2.2% of hydroxyanthracene glycosides, calculated as sennoside B ($C_{42}H_{38}O_{20}$ = 862.7) with reference to the dried drug. Protect from light and moisture.

Ph. Eur. 6.2 (Senna Leaf; Sennae Folium). The dried leaflets of *Cassia senna* (=*Cassia acutifolia*), known as Alexandrian or Khartoum senna, or *Cassia angustifolia*, known as Tinnevelly senna, or a mixture of the two species. It contains not less than 2.5% of hydroxyanthracene glycosides, calculated as sennoside B ($C_{42}H_{38}O_{20}$ = 862.7) with reference to the dried drug. Protect from light and moisture.

USP 31 (Senna Leaf). The dried leaflet of *Cassia acutifolia*, known in commerce as Alexandria senna, or *Cassia angustifolia*, known in commerce as Tinnevelly senna (Leguminosae). Protect from moisture and from light.

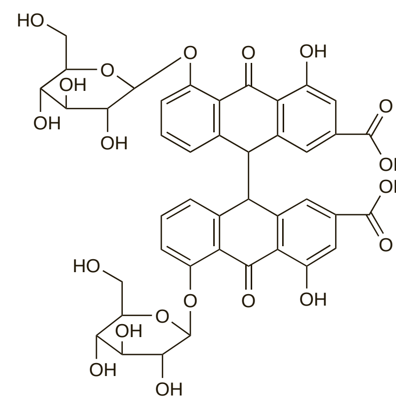
USP 31 (Senna Pods). The dried ripe fruit of *Cassia acutifolia* (Alexandrian senna) or *Cassia angustifolia* (Tinnevelly senna) containing not less than 3.4% or 2.2% respectively of anthraquinone glucosides, calculated as sennosides, on the dried basis. Protect from moisture and from light.

Sennosides

Senósidos.

Сеннозиды

CAS — 81-27-6 (sennoside A); 128-57-4 (sennoside B); 52730-36-6 (sennoside A, calcium salt); 52730-37-7 (sennoside B, calcium salt).



(sennoside A)

Pharmacopoeias. In *US.*

USP 31 (Sennosides). A partially purified natural complex of anthraquinone glucosides found in senna, isolated from *Cassia acutifolia* or *Cassia angustifolia* as calcium salts. It is a brownish powder. Soluble 1 in 35 of water, 1 in 2100 of alcohol, 1 in 3700 of chloroform, and 1 in 6100 of ether. A 10% solution in water has a pH of 6.3 to 7.3. Store at a temperature of 20° to 25°. Protect from moisture and from light.

Adverse Effects

Senna may cause mild abdominal discomfort such as colic or cramps. Prolonged use or overdosage can result in diarrhoea with excessive loss of water and electrolytes, particularly potassium; there is also the possibility of developing an atonic non-functioning colon. Anthraquinone derivatives may colour the urine yellowish-brown at acid pH, and red at alkaline pH. Reversible melanosis coli has been reported following chronic use.

Abuse. Prolonged use or abuse of senna laxatives has been associated with finger clubbing,[1-5] hypokalaemia[3] and tetany,[1] hypertrophic osteoarthropathy,[4,5] intermittent urinary excretion of aspartylglucosamine,[2] hypogammaglobulinaemia,[3] reversible cachexia,[3] and hepatitis[6] or hepatic failure.[7] In one case, nephrocalcinosis was attributed to hypercalcaemia caused by excessive ingestion of calcium sennosides.[5]

1. Prior J, White I. Tetany and clubbing in patient who ingested large quantities of senna. *Lancet* 1978; **ii:** 947.
2. Malmquist J, *et al.* Finger clubbing and aspartylglucosamine excretion in a laxative-abusing patient. *Postgrad Med J* 1980; **56:** 862–4.
3. Levine D, *et al.* Purgative abuse associated with reversible cachexia, hypogammaglobulinaemia, and finger clubbing. *Lancet* 1981; **i:** 919–20.
4. Armstrong RD, *et al.* Hypertrophic osteoarthropathy and purgative abuse. *BMJ* 1981; **282:** 1836.
5. Lim AKH, *et al.* Anorexia nervosa and senna misuse: nephrocalcinosis, digital clubbing and hypertrophic osteoarthropathy. *Med J Aust* 2008; **188:** 121–2.
6. Beuers U, *et al.* Hepatitis after chronic abuse of senna. *Lancet* 1991; **337:** 372–3.
7. Vanderperren B, *et al.* Acute liver failure with renal impairment related to the abuse of senna anthraquinone glycosides. *Ann Pharmacother* 2005; **39:** 1353–7.

Effects on the liver. Hepatitis has been reported in a patient drinking herbal tea containing senna. The patient was found to be a poor metaboliser for hepatic detoxification reactions; the authors cautioned against even small doses of herbal preparations in such patients.[1]

Hepatitis and hepatic failure have also been reported after abuse of senna laxatives, see Abuse, above.

1. Seybold U, *et al.* Senna-induced hepatitis in a poor metabolizer. *Ann Intern Med* 2004; **141:** 651.

Hypersensitivity. Hypersensitivity reactions manifesting as asthma and rhinoconjunctivitis have been reported in those manufacturing[1] or dispensing[2] senna products. However, a study of 125 workers involved in the manufacture of laxatives found only 4 cases of occupational asthma, although sensitisation to senna or ispaghula dust was present in 18 and 9 of the workers respectively, and other airway, eye, and skin symptoms were relatively frequent.[3]

A 2-year history of pruritic scaly erythematous plaques on the palmoplantar surfaces was reported[4] by a patient who had taken a sennoside laxative for 20 years. The lesions subsided over about 6 weeks on stopping the drug, and reappeared over the course of 8 weeks on restarting sennoside. However, patch testing and lymphocyte stimulation tests for sennoside were negative.

4. Fujita Y, *et al.* A case of interstitial granulomatous drug reaction due to sennoside. *Br J Dermatol* 2004; **150:** 1035–7.

Precautions

Senna should not be given to patients with nausea or vomiting, undiagnosed abdominal pain, or intestinal obstruction; care should also be taken in patients with inflammatory bowel disease. Prolonged use should generally be avoided.

Although anthraquinone derivatives may be distributed into breast milk the concentration achieved after usual maternal dosage is thought to be insufficient to affect the nursing infant (see also below).

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were receiving senna, and the American Academy of Pediatrics considers[1] that it is therefore usually compatible with breast feeding.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 21/11/06)

Colonic perforation. There were early reports of colonic perforation with faecal peritonitis,[1,2] in one case fatal,[1] after use of a senna preparation containing total sennosides 142 mg for bowel preparation before barium enema. In 1985, the strength of the UK preparation was halved to contain 72 mg of total sennosides; it was subsequently withdrawn, although a similar preparation, at the higher strength, remains available in some countries. To reduce the risk of colonic perforation, patients with suspected stricture, inflammatory bowel disease, or impending obstruction should not receive a bowel stimulant.[2]

1. Galloway D, *et al*. Faecal peritonitis after laxative preparation for barium enema. *BMJ* 1982; **284:** 472.
2. Cave-Bigley D. Faecal peritonitis after laxative preparation for barium enema. *BMJ* 1982; **284:** 740.

Pharmacokinetics

There is some absorption of anthraquinone laxatives after oral doses. Absorbed anthraquinones are metabolised in the liver. Unabsorbed senna is hydrolysed in the colon by bacteria to release the active free anthraquinones. Anthraquinones are excreted in urine and faeces and distributed into breast milk.

Uses and Administration

Senna is an anthraquinone stimulant laxative (p.1693) that is used to treat constipation (p.1693) and for bowel evacuation before investigational procedures or surgery. The active anthraquinones are liberated into the colon from the sennoside glycosides by colonic bacteria and an effect usually occurs within 6 to 12 hours of an oral dose.

For constipation, senna is usually given as tablets, granules, or syrup. In some countries it is available as suppositories. In the UK, doses of senna preparations are usually expressed in terms of total sennosides calculated as sennoside B. The usual adult oral dose is 15 to 30 mg as a single dose at bedtime. (For doses in children see Administration in Children, below.) In the USA, the usual adult dose is 15 to 30 mg once or twice daily, expressed in terms of total sennosides.

For bowel evacuation before investigational procedures, a dose of 105 to 157.5 mg of sennosides may be given orally as a liquid preparation on the day before the procedure (but see Colonic Perforation under Precautions, above).

The purified sennosides (sennosides A and B), and their calcium salts (calcium sennoside A and calcium sennoside B) are used similarly to senna.

Homoeopathy. Senna leaf has been used in homoeopathic medicines under the following names: Senna; Senna folium.

Administration in children. In the UK, the following oral doses of sennosides are licensed for use for constipation in children:

- aged 2 to 6 years: 3.75 to 7.5 mg once daily in the morning
- aged 6 to 12 years: 7.5 to 15 mg once daily at night or in the morning
- 12 years and over: 15 to 30 mg once daily, usually at bedtime

In addition, although not licensed for use in children under 2 years, the *BNFC* allows for an oral dose of syrup (containing sennosides 7.5 mg per 5 mL) of 0.5 mL/kg (to a maximum of 2.5 mL) once daily in those aged 1 month to 2 years.

Preparations

BP 2008: Senna Liquid Extract; Senna Tablets; Standardised Senna Granules;
Ph. Eur.: Senna Leaf Dry Extract, Standardised;
USP 31: Senna Fluidextract; Senna Syrup; Sennosides Tablets.

Simeticone *(BAN, rINN)*

Activated Dimethicone; Activated Dimethylpolysiloxane; Activated Dimeticone; Antifoam A; Antifoam AF; Simethicone *(USAN)*; Simeticona; Siméticone; Simeticonum; Simetikon; Simetikonas; Simetikoni; Szimetikon.

Симетикон

CAS — 8050-81-5.

NOTE. Do not confuse with Dimeticone (p.2032).

Compounded preparations of simeticone may be represented by the following names:

- Co-simalcite *x/y* (*BAN*)—where *x* and *y* are the strengths in milligrams of simeticone and hydrotalcite respectively.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Simeticone). It is prepared by incorporation of 4 to 7% silica into poly(dimethylsiloxane) with a degree of polymerisation between 20 and 400. It contains 90.5 to 99.0% of poly(dimethylsiloxane). It is a greyish-white, opalescent, viscous liquid. Practically insoluble in water and in methyl alcohol; very slightly soluble to practically insoluble in dehydrated alcohol; partly miscible with dichloromethane, with ethyl acetate, with methyl ethyl ketone, and with toluene.

USP 31 (Simeticone). A mixture of fully methylated linear siloxane polymers containing repeating units of the formula $[-(CH_3)_2SiO-]_n$, stabilised with trimethylsiloxy end-blocking units of the formula $[(CH_3)_3SiO-]$, and silicon dioxide. It contains not less than 90.5% and not more than 99% of polydimethylsiloxane and not less than 4% and not more than 7% of silicon dioxide. A translucent, grey, viscous fluid. Insoluble in water, in alcohol, and in dehydrated alcohol; the liquid phase is soluble 1 in 10 of chloroform, of ether, and of benzene, leaving a residue of silicon dioxide. Store in airtight containers.

Profile

Simeticone is a mixture of liquid dimeticones containing finely divided silicon dioxide to enhance the defoaming properties of the silicone. It lowers surface tension and when given by mouth causes bubbles of gas in the gastrointestinal tract to coalesce, thus aiding their dispersion.

Simeticone is used for the relief of flatulence and abdominal discomfort due to excess gastrointestinal gas in disorders such as dyspepsia (p.1695) and gastro-oesophageal reflux disease (p.1696). Doses of 100 to 250 mg three or four times daily have been given. For many gastrointestinal disorders, it is given with an antacid.

Doses of about 20 to 40 mg of simeticone have been given with feeds to relieve colic in infants (see Gastrointestinal Spasm, p.1696).

Simeticone is also used as a defoaming agent in radiography or endoscopy of the gastrointestinal tract.

◊ A brief review of the use of simeticone for gastrointestinal symptoms concluded that although it was commonly prescribed with an antacid, there was no good evidence that this provided additional benefit. When used alone simeticone probably helped to relieve minor postoperative and postprandial symptoms and was a useful aid in upper gastrointestinal endoscopy.[1] However, some considered there was no convincing evidence that simeticone, alone or with antacids, was effective for the treatment of eructation, flatulence, or other signs or symptoms of excess gastrointestinal gas.[2]

Smectites

Смектиты

ATC — A07BC05 (diosmectite).

ATC Vet — QA07BC05 (diosmectite).

Profile

Smectites are natural mineral clays composed mainly of aluminium silicates and include aluminium magnesium silicate (p.2141), bentonite (p.2141), and Fuller's earth (p.1447). They have adsorbent properties and some, such as dioctahedral smectite (diosmectite), have been used in the management of diarrhoea. They are also used as pharmaceutical excipients and in industry.

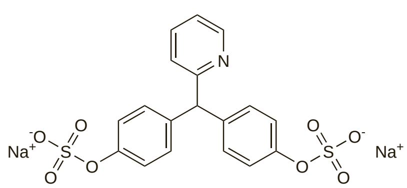
CAS — 10040-45-6.

ATC — A06AB08.

ATC Vet — QA06AB08.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.*

Ph. Eur. 6.2 (Sodium Picosulfate). A white or almost white, crystalline powder. Freely soluble in water; slightly soluble in alcohol.

Adverse Effects and Precautions

As for Bisacodyl, p.1710 and p.1710.

Bowel evacuation. Sodium picosulfate with magnesium citrate was considered a safe and effective bowel cleansing agent in adults[1] and children[2] with inflammatory bowel disease. They tolerated the preparation as well as patients with other colonic disorders with no adverse effect on their disease symptoms. Patients should be kept well hydrated (it may be appropriate to carry out bowel preparation in hospital in frail or elderly patients to avoid the risks of over- or underhydration[3,4]), and this procedure should not be used in suspected toxic dilatation of the colon.

In Australia, the Adverse Drug Reactions Advisory Committee has warned that low volume sodium picosulfate solutions may cause marked dehydration, hyponatraemia, other electrolyte abnormalities, and associated complications. Patients at particular risk include infants, the elderly, the frail, and those with congestive heart failure or with renal impairment.[5]

A grand mal seizure in a 64-year-old female given sodium picosulfate with magnesium citrate was assumed to have been caused by hyponatraemia; the patient had normal electrolyte concentrations in the period before taking the bowel preparation. Care is needed when sodium picosulfate solutions are used in those with a low seizure threshold or potential sodium depletion.[6]

6. Frizelle FA, *et al.* Hyponatremia and seizures after bowel preparation: report of three cases. *Dis Colon Rectum* 2005; **48:** 393–6.

Pharmacokinetics

Like bisacodyl (p.1710), sodium picosulfate is metabolised by colonic bacteria to the active compound bis(*p*-hydroxyphenyl)pyridyl-2-methane. Only a small amount of sodium picosulfate is absorbed after an oral dose; this is subsequently excreted in the urine.

Uses and Administration

Sodium picosulfate is a stimulant laxative related to bisacodyl (p.1710) used for the treatment of constipation (p.1693) and for evacuation of the colon before investigational procedures or surgery. When taken orally it is metabolised by colonic bacteria to an active form that stimulates bowel movements. It is usually effective within 6 to 12 hours although when used with magnesium citrate for bowel evacuation an effect may be seen within 3 hours.

For constipation it is given as a single oral dose of 5 to 10 mg, usually at bedtime. (For doses in children see below.)

For bowel evacuation, a dose of sodium picosulfate 10 mg with magnesium citrate (p.1743) is given in the morning and again in the afternoon of the day before examination.

Administration in children. In the UK, the following oral doses of sodium picosulfate have been recommended for children in the treatment of **constipation**; the dose is usually given at night:

- 1 month to 4 years: 250 micrograms/kg (maximum 5 mg)
- 4 to 10 years: 2.5 to 5 mg
- over 10 years: 5 to 10 mg

Most UK licensed product information gives similar doses to those above for **bowel cleansing**. Alternatively, some recommend that children may be given the following doses of a sachet containing sodium picosulfate 10 mg (with magnesium citrate):

- 1 to 2 years: ⁄ sachet in the morning and ⁄ sachet in the afternoon
- 2 to 4 years: ⁄ sachet in the morning and ⁄ sachet in the afternoon
- 4 to 9 years: 1 sachet in the morning and ⁄ sachet in the afternoon
- over 9 years: 1 sachet in the morning and 1 sachet in the afternoon

Preparations

CAS — 7757-82-6.

ATC — A06AD13; A12CA02.

ATC Vet — QA06AD13; QA12CA02.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *Viet.*

US includes a single monograph for both the anhydrous form and the decahydrate.

Ph. Eur. 6.2 (Sodium Sulphate, Anhydrous). A white or almost white, hygroscopic powder. Freely soluble in water. Store in airtight containers.

USP 31 (Sodium Sulfate). It contains 10 molecules of water of hydration or is anhydrous. The decahydrate loses between 51 and 57% of its weight on drying and the anhydrous form loses not more than 0.5% of its weight. Large, colourless, odourless, transparent crystals or a granular powder. It effloresces rapidly in air, liquefies in its water of hydration at about 33°, and loses all of its water of hydration at about 100°. Freely soluble in water; insoluble in alcohol; soluble in glycerol. Store in airtight containers, preferably at a temperature not exceeding 30°.

ATC Vet — QA06AD13; QA12CA02.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *Viet.*

US includes a single monograph for both the anhydrous form and the decahydrate.

Ph. Eur. 6.2 (Sodium Sulphate Decahydrate; Sodium Sulphate BP 2008). A white or almost white, crystalline powder or colourless, transparent crystals. Freely soluble in water; practically insoluble in alcohol. It partly dissolves in its own water of crystallisation at about 33°. It loses between 52.0 and 57.0% of its weight on drying.

USP 31 (Sodium Sulfate). It contains 10 molecules of water of hydration or is anhydrous. The decahydrate loses between 51 and 57% of its weight on drying and the anhydrous form loses not more than 0.5% of its weight. Large, colourless, odourless, transparent crystals or a granular powder. It effloresces rapidly in air, liquefies in its water of hydration at about 33°, and loses all of its water of hydration at about 100°. Freely soluble in water; insoluble in alcohol; soluble in glycerol. Store in airtight containers, preferably at a temperature not exceeding 30°.

Profile

Sodium sulfate has been used as an osmotic laxative (p.1693). It is also given in dilute solution (about 0.5%) with a high molecular weight macrogol for prompt bowel evacuation before investigational procedures or surgery (see Macrogols, p.2336).

Sodium sulfate is also used as an additive in foods.

For the general properties of sodium salts, see p.1686.

Preparations

USP 31: Sodium Sulfate Injection.

USNF 26 (Sodium Tartrate). Transparent, colourless, odourless crystals. Freely soluble in water; insoluble in alcohol. pH of a 10% solution in water is between 7 and 9. Store in airtight containers.

Profile

Sodium tartrate has been used as an osmotic laxative. It is used as a food additive.

For the general properties of sodium salts, see p.1686.

Preparations

Proprietary Preparations (details are given in Part 3)

Canad.: Limonade Asepta.

Multi-ingredient: ***Arg.:*** Oral-B Enjuague Bucal Amosan†.

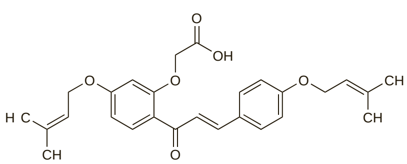
Sofalcone *(pINN)*

Sofalcona; Sofalconum; SU-88. {5-[(3-Methyl-2-butenyl)oxy]-2-{*p*-[(3-methyl-2-butenyl)oxy]cinnamoyl}phenoxy}acetic acid.

Софалькон

$C_{27}H_{30}O_6 = 450.5.$

CAS — 64506-49-6.



Profile

Sofalcone is reported to possess cytoprotective properties and is used in the treatment of gastritis and peptic ulcer disease (p.1702). An oral dose of 100 mg is given 3 times daily.

◊ References.

Preparations

Proprietary Preparations (details are given in Part 3)

Jpn: Solon.

Sterculia

E416; Goma esterculia; Indian Tragacanth; Karaya; Karaya Gum; Sterculia Gum; Sterkülia.

Камедь Карайи; Стеркулия Жгучая (*Sterculia urens*)

CAS — 9000-36-6.

ATC — A06AC03.

ATC Vet — QA06AC03.

Pharmacopoeias. In *Br.* and *Fr.*

BP 2008 (Sterculia). The gum obtained from *Sterculia urens* and other species of *Sterculia*. Irregular or vermiform pieces, greyish-white with a brown or pink tinge, with an odour resembling that of acetic acid. It contains not less than 14.0% of volatile acid (or not less than 10.0% if supplied in powdered form), calculated as acetic acid. Sparingly soluble in water, but swells into a homogeneous, adhesive, gelatinous mass; practically insoluble in alcohol. Store at a temperature not exceeding 25°.

Adverse Effects and Precautions

As for Ispaghula, p.1737. There is a risk of intestinal or oesophageal obstruction and faecal impaction, especially if such compounds are swallowed dry. Therefore they should always be taken with sufficient fluid and should not be taken immediately before going to bed. They should be avoided by patients who have difficulty swallowing.

Uses and Administration

Sterculia is used similarly to ispaghula (p.1737) as a bulk laxative and for adjusting faecal consistency. It has also been used as an aid to appetite control in the management of obesity (p.2149) but there is little evidence of efficacy. It is usually taken in the form of granules containing sterculia 62%; the dose is 1 to 2 sachets or 1 to 2 heaped 5 mL spoonfuls orally once or twice daily after meals. (For a dose in children see below.) The granules are washed down without chewing with plenty of water. They may also be taken sprinkled onto soft foods such as yogurt.

Sterculia is used topically, as a paste or powder, for skin protection and sealing in the fitting of ileostomy and colostomy appliances. It has also been used in dental fixative powders, and as an emulsifier and stabiliser in foods.

Administration in children. In the UK, the recommended oral dose of granules, containing sterculia 62%, for constipation in children aged 6 to 12 years is ⁄ to 1 sachet, or ⁄ to one 5 mL spoonful, once or twice daily after meals. Children over 12 years may be dosed as for adults, see Uses and Administration, above. The granules are washed down without chewing with plenty of water. They may also be taken sprinkled onto soft foods such as yogurt.

Preparations

BP 2008: Sterculia Granules.

Sucralfate *(BAN, USAN, rINN)*

Sucralfato; Sucralfatum; Sukralfaatti; Sükralfat; Sukralfat. Sucrose hydrogen sulphate basic aluminium salt; Sucrose octakis(hydrogen sulphate) aluminium complex; β-D-Fructofuranosyl-α-D-glucopyranoside octakis (hydrogen sulphate) aluminium complex.

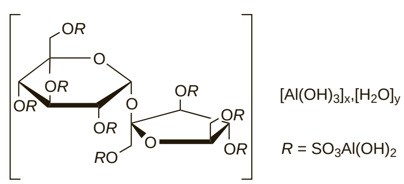
Сукральфат

$C_{12}H_mAl_{16}O_nS_8.$

CAS — 54182-58-0.

ATC — A02BX02.

ATC Vet — QA02BX02.



Pharmacopoeias. In *Chin., Jpn,* and *US.*

USP 31 (Sucralfate). The hydrous basic aluminium salt of sucrose octasulfate. Store in airtight containers.

Adverse Effects and Precautions

Constipation is the most frequently reported adverse effect of sucralfate although diarrhoea, nausea, vomiting, flatulence, or gastric discomfort may also occur. Other adverse effects include dry mouth, dizziness, drowsiness, headache, vertigo, back pain, and skin rashes. Hypersensitivity reactions such as pruritus, oedema, urticaria, respiratory difficulty, rhinitis, laryngospasm, and facial swelling have been reported.

Great caution is needed in patients with renal impairment (below) as absorption and accumulation of aluminium may cause adverse effects.

Bezoar formation. As of March 1999, the UK CSM was aware of 7 reports worldwide of bezoar formation associated with sucralfate use in intensive care patients.[1] It advised caution in the use of sucralfate in seriously ill patients because of the risks of bezoar formation and intestinal obstruction.[1] Patients with delayed gastric emptying or receiving concomitant enteral feeds may be at increased risk. A report by the French Pharmacovigilance System at about the same time made similar recommendations but also contra-indicated the use of sucralfate in premature and immature neonates.[2]

Renal impairment. Sucralfate under acid conditions can release aluminium ions that may be absorbed systemically. Significant increases in the urinary excretion of aluminium have been seen in healthy subjects given sucralfate 4 g daily,[1,2] reflecting gastrointestinal absorption of aluminium; aluminium concentrations in serum and urine were significantly higher in patients with chronic renal impairment than in subjects with normal renal function,[3] and similar serum increases have been seen in children with acute renal failure.[4] Aluminium toxicity in patients with normal renal function receiving sucralfate would not be expected, but seizures, muscle weakness, bone pain,[1] and severe aluminium encephalopathy[5] have been reported in patients with end-stage renal disease requiring dialysis. Sucralfate should be used with caution in patients with renal impairment, especially if other aluminium-containing agents are also taken, and such patients should be monitored for signs of aluminium toxicity.[4,6]

Interactions

Sucralfate may interfere with the absorption of other drugs and it has been suggested that there should be an interval of 2 hours between giving sucralfate and other non-antacid medication. Some of the drugs reported to be affected by sucralfate include cimetidine, ranitidine, digoxin, fluoroquinolone antibacterials, ketoconazole, levothyroxine, phenytoin, tetracycline, quinidine, theophylline, and possibly warfarin. The recommended interval between sucralfate and antacids is 30 minutes. An interval of 1 hour should elapse between giving sucralfate and enteral feeding.

Pharmacokinetics

Sucralfate is only slightly absorbed from the gastrointestinal tract after oral doses. However, there can be some release of aluminium ions and of sucrose sulfate; small quantities of sucrose sulfate may then be absorbed and excreted, primarily in the urine; some absorption of aluminium may also occur (see Renal Impairment, above).

Uses and Administration

Sucralfate is a cytoprotective drug that, under acid gastrointestinal conditions, forms an adherent complex with proteins which coats the gastric mucosa and is reported to have a special affinity for ulcer sites. It also inhibits the action of pepsin and adsorbs bile salts.

Sucralfate has been used in the treatment of peptic ulcer disease (p.1702) and chronic gastritis. It is given orally and should be taken on an empty stomach before meals and at bedtime. The usual dose is 1 g four times daily or 2 g twice daily for 4 to 8 weeks; if necessary the dose may be increased to a maximum of 8 g daily. If longer-term therapy is required sucralfate may be given for up to 12 weeks. Where appropriate a maintenance dose of 1 g twice daily may be given to prevent the recurrence of duodenal ulcers.

For prophylaxis of gastrointestinal haemorrhage from stress ulceration the usual dose of sucralfate is 1 g six times daily; a dose of 8 g daily should not be exceeded. For children's doses see below.

Administration in children. Although sucralfate is not licensed in the UK for use in children under 15 years, the *BNFC* recommends the following oral doses for the treatment of peptic ulcer disease, or the prophylaxis of stress ulceration in children in intensive care (but see also under Bezoar Formation, above):

- 1 month to 2 years: 250 mg four to six times daily
- 2 to 12 years: 500 mg four to six times daily
- 12 to 18 years: 1 g four to six times daily

The oral suspension blocks fine-bore feeding tubes and tablets should be crushed and dispersed in water instead.

Gastrointestinal bleeding. Sucralfate is an effective drug for the prophylaxis and management of stress-induced gastrointestinal bleeding in severely ill patients but whether it should be chosen over an H_2-antagonist has been subject to debate. One study suggested it might reduce the risk of late-onset pneumonia compared with ranitidine.[1] Another study[2] found ranitidine to be more effective than sucralfate in reducing the risk of gastrointestinal bleeding; while there was a trend towards a lower rate of pneumonia among patients receiving sucralfate, the difference was not significant. However, meta-analyses[3] found an increased risk of pneumonia with ranitidine compared with sucralfate, but no difference in the rate of pneumonia with sucralfate and placebo; insufficient data were available to conduct a meta-analysis of sucralfate's efficacy in terms of rates of bleeding, and a re-assessment of recommendations for the prophylaxis of stress ulcers was called for. Later guidelines[4] concluded that the use of sucralfate did not influence the incidence of ventilator-associated pneumonia compared with placebo. For further discussion of stress ulceration and bleeding, including the use of sucralfate, see under Peptic Ulcer Disease, p.1702. There is also some evidence from a study[5] that sucralfate reduces gastrointestinal bleeding associated with NSAID use, although it does not prevent drug-induced gastric erosion.

In a study to assess whether oral prophylactic sucralfate could ameliorate the symptoms of acute radiation proctitis, sucralfate was found to increase the incidence of rectal bleeding compared with placebo; the cause of this increased bleeding was unclear.[6]

Gastro-oesophageal reflux disease. Although sucralfate has been tried for gastro-oesophageal reflux disease (p.1696) the results of studies have been inconsistent.[1-3] However, if lifestyle or dietary measures prove insufficient for the management of heartburn in pregnancy, sucralfate may be considered for first-line therapy.

Mouth ulceration. Sucralfate has been investigated as a mouth rinse in the treatment and prophylaxis of stomatitis induced by cancer chemotherapy[1-3] although evidence of benefit for any drug is ambiguous (see Mucositis, p.640). One study[2] in 40 patients found a significant reduction in symptoms among 23 evaluable patients given sucralfate prophylactically. Seven patients withdrew due to aggravation of chemotherapy-induced nausea. It was suggested that to overcome this problem, the suspension should have a neutral taste, should not be swallowed after rinsing, and that rinsing should not be started until nausea had stopped. However, another study[4] involving 80 patients treated with fluorouracil for colorectal cancer found no significant difference in self-reported mucositis symptoms between patients given sucralfate suspension and those given placebo.

Sucralfate has also been reported to be of benefit in patients with recurrent aphthous stomatitis (mouth ulceration—p.1700). A study involving 21 such patients over 2 years found that topical application of sucralfate suspension 4 times daily was superior to treatment with an antacid (aluminium hydroxide with magnesium hydroxide) or placebo.[5]

In patients with Behçet's syndrome (p.1499), topical sucralfate suspension significantly decreased the frequency, healing time, and pain of oral ulceration, as well as the healing time and pain of genital ulceration,[6] when compared with placebo.

Skin ulceration. Sucralfate has reportedly been applied topically with some success to treat bleeding skin ulcers (p.1585) associated with malignancy,[1] and to promote the healing of venous stasis ulcers.[2] It has been suggested that sucralfate promotes angiogenesis by binding to, and preventing degradation of, basic fibroblast growth factor (bFGF).[2] Topical sucralfate 7% cream was also reported to decrease pain and speed healing of the wound after open surgical removal of haemorrhoids.[3]

Sulfasalazine *(BAN, USAN, rINN)*

Salatsosulfapyridiini; Salazosulfapyridin; Salazosulfapyridine; Salazosulfapyridinum; Salicylazosulfapyridine; SI-88; Sulfasalatsiini; Sülfasalazin; Sulfasalazin; Sulfasalazina; Sulfasalazinas; Sulfasalazinum; Sulfasalazyna; Sulphasalazine; Szulfaszalazin. 4-Hydroxy-4′-(2-pyridylsulphamoyl)azobenzene-3-carboxylic acid.

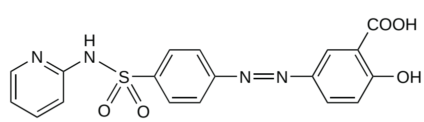
Сульфасалазин

$C_{18}H_{14}N_4O_5S$ = 398.4.

CAS — 599-79-1.

ATC — A07EC01.

ATC Vet — QA07EC01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Sulfasalazine). A bright yellow or brownish-yellow, fine powder. Practically insoluble in water and in dichloromethane; very slightly soluble in alcohol; dissolves in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Sulfasalazine). A fine odourless bright yellow or brownish-yellow powder. Practically insoluble in water, in chloroform, in ether, and in benzene; soluble 1 in 2900 of alcohol, and 1 in 1500 of methyl alcohol; soluble in aqueous solutions of alkali hydroxides. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Since sulfasalazine is metabolised to sulfapyridine and 5-aminosalicylic acid (mesalazine), its adverse effects and precautions are similar to those of sulfonamides (see Sulfamethoxazole, p.340) and of mesalazine (p.1745). Many adverse effects have been attributed to the sulfapyridine moiety and appear to be more common if serum-sulfapyridine concentrations are greater than 50 micrograms/mL, if the daily dose of sulfasalazine is 4 g or more, or in slow acetylators of sulfapyridine.

The most commonly reported adverse effects include nausea and vomiting, abdominal discomfort, headache, fever, and skin rash.

Adverse effects can be broadly divided into 2 groups:

- dose-related effects are dependent on acetylator phenotype, and largely predictable; this group includes nausea and vomiting, headache, haemolytic anaemia, and methaemoglobinaemia
- hypersensitivity reactions are essentially unpredictable and usually occur at the start of treatment; this group includes skin rash, aplastic anaemia, hepatic and pulmonary dysfunction, and auto-immune haemolysis

Oligospermia, reversible on withdrawal of sulfasalazine, has also been reported. Sulfasalazine treatment may result in yellow-orange discoloration of skin, urine, and other body fluids. Some soft contact lenses may be stained.

Sulfasalazine should not be given to patients with a history of sensitivity to sulfonamides or salicylates. Use in children under 2 years of age is contra-indicated because of the risk of kernicterus.

Blood counts should be performed at the start of therapy and at least once a month for a minimum of the first 3 months of treatment. If a blood dyscrasia is suspected treatment should be stopped immediately and a blood count performed. Patients or their carers should be told how to recognise signs of blood toxicity and should be advised to seek immediate medical attention if symptoms such as fever, sore throat, mouth ulcers, bruising or bleeding develop. Care is advisable in patients with G6PD deficiency because of the risk of haemolytic anaemia.

Sulfasalazine should be used with caution in hepatic or renal impairment. Liver function tests should be carried out at monthly intervals for the first 3 months of treatment. Periodic monitoring of kidney function has also been recommended.

◊ The adverse effects associated with the use of sulfasalazine in patients with inflammatory bowel disease[1] or rheumatoid arthritis have been reviewed.[2,3] The type and incidence of adverse effects appear to be similar in both groups of patients.[2] Although most reactions are minor and patients may continue therapy at the same or reduced dosage, some patients stop treatment because of adverse effects and in these cases a hyposensitisation regimen may be considered.[1,4,5] **Hyposensitisation** should not be attempted in patients with a history of a serious adverse effect such as agranulocytosis, toxic epidermal necrolysis, erythema multiforme, frank haemolysis, or a severe hypersensitivity reaction.[1,4,5] An alternative to hyposensitisation in patients with inflammatory bowel disease who cannot tolerate sulfasalazine is to try a drug that supplies the active 5-aminosalicylic acid component without sulfapyridine, as the latter is thought to be responsible for many of the adverse effects. Examples include balsalazide, mesalazine, and olsalazine; however, some patients still experience hypersensitivity, see under Mesalazine, p.1745.

Breast feeding. Small amounts of sulfasalazine and its sulfapyridine metabolites are excreted in breast milk; the concentrations of sulfasalazine and total sulfapyridine may be up to 30% and 50% of maternal serum concentrations respectively.[1] Bloody diarrhoea in a breast-fed infant whose mother was taking sulfasalazine 3 g daily has been reported.[2] The mother was a slow acetylator with a relatively high blood concentration of sulfapyridine, which contributed to the appearance of the drug in the infant's blood. Based on this report, the American Academy of Pediatrics[3] considers that sulfasalazine should be given with caution to breast-feeding mothers. However, others consider that continued treatment with sulfasalazine can generally be recommended to breast-feeding mothers of healthy infants.[4] A small study initially involving 17 mother-child pairs concluded sulfasalazine treatment could continue throughout pregnancy and lactation. The study found negligible amounts of sulfasalazine, and its main metabolite sulfapyridine, were transferred to the child via breast feeding. The authors did however warn that this conclusion could not be applied to a prematurely born child or a child with haemolytic disease.[5]

Effects on the blood. Blood disorders constitute 19% of all reactions reported with sulfasalazine.[1] As of June 1993 the UK CSM was aware of 191 reports of neutropenia, leucopenia, or agranulocytosis (22 fatal), 44 reports of bone marrow depression or aplastic anaemia (13 fatal) and 30 reports of thrombocytopenia (1 fatal).[1]

Although blood dyscrasias were initially thought to be caused by the sulfapyridine moiety, subsequent experience has shown that the aminosalicylates can also cause haematological reactions (see Mesalazine, p.1745). The risk of blood dyscrasias with sulfasalazine has been estimated at 0.6 per 1000 in those given the drug for inflammatory bowel disease, but about 10 times greater in patients receiving sulfasalazine for rheumatoid arthritis.[2]

Sulfasalazine inhibits folic acid absorption, interferes with its metabolism, and can increase folic acid requirements through haemolysis of red blood cells.[3,4] These effects are not usually significant in patients with inflammatory bowel disease unless there are additional factors causing folate deficiency, such as intercurrent illness or an exacerbation of bowel disease.[3,4] However, clinical folate deficiency with macrocytosis, megaloblastic anaemia, or pancytopenia has been reported rarely.[3,4] Macrocytic anaemia associated with sulfasalazine may occur more commonly in patients with rheumatoid arthritis; it was found in 7 of 50 patients within 3 to 4 months of starting treatment with sulfasalazine.[5] The effects of sulfasalazine on folic acid metabolism appear to be dose-related and respond to withdrawal or dosage reduction, and folic acid supplements;[3-5] intravenous folinic acid may sometimes be needed.[4] Although the effects may be potentially serious, they are not a contra-indication to continuing sulfasalazine treatment.[4,5]

Patients with a history of leucopenia associated with gold therapy for rheumatoid arthritis should not be given sulfasalazine since a similar reaction may occur.[6]

Effects on the cardiovascular system. Reports include Raynaud's syndrome with sulfasalazine[1] and myocarditis with sulfasalazine and with mesalazine.[2] Myocarditis leading to fatal cardiogenic shock has been reported in a patient receiving mesalazine and it has been recommended that sulfasalazine or mesalazine should be replaced by glucocorticoids if cardiac symptoms arise.[3]

3. Kristensen KS, *et al.* Fatal myocarditis associated with mesalazine. *Lancet* 1990; **335:** 605.

Effects on fertility. Although successful pregnancies have been reported in the partners of men taking sulfasalazine,[1,2] male infertility is a well recognised complication of sulfasalazine treatment. Untreated inflammatory bowel disease is not associated with abnormal seminal quality or infertility, but oligospermia, reduced sperm motility, and an increase in morphological abnormalities are seen after treatment with sulfasalazine which may lead to infertility.[1-4] Oligospermia has been reported in 86% of men with inflammatory bowel disease treated with sulfasalazine.[1] Seminal characteristics and fertility return to normal within 2 to 3 months of withdrawing sulfasalazine and successful pregnancies have been reported after withdrawal.[1-3] The mechanism involved is thought to be a direct toxic effect on immature and developing spermatozoa, possibly due to the sulfapyridine moiety.[2-4] Improvement in seminal characteristics and successful pregnancies have been reported following substitution of mesalazine[4,5] or balsalazide[6] for sulfasalazine in patients with ulcerative colitis. However, reversible infertility, similar to that caused by sulfasalazine, has also been reported with mesalazine.[7]

Effects on the gastrointestinal tract. Sulfasalazine-induced exacerbations of ulcerative colitis have been reported[1,2] and are probably caused by the salicylate moiety rather than sulfapyridine.[3] Other reported effects include intestinal villous atrophy.[4]

4. Smith MA, *et al.* Angioimmunoblastic lymphadenopathy, sulphasalazine exposure and villous atrophy. *Postgrad Med J* 1985; **61:** 337–8.

Effects on the hair. Alopecia occurred on 2 occasions[1] after starting sulfasalazine 2 or 3 g daily in a patient with ulcerative colitis. On both occasions normal hair growth returned after treatment was stopped, and the patient was later successfully desensitised. However, alopecia that developed in another patient during sulfasalazine treatment did not recur on rechallenge.[2] In this case postpartum alopecia was considered to be the cause and these authors doubted whether sulfasalazine causes alopecia at all. Hair loss has been reported in 2 patients receiving mesalazine enemas.[3] However, remission of alopecia universalis has been reported during sulfasalazine treatment of rheumatoid arthritis.[4]

4. Jawad ASM, Scott DGI. Remission of alopecia universalis during sulphasalazine treatment for rheumatoid arthritis. *BMJ* 1989; **298:** 675.

Effects on the kidneys. UK licensed product information advises that adequate fluid intake and avoidance of urinary acidifiers may reduce the incidence of crystalluria and stone formation. For reports of nephrotic syndrome and of interstitial nephritis associated with sulfasalazine treatment, see under Mesalazine, p.1745.

Effects on the pancreas. The UK CSM had received 6 reports of pancreatitis associated with sulfasalazine as of February 1994.[1] There had been further reports associated with mesalazine (see p.1746). However, a large Danish population-based case-control study concluded neither sulfasalazine nor mesalazine was associated with an increased risk of pancreatitis, and that any increased risk might be associated with inflammatory bowel disease itself.[2]

1. Committee on Safety of Medicines/Medicines Control Agency. Drug-induced pancreatitis. *Current Problems* 1994; **20:** 2–3. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2024457&RevisionSelectionMethod=LatestReleased (accessed 02/07/08)
2. Munk EM, *et al.* Inflammatory bowel diseases, 5-aminosalicylic acid and sulfasalazine treatment and risk of acute pancreatitis: a population-based case-control study. *Am J Gastroenterol* 2004; **99:** 884–8.

Effects on the respiratory system. Although one study reviewed 50 cases of sulfasalazine-induced pulmonary complications, pulmonary toxicity remains a rare adverse effect.[1] Most reports include dyspnoea, cough, pulmonary infiltrates, fever, and eosinophilia, usually developing in the first few months of treatment although they may occur after several years.[1-3] Symptoms are generally readily reversible on withdrawal of sulfasalazine, although death due to fibrosing alveolitis has been reported,[2] and the need for corticosteroid therapy remains debatable.[1] These effects have also occurred with mesalazine, p.1746; they have been reported in patients with a history of sensitivity to salicylates, sulfonamides, or with no known sensitivity to these drugs.[2,3] Bronchiolitis obliterans organising pneumonia has been reported in a patient with rheumatoid arthritis receiving sulfasalazine;[4] clinical improvement occurred after sulfasalazine was stopped and corticosteroid therapy started.

2. Wang KK, *et al.* Pulmonary infiltrates and eosinophilia associated with sulfasalazine. *Mayo Clin Proc* 1984; **59:** 343–6.
3. Jordan A, Cowan RE. Reversible pulmonary disease and eosinophilia associated with sulphasalazine. *J R Soc Med* 1988; **81:** 233–5.
4. Ulubaş B, *et al.* Bronchiolitis obliterans organizing pneumonia associated with sulfasalazine in a patient with rheumatoid arthritis. *Clin Rheumatol* 2004; **23:** 249–51.

Effects on taste. Metallic taste has occurred in patients taking sulfasalazine for ulcerative colitis,[1] although diseases causing changes in gastrointestinal absorption may lead to zinc deficiency, which has itself been associated with a metallic taste. There has also been a report of two patients developing a reversible taste dysfunction, while taking sulfasalazine for rheumatoid arthritis.[2]

2. Marcus RW. Sulfasalazine induced taste disturbances. *J Rheumatol* 1991; **18:** 634–5.

Lupus. A study in 11 patients with sulfasalazine-induced lupus found that induction of disease was more likely in patients who were slow acetylators of sulfapyridine, and who had HLA haplotypes associated with idiopathic SLE.[1] Furthermore, the risk of developing persistent SLE and lupus nephritis increased with duration of treatment and cumulative dose of sulfasalazine. Lupus-like syndrome has also occurred with mesalazine, see Lupus, p.1746.

1. Gunnarsson I, *et al.* Predisposing factors in sulphasalazine-induced systemic lupus erythematosus. *Br J Rheumatol* 1997; **36:** 1089–94.

Porphyria. Sulfasalazine has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Pregnancy. Sulfasalazine and its sulfapyridine metabolites readily cross the placenta resulting in similar concentrations in the cord serum and maternal serum at delivery.[1,2] The concentration of the 5-aminosalicylic acid component of sulfasalazine in both cord serum and maternal serum is negligible.[1] There have been isolated reports of congenital abnormalities associated with use of sulfasalazine during pregnancy including coarctation of the aorta with a ventricular septal defect,[3,4] and genito-urinary disorders.[4] There is also a theoretical risk of kernicterus in the neonate if sulfasalazine is given close to delivery (see p.341). However, given the concentrations of sulfasalazine and its metabolites found in cord blood, the risk of kernicterus from maternal use is considered minimal.[2] There have been many successful and uncomplicated pregnancies during sulfasalazine therapy and the general consensus favours continuing sulfasalazine throughout pregnancy when indicated.[1,3-6] (See also Mesalazine, p.1746.) The minimum effective dose should be used and since sulfasalazine may precipitate folate deficiency (see Effects on the Blood, above), folic acid supplements are recommended.[7]

Interactions

Giving sulfasalazine with antibacterial therapy may reduce conversion of sulfasalazine to its active metabolite (see below).

Sulfasalazine has been reported to interfere with the absorption of digoxin (p.1262) or folic acid (see Effects on the Blood, above) from the gastrointestinal tract.

Antibacterials. Since the effects of sulfasalazine depend on release of 5-aminosalicylic acid by bacterial metabolism in the gut, any drug that reduces the intestinal microflora may reduce the production of active metabolite. Evidence for this has been seen in patients also given *rifampicin* and *ethambutol*,[1] or in subjects also given *ampicillin*.[2] However, a decrease in clinical effect does not seem to have been seen.

1. Shaffer JL, Houston JB. The effect of rifampicin on sulphapyridine plasma concentrations following sulphasalazine administration. *Br J Clin Pharmacol* 1985; **19:** 526–8.
2. Houston JB, *et al.* Azo reduction of sulphasalazine in healthy volunteers. *Br J Clin Pharmacol* 1982; **14:** 395–8.

Antineoplastics. For mention of 5-aminosalicylates such as sulfasalazine inhibiting the metabolism of thiopurine antineoplastics, and increasing their toxicity, see Mercaptopurine, p.744.

Pharmacokinetics

About 15% of an oral dose of sulfasalazine is absorbed from the small intestine, although some of this is subsequently returned to the intestine in bile via enterohepatic circulation. The great majority of the dose reaches the colon where the azo bond is cleaved by the action of the intestinal flora, producing sulfapyridine and 5-aminosalicylic acid (mesalazine). Results in patients who have undergone colectomy suggest that between 60 and 90% of the total dose is metabolised in this way, but the degree of metabolism depends both on the activity of the intestinal flora and the speed of intestinal transit; colonic metabolism is reduced in patients with diarrhoea (for example, in active inflammatory bowel disease).

The small amount of intact sulfasalazine that is absorbed is extensively protein bound and subsequently excreted unchanged in urine. It crosses the placenta and is found in breast milk.

After cleavage of the sulfasalazine molecule about 60 to 80% of available sulfapyridine is absorbed, and undergoes extensive metabolism by acetylation, hydroxylation, and glucuronidation. Peak steady-state concentrations of sulfapyridine are higher in slow acetylators than fast acetylators after similar doses and the former are 2 to 3 times more likely to have adverse effects. Some 60% of the original dose of sulfasalazine is excreted in urine as sulfapyridine and its metabolites. As with sulfasalazine, absorbed sulfapyridine crosses the placenta and is found in breast milk.

The 5-aminosalicylic acid (5-ASA) moiety is much less well absorbed. About one-third of liberated 5-ASA is absorbed and almost all of this is acetylated and excreted in urine. For further details of the pharmacokinetics of 5-aminosalicylic acid see under Mesalazine, p.1746.

◊ Reviews.

Uses and Administration

Sulfasalazine is a compound of a sulfonamide, sulfapyridine, with 5-aminosalicylic acid (mesalazine). Its activity is generally considered to lie in the 5-aminosalicylic acid moiety, which is released in the colon by bacterial metabolism, although intact sulfasalazine has some anti-inflammatory properties in its own right.

In inflammatory bowel disease (p.1697) it is used alone or as an adjunct to corticosteroids in the treatment of active ulcerative colitis and is effective in maintaining remission. Sulfasalazine may also be effective in the treatment of active Crohn's disease, particularly of the colon, but it does not appear to be of value in maintaining remissions. Sulfasalazine is also used as a disease modifying drug in the treatment of severe or progressive rheumatoid arthritis (below).

In **inflammatory bowel disease** the usual initial adult dose of sulfasalazine is 1 to 2 g orally 4 times daily in the UK. However, doses over 4 g daily are associated with an increased risk of toxicity, and in the USA, therefore, the usual dose is 1 g given 3 or 4 times daily, and an initial dose of 500 mg every 6 to 12 hours may be recommended to lessen gastrointestinal adverse effects. Enteric-coated tablets are also claimed to reduce the incidence of adverse gastrointestinal effects. The overnight interval between doses should not exceed 8 hours. On remission the dose in patients with ulcerative colitis is gradually reduced to 2 g daily and then generally continued indefinitely. For children 2 years of age or older doses should be proportional to body-weight; initially 40 to 60 mg/kg may be given daily in divided doses reduced to 20 to 30 mg/kg daily for the maintenance of remission.

Sulfasalazine is also given rectally, as suppositories, initially at a dose of 1 g at night and in the morning. After three weeks the dosage is gradually reduced according to response. Rectal sulfasalazine can be given as 0.5 to 1 g night and morning as an adjunct to treatment by mouth. Sulfasalazine may also be given by enema in a dose of 3 g at bedtime. The *BNFC* suggests the following daily dosage may be given in divided doses to children as suppositories according to age: 5 to 8 years old: 1 g; 8 to 12 years old: 1.5 g; 12 to 18 years old: 2 g. Enemas, to be retained for at least 1 hour, may be given at night in doses of 1 to 1.5 g for children aged 2 to 7 years, 1.5 to 2.25 g for children aged 7 to 12 years, and 3 g for children 12 to 18 years.

In adult **rheumatoid arthritis** treatment is usually started with an oral dose of 500 mg daily, as enteric-coated tablets, for the first week; dosage is then increased by 500 mg daily each week to a maximum of 3 g daily given in 2 to 4 divided doses according to tolerance and response. In the USA, sulfasalazine can also be used for polyarticular juvenile rheumatoid arthritis in children aged 6 years and older who have not responded adequately to salicylates or other NSAIDs. A dose of 30 to 50 mg/kg daily is given in two divided doses, to a maximum dose of 2 g daily. To reduce adverse gastrointestinal effects, an enteric-coated tablet is used and the initial dose should be a quarter to a third of the planned maintenance; it is then increased weekly to reach the maintenance dose after one month.

Although sulfasalazine is not licensed for juvenile rheumatoid arthritis in the UK, the *BNFC* suggests that children aged 2 to 18 years are given an initial oral dose of 5 mg/kg twice daily for 1 week. The dose is then increased to 10 mg/kg twice daily for 1 week, then 20 mg/kg twice daily for 1 week, and maintained on a dose of 20 to 25 mg/kg twice daily. For children aged 2 to 12 years the maximum dose suggested is 2 g daily, and for children aged 12 to 18 years 3 g daily.

Psoriasis. In a double-blind placebo-controlled study involving 50 patients with moderate to severe plaque-type psoriasis (p.1583), sulfasalazine 3 to 4 g daily produced a significantly greater clinical improvement than placebo after 4 weeks of treatment with a further improvement at 8 weeks.[1]

Rheumatoid arthritis. Sulfasalazine is considered to be a useful disease-modifying antirheumatic drug (DMARD) in the treatment of rheumatoid arthritis (p.11). Studies have found a beneficial clinical effect of sulfasalazine, compared with placebo, on tender and swollen joints, pain, and erythrocyte sedimentation rate.[1,2] Meta-analyses[3,4] of generally short-term comparative studies suggest that sulfasalazine is roughly comparable in efficacy to methotrexate, intramuscular gold (sodium aurothiomalate), and penicillamine. Other reviews[2,5] have also suggested that it may have similar efficacy to hydroxychloroquine and leflunomide. Although there are regional differences in the prescription of DMARDs, sulfasalazine has been widely used for initial therapy, especially of less severe disease.[5] In an open study[6] of 200 patients with rheumatoid arthritis who were randomly allocated to treatment with sulfasalazine or auranofin, 31% of the sulfasalazine recipients were still taking the drug after 5 years compared with 15% of auranofin recipients. Improvement over baseline was still significant at 5 years for those patients receiving sulfasalazine but not in those treated with auranofin. Although one study[7] failed to find convincing evidence that using sulfasalazine with methotrexate was more effective than either drug alone, other studies have shown that combination treatment with sulfasalazine plus methotrexate and hydroxychloroquine was more effective than methotrexate alone or with sulfasalazine or hydroxychloroquine or the combination of sulfasalazine with hydroxychloroquine.[8,9] A review of sulfasalazine use in the management of rheumatoid arthritis concluded that combination therapy may be of benefit in patients with early or advanced rheumatoid arthritis but that there is still a need for studies to determine the efficacy and tolerability of various combinations.[5]

JUVENILE IDIOPATHIC ARTHRITIS. Juvenile idiopathic arthritis (p.10) is generally managed similarly to rheumatoid arthritis, but there is limited experience with the use of some antirheumatic drugs in children. Sulfasalazine has produced significant improvement in studies of patients with juvenile chronic arthritis; a literature review found that it was consistently reported to be of benefit.[1] Adverse effects were reported to be similar to those in adults, with the exception of a serum-sickness-like reaction which was mostly seen in systemic onset patients and may be unique to juvenile rheumatoid arthritis.[1]

1. Brooks CD. Sulfasalazine for the management of juvenile rheumatoid arthritis. *J Rheumatol* 2001; **28:** 845–53.

Spondyloarthropathies. ***ANKYLOSING SPONDYLITIS.*** Sulfasalazine has been found to be effective[1] in the treatment of active ankylosing spondylitis (p.13), but there is evidence that it is more useful in the treatment of active disease and peripheral articular manifestations than in the management of chronic long-standing disease.[2-4] The active moiety appears to be sulfapyridine rather than mesalazine.[5] Sulfasalazine was no better than placebo for the treatment of inflammatory back pain due to undifferentiated spondyloarthritis and early ankylosing spondylitis, but it was more effective than placebo in a subgroup of patients with no peripheral arthritis.[6]

PSORIATIC ARTHRITIS. A systematic review[1] of interventions for psoriatic arthritis (see p.13) concluded that sulfasalazine was one of only two drugs with published evidence of well proven efficacy in psoriatic arthritis (the other being high-dose parenteral methotrexate).

Tegaserod Maleate *(BANM, USAN, rINNM)*

HTF-919; Maleato de tegaserod; SDZ-HTF-919; Tégasérod, Maléate de; Tegaserodi Maleas. 1-{[(5-Methoxyindol-3-yl)methylene]amino}-3-pentylguanidine maleate.

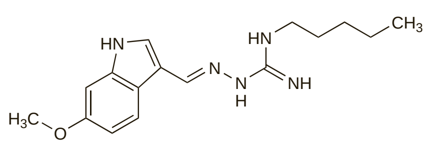
Тегасерода Малеат

$C_{16}H_{23}N_5O,C_4H_4O_4$ = 417.5.

CAS — 145158-71-0 (tegaserod); 189188-57-6 (tegaserod maleate).

ATC — A03AE02.

ATC Vet — QA03AE02.



(tegaserod)

Stability and compatibility. Crushed tablets of tegaserod were found to be stable in water, and apple juice; the latter may mask the taste of the drug. Orange juice, milk, or yogurt were not recommended as vehicles because of incomplete dissolution or uncertainty about stability.[1]

1. Carrier M-N, *et al.* Stability and compatibility of tegaserod from crushed tablets mixed in beverages and foods. *Am J Health-Syst Pharm* 2004; **61:** 1135–42.

Adverse Effects

The most common adverse effects of tegaserod are gastrointestinal disturbances including abdominal pain, diarrhoea, nausea, vomiting, and flatulence. Diarrhoea generally occurs within the first week of treatment and is usually transient but may be severe. Ischaemic colitis has been reported. Headache, dizziness, migraine, insomnia, fatigue, leg or back pain, and arthropathy have also been commonly reported. Cardiovascular adverse effects include hypotension and arrhythmias. Serious cardiovascular ischaemic events such as myocardial infarction, unstable angina pectoris, and stroke have occurred; fatalities have been reported. Other adverse effects include effects on the nervous system such as depression, and other gastrointestinal effects including cholelithiasis and dyspepsia.

Effects on the gastrointestinal tract. Severe diarrhoea, leading to hypovolaemia, hypotension, and syncope has been seen occasionally in patients receiving tegaserod. Some patients required hospitalisation for rehydration, and patients should be advised to stop taking the drug and seek medical attention if severe diarrhoea or associated dizziness or lightheadedness develop. In addition, ischaemic colitis has been reported rarely, and the drug should be stopped immediately in patients who develop symptoms such as rectal bleeding, bloody diarrhoea, or new and worsening abdominal pain.[1] The FDA noted that it had received 20 reports of ischaemic colitis in patients taking tegaserod between August 2002 and March 2004; in 3 cases, the effect only developed after several months (7 to 13) of therapy.[2] However, in reply the manufacturer (*Novartis*) suggested that there was no evidence from postmarketing surveillance to support an increased rate of ischaemic colitis over that normally seen in patients with irritable bowel syndrome, who are at increased risk of this diagnosis, nor any obvious pharmacological mechanism for such an adverse effect.[3]

Effects on the heart. In an analysis of pooled data from 29 studies, 13 out of 11 614 patients taking tegaserod had serious cardiovascular ischaemic events, compared with 1 out of 7031 patients taking placebo. Events included unstable angina pectoris, stroke, and myocardial infarction, one of which was fatal.[1-3] Most of these patients had at least one cardiovascular risk factor, but for some, no cardiovascular disease or risk had been diagnosed at the onset of treatment with tegaserod.[2] Patients taking tegaserod should seek medical attention if they have severe chest pain, dyspnoea, dizziness, sudden onset of weakness, difficulty walking or talking, or any other symptoms suggestive of myocardial infarction or stroke.[1]

Precautions

Tegaserod is contra-indicated in patients with a history of bowel obstruction, symptomatic gallbladder disease, suspected sphincter of Oddi dysfunction, or abdominal adhesions. Tegaserod should also not be given to patients who have diarrhoea or who frequently experience diarrhoea. It should be stopped in patients with new or sudden worsening of abdominal symptoms, hypotension, or syncope. Tegaserod should not be used in patients with severe renal impairment or moderate to severe hepatic impairment. For the possible cardiovascular risks of tegaserod therapy, see above; in the USA use is restricted, and it is contra-indicated in patients with a history of heart disease or symptoms suggestive of cardiac disorders.

Pharmacokinetics

Tegaserod is rapidly absorbed from the gastrointestinal tract with peak plasma levels occurring after about 1 hour. The absolute bioavailability of an oral dose is 10%; this is reduced by the presence of food. Tegaserod is widely distributed into the tissues and is about 98% bound to plasma proteins. Presystemic acid-catalysed hydrolysis in the stomach, and then oxidation and glucuronidation, produces the main metabolite, which is inactive; direct systemic glucuronidation also occurs. Two-thirds of an oral dose is excreted unchanged in the faeces and one-third excreted in the urine primarily as the main metabolite. The terminal half-life of tegaserod is about 11 hours.

◊ Reviews.

1. Appel-Dingemanse S. Clinical pharmacokinetics of tegaserod, a serotonin 5-HT receptor partial agonist with promotile activity. *Clin Pharmacokinet* 2002; **41:** 1021–42.

Uses and Administration

Tegaserod is a partial agonist at $5\text{-}HT_4$ receptors and has prokinetic properties. It is used in women for the short-term treatment of irritable bowel syndrome (p.1699), particularly the constipation-predominant form. It has also been used for the treatment of chronic idiopathic constipation (p.1693) in men and women less than 65 years of age.

Tegaserod is given orally as the maleate but doses are expressed in terms of the base; 8.31 mg of tegaserod maleate is equivalent to about 6 mg of tegaserod. It is given in a dose of 6 mg twice daily before food. For irritable bowel syndrome, it is given for 4 to 6 weeks; a further 4 to 6 weeks of treatment may be given if a beneficial response is seen.

In March 2007, marketing of tegaserod was suspended in some countries because of a high incidence of cardiovascular ischaemic events (see Effects on the Heart, above). In the USA, the use of tegaserod was subsequently restricted to women younger than 55 years of age who have either constipation-predominant irritable bowel syndrome or chronic idiopathic constipation, and who meet specific guidelines; patients should have no known or pre-existing cardiac problems.

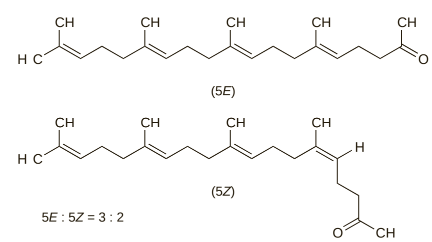
Teprenone *(rINN)*

E-671; Geranylgeranylacetone (5*E*, 9*E*,13*E* isomer); Teprenona; Téprénone; Teprenonum. 6,10,14,18-Tetramethyl-5,9,13,17-nonadecatetraen-2-one, mixture of (5*E*,9*E*,13*E*) and (5*Z*,9*E*,13*E*) isomers.

Тепренон

$C_{23}H_{38}O$ = 330.5.

CAS — 6809-52-5 (teprenone); 3796-63-2 (5E,9E,13E isomer); 3796-64-3 (5Z,9E,13E isomer).



Profile

Teprenone is a cytoprotective drug that is used in the treatment of gastritis and peptic ulcer disease (p.1702) in a usual oral dose of 50 mg three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)

Indon.: Purubex; ***Jpn:*** Selbex; ***Philipp.:*** Selbex; ***Thai.:*** Selbex.

Tiemonium Iodide *(BAN, rINN)*

Ioduro de tiemonio; TE-114; Tiemonii Iodidum; Tiémonium, Iodure de. 4-[3-Hydroxy-3-phenyl-3-(2-thienyl)propyl]-4-methylmorpholinium iodide.

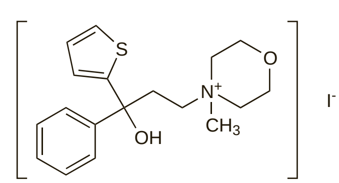
Тиемония Йодид

$C_{18}H_{24}INO_2S$ = 445.4.

CAS — 6252-92-2 (tiemonium); 144-12-7 (tiemonium iodide).

ATC — A03AB17.

ATC Vet — QA03AB17.



Tiemonium Metilsulfate

Tiemonio, metilsulfato de; Tiemonium Methylsulphate. 4-[3-Hydroxy-3-phenyl-3-(2-thienyl)propyl]-4-methyl-morpholinium methylsulphate.

$C_{19}H_{27}NO_6S_2$ = 429.6.

CAS — 6504-57-0.

Profile

Tiemonium iodide and tiemonium metilsulfate are quaternary ammonium antimuscarinics with peripheral effects similar to those of atropine (p.1219) and are used in the relief of visceral spasms.

Tiemonium metilsulfate is given in an oral dose of 100 to 300 mg daily in divided doses. A dose of 5 mg has been given three times daily by intramuscular or slow intravenous injection. Tiemonium metilsulfate has also been given as a rectal suppository in daily doses of 20 to 40 mg.

Tiemonium iodide has been used similarly.

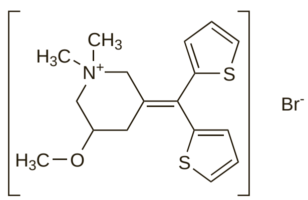
ATC Vet — QA03AB19.



Pharmacopoeias. In *Jpn.*

Profile

Timepidium bromide is a quaternary ammonium antimuscarinic with peripheral actions similar to those of atropine (p.1219). It has been given for the symptomatic treatment of visceral spasms in usual oral doses of 30 mg three times daily. It has also been given by subcutaneous, intramuscular, and intravenous injection in a dose of 7.5 mg.

Urinary metabolites of timepidium may cause a reddish coloration of the urine.

Preparations

Proprietary Preparations (details are given in Part 3)

Трописетрона Гидрохлорид

$C_{17}H_{20}N_2O_2,HCl = 320.8.$

CAS — 105826-92-4.

ATC — A04AA03.

ATC Vet — QA04AA03.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Tropisetron Hydrochloride). A white or almost white powder. Freely soluble or soluble in water; sparingly soluble in alcohol; very slightly soluble in dichloromethane.

Adverse Effects and Precautions

As for Ondansetron, p.1757. Fatigue, abdominal pain, and diarrhoea may also occur. Visual hallucinations, and an increase in blood pressure in patients with pre-existing hypertension, have been noted at high repeated doses. ECG changes such as prolongation of QT interval have been noted with high-dose intravenous tropisetron. The drug should therefore be used with caution in patients with cardiac rhythm or conduction disturbances. Care should be taken when driving or operating machinery. No dosage reduction is considered necessary in renal or hepatic impairment despite possible reductions in clearance.

Carcinogenicity. The manufacturer (*Novartis, UK*) has reported an increased incidence of hepatic neoplasms in male *mice* given high doses of tropisetron but it is suggested that these effects are both species and sex specific.

Effects on the cardiovascular system. For a discussion of the effects of 5-HT_3 antagonists on the cardiovascular system, see under Ondansetron, p.1757.

Interactions

Drugs that induce or inhibit hepatic enzymes may affect plasma concentrations of tropisetron. Licensed product information considers that any changes are usually unlikely to be clinically relevant with the recommended doses.

Tropisetron should be used with caution with antiarrhythmics, beta blockers, or drugs likely to prolong the QT interval, including those likely to cause electrolyte disturbances (see also p.1757).

Pharmacokinetics

Tropisetron is well absorbed after oral doses. Peak plasma concentrations are achieved within 3 hours. Absolute bioavailability depends on the dose since first-pass metabolism is saturable. It is 71% bound to plasma proteins. Tropisetron is metabolised by hydroxylation and conjugation, and metabolites are excreted mainly in the urine with a small amount in the faeces. The cytochrome P450 isoenzyme CYP2D6 is involved in tropisetron metabolism, and shows genetic polymorphism. The elimination half-life is about 8 hours in extensive metabolisers and up to 45 hours in poor metabolisers. Clearance is also reduced in patients with renal impairment.

Uses and Administration

Tropisetron is a 5-HT_3 antagonist with an antiemetic action similar to that of ondansetron (p.1757). It is used in the prevention of nausea and vomiting induced by cytotoxic therapy and in the treatment and prevention of postoperative nausea and vomiting (p.1700).

Tropisetron is given as the hydrochloride by slow intravenous injection or infusion, or orally. Doses are expressed in terms of tropisetron base; 5.64 mg of tropisetron hydrochloride is equivalent to about 5 mg of tropisetron base.

For the *prophylaxis* of acute **nausea and vomiting** associated with cytotoxic **chemotherapy** a single dose of 5 mg may be given by slow intravenous injection or infusion on the day of treatment, shortly before chemotherapy. The injection is given over not less than 1 minute; it may be given into a running infusion. For infusion, it is diluted into 100 mL of a suitable infusion fluid (such as sodium chloride 0.9% or glucose 5%), and given over 15 minutes. Subsequent doses of 5 mg daily are given orally, in the morning at least one hour before food, for a further 5 days.

Children over 2 years of age may be given 200 micrograms/kg (maximum dose 5 mg) before chemotherapy, by intravenous injection over at least 1 minute, or by infusion (at a concentration of 50 micrograms/mL in a suitable infusion fluid). In children weighing less than 25 kg the same dose may be given intravenously once daily for up to a further 4 days as required. In those weighing more than 25 kg, a dose of 5 mg may be given orally once daily for up to a further 5 days; if oral dosage is not possible the same dose may be given intravenously.

For the *treatment* of **postoperative** nausea and vomiting in adults 2 mg may be given by slow intravenous injection (over not less than 30 seconds), or by infusion (over 15 minutes), within 2 hours of the end of anaesthesia. For *prophylaxis*, the same dose may be given shortly before induction of anaesthesia.

Urogastrone

Anthelone; EGF-URO; Epidermal Growth Factor; Murodermina; Uroanthelone; Uroenterone; Urogastrona.

Урогастрон

CAS — 9010-53-1.

Pharmacopoeias. *Chin.* includes monographs for recombinant human epidermal growth factor suitable for external use.

Uses

Urogastrone is a polypeptide first isolated from human urine. Two forms have been identified, β and γ urogastrone. The β form consists of 53 amino acids and is distinguishable from the γ form by an additional terminal arginine residue. The β form is reported to be identical to human epidermal growth factor and this term is widely used in the literature.

Urogastrone inhibits gastric acid secretion and has been tried in the treatment of peptic ulcer disease and other gastrointestinal disorders but its rapid destruction in the stomach has limited its clinical use.

It is a potent stimulator of cellular proliferation and has also been used as an aid to wound healing.

Gastrointestinal disorders. Intravenous infusion of urogastrone 250 nanograms/kg over 1 hour has been reported[1,2] to reduce the secretion of gastric acid in patients with duodenal ulcer (p.1702) or the Zollinger-Ellison syndrome (p.1704). Ulcer pain was relieved 30 to 60 minutes after the start of the infusion.[2] A dose of 100 nanograms/kg per hour by intravenous infusion has been used with partial success in an infant with microvillous atrophy[3] and was apparently beneficial in an infant with necrotising enteritis.[4]

Human epidermal growth factor has also shown some promise in the treatment of active ulcerative colitis. In a small study,[5] patients received daily enemas containing either recombinant human epidermal growth factor (5 micrograms in 100 mL) or placebo; all patients also received oral mesalazine. Ten of the 12 patients in the urogastrone group were in remission after 2 weeks treatment compared with 1 of the 12 patients in the placebo group, and this benefit was maintained for up to 12 weeks.

Wound healing. For a general discussion of the management of wounds and ulcers, see p.1585.

In a randomised double-blind study in 61 patients with diabetic foot ulcers, adding human epidermal growth factor 0.04% to an ulcer cream containing protein-free bovine blood extract was shown to significantly enhance wound healing and reduce healing time compared with either the cream alone or the cream plus human epidermal growth factor 0.02%.[1] Topical application of recombinant human epidermal growth factor 0.02% has also been reported to reduce pain and promote healing of exfoliated skin lesions in a patient with drug-induced Stevens-Johnson syndrome.[2]

The effect on the rate of wound healing of a cream containing sulfadiazine silver plus recombinant human epidermal growth factor (10 micrograms/mL) was compared with sulfadiazine silver alone in 12 patients each requiring skin grafts at 2 donor sites.[3] The cream containing epidermal growth factor accelerated the rate of epidermal regeneration in all patients and reduced the average time to 100% healing by about 1.5 days. Patients were followed up for a maximum of 1 year after cessation of therapy and no complications or clinical evidence of neoplasia at the healed donor sites occurred.

In contrast, recombinant human epidermal growth factor as an ophthalmic solution containing 30 or 100 micrograms/mL was investigated in patients who had undergone keratoplasty, but the weaker solution had no effect on the rate of re-epithelialisation, and the more concentrated one was actually associated with slower healing.[4]

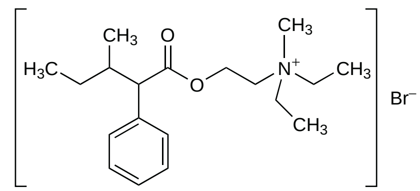
CAS — 16376-74-2 (valethamate); 90-22-2 (valethamate bromide).



Profile

Valethamate bromide is a quaternary ammonium antimuscarinic with peripheral effects similar to those of atropine (p.1219). It has been given orally, by injection or rectally in the symptomatic treatment of visceral spasms.

Preparations

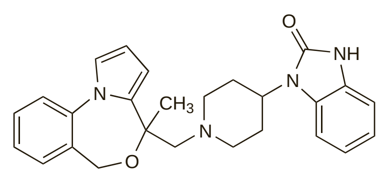
Proprietary Preparations (details are given in Part 3)
India: Epidosin; Valosin; ***Indon.:*** Epidosin; ***Turk.:*** Epidosin.
Multi-ingredient: ***Turk.:*** Epidosin Compozitum.

Zaldaride *(rINN)*

CGS-9343B (zaldaride maleate); Zaldarida; Zaldaridum. (±)-1-{1-[(4-Methyl-4*H*,6*H*-pyrrolo[1,2-*a*][4,1]benzoxazepin-4-yl)methyl]-4-piperidyl}-2-benzimidazolinone.

Зальдарид

$C_{26}H_{28}N_4O_2$ = 428.5.
CAS — 109826-26-8 (zaldaride); 109826-27-9 (zaldaride maleate).



Profile

Zaldaride is a calmodulin antagonist that has been investigated as the maleate for the treatment of diarrhoea.

Diarrhoea. Studies in patients with travellers' diarrhoea (p.1694) have indicated that zaldaride in oral doses of 20 mg as the maleate four times daily is an effective antidiarrhoeal.[1,2] It was somewhat less effective than loperamide when given without a loading dose,[2] but a regimen of 40 mg initially, followed by 20 mg, about every 6 hours was as effective as loperamide 4 mg initially followed by 2 mg after each unformed stool.[3]

General Anaesthetics

This chapter includes drugs used for the induction and maintenance of general anaesthesia. General anaesthetics are given either by inhalation or by intravenous or occasionally intramuscular injection (see Table, below).

Injectable	Inhalational
Barbiturate	*Halogenated*
Methohexital	Chloroform
Thiamylal	Desflurane
Thiopental	Enflurane
	Halothane
Miscellaneous	Isoflurane
Alfadolone	Methoxyflurane
Alfaxolone	Sevoflurane
Etomidate	Trichloroethylene
Ketamine	*Miscellaneous*
Propanidid	Cyclopropane
Propofol	Anaesthetic Ether
Sodium Oxybate	Nitrous Oxide
Tiletamine	Xenon

Adverse Effects of General Anaesthetics and their Treatment

The complex regimens used in general anaesthesia may produce complications both during and after the procedure. Adverse effects that may occur with general anaesthesia include involuntary muscle movements, hiccup, coughing, bronchospasm, laryngospasm, respiratory depression, hypotension, cardiac arrhythmias, and mild hypothermia.

After general anaesthesia many patients will experience drowsiness and impaired mental performance for at least 24 hours. Postoperative nausea with or without vomiting is common in the absence of antiemetic prophylaxis; nausea may last for 2 days but vomiting seldom persists beyond the first day. Other relatively common postanaesthetic effects include anorexia, malaise, fatigue, dizziness, and headache. Delirium has been noted in at least 10% of elderly general surgical patients and in up to 50% of elderly patients undergoing hip fracture repair.

Sore throat is frequent in patients who have been intubated or have had a throat pack inserted. Dry mouth as a result of premedication can add to the patient's discomfort. Manipulations for the maintenance of a clear airway may result in postoperative jaw pain.

Muscle pain, typically involving the neck, shoulders, and upper abdomen, may occur if the neuromuscular blocker suxamethonium has been given. It is usually worse on the second postoperative day and may last up to 6 days. Shoulder ache after laparoscopy resolves after 24 hours; it is due to accumulation of carbon dioxide under the diaphragm. Backache may occur after epidural or spinal anaesthesia. Urinary retention may follow regional block, cystoscopic or gynaecological surgery, or when there is prostatism.

Malignant hyperthermia (malignant hyperpyrexia—see under Dantrolene, p.1896) is a rare but potentially fatal complication of general anaesthesia that may be induced by inhalational anaesthetics (mainly halogenated hydrocarbons).

Sensitisation of the myocardium to beta-adrenergic stimulation occurs with some anaesthetics.

There has been concern over the possible danger to anaesthetists, dentists, and other personnel from exposure to volatile anaesthetics.

Hypersensitivity. Type I hypersensitivity reactions have occurred with general anaesthetics.[1,2] In most patients the release of histamine and other mediators such as prostaglandins and leukotrienes is of no clinical importance but in a few susceptible individuals anaphylaxis may result. Numerous factors to identify those at risk have been proposed over the years along with suggested modifications for anaesthetic management. Of the drugs used in anaesthesia, neuromuscular blockers are associated with the highest incidence of anaphylaxis; the most commonly implicated is reported to be suxamethonium, followed by alcuronium[3] (see under the Adverse Effects of Suxamethonium, p.1910). It has been suggested[4] that routine prophylaxis with histamine H_1- and histamine H_2-antagonists should be considered as part of anaesthetic management but others[3] thought it better to avoid the use of combinations such as thiopental, suxamethonium, and alcuronium that are well known to cause histamine release.

Nausea and vomiting. For a discussion on postoperative nausea and vomiting and its management, see p.1700.

Shivering and its treatment. Postoperative shivering, also referred to as spontaneous postanaesthetic tremor, can occur in up to 65% of patients recovering from general anaesthesia;[1,2] its aetiology and relationship to thermoregulation is unclear.[1,3,4] Postoperative shivering may be part of a more generalised neurological disturbance associated with anaesthesia.[1] It also occurs after regional anaesthesia, especially when given epidurally, but this is probably produced by different mechanisms.[3] Muscular activity during shivering greatly increases metabolic rate, oxygen consumption, and cardiac output and may cause complications in patients with cardiac or respiratory disorders. It can also strain surgical sutures, raise intra-ocular pressure, and impede haemodynamic monitoring.

Although the relationship between postoperative shivering, body temperature, and heat loss is unclear, patients may respond to warming their environment and the use of blankets.[1,3] Postoperative shivering may sometimes be an appropriate thermoregulatory response to a low body temperature,[3] and it is important before starting therapy to check the patient's temperature and take suitable steps to avoid hypothermia.[1]

Numerous drugs have been tried for the management of postoperative shivering including the central and respiratory stimulant doxapram, the α_2-agonist clonidine, and the opioid analgesic pethidine.[2,4,5] Reviews have discussed[1-4] a number of other opioids that have been tried including morphine, alfentanil, butorphanol, fentanyl, and sufentanil but studies suggest that not all opioids are effective or that some may only be effective when given epidurally. However, this may be due to the use of insufficient doses rather than a true difference between opioids.[6] Tramadol and nefopam have also been tried.[2,5] Neuromuscular blockers have been used after cardiac surgery in order to reduce cardiovascular stress.[7] Vecuronium might be preferable to pancuronium as it does not increase myocardial work and may be associated with fewer complications.[8] However, as profound neuromuscular block is required to inhibit shivering, repeated or higher doses of vecuronium might be required to prevent recurrence. Other drugs that have been investigated include ketanserin,[2] ketamine,[9] and magnesium sulfate.[2]

Precautions for General Anaesthetics

Patients with impaired function of the adrenal cortex, for example, those who are being treated, or have recently been treated, with corticosteroids, may experience hypotension with the stress of anaesthesia. Treatment with corticosteroids, pre-operatively and postoperatively, may be necessary. Patients taking other long-term medication such as aspirin, oral anticoagulants, oestrogens, MAOIs, or lithium, may need to change their dosage or stop therapy before major elective surgery.

Patients with chronic diseases such as diabetes or hypertension may need adjustment to their therapy before anaesthesia. Anaesthetics should be used with caution in patients with cardiac, respiratory, renal, or hepatic impairment and care may be needed in elderly or obese patients.

Patients should not undertake hazardous tasks such as driving for at least 24 hours after a general anaesthetic; alcohol should also be avoided.

Intraoperative awareness. The use of neuromuscular blockers has enabled anaesthetic doses to be reduced. However, lack of a reliable method for detecting conscious awareness in patients with complete neuromuscular block has resulted in paralysed patients who have received inadequate anaesthesia being aware during surgery.[1,2] Recommendations to control this problem include premedication with sedative or amnesic drugs, induction with sufficient doses of intravenous anaesthetic, the use of effective analgesic techniques during surgery, and, in particular, adequate concentrations of inspired anaesthetic gas. However, even patients given lorazepam or opioids may have some recall and there is no certain way to avoid awareness in paralysed patients. One commentator[3] considered that the routine use of neuromuscular blockers during surgery should be re-assessed since modern anaesthetics and analgesics could provide good operating conditions without paralysis for most major surgical procedures.

3. Ponte J. Neuromuscular blockers during general anaesthesia. *BMJ* 1995; **310:** 1218–19.

Interactions of General Anaesthetics

Sensitisation of the myocardium to beta-adrenergic stimulation occurs with some anaesthetics and ventricular fibrillation may occur if *sympathomimetics* such as adrenaline and isoprenaline are also used. Enhanced hypotensive effects may result when anaesthetics are given with *ACE inhibitors*, *tricyclic antidepressants* (which may also increase the risk of arrhythmias), *MAOIs* (see also Anaesthesia, under Precautions for Phenelzine, p.417), *antihypertensives*, *antipsychotics*, or *beta blockers*. The effects of *competitive neuromuscular blockers* may be increased by inhalational anaesthetics. The use of anaesthetics with other *CNS depressant drugs* such as those used for premedication may produce synergistic effects on the CNS and, in some cases, a smaller dose of general anaesthetic should be given.

Uses of General Anaesthetics

General anaesthetics depress the CNS and cause loss of consciousness associated with an inability to perceive pain. An ideal anaesthetic would produce unconsciousness, analgesia, and muscle relaxation suitable for all surgical procedures and would be metabolically inert and rapidly eliminated. No anaesthetic fulfils all these requirements in safe concentrations and it is customary to use a number of drugs to achieve the required conditions while minimising the risk of toxicity.

The activity of any anaesthetic is dependent on its ability to reach the brain. With inhalational anaesthetics there has to be a transfer from the alveolar space to the blood, then to the brain; recovery is a function of the removal of the anaesthetic from the brain. With injectable anaesthetics their activity is similarly dependent on their ability to penetrate the blood/brain barrier and recovery in turn is governed by their redistribution and excretion. The potency of inhalational anaesthetics is often expressed in terms of *minimum alveolar concentrations*, known as MAC values. The MAC of an anaesthetic is the concentration at 1 atmosphere that will produce immobility in 50% of subjects exposed to a noxious stimulus. Values given under the individual monographs are based on use without nitrous oxide as the latter can reduce the MAC. Other factors including age, body temperature, and concurrent medication such as opioid analgesics can also affect MAC values.

Anaesthesia. Many drugs are involved in achieving and maintaining conditions suitable for surgery. Conventional general anaesthesia may be divided into a number of stages including:

- premedication
- induction
- muscle relaxation and intubation
- maintenance
- analgesia
- reversal

A brief outline of the drugs typically used in each stage follows.

For **premedication**, benzodiazepines and some phenothiazines such as promethazine or alimemazine may be given to sedate and relieve *anxiety* in apprehensive patients. Butyrophenones such as droperidol have also been used. The benzodiazepines have useful amnesic and muscle-relaxant properties and short-acting oral forms are common in current regimens. The phenothiazines and butyrophenones are rarely used now although their antiemetic actions may be useful to control *postoperative nausea and vomiting* (see p.1700). Cloral hydrate is still used in some countries for pre-operative sedation. The use of barbiturates has largely ceased. For sedation of children the oral route is often preferred to injections, or the rectal route may be used in exceptional circumstances.

Antimuscarinics such as atropine, glycopyrronium, and hyoscine may be given to inhibit excessive *bronchial* and *salivary secretions* induced by intubation and some anaesthetics, although such use is less common nowadays. Antimuscarinics are also given as premedicants to reduce the intra-operative bradycardia and hypotension induced by drugs such as suxamethonium, halothane, or propofol or by vagal stimulation. Hyoscine also provides some degree of amnesia.

Opioids, including morphine and its derivatives, papaveretum and pethidine, have been widely used before surgery to reduce anxiety, smooth induction of anaesthesia, reduce overall anaesthetic requirements, and provide pain relief during and after surgery. The routine use of opioids as premedicants is now rare and generally restricted to patients already in pain. However, they continue to find a role at induction (below).

Patients may also be given drugs that reduce the danger from regurgitation and *aspiration* of gastric contents (see under Aspiration Syndromes, p.1693), such as the histamine H_2-antagonists, cimetidine and ranitidine, and the proton pump inhibitor, omeprazole. Cardiovascular drugs may be needed during surgery to control *blood pressure* and counteract *arrhythmias*.

The aim of **induction** is to produce anaesthesia rapidly and smoothly. Induction may be achieved with intravenous or inhalational anaesthetics but intravenous induction may be more pleasant for the patient. Intravenous drugs used include the barbiturate thiopental, the benzodiazepine midazolam, and other anaesthetics such as etomidate, propofol, or ketamine. Small doses of short-acting opioids, for example alfentanil, fentanyl, or remifentanil, given before or at induction allow the use of smaller induction doses of some drugs used for anaesthesia, and this technique is particularly suitable for poor-risk patients.

After induction, **muscle relaxation** with a rapidly acting depolarising neuromuscular blocker such as suxamethonium aids **intubation** of the patient. Longer acting, competitive neuromuscular blockers may then be given to allow procedures such as abdominal surgery to be carried out under lighter anaesthesia. For more detail, see Anaesthesia, p.1900.

Maintenance of anaesthesia may be achieved with an inhalational anaesthetic, an intravenous anaesthetic, or an intravenous opioid, either alone or in combination.

Opioid analgesics may also be given for **analgesia** as supplements during general anaesthesia (see also Balanced Anaesthesia, under Anaesthetic Techniques, below). Long-acting opioids such as morphine or papaveretum may cause postoperative respiratory depression. The short-acting opioid fentanyl, and its congeners alfentanil and sufentanil, appear to produce fewer circulatory changes and may be preferred to other opioids, especially in cardiovascular surgery; remifentanil may be valuable for its very short duration of action. Various combinations of analgesic techniques, including the use of pre-emptive analgesia, are used or are being investigated for the management of surgical pain (see Postoperative Analgesia, p.4).

At the end of surgery drugs are sometimes given to accelerate recovery by **reversal** of the effects of the various agents used during anaesthesia. The *neuromuscular block* produced by competitive neuromuscular blockers may be reversed with anticholinesterases such as neostigmine and edrophonium but atropine or glycopyrronium are also needed to prevent bradycardia and other muscarinic actions developing. The opioid antagonist naloxone has been given to reverse opioid-induced *respiratory depression*. However, it may antagonise the analgesic effects of the opioids in the control of postoperative pain and the increasing use of short-acting intravenous opioid analgesics should reduce the need for its use. Flumazenil is a benzodiazepine antagonist that is used to reverse the *central sedative effects* of benzodiazepines in anaesthetic procedures.

ANAESTHETIC TECHNIQUES. A balanced combination of drugs with different actions is often used to provide the various components of general anaesthesia including unconsciousness, muscle relaxation, and analgesia. This technique, termed **balanced anaesthesia**, has been reported to minimise intra-operative cardiovascular depression, to facilitate a rapid return of consciousness, and to have a low incidence of postoperative adverse effects such as nausea and vomiting, and excitation. Typically an opioid is given before or with induction and anaesthesia is induced using nitrous oxide and an intravenous barbiturate such as thiopental. The opioid is then given in small incremental doses to achieve and maintain adequate analgesia during surgery. Opioid analgesics commonly used in this technique include morphine, fentanyl, sufentanil, and alfentanil; buprenorphine and nalbuphine have also been used.

In **total intravenous anaesthesia** (TIVA), induction and maintenance of anaesthesia is achieved with one or more anaesthetics given intravenously. This allows high inspired oxygen concentrations in situations where hypoxaemia may otherwise occur, and is advantageous in surgery where delivery of inhaled anaesthetic may be difficult (for example in bronchoscopy). Combinations used in TIVA include propofol with alfentanil or fentanyl, and midazolam with alfentanil. Neuromuscular blockers are given to produce muscle relaxation but there can be difficulty in assessing the depth of anaesthesia in patients who are paralysed for mechanical ventilation, and there have been reports of awareness during procedures under total intravenous anaesthesia (see also Intraoperative Awareness under Precautions, above).

Although now largely obsolete, use of a neuroleptic with an opioid analgesic produces an altered state of consciousness known as **neuroleptanalgesia** in which the patient is calm and indifferent to the surroundings yet is responsive to commands. The technique was used for diagnostic or therapeutic procedures such as minor surgery, endoscopy, and changing dressings. Neuroleptanalgesia can be converted to **neuroleptanaesthesia** by the concurrent administration of nitrous oxide in oxygen; a muscle relaxant may also be included. Neuroleptanaesthesia is particularly useful if the patient's cooperation is required, as consciousness soon returns once the nitrous oxide is stopped. The neuroleptic most commonly employed was droperidol and it was usually used with fentanyl although other opioids have also been used. These procedures have since evolved into **conscious sedation** and **monitored anaesthetic care** techniques employing newer drugs.

Ketamine used alone can produce a state of **dissociative anaesthesia** similar to that of neuroleptanalgesia in which the patient may appear to be awake but is unconscious. Marked analgesia and amnesia are produced, but there may be an increase in muscle tone and emergence reactions. Dissociative anaesthesia is considered suitable for use in various diagnostic procedures, dressing changes, and in minor surgery not requiring muscle relaxation.

Techniques using **local anaesthetics** are discussed on p.1853.

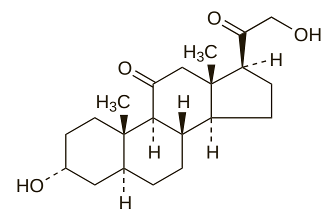
Alfadolone Acetate *(BANM, rINNM)*

Acetato de alfadolona; Alfadolone, Acétate d'; Alfadoloni Acetas; Alphadolone Acetate; GR-2/1574. 3α,21-Dihydroxy-5α-pregnane-11,20-dione 21-acetate.

Альфадолона Ацетат

$C_{23}H_{34}O_5$ = 390.5.

CAS — 14107-37-0 (alfadolone); 23930-37-2 (alfadolone acetate).



(alfadolone)

Pharmacopoeias. In *BP(Vet)*.

BP(Vet) 2008 (Alfadolone Acetate). A white to creamy white powder. Practically insoluble in water and in petroleum spirit; soluble in alcohol; freely soluble in chloroform.

Profile

Alfadolone acetate has been used to enhance the solubility of alfaxalone (below). It possesses some anaesthetic properties and is considered to be about half as potent as alfaxalone.

Alfaxalone *(BAN, rINN)*

Alfaksaloni; Alfaxalon; Alfaxalona; Alfaxalonum; Alphaxalone; GR-2/234. 3α-Hydroxy-5α-pregnane-11,20-dione.

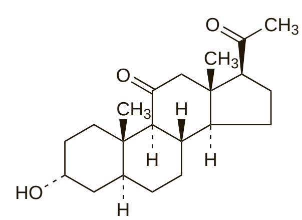
Альфаксалон

$C_{21}H_{32}O_3$ = 332.5.

CAS — 23930-19-0.

ATC — N01AX05.

ATC Vet — QN01AX05.



Pharmacopoeias. In *BP(Vet)*.

BP(Vet) 2008 (Alfaxalone). A white to creamy white powder. Practically insoluble in water and in petroleum spirit; soluble in alcohol; freely soluble in chloroform.

Profile

Alfaxalone was formerly used with alfadolone acetate (above) ['Althesin'], as an intravenous anaesthetic for induction and maintenance of general anaesthesia.

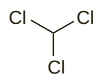
Adverse reactions associated with polyethoxylated castor oil (present as a vehicle) led to the general withdrawal of alfaxalone with alfadolone acetate from human use. It is still used in veterinary medicine.

Porphyria. Alfaxalone:alfadolone has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Chloroform

Chloroformium Anesthesicum; Chloroformum; Chloroformum pro Narcosi; Cloroformo. Trichloromethane.

$CHCl_3$ = 119.4.
CAS — 67-66-3.
ATC — N01AB02.
ATC Vet — QN01AB02.



Pharmacopoeias. In *Br.*, *Chin.*, and *Viet.*
BP 2008 (Chloroform). A colourless volatile liquid with a characteristic odour. Not more than 5.0% v/v distils below 60° and the remainder distils at 60° to 62°. It contains 1.0 to 2.0% v/v of ethyl alcohol; amylene 50 micrograms/mL is permitted as an alternative to ethyl alcohol.
Slightly soluble in water; miscible with dehydrated alcohol, with ether, with fixed and volatile oils, and with most other organic solvents. Store in containers with glass stoppers or other suitable closures. Protect from light. The label should state whether it contains ethyl alcohol or amylene.

Stability. The addition of a small percentage of alcohol greatly retards the gradual oxidation that occurs when chloroform is exposed to air and light, and which results in its becoming contaminated with the very poisonous carbonyl chloride (phosgene) and with chlorine; the alcohol also serves to decompose any carbonyl chloride that may have been formed.

From a study[1] of chloroform losses from chloroform water and from 6 typical BPC mixtures under various conditions of storage the following shelf-lives were recommended: chloroform solutions and non-sedimented mixtures could be stored in well-closed well-filled containers for 2 months at ambient temperatures; when stored in partially-filled containers and periodically opened the shelf-life should not exceed 2 weeks; sedimented mixtures could be stored for 2 months in well-closed well-filled containers, but because loss of chloroform could be expected in containers periodically opened such mixtures should be prepared as required or packed in their final containers; for chloroform-containing mixtures in the home a shelf-life of 2 weeks was suggested.

1. Lynch M, *et al*. Chloroform as a preservative in aqueous systems: losses under "in-use" conditions and antimicrobial effectiveness. *Pharm J* 1977; **219:** 507–10.

Storage. It has been recommended[1] that if the period of use would exceed 6 weeks, PVC bottles should not be used for storing or dispensing: Chloroform and Morphine Tincture, or aqueous mixtures containing more than 5% thereof; mixtures or dispersions in which chloroform is present in excess of its aqueous solubility; aqueous mixtures containing chloroform and high concentrations of electrolytes; or of mixtures containing chloroform water.

1. Anonymous. Plastics medicine bottles of rigid PVC. *Pharm J* 1973; **210:** 100.

Adverse Effects and Precautions

Chloroform depresses respiration and produces hypotension. Cardiac output is reduced and arrhythmias may develop. Poisoning can lead to respiratory depression and cardiac arrest. Delayed hepatotoxic and nephrotoxic reactions have occurred 6 to 24 hours after a dose; symptoms may include abdominal pain, vomiting, and, at a later stage, jaundice.

Liquid chloroform is irritant to the skin and mucous membranes and may cause burns if spilt on them. Suitable precautions should be taken to avoid skin contact with chloroform as it can penetrate skin and produce systemic toxicity. Chloroform is not flammable. Care should be taken not to vaporise chloroform in the presence of a flame because of the production of toxic gases.

In the UK medicinal products are limited to a chloroform content of not more than 0.5% (w/w or v/v as appropriate) of chloroform. Exceptions include supply by a doctor or dentist, or in accordance with his prescription, to a particular patient, and supply for anaesthetic purposes.

In the USA the FDA has banned the use of chloroform in medicines and cosmetics, because of reported carcinogenicity in *animals*. It has also been withdrawn from systemic use in other countries.

The sale within or import into England and Wales and Scotland of food containing any added chloroform is prohibited.

See also Adverse Effects and Precautions for General Anaesthetics, p.1779.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were receiving chloroform, and the American Academy of Pediatrics[1] considers that it is therefore usually compatible with breast feeding.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 25/05/04)

Porphyria. Chloroform has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Uses and Administration

Chloroform is a volatile halogenated anaesthetic that was used by inhalation, but safer drugs are now preferred in general anaesthesia.

Chloroform is used as a carminative and as a flavouring agent and preservative. For these purposes it is usually employed as Chloroform Spirit (BP 2008) or Double-strength Chloroform Water (BP 2008) but doubts have been cast on the safety of the long-term use of chloroform in mixtures.

Externally, chloroform has a rubefacient action.

Chloroform is also used as a solvent.

Anaesthesia. An historical review of the use of chloroform in clinical anaesthesia.[1]

Cyclopropane *(rINN)*

Ciclopropano; Cyclopropanum; Trimethylene.

Циклопропан

C_3H_6 = 42.08.
CAS — 75-19-4.

Pharmacopoeias. In *US.*
USP 31 (Cyclopropane). A colourless highly flammable gas with a characteristic odour and pungent taste. Freely soluble in alcohol; soluble in fixed oils. One volume dissolves in about 2.7 volumes of water at 15°.

Stability. CAUTION. Mixtures of cyclopropane with oxygen or air at certain concentrations are explosive. Cyclopropane should not be used in the presence of an open flame or of any electrical apparatus liable to produce a spark. Precautions should be taken against the production of static electrical discharge.

Storage and supply. Cyclopropane is supplied compressed in metal cylinders. National standards are usually in operation for the labelling and marking of such cylinders.

Adverse Effects and Precautions

Cyclopropane depresses respiration to a greater extent than many other anaesthetics. Laryngospasm, cardiac arrhythmias, or hepatic injury may occur. Cyclopropane increases the sensitivity of the heart to sympathomimetic amines. Malignant hyperthermia has also been reported. Postoperative nausea, vomiting, and headache are frequent.

Cyclopropane should be used with caution in patients with bronchial asthma and cardiovascular disorders. Premedication with atropine may be advisable to reduce vagal tone.

See also Adverse Effects and Precautions for General Anaesthetics, p.1779.

Abuse. Two of 4 deaths from abuse of volatile anaesthetics in operating rooms were attributed to cyclopropane.[1]

1. Bass M. Abuse of inhalation anesthetics. *JAMA* 1984; **251:** 604.

Malignant hyperthermia. Malignant hyperthermia was associated with cyclopropane.[1]

1. Lips FJ, *et al*. Malignant hyperthermia triggered by cyclopropane during cesarean section. *Anesthesiology* 1982; **56:** 144–6.

Interactions

Care is advised if adrenaline or other sympathomimetics are given during cyclopropane anaesthesia. Potentiation of competitive neuromuscular blockers occurs after use of cyclopropane.

See also Interactions for General Anaesthetics, p.1779.

Uses and Administration

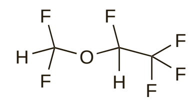
Cyclopropane is an anaesthetic that has been given by inhalation for analgesia and induction and maintenance of general anaesthesia. It produces skeletal muscle relaxation, is non-irritant, and induction and recovery are rapid, but it is difficult to use and handle and other anaesthetics are generally preferred. Because of the risk of explosion, it has usually been given by means of a closed circuit. It has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) of 9.2%.

Desflurane *(USAN, rINN)*

Desfluraani; Desfluran; Desflurano; Desfluranum; I-653. (±)-2-Difluoromethyl 1,2,2,2-tetrafluoroethyl ether.

Десфлуран

$C_3H_2F_6O$ = 168.0.
CAS — 57041-67-5.
ATC — N01AB07.
ATC Vet — QN01AB07.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Desflurane). A clear, colourless, mobile, heavy liquid. B.p. about 22°. Practically insoluble in water; miscible with anhydrous alcohol. Store in a glass bottle fitted with a polyethylene-lined cap. Before opening the bottle, cool the contents to below 10°.
USP 31 (Desflurane). Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°. Replace cap securely after each use. Protect from light.

Adverse Effects and Precautions

As with other halogenated anaesthetics, respiratory depression, hypotension, and arrhythmias may occur. Desflurane may rarely precipitate malignant hyperthermia in susceptible individuals. It appears to sensitise the myocardium to sympathomimetics to a lesser extent than halothane or enflurane. Nausea and vomiting have been reported in the postoperative period.

Desflurane is irritant to the airways and may provoke breath holding, apnoea, coughing, increased salivation, and laryngospasm. It is therefore not recommended for induction of anaesthesia in paediatric patients.

As with other halogenated anaesthetics, patients with known or suspected susceptibility to malignant hyperthermia should not be anaesthetised with desflurane. Desflurane may increase CSF pressure and should therefore be used with caution in patients with, or at risk from, raised intracranial pressure.

In order to minimise the risk of developing elevated carboxyhaemoglobin levels carbon dioxide absorbents in anaesthetic apparatus should not be allowed to dry out when delivering volatile anaesthetics such as desflurane (see below).

See also Adverse Effects and Precautions of General Anaesthetics, p.1779.

Carbon dioxide absorbents. Significant carboxyhaemoglobinaemia may develop rarely during anaesthesia with volatile anaesthetics given by circle breathing systems containing carbon dioxide absorbents.[1] The effect is only seen when the absorbent has become excessively dried out. The use of barium hydroxide lime (which is not available in the UK) as an absorbent produces more carbon monoxide than soda lime, particularly at low water content. No cases of this complication had been reported to date in the UK.

1. CSM/MCA. Safety issues in anaesthesia: volatile anaesthetic agents and carboxyhaemoglobinaemia. *Current Problems* 1997; **23:** 7. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2023230&RevisionSelectionMethod=LatestReleased (accessed 16/05/06)

Effects on the cardiovascular system. A review[1] of *animal* and human studies concluded that the cardiorespiratory effects of desflurane were similar to those of isoflurane but that there might be better control of arterial pressure with desflurane during stressful stimuli. A study[2] in patients undergoing coronary artery bypass surgery showed that a state of haemodynamic stability suitable for patients at risk of myocardial ischaemia could be maintained when desflurane was used with the opioid analgesic fentanyl.

1. Warltier DC, Pagel PS. Cardiovascular and respiratory actions of desflurane: is desflurane different from isoflurane? *Anesth Analg* 1992; **75:** S17–S31.
2. Parsons RS, *et al*. Comparison of desflurane and fentanyl-based anaesthetic techniques for coronary artery bypass surgery. *Br J Anaesth* 1994; **72:** 430–8.

Effects on the liver. Although considered to be less hepatotoxic than some other halogenated anaesthetics (see under Adverse Effects of Halothane, p.1784), delayed hepatotoxicity has occurred in a 65-year-old woman after maintenance anaesthesia involving desflurane.[1] She had received halothane on two previous occasions which may have caused sensitisation. Investigation of hepatocellular integrity (by measuring glutathione transferase alpha) in 30 women given desflurane indicated a mild subclinical disturbance.[2]

1. Martin JL, *et al.* Hepatotoxicity after desflurane anesthesia. *Anesthesiology* 1995; **83:** 1125–9.
2. Tiainen P, *et al.* Changes in hepatocellular integrity during and after desflurane or isoflurane anaesthesia in patients undergoing breast surgery. *Br J Anaesth* 1998; **80:** 87–9.

Effects on the respiratory tract. The irritant effect of desflurane on the lungs limits its role in the induction of anaesthesia, especially in children. Pre-operative use of nebulised lidocaine 4% failed to alleviate the response[1] although pretreatment with intravenous opioids may reduce the irritation.[2]

1. Bunting HE, *et al.* Effect of nebulized lignocaine on airway irritation and haemodynamic changes during induction of anaesthesia with desflurane. *Br J Anaesth* 1995; **75:** 631–3.
2. Kong CF, *et al.* Intravenous opioids reduce airway irritation during induction of anaesthesia with desflurane in adults. *Br J Anaesth* 2000; **85:** 364–7.

Interactions

The effects of competitive neuromuscular blockers such as atracurium are enhanced by desflurane (see p.1904). Lower doses of desflurane are required in those receiving opioids, benzodiazepines or other sedatives. Care is advised if adrenaline or other sympathomimetics are given to patients during desflurane anaesthesia.

See also Interactions of General Anaesthetics, p.1779.

◊ References.

Pharmacokinetics

Desflurane has a low blood/gas partition coefficient and on inhalation its absorption, distribution, and elimination are reported to be more rapid than for other halogenated anaesthetics such as isoflurane or halothane. It is excreted mainly unchanged through the lungs. A small amount diffuses through the skin. About 0.02% of inhaled desflurane is metabolised in the liver and trichloroacetic acid has been detected in the serum and urine of patients given desflurane.

Uses and Administration

Desflurane is a volatile halogenated anaesthetic administered by inhalation. It is structurally similar to isoflurane and has anaesthetic actions similar to those of halothane (p.1785). The minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) ranges from about 6% in the elderly to about 11% in infants. It is non-flammable and non-explosive in clinical concentrations but, because of its low boiling-point, it must be delivered by a special vaporiser, preferably within a closed circuit system.

Desflurane is used for induction and maintenance of general anaesthesia (p.1780), but because of its pungency is not recommended for induction in children. Concentrations of 4 to 11% v/v have been used for induction and usually produce surgical anaesthesia in 2 to 4 minutes. Concentrations of 2 to 6% v/v with nitrous oxide or 2.5 to 8.5% v/v in oxygen or oxygen-enriched air may be used to maintain anaesthesia. Higher concentrations of desflurane have been used but it is important to ensure adequate oxygenation; concentrations in excess of 17% v/v are not recommended. For concentrations used in patients with hepatic or renal impairment, see below.

As with other volatile halogenated anaesthetics supplemental neuromuscular blockers may be required. Recovery from anaesthesia is reported to be more rapid than with other halogenated anaesthetics.

Administration in hepatic or renal impairment. Desflurane concentrations of 1 to 4% v/v in oxygen and nitrous oxide have been used in patients with chronic renal or hepatic impairment and during renal transplantation surgery.

Anaesthesia. The characteristics of desflurane have been discussed in a number of reviews.[1-6] Its advantages are considered to include rapid induction and emergence from anaesthesia, and minimal metabolism makes end-organ toxicity unlikely. Emergence from anaesthesia and recovery of psychomotor and cognitive skills with desflurane is more rapid than after anaesthesia with other halogenated volatile anaesthetics such as isoflurane and possibly than after the intravenous anaesthetic propofol. This is considered to be of particular advantage for outpatient treatment, but studies so far have found no difference in time to discharge with desflurane or other general anaesthetics. Furthermore, the incidence of nausea and vomiting with desflurane is significantly greater than after the use of propofol. Desflurane's pungency may also limit its use for induction especially in children, although it is suitable for maintenance in this group and may be particularly suitable for neonates.[4]

Enflurane *(BAN, USAN, rINN)*

Anaesthetic Compound No. 347; Compound 347; Enfluraani; Enfluran; Enflurano; Enfluranum; Methylflurether; NSC-115944. 2-Chloro-1,1,2-trifluoroethyl difluoromethyl ether; 2-Chloro-1-(difluoromethoxy)-1,1,2-trifluoroethane.

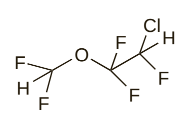
Энфлуран

$C_3H_2ClF_5O$ = 184.5.

CAS — 13838-16-9.

ATC — N01AB04.

ATC Vet — QN01AB04.



Pharmacopoeias. In *Jpn* and *US.*

USP 31 (Enflurane). A clear colourless volatile liquid having a mild sweet odour. Non-flammable. Distilling range 55.5° to 57.5°. Slightly soluble in water; miscible with organic solvents, with fats, and with oils. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Adverse Effects

As with other halogenated anaesthetics, respiratory depression, hypotension, and arrhythmias have been reported although the incidence of arrhythmias is lower with enflurane than with halothane. It sensitises the myocardium to sympathomimetics to a lesser extent than halothane. Compared with halothane, enflurane has a stimulant effect on the CNS and convulsions may occur when concentrations of enflurane are high or hypocapnia is present. Malignant hyperthermia has also been reported. Asthma and bronchospasm may occur. There have been reports of elevated serum-fluoride concentrations although resulting renal damage appears to be rare. There have been changes in measurements of hepatic enzymes and a number of reports of liver damage. Shivering, nausea, and vomiting have been reported in the postoperative period.

See also Adverse Effects of General Anaesthetics, p.1779.

Effects on the blood. The development of carboxyhaemoglobinaemia in patients anaesthetised with volatile anaesthetics is discussed under Precautions, below.

Effects on the kidneys. The nephrotoxicity of volatile anaesthetics has been reviewed.[1] Although enflurane released inorganic fluoride it appeared to be safe in patients with normal renal function. It had also been given to patients with mild to moderate renal impairment without any further deterioration. There was an increase in serum-fluoride concentrations when enflurane was given to a group of patients who had been receiving isoniazid, but there was no change in kidney function. Pretreatment of patients with a single dose of disulfiram before anaesthesia was found to produce a consistent and almost complete inhibition of enflurane metabolism as shown by substantial reductions in plasma-fluoride concentrations and urinary excretion of fluoride.[2]

2. Kharasch ED, *et al.* Clinical enflurane metabolism by cytochrome P450 2E1. *Clin Pharmacol Ther* 1994; **55:** 434–40.

Effects on the liver. A review[1] of 58 cases of suspected enflurane hepatitis considered enflurane to be the likely cause of the liver damage in 24. There was biochemical evidence of liver damage in 23 of these cases. Histology reports were available for 15 patients and all showed some degree of hepatocellular necrosis and degeneration.

While the incidence of liver damage from enflurane seemed to be lower than from halothane, the character of the injury was similar.

Another review[2] of the same cases plus an additional 30 (88 in all) came to different conclusions; the main author was a consultant to the manufacturer of enflurane. Of the 88 patients with suspected enflurane hepatitis, 30 were rejected because of insufficient evidence and 43 were considered to have other factors known to produce liver injury. This left 15 possible cases of enflurane hepatitis compared with the 24 identified by the first review. While agreeing that in the rare patient unexplained liver damage follows enflurane anaesthesia, it was considered that the incidence was too small to suggest an association. No consistent histological pattern was identified in this study.

See also under Adverse Effects in Halothane, p.1784.

2. Eger EI, *et al.* Is enflurane hepatotoxic? *Anesth Analg* 1986; **65:** 21–30.

Effects on respiration. Overall, enflurane is considered to produce more respiratory depression than halothane or isoflurane.[1,2]

1. Quail AW. Modern inhalation anaesthetic agents: a review of halothane, isoflurane and enflurane. *Med J Aust* 1989; **150:** 95–102.
2. Merrett KL, Jones RM. Inhalational anaesthetic agents. *Br J Hosp Med* 1994; **52:** 260–3.

Precautions

Enflurane should be used with caution in patients with convulsive disorders. High concentrations of enflurane may cause uterine relaxation. In order to minimise the risk of developing elevated carboxyhaemoglobin levels, carbon dioxide absorbents in anaesthetic apparatus should not be allowed to dry out when delivering volatile anaesthetics such as enflurane.

As with other halogenated anaesthetics, patients with known or suspected susceptibility to malignant hyperthermia should not be anaesthetised with enflurane.

See also Precautions for General Anaesthetics, p.1779.

Abuse. Report[1] of a fatality in a 29-year-old student nurse anaesthetist who had applied enflurane to the herpes simplex lesions of her lower lip. She was found with an empty 250 mL bottle of enflurane.

1. Lingenfelter RW. Fatal misuse of enflurane. *Anesthesiology* 1981; **55:** 603.

Carbon dioxide absorbents. Significant carboxyhaemoglobinaemia may develop rarely during anaesthesia with volatile anaesthetics given by circle breathing systems containing carbon dioxide absorbents.[1] The effect is only seen when the absorbent has become excessively dried out. The use of barium hydroxide lime (which is not available in the UK) as an absorbent produces more carbon monoxide than soda lime, particularly at low water content. No cases of this complication had been reported to date in the UK.

1. CSM/MCA. Safety issues in anaesthesia: volatile anaesthetic agents and carboxyhaemoglobinaemia. *Current Problems* 1997; **23:** 7. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2023230&RevisionSelectionMethod=LatestReleased (accessed 16/05/06)

Porphyria. Enflurane is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals*.

Interactions

Care is advised if adrenaline or other sympathomimetics are given to patients during enflurane anaesthesia. The effects of competitive neuromuscular blockers such as atracurium are enhanced by enflurane (see p.1904).

See also Interactions of General Anaesthetics, p.1779.

Antibacterials. For the effects of *isoniazid* on enflurane defluorination, see Effects on the Kidneys under Adverse Effects, above.

Antidepressants. It appeared likely that the enflurane-induced seizure activity seen in 2 patients could have been enhanced by *amitriptyline*.[1] It may be advisable to avoid the use of enflurane in patients requiring tricyclic antidepressants, especially when the patient has a history of seizures or when hyperventilation or high enflurane concentrations are a desired part of the anaesthetic technique.

1. Sprague DH, Wolf S. Enflurane seizures in patients taking amitriptyline. *Anesth Analg* 1982; **61:** 67–8.

Disulfiram. For the effect of disulfiram on the metabolism of enflurane, see Effects on the Kidneys under Adverse Effects, above.

Pharmacokinetics

Enflurane is absorbed on inhalation. The blood/gas partition coefficient is low. It is mostly excreted unchanged through the lungs. Up to 10% of inhaled administered enflurane is metabolised in the liver, mainly to inorganic fluoride.

◊ References.

2. Devchand D, *et al.* The uptake of enflurane during anaesthesia. *Anaesthesia* 1995; **50:** 491–5.

Uses and Administration

Enflurane is a volatile halogenated anaesthetic given by inhalation. It is an isomer of isoflurane. It has anaesthetic actions similar to those of halothane (p.1785). Enflurane has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) ranging from 1.7% in middle age to 2.5% in children. Enflurane is given using a calibrated vaporiser for induction and maintenance of general anaesthesia (p.1780); it is also used in subanaesthetic doses to provide analgesia in obstetrics and other painful procedures (below).

To avoid CNS excitement a short-acting barbiturate or other intravenous induction agent is recommended before the inhalation of enflurane. Anaesthesia may be induced using enflurane alone with oxygen or in nitrous oxide-oxygen mixtures. In general, enflurane concentrations of 2 to 4.5% v/v produce surgical anaesthesia in 7 to 10 minutes. Anaesthesia may be maintained with a concentration of 0.5 to 3% v/v of enflurane; a concentration of 3% v/v should not be exceeded during spontaneous respiration. Although enflurane is reported to possess muscle relaxant properties, neuromuscular blockers may nevertheless be required. Postoperative analgesia may be necessary.

Concentrations of 0.25 to 1% v/v of enflurane are used to provide analgesia for vaginal delivery during childbirth and of 0.5 to 1% v/v to supplement other general anaesthetics during caesarean section.

Pain. Enflurane is used in subanaesthetic doses to provide analgesia in obstetrics and other painful procedures although a study[1] was unable to confirm that it had an analgesic effect at subanaesthetic concentrations.

1. Tomi K, *et al.* Alterations in pain threshold and psychomotor response associated with subanaesthetic concentrations of inhalation anaesthetics in humans. *Br J Anaesth* 1993; **70:** 684–6.

Aether ad Narcosin; Aether anaesthetícus; Aether pro Narcosi; Aether Purissimus; Altatáshoz való éter; Anestesiaeetteri, narkoosieetteri; Anestetinis eteris; Diethyl Ether; Éter anestésico; Eter do nakozy; Eter etylowy; Éter Puríssimo; Ether; Ether Anesthesicus; Éther anesthésique; Ether Anestheticus; Ether Ethylicus; Ether Ethylicus pro Narcosi; Ether k narkóze; Ethyl Ether; Narkoseter.

$(C_2H_5)_2O$ = 74.12.
CAS — 60-29-7.
ATC — N01AA01.
ATC Vet — QN01AA01.

NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of anaesthetic ether:
Sweet Vitriol.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Ether, Anaesthetic). Diethyl ether to which an appropriate quantity of a non-volatile antoxidant may have been added. It contains not more than 2 g/litre of water. A clear, colourless, volatile, highly flammable, and very mobile liquid. Distillation range 34° to 35°.

Soluble 1 in 15 of water; miscible with alcohol and with fatty oils. Store at a temperature of 8° to 15° in airtight containers. Protect from light. Ether remaining in a partly used container may deteriorate rapidly. The label should state the name and concentration of any added non-volatile antoxidant.

USP 31 (Ether). It consists of 96 to 98% of $C_4H_{10}O$, the remainder consisting of alcohol and water. Ether for anaesthetic use contains not more than 0.2% of water. It is a colourless, mobile, highly flammable, highly volatile liquid, having a characteristic sweet, pungent odour. It is slowly oxidised by the action of air and light, with the formation of peroxides. Its vapour, when mixed with air and ignited, may explode. B.p. about 35°.

Soluble 1 in 12 of water; miscible with alcohol, with chloroform, with dichloromethane, with petroleum spirit, with benzene, and with fixed and volatile oils; soluble in hydrochloric acid. Store in partly-filled, airtight containers, remote from fire and at a temperature not exceeding 40°. Protect from light. Ether to be used for anaesthesia must be preserved in airtight containers of not more than 3 kg capacity and is not to be used for anaesthesia if it has been removed from the original container longer than 24 hours.

Labelling. The label should state that it is suitable for use as an anaesthetic.

Stability. Ether is very volatile and flammable and mixtures of its vapour with oxygen, nitrous oxide, or air at certain concentrations are explosive. It should not be used in the presence of an open flame or any electrical apparatus liable to produce a spark. Precautions should be taken against the production of static electrical discharge.

Storage. The Pharmaceutical Society of Great Britain's Department of Pharmaceutical Sciences found that free ether, even in low concentrations, caused softening of PVC bottles and was associated with loss by permeation.[1]

1. Anonymous. Plastics medicine bottles of rigid PVC. *Pharm J* 1973; **210:** 100.

Adverse Effects

Ether has an irritant action on the mucous membrane of the respiratory tract; it stimulates salivation and increases bronchial secretion. Laryngeal spasm may occur. Ether causes vasodilatation which may lead to a severe fall in blood pressure and it reduces blood flow to the kidneys; it also increases capillary bleeding. The bleeding time is unchanged but the prothrombin time may be prolonged. Ether may cause malignant hyperthermia in certain individuals. Alterations in kidney and liver function have been reported. Convulsions occasionally occur. Hyperglycaemia due to gluconeogenesis has been noted.

Recovery is slow from prolonged ether anaesthesia and postoperative vomiting is common. Acute overdosage of ether is characterised by respiratory failure and cardiac arrest.

Dependence on ether or ether vapour has been reported. Prolonged contact with ether spilt on any tissue produces necrosis.

See also Adverse Effects of General Anaesthetics, p.1779.

Precautions

Ether anaesthesia is contra-indicated in patients with diabetes mellitus, impaired kidney function, raised CSF pressure, and severe liver disease. Its use is not advisable in hot and humid conditions in patients with fever, as convulsions are liable to occur, particularly in children and in patients who have been given atropine.

See also Precautions for General Anaesthetics, p.1779.

Interactions

Ether enhances the action of competitive neuromuscular blockers to a greater degree than most other anaesthetics. However, it does not potentiate the arrhythmogenic effect of sympathomimetics, including adrenaline, as much as other inhalational anaesthetics.

See also Interactions of General Anaesthetics, p.1779.

Uses and Administration

Ether is an anaesthetic given by inhalation. It has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) of 1.92%. Ether is still used in some countries for the induction and maintenance of general anaesthesia although it has been replaced in many other countries by the halogenated anaesthetics. It possesses a respiratory stimulant effect in all but the deepest planes of anaesthesia. Ether also possesses analgesic and muscle relaxant properties. Premedication with an antimuscarinic such as atropine is necessary to reduce salivary and bronchial secretions.

Solvent ether is described on p.2023.

Preparations

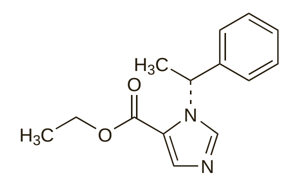
Proprietary Preparations (details are given in Part 3)
S.Afr.: Hoffmans Druppels.

Etomidate *(BAN, USAN, rINN)*

Etomidaatti; Etomidát; Etomidat; Etomidatas; Étomidate; Etomidato; Etomidatum; R-16659; R-26490 (etomidate sulfate). *R*-(+)-Ethyl 1-(α-methylbenzyl)imidazole-5-carboxylate.

Этомидат

$C_{14}H_{16}N_2O_2$ = 244.3.
CAS — 33125-97-2.
ATC — N01AX07.
ATC Vet — QN01AX07.



NOTE. Do not confuse with edetate; see Inappropriate Administration under Sodium Edetate, p.1464.

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).

Ph. Eur. 6.2 (Etomidate). A white or almost white powder. M.p. about 68°. Very slightly soluble in water; freely soluble in alcohol and in dichloromethane. Protect from light.

Adverse Effects and Precautions

Excitatory phenomena (especially involuntary myoclonic muscle movements, which are sometimes severe) are common after injection of etomidate, but may be reduced by giving an opioid analgesic or a short-acting benzodiazepine beforehand. Pain on injection may be reduced by giving etomidate into a large vein in the arm rather than into the hand, or, again, by premedication with an opioid analgesic. Convulsions may occur rarely, as may laryngospasm and cardiac arrhythmias. Hypersensitivity reactions including anaphylaxis have been reported. Etomidate is associated with less hypotension than other drugs commonly used for induction.

Because etomidate inhibits adrenocortical function during maintenance anaesthesia (see below) its use is limited to induction of anaesthesia. In addition it should not be used in patients whose adrenocortical function is already reduced or at risk of being reduced.

Etomidate should be used with care in the elderly, who may be more prone to cardiac depression; lower doses may be required. The dose of etomidate should also be reduced in patients with hepatic cirrhosis. Caution may be appropriate in patients with pre-existing epilepsy.

See also Adverse Effects and Precautions for General Anaesthetics, p.1779.

Effects on the endocrine system. Etomidate used for sedation in an intensive care unit was implicated in an increase in mortality.[1] The UK CSM agreed that etomidate could cause a significant fall in circulating plasma-cortisol concentrations, unresponsive to corticotropin stimulation.[2] As a result of this effect, use of etomidate is restricted to induction of anaesthesia. Licensed product information advises that the postoperative rise in serum-cortisol concentration, which has been observed after thiopental induction, is delayed for about 3 to 6 hours when etomidate is used for induction.

A study comparing the effects of etomidate with those of methohexital on the adrenocortical function of neonates borne by mothers who received these agents for induction of anaesthesia before caesarean section indicated that there was no evidence to preclude the use of etomidate in such patients. However, regardless of which anaesthetic agent was used, early feeding was recommended to avoid neonatal hypoglycaemia.[3]

3. Krumholz W, *et al.* Ein fall von anaphylaktoider reaktion nach gabe von etomidat. *Anaesthesist* 1984; **33:** 161–2.

Porphyria. Etomidate is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals*.

Interactions

A reduced dose of etomidate may be necessary in patients who have received antipsychotics, sedatives, or opioids. The hypnotic effect of etomidate has been potentiated by other sedative drugs.

See also Interactions of General Anaesthetics, p.1779.

Calcium-channel blockers. Prolonged anaesthesia and Cheyne-Stokes respiration following etomidate injection has been reported in 2 patients also given *verapamil*.[1]

1. Moore CA, *et al.* Potentiation of etomidate anesthesia by verapamil: a report of two cases. *Hosp Pharm* 1989; **24:** 24–5.

General anaesthetics. For a report of synergy between *propofol* and etomidate, see p.1792.

Pharmacokinetics

After injection, etomidate is rapidly redistributed from the CNS to other body tissues, and undergoes rapid metabolism in the liver and plasma. Pharmacokinetics are complex and have been described by both 2- and 3-compartment models. Etomidate is about 76% bound to plasma proteins. It is mainly excreted in the urine, but some is excreted in the bile. It may cross the placenta and is distributed into breast milk.

Uses and Administration

Etomidate is an intravenous anaesthetic used for the induction of general anaesthesia (p.1780). Anaesthesia is rapidly induced and may last for 6 to 10 minutes with a single usual dose. Recovery is usually rapid without hangover effect. Etomidate has no analgesic activity.

For the induction of anaesthesia, etomidate is available as a conventional or an emulsion injection formulation. The usual dose is 300 micrograms/kg of etomidate given slowly, preferably into a large vein in the arm, although a lower dose of 150 micrograms/kg of the emulsion formulation may be sufficient. An initial dose of 150 to 200 micrograms/kg is recommended in the elderly, subsequently adjusted according to effects. Dosage should also be reduced in hepatic cirrhosis. Children may require up to 30% more than the usual adult dose of the emulsion formulation. Opioid analgesics or benzodiazepines as premedication reduce myoclonic muscle movements; opioids also reduce injection site pain. A neuromuscular blocker is necessary if intubation is required.

Administration in the elderly. A study[1] in elderly patients has demonstrated that although reducing the rate of intravenous injection of etomidate reduces the speed of induction, the dosage required is also reduced. Giving etomidate 0.2% solution at a rate of 10 mg/minute induced anaesthesia in a mean of 89.6 seconds and required a mean dose of 0.11 mg/kg. Corresponding values for a rate of 40 mg/minute were 47.7 seconds and 0.26 mg/kg, respectively.

Anaesthesia. Etomidate might be useful for induction if rapid tracheal intubation is required with a competitive neuromuscular blocker as it has been shown to reduce the time to onset of block with vecuronium.[1,2]

Status epilepticus. General anaesthesia may be used to control refractory tonic-clonic status epilepticus (p.469). A short-acting barbiturate such as thiopental is usually used, but other anaesthetics including etomidate have also been tried[1] for intractable convulsive status epilepticus. However, like a number of other anaesthetics there have been reports of seizures associated with its use in anaesthesia,[2] especially in patients with epilepsy.

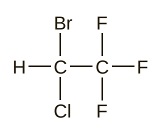
CAS — 151-67-7.

ATC — N01AB01.

ATC Vet — QN01AB01.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Halothane). A clear, colourless, mobile, dense, non-flammable liquid. Distillation range 49° to 51°. Slightly soluble in water; miscible with dehydrated alcohol and with trichloroethylene. Halothane contains 0.01% w/w of thymol. Store at a temperature not greater than 25° in airtight containers. Protect from light.

USP 31 (Halothane). A colourless, mobile, non-flammable, heavy liquid having a characteristic odour resembling that of chloroform. It contains not less than 0.008% and not more than 0.012% of thymol, by weight, as a stabiliser. It should contain not more than 0.03% of water. Distillation range 49° to 51°.

Slightly soluble in water; miscible with alcohol, with chloroform, with ether, and with fixed oils. Store in airtight containers at a temperature not greater than 40°. Protect from light. Dispense only in the original container.

Incompatibility. In the presence of moisture, halothane reacts with many metals. Rubber and some plastics deteriorate when in contact with halothane vapour or liquid.

Stability. Halothane contains 0.01% w/w of thymol as a stabiliser; some commercial preparations may also contain up to 0.00025% w/w of ammonia. Thymol does not volatilise with halothane and therefore accumulates in the vaporiser. It may give a yellow colour to any remaining liquid; halothane that has discoloured should be discarded.

Adverse Effects

As with other halogenated anaesthetics, halothane has a depressant action on the cardiovascular system and reduces blood pressure; signs of overdosage are bradycardia and profound hypotension. It is also a respiratory depressant and can cause cardiac arrhythmias; there have been instances of cardiac arrest. The sensitivity of the heart to sympathomimetic amines is increased.

Adverse effects on the liver have limited its use in recent years (see below); these effects range from liver dysfunction to fatal hepatitis and necrosis and are more frequent following repeated use.

Halothane can produce nausea, vomiting, and shivering. Malignant hyperthermia has been reported.

See also Adverse Effects of General Anaesthetics, p.1779.

Effects on the cardiovascular system. The incidence of cardiac arrhythmias is higher with halothane than with enflurane or isoflurane; also the arrhythmogenic threshold with injected adrenaline is lower with halothane than isoflurane or enflurane.

Arrhythmias are considered to be very common in children anaesthetised with halothane and in the UK it is recommended that it should not be used for dental procedures outside hospital in those under 18 years old.

Effects on the kidneys. Renal failure has been reported after halothane anaesthesia,[1,2] sometimes with concurrent liver failure.[2]

1. Cotton JR, *et al.* Acute renal failure following halothane anesthesia. *Arch Pathol Lab Med* 1976; **100:** 628–9.
2. Gelman ML, Lichtenstein NS. Halothane-induced nephrotoxicity. *Urology* 1981; **17:** 323–7.

Effects on the liver. Liver damage has been recognised as an adverse effect of halothane for many years.[1-3] It may be severe, and associated with a high mortality.

Two types of hepatotoxicity are recognised; in **type I** there is a minor disturbance in liver function shown by increases in liver enzyme values; this may occur in up to 30% of patients given halothane,[4] or more if activity is measured by glutathione S-transferase rather than serum aminotransferase.[5] Subsequent re-exposure to halothane is not necessarily associated with liver damage.[2,6]

Type II hepatotoxicity, which is rarer, involves massive liver cell necrosis; reported incidences[2] range from 1 in 2500 to 1 in 36 000. Type II liver toxicity is characterised by several clinical features: non-specific gastrointestinal upset, delayed pyrexia, jaundice, eosinophilia, serum autoantibodies, rash, and arthralgia.[1,3] Biochemical tests of liver function show changes typical of hepatocellular damage; histological features are typified by centrilobular necrosis.[1] Several **risk factors** for development of serious toxicity have become apparent;[1-3] they include repeated exposure, previous adverse reactions to halothane (jaundice, pyrexia), female gender, obesity, middle age, genetic predisposition, enzyme induction, and a history of drug allergy.

The **causes** of halothane hepatotoxicity have been debated. Type I reactions may result from toxic products of halothane metabolism, possibly influenced by genetic factors or from an imbalance between hepatic oxygen supply and demand. Changes in cellular calcium homoeostasis may also be involved. Type II reactions are most likely immune-mediated.[1,2] It has been suggested[4] that metabolism of halothane produces a reactive metabolite which binds covalently to proteins in the endoplasmic reticulum of hepatocytes. In susceptible patients it is believed that these metabolite-modified proteins provoke an immune response which is responsible for the liver damage. Findings[7,8] have implicated the cytochrome P450 isoenzyme CYP2E1 as having a major role in the metabolism of halothane and patients with high levels of this isoenzyme may be predisposed to developing immune-medicated liver damage after halothane exposure.

The UK CSM,[9] after receiving 84 further reports of hepatotoxicity between 1978 and 1985, issued the following **guidelines** on **precautions** to be taken before using halothane:

- a careful anaesthetic history should be taken to determine previous exposure and previous reactions to halothane
- repeated exposure to halothane within a period of at least 3 months should be avoided unless there are overriding clinical circumstances. An opinion has been expressed that the 3-month interval between exposures would be unlikely to prevent hepatotoxicity[2]
- a history of unexplained jaundice or pyrexia in a patient following exposure to halothane is an absolute contra-indication to its future use in that patient

These guidelines were reiterated in 1997 after the CSM were notified of a further 15 cases of acute liver failure all requiring transplantation.[10]

The problem of patients sensitised to halothane who require **subsequent anaesthesia** with a volatile anaesthetic has been discussed.[4] Although the incidence of hepatotoxicity produced by *enflurane* appears to be less than with halothane it is of a similar nature and there have been reports of several patients who apparently had cross-sensitivity to both. Hepatotoxicity with *isoflurane* appears to be rare and it was suggested that for the majority of patients sensitised to halothane, isoflurane would be likely to be free from hepatotoxic effects. However, there has been a report[11] of a patient who had had two previous exposures to isoflurane and subsequently developed liver function abnormalities after receiving halothane. Hepatotoxicity with *desflurane* (see p.1781) might also be associated with sensitisation to halothane.

Precautions

The risk of halothane hepatitis led the UK CSM to issue guidelines on its use (see Effects on the Liver, under Adverse Effects, above). It is also recommended that patients be informed of any reactions and that this be done in addition to the updating of the patients' medical records.

It is recommended in the UK that halothane should not be used for dental procedures outside hospital in patients under 18 years old.

Halothane reduces uterine muscle tone during pregnancy and generally its use is not recommended in obstetrics because of the increased risk of postpartum haemorrhage.

Premedication with atropine has been recommended to reduce vagal tone and to prevent bradycardia and severe hypotension.

Allowance may need to be made for any increase in CSF pressure or in cerebral blood flow. Halothane should be used with caution in patients with phaeochromocytoma.

As with other halogenated anaesthetics, patients with known or suspected susceptibility to malignant hyperthermia should not be anaesthetised with halothane.

See also Precautions for General Anaesthetics, p.1779.

Abuse. A brief review[1] of abuse of volatile anaesthetics found that of 14 patients who had ingested or sniffed halothane 10 had died. Another patient who had injected halothane intravenously also died. There has also been another report[2] of fatalities resulting from acute pulmonary oedema after intravenous injection of halothane.

2. Berman P, Tattersal M. Self-poisoning with intravenous halothane. *Lancet* 1982; **i:** 340.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were receiving halothane, and the American Academy of Pediatrics[1] considers that it is therefore usually compatible with breast feeding.

Trace amounts of halothane have been detected in the breast milk of an anaesthetist exposed to environmental halothane in the operating theatre.[2]

2. Coté CJ, *et al.* Trace concentrations of halothane in human breast milk. *Br J Anaesth* 1976; **48:** 541–3.

Porphyria. Halothane has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Interactions

Adrenaline and most other sympathomimetics, and theophylline should be avoided during halothane anaesthesia since they can produce cardiac arrhythmias; the risk of arrhythmias is also increased if halothane is used in patients receiving dopaminergics. The effects of competitive neuromuscular blockers such as atracurium, and of ganglion blockers such as trimetaphan are enhanced by halothane and if required they should be given in reduced dosage. Morphine increases the depressant effects of halothane on respiration. Chlorpromazine also enhances the respiratory depressant effect of halothane. The effects of both ergometrine and oxytocin on the parturient uterus are diminished by halothane.

See also Interactions of General Anaesthetics, p.1779.

Antiepileptics. For a case of *phenytoin* intoxication associated with halothane anaesthesia, see p.497.

Benzodiazepines. *Midazolam* has been reported to potentiate the anaesthetic action of halothane.[1]

1. Inagaki Y, *et al.* Anesthetic interaction between midazolam and halothane in humans. *Anesth Analg* 1993; **76:** 613–17.

General anaesthetics. For a report that halothane increases serum concentrations of *propofol*, see p.1792.

Neuromuscular blockers. For the potentiation of the neuromuscular blockade of neuromuscular blockers such as *atracurium* by halothane, see p.1904. For increased toxicity during halothane anaesthesia, see *suxamethonium* p.1911.

Trichloroethane. A report[1] of 2 patients showing evidence of chronic cardiac toxicity after repeated exposure to trichloroethane. In both cases there was circumstantial evidence of a deterioration after routine anaesthetic use of halothane.

1. McLeod AA, *et al.* Chronic cardiac toxicity after inhalation of 1,1,1-trichloroethane. *BMJ* 1987; **294:** 727–9.

Xanthines. For references to increased cardiotoxicity when patients taking *theophylline* were anaesthetised with halothane, see p.1145.

Pharmacokinetics

Halothane is absorbed on inhalation. It has a relatively low solubility in blood and is more soluble in the neutral fats of adipose tissue than in the phospholipids of brain cells. Up to 80% of inhaled halothane is excreted unchanged through the lungs. Up to 20% is metabolised by the liver by oxidative and, under hypoxic conditions, reductive pathways. Urinary metabolites include trifluoroacetic acid and bromide and chloride salts (oxidative pathway) and fluoride salts (reductive pathway). Halothane diffuses across the placenta and has been detected in breast milk.

Uses and Administration

Halothane is a volatile halogenated anaesthetic given by inhalation. It has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) ranging from 0.64% in the elderly to 1.08% in infants. It is non-flammable and is not explosive when mixed with oxygen at normal atmospheric pressure. It is not irritant to the skin and mucous membranes and does not produce necrosis when spilt on tissues. It suppresses salivary, bronchial, and gastric secretions and dilates the bronchioles. However, its use has diminished due to the risk of hepatotoxicity; in the UK, it is only available on a named-patient basis and in other countries, such as the USA, it has been withdrawn from the market.

Halothane is used for the induction and maintenance of general anaesthesia (p.1780) and is given using a calibrated vaporiser to provide close control over the concentration of inhaled vapour.

Anaesthesia may be induced with 2 to 4% v/v of halothane in oxygen or mixtures of nitrous oxide and oxygen; induction may also be started at a concentration of 0.5% v/v and increased gradually to the required level. For induction in children a concentration of 1.5 to 2% v/v has been used. It takes up to about 5 minutes to attain surgical anaesthesia and halothane produces little or no excitement in the induction period. The more usual practice is to induce anaesthesia with an intravenous agent. Anaesthesia is maintained with concentrations of 0.5 to 2% v/v depending on the flow rate used; the lower concentration is usually suitable for the elderly.

Adequate muscle relaxation is only achieved with deep anaesthesia so a neuromuscular blocker is given to increase muscular relaxation if necessary.

Isoflurane *(BAN, USAN, rINN)*

Compound 469; Isofluraani; Isofluran; Isoflurano; Isofluranum; Izoflurán; Izofluran; Izofluranas. 1-Chloro-2,2,2-trifluoroethyl difluoromethyl ether; 2-Chloro-2-(difluoromethoxy)-1,1,1-trifluoroethane.

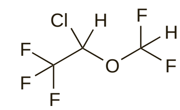
Изофлуран

$C_3H_2ClF_5O$ = 184.5.

CAS — 26675-46-7.

ATC — N01AB06.

ATC Vet — QN01AB06.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Isoflurane). A clear, colourless, mobile, heavy liquid. B.p. about 48°. It is non-flammable. Practically insoluble in water; miscible with dehydrated alcohol and with trichloroethylene. Store in airtight containers. Protect from light.

USP 31 (Isoflurane). A clear, colourless, volatile liquid having a slight odour. B.p. about 49°. Insoluble in water; miscible with common organic solvents and with fats and oils. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°.

Adverse Effects and Precautions

As with other halogenated anaesthetics, respiratory depression, hypotension, arrhythmias, and malignant hyperthermia have been reported; patients with known or suspected susceptibility to malignant hyperthermia should not be anaesthetised with isoflurane. Isoflurane differs from halothane and enflurane in that it produces less cardiac depression than either drug and heart rate may be increased. Also isoflurane sensitises the myocardium to sympathomimetics to a lesser extent than halothane and enflurane. The incidence of cardiac arrhythmias is lower with isoflurane than with halothane. Shivering, nausea, and vomiting have been reported in the postoperative period.

Induction with isoflurane is not as smooth as with halothane and this may be connected with its pungency; breath holding, coughing, and laryngospasm may occur. It has been reported to increase the cerebrospinal pressure and should be used with caution in patients with raised intracranial pressure. Isoflurane relaxes the uterine muscle; increased blood loss may occur after curettage or termination of pregnancy.

In order to minimise the risk of developing elevated carboxyhaemoglobin levels, carbon dioxide absorbents in anaesthetic apparatus should not be allowed to dry out when delivering volatile anaesthetics such as isoflurane (see below).

See also Adverse Effects and Precautions of General Anaesthetics, p.1779.

◊ A comparison[1] of isoflurane and halothane for outpatient dental anaesthesia in children considered that isoflurane would produce fewer arrhythmias than halothane, but that the ease of induction and the quality of anaesthesia was inferior to that with halothane. Others[2] also found a higher incidence of coughing, salivation, and laryngospasm with isoflurane than halothane, but felt that it could be used as an alternative.

Further information on the adverse effects profile of isoflurane can be obtained from the report of and commentaries on an extensive multicentre study of patients undergoing anaesthesia with this agent.[3,4]

Carbon dioxide absorbents. Significant carboxyhaemoglobinaemia may develop rarely during anaesthesia with volatile anaesthetics given by circle breathing systems containing carbon dioxide absorbents.[1] The effect is only seen when the absorbent has become excessively dried out. The use of barium hydroxide lime (which is not available in the UK) as an absorbent produces more carbon monoxide than soda lime, particularly at low water content. No cases of this complication had been reported to date in the UK.

1. Committee on Safety of Medicines/Medicines Control Agency. Safety issues in anaesthesia: volatile anesthetic agents and carboxy-haemoglobinaemia. *Current Problems* 1997; **23:** 7. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2023230&RevisionSelectionMethod=LatestReleased (accessed 16/05/06)

Effects on the cardiovascular system. Isoflurane is considered to produce less cardiovascular depression than halothane. However, the results of a study[1] suggest that while this may be true for young patients, in elderly patients isoflurane appears to have a cardiac depressant effect similar to that of halothane.

1. McKinney MS, *et al.* Cardiovascular effects of isoflurane and halothane in young and elderly adult patients. *Br J Anaesth* 1993; **71:** 696–701.

CEREBRAL BLOOD FLOW. Autoregulation of cerebral blood flow appears to be impaired at higher concentrations of isoflurane. A study[1] in healthy subjects found that increasing isoflurane anaesthesia from a concentration of 1 to 2 MAC increased cerebral blood flow and reduced cerebral oxygen metabolism.

1. Olsen KS, *et al.* Effect of 1 or 2 MAC isoflurane with or without ketanserin on cerebral blood flow autoregulation in man. *Br J Anaesth* 1994; **72:** 66–71.

CORONARY CIRCULATION. Halothane, enflurane, and isoflurane decrease coronary perfusion pressure, coronary blood flow, ventricular function, and myocardial oxygen demand. Halothane and enflurane have a variable effect on coronary vascular resistance, but isoflurane dilates coronary vessels.[1] There has been concern over the potential of isoflurane to produce coronary steal and whether this effect is detrimental in patients with ischaemic heart disease.[2] However, despite conflicting results of individual studies[3-6] an early review[7] concluded that isoflurane could be used safely even in high-risk patients with coronary artery disease provided that blood pressure and heart rate were maintained close to baseline concentrations. A subsequent review[8] considered that more recent evidence supported the use of isoflurane as the anaesthetic agent of choice in patients with coronary heart disease.

Effects on the kidneys. See under Metabolism in Pharmacokinetics, below.

Effects on the liver. Of 45 cases of isoflurane-associated hepatotoxicity reported to the FDA between 1981 and 1984 there was some other cause for the liver damage in 29. While isoflurane might have been one of the causes of the damage in the other 16 cases, there was not a reasonable likelihood of an association between isoflurane and postoperative liver impairment.[1] Subsequent rare cases of hepatotoxicity,[2-7] sometimes fatal,[2,5,7] have suggested that isoflurane may induce hepatitis, though much less frequently than halothane, and that there may be cross-sensitisation with other halogenated anaesthetics.

Effects on the nervous system. Seizures associated with induction of anaesthesia with isoflurane have been reported in patients without known neurological abnormalities and not undergoing neurosurgery.[1,2] However, data from a retrospective analysis of patients undergoing intracranial surgery indicated that when convulsions occurred postoperatively in these conditions, it was the neurosurgical procedures rather than the anaesthetics that were responsible.[3]

See also under Status Epilepticus in Uses, below.

3. Christys AR, *et al.* Retrospective study of early postoperative convulsions after intracranial surgery with isoflurane or enflurane anaesthesia. *Br J Anaesth* 1989; **62:** 624–7.

Effects on the respiratory tract. A study[1] conducted mainly in adults found that humidification of anaesthetic mixtures containing isoflurane could reduce respiratory complications such as coughing, laryngospasm, and breath-holding that were usually associated with the use of isoflurane for induction. However, a similar study[2] in children failed to confirm these findings.

Porphyria. Isoflurane is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals*.

Interactions

The effects of competitive neuromuscular blockers such as atracurium are enhanced by isoflurane (see p.1904). Care is advised if adrenaline and other sympathomimetics are given during isoflurane anaesthesia.

See also Interactions of General Anaesthetics, p.1779.

General anaesthetics. For a report that isoflurane increases serum concentrations of *propofol*, see p.1792.

Pharmacokinetics

Isoflurane is absorbed on inhalation. The blood/gas partition coefficient is lower than that of enflurane or halothane. It is mostly excreted unchanged through the lungs. About 0.2% of inhaled isoflurane is metabolised, mainly to inorganic fluoride.

Metabolism. In 26 patients sedated with isoflurane for 24 hours, plasma fluoride ion concentration increased from a mean of 4.03 nanomol/mL to 13.57 nanomol/mL in 12 hours after stopping sedation.[1] These fluoride concentrations were considered to be too low to cause clinical renal dysfunction. In 30 patients sedated with isoflurane for up to 127 hours (mean duration was 36 hours), mean plasma fluoride ion concentration increased[2] to 20.01 nanomol/mL during sedation and continued rising for 16 hours after stopping isoflurane to a maximum mean concentration of 25.34 nanomol/mL; thereafter, levels gradually declined to normal values by the fifth day. Despite the increased plasma fluoride ion concentrations, no biochemical or clinical evidence of deterioration in renal function was found. Giving isoflurane for 34 days to a patient with tetanus who required sedation to facilitate mechanical ventilation resulted[3] in sustained fluoride ion concentrations of 50 nanomol/mL and a peak concentration of 87 nanomol/mL. Although such concentrations are considered to be potentially nephrotoxic no clinical effect on renal function was found.

3. Stevens JJWM, *et al.* Prolonged use of isoflurane in a patient with tetanus. *Br J Anaesth* 1993; **70:** 107–109.

Uses and Administration

Isoflurane is a volatile halogenated anaesthetic given by inhalation. It is an isomer of enflurane and has anaesthetic actions similar to those of halothane (p.1785). Isoflurane has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) ranging from 1.05% in the elderly to 1.87% in infants. It is used in the induction and maintenance of general anaesthesia (p.1780) although induction is more often carried out using an intravenous anaesthetic. Isoflurane is also used in subanaesthetic doses to provide analgesia in obstetrics and other painful procedures.

Isoflurane is given using a calibrated vaporiser. If it is used for induction then it is given with oxygen or oxygen and nitrous oxide mixtures and induction should start with an isoflurane concentration of 0.5% v/v increased to 1.5 to 3% v/v which generally produces surgical anaesthesia within 10 minutes. Its pungency may limit the rate of induction. Anaesthesia may be maintained with a concentration of 1 to 2.5% v/v with oxygen and nitrous oxide mixtures; 1.5 to 3.5% v/v may be required if used only with oxygen. Isoflurane 0.5 to 0.75% v/v with oxygen and nitrous oxide mixtures is suitable to maintain anaesthesia for caesarean section. Although isoflurane is reported to possess muscle relaxant properties, neuromuscular blockers may nevertheless be required. Recovery is rapid.

Anaesthesia. *CAESAREAN SECTION.* Isoflurane 0.8% v/v has been found to be a suitable supplement to nitrous oxide-oxygen anaesthesia for patients undergoing caesarean section.[1] It has been suggested[2] that an overpressure technique might be of use to further reduce awareness in such patients. Giving isoflurane at a concentration of 2% v/v for 5 minutes followed by concentrations of 1.5% v/v for the next 5 minutes and 0.8% v/v thereafter produced higher arterial concentrations of isoflurane in patients undergoing caesarean section than when it was given at a concentration of 1% v/v throughout.[2]

2. McCrirrick A, *et al.* Overpressure isoflurane at Caesarean section: a study of arterial isoflurane concentrations. *Br J Anaesth* 1994; **72:** 122–4.

Pain. Isoflurane is used in subanaesthetic doses to provide analgesia in obstetrics and other painful procedures but studies[1,2] have been unable to confirm that it had an analgesic effect at subanaesthetic concentrations. The use of isoflurane 0.2 or 0.25% v/v in a mixture of nitrous oxide 50% v/v and oxygen 50% v/v has been studied.[3,4]

4. Bryden FM, *et al.* Isoflurane for removal of chest drains after cardiac surgery. *Br J Anaesth* 1994; **73:** 712P–713P.

Sedation. *INTENSIVE CARE.* The various drugs used to provide sedation in intensive care are discussed on p.957. Isoflurane is not usually considered for such a purpose but in a comparative 24-hour study[1] in 60 patients requiring mechanical ventilation, isoflurane 0.1 to 0.6% v/v in an air-oxygen mixture produced satisfactory sedation for a greater proportion of time than did the continuous infusion of midazolam 10 to 200 micrograms/kg per hour. Patients given isoflurane also recovered more rapidly. Isoflurane has also been used successfully for sedation over 5 days in a 3-year-old infant who required ventilation for pneumonia, a complication of the child's myasthenia gravis.[2] However, there has been some concern over high plasma fluoride concentrations after prolonged use of isoflurane (see under Metabolism in Pharmacokinetics, above).

2. McBeth C, Watkins TGL. Isoflurane for sedation in a case of congenital myasthenia gravis. *Br J Anaesth* 1996; **77:** 672–4.

Status epilepticus. General anaesthesia may be used to control refractory tonic-clonic status epilepticus (p.469). A short-acting barbiturate such as thiopental is usually used. Despite rare reports of seizures associated with the use of isoflurane in anaesthetic procedures (see Effects on the Nervous System, above) it has been used successfully,[1-3] typically in concentrations of 0.5 to 1% v/v, to control refractory convulsive status epilepticus. Although some[4] consider that isoflurane-induced coma may be more easy to control than barbiturate-induced coma, the use of isoflurane may be limited by the need for special anaesthetic equipment and continuous EEG monitoring.

Ketamine Hydrochloride

(BANM, USAN, rINNM)

CI-581; CL-369; CN-52372-2; Hidrocloruro de ketamina; Ketamiinihydrokloridi; Ketamin Hidroklorür; Kétamine, chlorhydrate de; Ketamin-hidroklorid; Ketamin-hydrochlorid; Ketaminhydroklorid; Ketamini hydrochloridum; Ketamino hidrochloridas; Ketaminy chlorowodorek. (±)-2-(2-Chlorophenyl)-2-methylaminocyclohexanone hydrochloride.

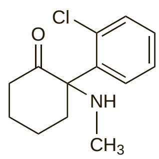
Кетамина Гидрохлорид

$C_{13}H_{16}ClNO,HCl = 274.2.$

CAS — 6740-88-1 (ketamine); 1867-66-9 (ketamine hydrochloride).

ATC — N01AX03.

ATC Vet — QN01AX03.



(ketamine)

NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of ketamine:

Animal trank; Animal tranquilizer; Bump; Cat tranquilizer; Cat valium; Elephant tranquilizer; Green; Honey oil; Horse tranquilizer; Jet; Jet fuel; K; "K"; K wire; Kay Jay; K-blast; Keets; Keezy; Keller; Kellys day; Kenny; Ket; Keta; Ketaset; KFC; Kit kat; Kit-Kat; Kitty; KKK; Klarko K Kat; Klarky Kat; Kustard; Lady K; Naughty horsey; Old Man; Property of Sir John; Purple; Regretamine; Special K; Special "K"; Special la coke; Super acid; Super C; Super K; Tranquilizer; Triple K; Vetamine; Vitamin K; Wonky.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Ketamine Hydrochloride). A white or almost white crystalline powder. Freely soluble in water and in methyl alcohol; soluble in alcohol. A 10% solution in water has a pH of 3.5 to 4.1. Protect from light.

USP 31 (Ketamine Hydrochloride). A white crystalline powder having a slight characteristic odour. Soluble 1 in 4 of water, 1 in 14 of alcohol, 1 in 60 of dehydrated alcohol and of chloroform, and 1 in 6 of methyl alcohol; practically insoluble in ether. pH of a 10% solution in water is between 3.5 and 4.1. Store at a temperature of 25°, excursions permitted between 15° and 30°.

Incompatibility. Ketamine hydrochloride is incompatible with soluble barbiturates. The US licensed product information recommends that when use of diazepam and ketamine is required they should be given separately and not mixed in the same giving equipment.

Esketamine Hydrochloride *(BANM, rINNM)*

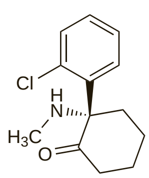
Esketamiinihydrokloridi; Eskétamine, Chlorhydrate d'; Eskétamine, chlorhydrate de; Esketamin-hydrochlorid; Esketaminhydroklorid; Esketamini hydrochloridum; Esketamino hidrochloridas; Hidrocloruro de esketamina; *S*-Ketamine Hydrochloride.

Эскетамина Гидрохлорид

CAS — 33643-46-8 (esketamine).

ATC — N01AX14.

ATC Vet — QN01AX14.



(esketamine)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Esketamine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water and in methyl alcohol; soluble in alcohol. A 10% solution in water has a pH of 3.5 to 4.5. Protect from light.

Adverse Effects

Emergence reactions are common during recovery from ketamine anaesthesia and include vivid often unpleasant dreams, confusion, hallucinations, and irrational behaviour. Children and elderly patients appear to be less sensitive. Patients may also experience increased muscle tone, sometimes resembling seizures. Blood pressure and heart rate may be temporarily increased by ketamine; hypotension, arrhythmias, and bradycardia have occurred rarely.

Respiration may be depressed after rapid intravenous injection or with high doses. Apnoea and laryngospasm have occurred. Diplopia and nystagmus may occur. Nausea and vomiting, lachrymation, hypersalivation, and raised intra-ocular and CSF pressure have also been reported. Transient skin rashes and pain at the site of injection may occur.

See also Adverse Effects of General Anaesthetics, p.1779.

Effects on the cardiovascular system. Ketamine has been advocated by some for maintaining or increasing cardiovascular performance in selected patients during induction of anaesthesia as it may increase blood pressure and heart rate.[1] However, there have been reports of reduced cardiac and pulmonary performance in severely ill patients[1] and of arrhythmias.[2]

Some of the cardiovascular effects of ketamine may be attenuated by premedication with diazepam[2] or clonidine.[3]

1. Waxman K, *et al*. Cardiovascular effects of anesthetic induction with ketamine. *Anesth Analg* 1980; **59:** 355–8.
2. Cabbabe EB, Behbahani PM. Cardiovascular reactions associated with the use of ketamine and epinephrine in plastic surgery. *Ann Plast Surg* 1985; **15:** 50–2.
3. Tanaka M, Nishikawa T. Oral clonidine premedication attenuates the hypertensive response to ketamine. *Br J Anaesth* 1994; **73:** 758–62.

Effects on the liver. Changes in liver enzyme values have occurred after ketamine in an initial dose of 1 mg/kg followed by continuous infusion as a 0.1% solution.[1]

1. Dundee JW, *et al*. Changes in serum enzyme levels following ketamine infusions. *Anaesthesia* 1980; **35:** 12–16.

Effects on mental state. Mental disturbances following ketamine anaesthesia may vary in incidence from less than 5% to greater than 30%.[1] See also Abuse, below.

1. White PF, *et al.* Ketamine—its pharmacology and therapeutic uses. *Anesthesiology* 1982; **56:** 119–36.

Effects on the skin. Harlequin-like colour skin changes were reported[1] in a 9-month-old boy during anaesthesia with ketamine 15 mg.

1. Wagner DL, Sewell AD. Harlequin color change in an infant during anesthesia. *Anesthesiology* 1985; **62:** 695.

Malignant hyperthermia. Malignant hyperthermia has been reported in a patient given ketamine.[1]

1. Rasore-Quartino A, *et al.* Forma atipica di ipertermia maligna: osservazione di un caso da ketamina. *Pathologica* 1985; **77:** 609–17.

Precautions

Ketamine is contra-indicated in patients in whom elevation of blood pressure would be a serious hazard including those with hypertension or a history of cerebrovascular accident. Cardiac function should be monitored in patients found to have hypertension or cardiac decompensation. Ketamine should be used with caution in patients with elevated CSF pressure. It can raise intra-ocular pressure and should not be used in the presence of eye injury or increased intra-ocular pressure.

Ketamine does not reliably suppress pharyngeal and laryngeal reflexes and mechanical stimulation of the pharynx should be avoided unless a muscle relaxant is used.

The use of ketamine should be avoided in patients prone to hallucinations or psychotic disorders. Verbal, tactile, and visual stimuli should be kept to a minimum during recovery in an attempt to reduce the risk of emergence reactions.

See also Precautions for General Anaesthetics, p.1779.

Abuse. Health care workers in the USA were alerted to the dangers associated with the abuse of ketamine as long ago as 1979.[1] Similar concern had also been voiced in the UK[2] over the abuse of ketamine at social gatherings where it has been taken intranasally or orally. A WHO expert committee[3] considered in 2006 that the available information on ketamine was not sufficient to warrant international control. Studies in *animals* have shown that ketamine can produce dependence, however, reports of dependence in humans are limited (see below). Although tolerance may occur there is no evidence of a withdrawal syndrome (but see below). Ketamine abuse has been reported in a number of countries.

Ketamine produces a state of psychological dissociation resulting in hallucinations and out of body or near death experiences. It can induce a state of helplessness in which the user loses awareness of the environment and this together with severe loss of coordination and pronounced analgesia can put the user at great risk. Furthermore, some users experience a state in which they are unconcerned about whether they live or die. Ketamine has the potential for compulsive repeated use and there have been reports of users self-injecting ketamine several times a day for prolonged periods. Dependency may develop[4,5] and withdrawal symptoms requiring detoxification can occur.[4] Frequent use may produce long-lasting memory impairment.[6] Other adverse effects include a report[7] of an acute dystonic reaction in a 20-year old man following self-administration of ketamine intravenously.

In one case series[8] of 20 patients presenting to hospital after ketamine abuse the most common symptoms included anxiety, chest pain, and palpitations. Frequent complications included agitation and rhabdomyolysis. Symptoms were generally short lived with most patients discharged within 5 hours.

Some[2] suggest that patients seeking medical attention are best placed in a quiet darkened room to recover with diazepam being given for unresponsive panic attacks while others advocate that such patients should be admitted to an intensive care unit for close monitoring.[9] The use of intravenous fluids to prevent rhabdomyolysis has also been recommended.[8]

Long-term and frequent abuse of ketamine has been associated with adverse effects on the urinary tract.[10-12] Patients may present with symptoms of dysuria, frequency, urgency, urinary incontinence, suprapubic pain, and haematuria. Examination has shown in some cases a contracted shrunken bladder and ulcerative cystitis. Complications have included hydronephrosis and renal impairment.

Ketamine is tasteless, odourless, and colourless and has been misused to incapacitate the victim and produce amnesia in sexual assaults and drug-facilitated rape ('date rape').[4]

Neurosurgery. Although the idea that ketamine should not be used in patients at risk from rises in intracranial pressure has limited its use in neurosurgical patients, a review[1] considered that if used with controlled ventilation and a GABA receptor agonist, and without nitrous oxide, it did not appear to have adverse effects in this group, and there was some evidence from *animal* studies that it might have neuroprotective properties.

1. Himmelseher S, Durieux ME. Revising a dogma: ketamine for patients with neurological injury? *Anesth Analg* 2005; **101:** 524–34.

Interactions

Inhalational anaesthetics, such as ether and halothane, and other cerebral depressants may prolong the effect of ketamine and delay recovery. Prolonged recovery has also occurred when barbiturates and/or opioids have been given with ketamine. It has been recommended that ketamine should not be used with ergometrine.

Xanthines. For a reference to seizures and tachycardia attributed to an interaction between ketamine and *theophylline*, see p.1145.

Pharmacokinetics

After intravenous boluses, ketamine shows a bi- or triexponential pattern of elimination. The alpha phase lasts about 45 minutes with a half-life of 10 to 15 minutes. This first phase, which represents ketamine's anaesthetic action, is terminated by redistribution from the CNS to peripheral tissues and hepatic biotransformation to an active metabolite norketamine. Other metabolic pathways include hydroxylation of the cyclohexone ring and conjugation with glucuronic acid. The beta phase half-life is about 2.5 hours. Ketamine is excreted mainly in the urine as metabolites. It crosses the placenta.

Uses and Administration

Ketamine is an anaesthetic given by intravenous injection, intravenous infusion, or intramuscular injection. It produces dissociative anaesthesia characterised by a trance-like state, amnesia, and marked analgesia which may persist into the recovery period. There is often an increase in muscle tone and the patient's eyes may remain open for all or part of the period of anaesthesia. Ketamine is used in general anaesthesia for diagnostic or short surgical operations that do not require skeletal muscle relaxation, for the induction of anaesthesia to be maintained with other drugs, and as a supplementary anaesthetic (see p.1780). It also has good analgesic properties in subanaesthetic doses. It is considered to be of particular value in children requiring frequent repeated anaesthesia. Recovery is relatively slow.

Ketamine is given as the hydrochloride but doses are expressed in terms of the equivalent amount of base; ketamine hydrochloride 1.15 mg is equivalent to about 1 mg of ketamine.

- For induction in adults and children the dose given by *intravenous injection* may range from the equivalent of 1 to 4.5 mg/kg of ketamine; a dose of 2 mg/kg given intravenously over 60 seconds usually produces surgical anaesthesia within 30 seconds of the end of the injection and lasting for 5 to 10 minutes.
- The initial *intramuscular* dose may range from 6.5 to 13 mg/kg; an intramuscular dose of 10 mg/kg usually produces surgical anaesthesia within 3 to 4 minutes lasting for 12 to 25 minutes. For diagnostic or other procedures not involving intense pain an initial intramuscular dose of 4 mg/kg has been used. Additional doses may be given for maintenance.
- For induction by *intravenous infusion* a total dose of 0.5 to 2 mg/kg is usually given at an appropriate infusion rate. Maintenance is achieved with 10 to 45 micrograms/kg per minute, the infusion rate being adjusted according to response.

Use should be preceded by atropine or another suitable antimuscarinic. Diazepam or another benzodiazepine may be given before surgery or as an adjunct to ketamine to reduce the incidence of emergence reactions.

The *S*-isomer, esketamine, is also given for similar uses in anaesthesia.

◊ Reviews.

Administration. Although ketamine hydrochloride is usually given intravenously or intramuscularly, oral[1,2] and rectal[3] dosage has been used successfully in children. Intranasal use of ketamine with midazolam in a neonate requiring anaesthesia has also been reported.[4] Unfortunately the onset of sedation with these three routes is too slow for emergency procedures and therefore a jet-injector of ketamine was developed[5] to provide non-traumatic, painless, and rapid anaesthesia in children. Intranasal and transdermal use may be useful in the management of pain (below); oral, rectal, and subcutaneous routes have also been tried.[6]

Nonketotic hyperglycinaemia. Ketamine was tried with strychnine in a newborn infant with severe nonketotic hyperglycinaemia (p.2393) and resulted in neurological improvement, although motor development remained unsatisfactory.[1] It was thought that ketamine might act by blocking N-methyl-D-aspartate (NMDA) receptors, which are activated in the CNS by glycine.

1. Tegtmeyer-Metadorf H, *et al.* Ketamine and strychnine treatment of an infant with nonketotic hyperglycinaemia. *Eur J Pediatr* 1995; **154:** 649–53.

Pain. For a discussion of pain and its management, see p.2. Ketamine is used for its analgesic action in neuropathic or other pain unresponsive to conventional analgesics. (For mention of its use for outpatient procedures in children, see p.3.) Systematic reviews have found the evidence for such use to be limited,[1,2] and have also differed on its value for postoperative pain,[3-5] but it has been suggested[1] that ketamine is a reasonable third-line option for pain where standard analgesics have failed. Subcutaneous, intramuscular, intravenous, epidural, intrathecal, intranasal, transdermal, rectal, and oral routes have all been tried.[1,6]

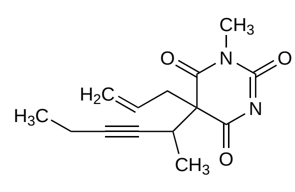
Methohexital *(BAN, rINN)*

Méthohexital; Methohexitalum; Methohexitone; Metoheksitaali; Metohexital. (±)-5-Allyl-1-methyl-5-(1-methylpent-2-ynyl)barbituric acid; 1-Methyl-5-(1-methyl-2-pentynyl)-5-(2-propenyl)-2,4,6(1*H*,3*H*,5*H*)-pyrimidinetrione.

Метогекситал

$C_{14}H_{18}N_2O_3$ = 262.3.
CAS — 151-83-7; 18652-93-2.
ATC — N01AF01; N05CA15.
ATC Vet — QN01AF01; QN05CA15.



Pharmacopoeias. In *US.*

USP 31 (Methohexital). A white to faintly yellowish-white crystalline odourless powder. M.p. 92° to 96° but the range between beginning and end of melting does not exceed 3°. Very slightly soluble in water; slightly soluble in alcohol, in chloroform, and in dilute alkalis.

Methohexital Sodium *(BANM, rINNM)*

Compound 25398; Enallynymalnatrium; Méthohexital Sodique; Methohexitone Sodium; Metohexital sódico; Natrii Methohexitalum.

Натрий Метогекситал

$C_{14}H_{17}N_2NaO_3$ = 284.3.
CAS — 309-36-4; 22151-68-4; 60634-69-7.
ATC — N01AF01; N05CA15.
ATC Vet — QN01AF01; QN05CA15.

Pharmacopoeias. *US* includes Methohexital Sodium for Injection.

USP 31 (Methohexital Sodium for Injection). A freeze-dried sterile mixture of methohexital sodium and anhydrous sodium carbonate as a buffer, prepared from an aqueous solution of methohexital, sodium hydroxide, and sodium carbonate. It is a white to off-white, essentially odourless, hygroscopic powder. pH of a 5% solution in water is between 10.6 to 11.6.

Incompatibility. Solutions of methohexital sodium are incompatible with acidic substances including a number of antibacterials, antipsychotics, neuromuscular blockers, antimuscarinics, and analgesics. Compounds commonly listed as incompatible include atropine sulfate, pethidine hydrochloride, metocurine iodide, fentanyl citrate, morphine sulfate, pentazocine lactate, silicones, suxamethonium chloride, tubocurarine chloride, and compound sodium lactate injection. Only preservative-free diluents should be used to reconstitute methohexital sodium; precipitation may occur if a diluent containing a bacteriostatic agent is used.

Stability. Solutions of methohexital sodium in Water for Injections are stable for at least 6 weeks at room temperature; however reconstituted solutions should be stored no longer than 24 hours as they contain no bacteriostatic agent. Solutions in glucose or sodium chloride injections are stable only for about 24 hours.

Adverse Effects and Precautions

As for Thiopental Sodium, p.1795.

Excitatory phenomena are more common and induction less smooth with methohexital than with thiopental. Methohexital should be used with caution, if at all, in patients with a history of epilepsy.

See also Adverse Effects and Precautions for General Anaesthetics, p.1779.

Incidence of adverse effects. In a study of 4379 uses of methohexital in 2722 dental patients the total dose ranged from 20 mg to 560 mg (with a mean of 151 mg), and the duration of treatment was 8 to 32 minutes.[1] Complications included: restlessness not controlled by diazepam (292 cases), respiratory complications (214), uncontrollable crying during recovery (73), pain along vein (45) with thrombophlebitis (5), jactitations (22), and allergic reactions (10).

1. McDonald D. Methohexitone in dentistry. *Aust Dent J* 1980; **25:** 335–42.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers were receiving methohexital, and the American Academy of Pediatrics[1] considers that it is therefore usually compatible with breast feeding.

In a study[2] of 9 breast-feeding women undergoing general anaesthesia, it was estimated that the exposure of a breast-fed infant to methohexital would be less than 1% of the maternal dose after induction with methohexital. Breast feeding was not interrupted during the study and none of the infants appeared drowsy or sedated.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 26/05/04)
2. Borgatta L, *et al.* Clinical significance of methohexital, meperidine, and diazepam in breast milk. *J Clin Pharmacol* 1997; **37:** 186–92.

Effects on the nervous system. Two case reports of seizures induced by methohexital in children with seizure disorders.[1] Seizures are considered a rare adverse effect of methohexital. In 48 000 patients given methohexital, only 3 developed clonic-type seizures.[2]

A case of a tonic-clonic seizure possibly due to an interaction between paroxetine and methohexital is discussed below.

1. Rockoff MA, Goudsouzian NG. Seizures induced by methohexital. *Anesthesiology* 1981; **54:** 333–5.
2. Metriyakool K. Seizures induced by methohexital. *Anesthesiology* 1981; **55:** 718.

Pain on injection. Methohexital is associated with severe pain particularly if veins on the back of the hands are used. The incidence of pain on injection may be reduced by using a forearm vein or by pre-injection with lidocaine.

Porphyria. Methohexital is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals*.

Rebound anaesthesia. Rebound of anaesthesia with abolition of reflexes and depression of respiration occurred in a 6-year-old boy[1] 100 minutes after anorectal induction with 27.6 mg/kg methohexital.

1. Kaiser H, Al-Rafai S. Wie sicher ist die rektale Narkoseeinleitung mit Methohexital in der Kinderanaesthesie? *Anaesthesist* 1985; **34:** 359–60.

Interactions

As for Thiopental Sodium, p.1795.

Antidepressants. A 42-year-old woman[1] had a generalised tonic-clonic seizure immediately after being anaesthetised with methohexital for the last in a series of 6 electroconvulsive therapies. She had been receiving *paroxetine* throughout the series. A previous course, without concurrent paroxetine, had been uneventful.

1. Folkerts H. Spontaneous seizure after concurrent use of methohexital anesthesia for electroconvulsive therapy and paroxetine: a case report. *J Nerv Ment Dis* 1995; **183:** 115–16.

Pharmacokinetics

Methohexital is less lipid soluble than thiopental but concentrations sufficient to produce anaesthesia are attained in the brain within 30 seconds of an intravenous dose. Methohexital is also absorbed when given rectally, producing an effect within about 5 to 11 minutes. Recovery from anaesthesia occurs quickly as a result of rapid metabolism and redistribution into other body tissues. Methohexital does not appear to concentrate in fatty tissues to the same extent as other barbiturate anaesthetics. Protein binding has been reported to be about 73%. Methohexital is rapidly metabolised in the liver through demethylation and oxidation. The terminal half-life ranges from 1.5 to 6 hours. Methohexital diffuses across the placenta and has been detected in breast milk.

Uses and Administration

Methohexital is a short-acting barbiturate anaesthetic that has actions similar to those of thiopental (p.1796) but it is about 2 to 3 times more potent. It is given as the sodium salt and has similar uses to thiopental in anaesthesia. Induction of anaesthesia is less smooth than with thiopental and there may be excitatory phenomena. It has a shorter duration of action than thiopental and recovery after an induction dose occurs within 5 to 7 minutes although drowsiness may persist for some time.

As with other barbiturate anaesthetics the dose of methohexital required varies greatly according to the state of the patient and the nature of other drugs also being used (see under Precautions of Thiopental, p.1795, and Interactions of Thiopental, p.1795, for further details). Methohexital sodium is usually given intravenously as a 1% solution. Higher concentrations may markedly increase the incidence of adverse effects. A typical dose for induction of anaesthesia is 50 to 120 mg given at a rate of about 10 mg (1 mL of a 1% solution) every 5 seconds. For the maintenance of general anaesthesia methohexital sodium may be given by intravenous injection in doses of 20 to 40 mg every 4 to 7 minutes as required or it may be given as a 0.2% solution by continuous intravenous infusion at a rate of 3 mL/minute.

For dosage in children, see below.

Administration in children. Although intravenous use is considered preferable in adults, in the USA methohexital sodium has been licensed for use in children only by the intramuscular and rectal routes: usual doses for the induction of anaesthesia are 6.6 to 10 mg/kg intramuscularly, as a 5% solution, or 25 mg/kg rectally, as a 1% solution. In some countries methohexital sodium has also been given intravenously to children: doses in the range of 1 to 2 mg/kg have been used.

Administration in the elderly. It is usually recommended that the dosage of barbiturate anaesthetics is reduced in the elderly. A study[1] in elderly patients has shown that although reducing the rate of intravenous dosage reduces the speed of induction, the dosage required is also reduced. Giving methohexital sodium 0.5% at a rate of 25 mg/minute induced anaesthesia in a mean of 83.8 seconds and required a mean dose of 0.56 mg/kg. Corresponding values for a rate of 100 mg/minute were 43.6 seconds and 1 mg/kg, respectively.

1. Berthoud MC, *et al.* Comparison of infusion rates of three i.v. anaesthetic agents for induction in elderly patients. *Br J Anaesth* 1993; **70:** 423–7.

Dental sedation. Some anaesthetics are used as sedatives in dental procedures (see p.956). Methohexital has been tried for patient-controlled sedation in oral surgery under local anaesthesia.[1] In a group of 42 patients, results with 2.5 mg of methohexital compared favourably with those obtained in patients receiving 5 mg of propofol on demand, although patients in the methohexital group experienced a greater degree of postoperative drowsiness.

1. Hamid SK, *et al.* Comparison of patient-controlled sedation with either methohexitone or propofol. *Br J Anaesth* 1996; **77:** 727–30.

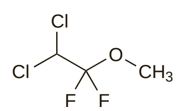
Methoxyflurane *(BAN, USAN, rINN)*

Méthoxyflurane; Methoxyfluranum; Metoksifluraani; Metoxifluran; Metoxiflurano; NSC-110432. 2,2-Dichloro-1,1-difluoro-1-methoxyethane; 2,2-Dichloro-1,1-difluoroethyl methyl ether.

Метоксифлуран

$C_3H_4Cl_2F_2O$ = 165.0.
CAS — 76-38-0.
ATC — N01AB03.
ATC Vet — QN01AB03.



Pharmacopoeias. In *US.*

USP 31 (Methoxyflurane). A clear, practically colourless, mobile liquid having a characteristic odour. It may contain a suitable stabiliser. B.p. about 105°. Soluble 1 in 500 of water; miscible with alcohol, with acetone, with chloroform, with ether, and with fixed oils. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Adverse Effects

As with other halogenated anaesthetics respiratory depression, hypotension, and malignant hyperthermia have been reported. Methoxyflurane sensitises the myocardium to sympathomimetics to a lesser extent than halothane; arrhythmias appear to be rare.

Methoxyflurane impairs renal function in a dose-related manner due to the effect of the released fluoride on the distal tubule and may cause polyuric or oliguric renal failure, oxaluria being a prominent feature. Nephrotoxicity is greater with methoxyflurane than with other halogenated anaesthetics because of slower metabolism over several days resulting in prolonged production of fluoride ions, and metabolism to other potentially nephrotoxic substances.

There have also been occasional reports of hepatic dysfunction, jaundice, and fatal hepatic necrosis. Headache has been reported by some patients. Cardiac arrest, gastrointestinal adverse effects, delirium, and prolonged postoperative somnolence have been observed.

See also Adverse Effects of General Anaesthetics, p.1779.

Precautions

The use of methoxyflurane is limited because of its potential to cause renal toxicity. It should not be used to achieve deep anaesthesia or for surgical procedures expected to last longer than 4 hours. Methoxyflurane is contra-indicated in the presence of renal impairment. Renal function and urine output should be monitored during anaesthesia. As with other halogenated anaesthetics it is advisable not to give methoxyflurane to patients who have shown signs of liver damage or fever after previous anaesthesia involving halogenated anaesthetics. Patients with known, or suspected, susceptibility to malignant hyperthermia should not be anaesthetised with methoxyflurane. Allowance may need to be made for any increase in CSF pressure or in cerebral blood flow.

There is significant absorption of methoxyflurane by the rubber and soda lime in anaesthetic circuits. PVC plastics are partially soluble in methoxyflurane.

See also Precautions for General Anaesthetics, p.1779.

Abuse. A 27-year-old nurse suffered from progressive renal disease and painful diffuse and multifocal periostitis, which had developed as a probable consequence of intermittent self-exposure to methoxyflurane possibly over a 9-year period.[1] There has also been a report[2] of hepatitis in a 39-year-old physician who repeatedly self-administered subanaesthetic concentrations of methoxyflurane for insomnia. Inhalation of about 2 mL of methoxyflurane had occurred once or twice almost every day for 6 weeks. A 125-mL bottle of methoxyflurane had been consumed in about 1 month.

1. Klemmer PJ, Hadler NM. Subacute fluorosis: a consequence of abuse of an organofluoride anesthetic. *Ann Intern Med* 1978; **89:** 607–11.
2. Okuno T, *et al.* Hepatitis due to repeated inhalation of methoxyflurane in subanaesthetic concentrations. *Can Anaesth Soc J* 1985; **32:** 53–5.

Porphyria. Methoxyflurane is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals* or *in-vitro* systems.

Interactions

Care is advised if adrenaline or other sympathomimetics are given to patients during methoxyflurane anaesthesia. The effects of competitive neuromuscular blockers are enhanced by methoxyflurane. The chronic use of hepatic enzyme-inducing drugs may enhance the metabolism of methoxyflurane thereby increasing the risk of nephrotoxicity. Use of nephrotoxic drugs with methoxyflurane should be avoided.

See also Interactions of General Anaesthetics, p.1779.

Pharmacokinetics

Methoxyflurane is absorbed on inhalation. The blood/gas partition coefficient is high. Methoxyflurane is metabolised to a greater extent than other inhalational anaesthetics. About 50 to 70% of absorbed methoxyflurane undergoes metabolism in the liver to free fluoride, oxalic acid, difluoromethoxyacetic acid, and dichloroacetic acid. Methoxyflurane is very soluble in adipose tissue and excretion may be slow. Peak plasma concentrations of fluoride occur 2 to 4 days after a dose. Methoxyflurane crosses the placenta.

Uses and Administration

Methoxyflurane is a volatile halogenated anaesthetic given by inhalation. It has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) of 0.16%, but because of its low vapour pressure, induction of general anaesthesia with methoxyflurane is slow. In recommended concentrations it is non-flammable and not explosive when mixed with oxygen. Methoxyflurane possesses good analgesic properties. It does not produce appreciable skeletal muscle relaxation at the concentrations used. Methoxyflurane does not relax the uterus and has little effect on uterine contractions during labour. It is used in subanaesthetic doses to provide analgesia for painful procedures and trauma. In anaesthetic doses, it has been used mainly for maintenance of general anaesthesia (p.1780), but safer anaesthetics are preferred because of its nephrotoxicity.

Concentrations of about 0.2 to 0.7% v/v are used to provide analgesia to conscious patients. The recommended maximum total dose for intermittent self-administration is 6 mL of liquid per day or 15 mL/week.

Nitrous Oxide

Azote, protoxyde d'; Azoto Protossido; Azotu(I) tlenek; Diazoto oksidas; Dikväveoxid; Dinitrogen Oxide; Dinitrogenii oxidum; Dinitrogén-oxid; Distickstoffmonoxid; Dityppioksidi; E942; Laughing Gas; Nitrogen Monoxide; Nitrogen Oxide; Nitrogenii Monoxidum; Nitrogenii Oxidum; Nitrogenium Oxydulatum; Oxid dusný; Óxido nitroso; Oxyde Nitreux; Oxydum Nitrosum; Protoxyde d'Azote; Stickoxydul.

N_2O = 44.01.
CAS — 10024-97-2.
ATC — N01AX13.
ATC Vet — QN01AX13.

$$N\equiv N^{+}-O^{-}$$

NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of nitrous oxide:
Bulb; Buzz bomb; Cartridges; Fall down; Gas; Going to the dentist; Grocery store high; Hippy crack; Hysteria; Laughing gas; Nang; Nie; Nigh; Nitro; Nitrogen; Nitrous; Noss; Pan; Shoot the breeze; Tanks; Whippets; Wippets.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Nitrous Oxide). A colourless gas. One vol. measured at a pressure of 101 kPa dissolves, at 20°, in about 1.5 vol. of water. Store liquefied under pressure in suitable containers complying with the legal regulations.

The BP 2008 directs that Nitrous Oxide should be kept in approved metal cylinders which are painted blue and carry a label stating 'Nitrous Oxide'. In addition, 'Nitrous Oxide' or the symbol 'N_2O' should be stencilled in paint on the shoulder of the cylinder.

USP 31 (Nitrous Oxide). A colourless gas, without appreciable odour or taste. One litre at 0° and at a pressure of 760 mmHg weighs about 1.97 g. One volume dissolves in about 1.4 volumes of water at 20° and at a pressure of 760 mmHg; freely soluble in alcohol; soluble in ether and in oils.

Flammability. Nitrous oxide supports combustion.

Storage and supply. Nitrous oxide is supplied compressed in metal cylinders. National standards are usually in operation for the labelling and marking of such cylinders.

Cylinders containing 50% nitrous oxide and 50% oxygen should be protected from the cold to prevent separation of the gases. Cylinders exposed to temperatures lower than −7° should be rolled at room temperature to ensure mixing or alternatively stored horizontally for 24 hours at a temperature of not less than 10°.

Adverse Effects

The main complications after use of nitrous oxide are those due to varying degrees of hypoxia. Prolonged use has been followed by megaloblastic anaemia and peripheral neuropathy. Depression of white cell formation may also occur. There is a risk of increased pressure and volume from the diffusion of nitrous oxide into air-containing cavities. Malignant hyperthermia has been reported rarely.

See also Adverse Effects of General Anaesthetics, p.1779.

◊ Reviews.

1. Louis-Ferdinand RT. Myelotoxic, neurotoxic and reproductive adverse effects of nitrous oxide. *Adverse Drug React Toxicol Rev* 1994; **13:** 193–206.
2. Donaldson D, Meechan JG. The hazards of chronic exposure to nitrous oxide: an update. *Br Dent J* 1995; **178:** 95–100.
3. Weimann J. Toxicity of nitrous oxide. *Best Pract Res Clin Anaesthesiol* 2003; **17:** 47–61.

Effects on the blood. Nitrous oxide interacts with vitamin B_{12}. This blocks the transmethylation reaction for which vitamin B_{12} is a coenzyme and results in depletion of methionine and tetrahydrofolate. Metabolic consequences have been attributed to depletion of either or both. Interference by nitrous oxide with DNA synthesis prevents production of both leucocytes and red blood cells by the bone marrow. Megaloblastic changes in bone marrow and impaired granulocyte production are found in patients exposed to anaesthetic concentrations of nitrous oxide for 24 hours. In patients with normal bone marrow, stores of mature granulocytes will normally be adequate to prevent leucopenia during exposure for up to 3 days; in patients exposed to nitrous oxide for longer periods of time, leucopenia will develop and exposure for 4 days or longer can result in agranulocytosis. In general, healthy surgical patients can be given nitrous oxide for up to 24 hours without harm. In situations where nitrous oxide is used for more than 24 hours, folinic acid 30 mg twice daily has been given to protect the haematopoietic system. Repeat exposure to nitrous oxide at intervals of less than 3 days will have a cumulative effect on DNA synthesis and megaloblastic marrow changes have been reported following multiple short-term exposure.[1] Depletion of methionine has been implicated in the neurological deficit (see below) seen mainly after chronic use of nitrous oxide. It may also account for the fetotoxicity observed in *rats*, see Pregnancy, under Precautions, below.

1. Nunn JF. Clinical aspects of the interaction between nitrous oxide and vitamin B . *Br J Anaesth* 1987; **59:** 3–13.

Effects on the nervous system. Neurological disorders (mainly myeloneuropathies and neuropathies) have occurred in chronic abusers of nitrous oxide.[1,2] Similar effects have been noted after repeated use of nitrous oxide in hospitalised patients. These neurological effects are considered to be due to nitrous oxide-induced methionine deficiency (see Effects on the Blood, above). Psychosis, responsive to treatment with vitamin B_{12}, has also been reported in a patient abusing nitrous oxide.[3]

In patients with undiagnosed subclinical deficiency of vitamin B_{12} (a coenzyme involved in methionine synthesis) neurological manifestations, including those consistent with subacute combined degeneration of the spinal cord, have occurred after a single exposure to nitrous oxide for anaesthesia.[4,5] Acute paralysis, due to degeneration of the spinal cord, has also been reported in a malnourished patient who had been abusing nitrous oxide for 10 days for the self-treatment of a painful sprained ankle.[6]

6. Cartner M, *et al.* Paralysis caused by "nagging". *Med J Aust* 2007; **187:** 366–7.

Malignant hyperthermia. An 11-year-old girl whose father had died from malignant hyperthermia after anaesthesia developed hyperthermia after anaesthesia with nitrous oxide and oxygen.[1]

1. Ellis FR, *et al.* Malignant hyperpyrexia induced by nitrous oxide and treated with dexamethasone. *BMJ* 1974; **4:** 270–1.

Precautions

Hypoxic anaesthesia is dangerous and nitrous oxide should always be given with at least 20 to 30% oxygen. Nitrous oxide diffuses into gas-filled body cavities and care is essential when using it in patients at risk from such diffusion such as those with abdominal distension, occlusion of the middle ear, pneumothorax, or similar cavities in the pericardium or peritoneum. Care is also required in patients during or after air encephalography. Oxygen should be given during emergence from prolonged anaesthesia with nitrous oxide to prevent diffusion hypoxia where the alveolar oxygen concentration is diminished. See also Precautions for General Anaesthetics, p.1779. In addition to the above precautions, mixtures of equal parts of nitrous oxide and oxygen should not be used for analgesia in patients with head injuries with impairment of consciousness, maxillofacial injuries, decompression sickness, or those heavily sedated.

Nitrous oxide has been subject to abuse.

Abuse. 'Recreational' use or abuse of nitrous oxide has been referred to as "nagging" or "nanging". For some of the resulting adverse effects of nitrous oxide abuse, see Effects on the Nervous System, above.

Driving. A slight but quantified impairment in driving ability was found up to 30 minutes after 15 minutes' inhalation of nitrous oxide/oxygen mixtures.[1]

1. Moyes DG, *et al.* Driving after anaesthetics. *BMJ* 1979; **1:** 1425.

Epidural anaesthesia. Nitrous oxide diffuses into gas-filled body cavities and can increase the size of any air bubbles injected into the epidural space to determine placement of the needle in epidural anaesthesia.[1] This could result in uneven spread of the local anaesthetic and produce inadequate analgesia. The volume of air injected should be limited or another technique used to determine placement of the needle if nitrous oxide is to be given subsequently.

1. Stevens R, *et al.* Fate of extradural air bubbles during inhalation of nitrous oxide. *Br J Anaesth* 1994; **72:** 482P–483P.

Hazard to user. A scavenging system and effective ventilation may be necessary to control the nitrous oxide pollution that can occur when this gas is used for analgesia or anaesthesia. Risk areas include, in addition to operating theatres, delivery rooms and dental surgeries.[1-3] Occupational exposure can lead to serious toxicity with bone-marrow and neurological impairment.[2,3] Reduced fertility has been reported in female dental workers exposed to high concentrations of nitrous oxide;[4] such women also appear to have a higher rate of spontaneous abortion.[5] It has been suggested that nitrous oxide can also affect male fertility;[6] in one study a dose-related increase in the incidence of spontaneous abortion was found in the wives of men with occupational exposure to nitrous oxide.[7]

Vitamin B_{12} deficiency. For reports of neurological dysfunction associated with the use of nitrous oxide in patients with undiagnosed subclinical vitamin B_{12} deficiency, see Effects on the Nervous System, above.

Interactions

Use of nitrous oxide with an inhalational anaesthetic accelerates the uptake of the latter from the lungs. This phenomenon is known as the *second gas effect*. It is due to the disproportionate absorption of nitrous oxide into the blood resulting in an increased alveolar concentration of the second gas.

The use of high doses of opioids such as fentanyl with nitrous oxide may result in a drop in heart rate and cardiac output.

See also Interactions for General Anaesthetics, p.1779.

Methotrexate. Combined use of nitrous oxide and methotrexate may increase some of the adverse effects of methotrexate therapy, see p.748.

Pharmacokinetics

Nitrous oxide is rapidly absorbed on inhalation. The blood/gas partition coefficient is low and most of the inhaled nitrous oxide is rapidly eliminated unchanged through the lungs though small amounts diffuse through the skin.

Uses and Administration

Nitrous oxide is an anaesthetic given by inhalation. It is a weak anaesthetic with a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) of 110%. It has strong analgesic properties, but produces little muscle relaxation. Nitrous oxide must be given with oxygen, otherwise hypoxia will occur.

Nitrous oxide with oxygen has been used in the induction and maintenance of general anaesthesia (p.1780). However, it is now mainly used as an adjuvant to other inhalational or intravenous anaesthetics, permitting them to be used at significantly lower concentrations. It is also used, with oxygen, in subanaesthetic concentrations for analgesia and sedation in emergency care and obstetric and other painful procedures, including dental procedures (see p.956).

For maintenance of anaesthesia a mixture containing 50 to 66% nitrous oxide with oxygen is commonly used. Recovery is usually rapid from nitrous oxide anaesthesia.

Nitrous oxide 25 to 50% v/v with oxygen is used for analgesia; cylinders containing premixed nitrous oxide 50% v/v and oxygen 50% v/v are available in some countries.

Alcohol withdrawal syndrome. The symptoms of acute alcohol withdrawal (p.1626) are usually managed with benzodiazepines but nitrous oxide has been reported[1] to reduce symptoms when tried in alcohol withdrawal. In mild to moderate cases a single inhalation of up to 20 minutes' duration of a nitrous oxide-oxygen mixture in analgesic doses has been used. However, a more recent controlled trial[2] did not find that treatment with nitrous oxide relieved the symptoms of alcohol withdrawal or reduce cravings.

2. Alho H, *et al.* Long-term effects of and physiological responses to nitrous oxide gas treatment during alcohol withdrawal: a double-blind, placebo-controlled trial. *Alcohol Clin Exp Res* 2002; **26:** 1816–22.

Pain. A mixture of nitrous oxide 50% v/v and oxygen 50% v/v can provide good relief of pain (see Choice of Analgesic, p.2) without loss of consciousness and is suitable for self-administration. It has been widely used for analgesia and sedation during dental procedures. It is also used for short procedures such as dressing changes,[1,2] venepuncture and biopsy,[3] for pain relief during childbirth,[4] in the management of postoperative pain,[1] as an aid to postoperative physiotherapy, and for acute pain in emergency situations such as in ambulances and in the hospital setting.[3,5,6] Continuous inhalation of nitrous oxide-oxygen has been tried for periods longer than 24 hours in the management of pain in terminal cancer.[7] However, such a practice is not usually otherwise recommended[1] as it may result in megaloblastic bone-marrow changes.

Preparations

Proprietary Preparations (details are given in Part 3)
Cz.: Pulmomix Forte†.

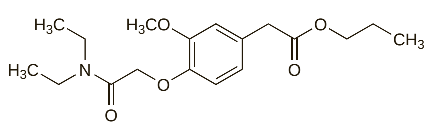
Multi-ingredient: ***Fr.:*** Kalinox; Medimix; ***S.Afr.:*** Entonox; ***UK:*** Entonox; Equanox.

Propanidid *(BAN, USAN, rINN)*

Bayer-1420; FBA-1420; Propanidide; Propanididum; TH-2180; WH-5668. Propyl 4-diethylcarbamoylmethoxy-3-methoxyphenylacetate.

Пропанидид

$C_{18}H_{27}NO_5$ = 337.4.
CAS — 1421-14-3.
ATC — N01AX04.
ATC Vet — QN01AX04.



Profile

Propanidid has been used as an intravenous anaesthetic for rapid induction and for maintenance of general anaesthesia of short duration.

Commercial preparations of propanidid were provided as a liquid in polyethoxylated castor oil. Anaphylactoid reactions associated with the vehicle led to the general withdrawal of propanidid from use.

Porphyria. Propanidid is considered to be unsafe in patients with porphyria although there is conflicting experimental evidence of porphyrinogenicity.

Preparations

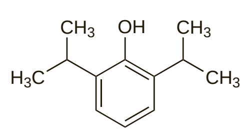
Proprietary Preparations (details are given in Part 3)
Arg.: Progray; ***Mex.:*** Panitol.

Propofol *(BAN, USAN, rINN)*

Disoprofol; ICI-35868; Propofoli; Propofolis; Propofolum. 2,6-Diisopropylphenol; 2,6-Bis(1-methylethyl)phenol.

Пропофол

$C_{12}H_{18}O$ = 178.3.
CAS — 2078-54-8.
ATC — N01AX10.
ATC Vet — QN01AX10.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Propofol). A colourless or very light yellow, clear liquid. Very slightly soluble in water; miscible with hexane and with methyl alcohol. Store under an inert gas. Protect from light.

USP 31 (Propofol). A clear, colourless to slightly yellowish liquid. Very slightly soluble in water; very soluble in dehydrated alcohol and in methyl alcohol; slightly soluble in cyclohexane and in isopropyl alcohol. Store under an inert gas in airtight containers. Protect from light.

Adverse Effects

Early studies with propofol used a preparation formulated with polyethoxylated castor oil. Because of anaphylactoid reactions the preparation was reformulated with a vehicle of soya oil and purified egg phosphatide. Adverse effects with this preparation include pain on injection especially if the injection is into a small vein. Local pain may be reduced by injection into a large vein or by injection of intravenous lidocaine. Apnoea may be frequent; apnoea lasting longer than 60 seconds has been reported to occur in 12% of patients. There are isolated reports of pulmonary oedema. Cardiovascular effects include a reduction in blood pressure and bradycardia. There have been reports of convulsions (sometimes delayed in onset) and involuntary movements. Fever and pancreatitis have occurred very rarely. Discoloration of urine has been reported following prolonged use. Anaphylactoid reactions have been reported. Nausea, vomiting, and headache may occur during recovery.

Children given propofol for prolonged sedation have suffered severe reactions and there have been fatalities, see below.

See also Adverse Effects of General Anaesthetics, p.1779.

Incidence of adverse effects. In May 1989 the UK CSM commented on the 268 reports of adverse reactions to propofol that it had received since propofol was introduced to the UK market, during which period about 2 million patients had been anaesthetised with the drug.[1] These included reports of:

- seizures (37 cases, 13 in known epileptics)
- involuntary movements (16 cases)
- opisthotonus (10 cases)
- anaphylactic reactions (32 cases)
- cardiac arrest (13 cases)
- delayed recovery (8 cases)

In 1992 the CSM pointed to the risk of **delayed convulsions** with propofol and its particular importance for day-case surgery.[2] While the incidence of convulsions was low (170 reports), 31% of the reports described the convulsions as delayed.

In June 1992 the CSM commented on the dangers of propofol for the **sedation of children** in intensive care,[3] a use for which it is contra-indicated in the UK. (This prohibition does not apply to its use for the sedation of ventilated adults—but see below—or to propofol's use as an *anaesthetic* in children. Sedation in children undergoing surgical and diagnostic procedures is not contra-indicated but is an unlicensed use, and is not recommended.[4])

The CSM reported that there had been 66 reports worldwide of serious adverse effects in children sedated with propofol, and some fatalities had ensued. The children had suffered neurological, cardiac, and renal effects, hyperlipidaemia, hepatomegaly, and metabolic acidosis. Five deaths had been reported to the CSM. These 5 children[5] were aged 4 weeks to 6 years and doses of propofol ranged from 4 to 10.7 mg/kg per hour. They developed metabolic acidosis, bradyarrhythmia, and progressive myocardial failure resistant to treatment. The latter has been reported by others to be significantly associated with the use of long-term, **high-dose** propofol infusions.[6]

Similar adverse effects resulting in fatalities have also been reported in **adult** patients with head injuries who received high doses of propofol infusion (greater than 5 mg/kg per hour) for long-term sedation.[7] The CSM subsequently reminded prescribers that the recommended dose range for sedation (up to 4 mg/kg per hour) should not be exceeded.[8] There has also been a report of death in a patient with a closed head injury who received propofol infusion at an average dose of 4.1 mg/kg per hour.[9]

The Australian Adverse Drug Reactions Advisory Committee[10] stated in December 2004 that it had received a report of lactic acidosis and another of torsade de pointes in adult patients receiving lower doses of propofol infusion, 30 and 100 mg/hour, respectively, for about 24 hours.

Effects on the cardiovascular system. The main effect of propofol on the cardiovascular system is a fall in both systolic and diastolic blood pressure of 20 to 30%. The compensatory tachycardia seen after a fall in arterial pressure with other intravenous anaesthetics is not usually seen with propofol. Propofol can also decrease systemic vascular resistance, cardiac output, myocardial blood flow, and myocardial oxygen consumption. Bradycardia can occur even in those premedicated with antimuscarinics, and can occasionally be profound and lead to asystole.[1] Despite these cardiodepressant effects propofol in doses of 1.5 to 2.5 mg/kg does not generally cause unacceptable haemodynamic changes in patients with a healthy cardiovascular system although concern has been expressed about its safety in cardiac surgical patients.[2]

Patients (especially children) given propofol for continuous sedation in intensive care units have suffered adverse cardiac reactions with bradyarrhythmia, progressive myocardial failure, and death—see above.

1. Tramèr MR, *et al.* Propofol and bradycardia: causation, frequency and severity. *Br J Anaesth* 1997; **78:** 642–51.
2. Ginsberg R, Lippmann M. Haemodynamic effects of propofol. *Br J Anaesth* 1994; **72:** 370–1.

Effects on lipids. Prolonged infusion of propofol may be associated with increases in serum triglycerides. In one patient this was believed to have been the cause of necrotising pancreatitis.[1]

1. Metkus AP, *et al.* A firefighter with pancreatitis. *Lancet* 1996; **348:** 1702.

Effects on mental function. There have been anecdotal reports[1] of disinhibited behaviour or sexually orientated hallucinations associated with the use of propofol, but a study using subanaesthetic doses found no evidence that propofol produced euphoria or other mood changes.[2]

1. Canaday BR. Amorous, disinhibited behaviour associated with propofol. *Clin Pharm* 1993; **12:** 449–51.
2. Whitehead C, *et al.* The subjective effects of low-dose propofol. *Br J Anaesth* 1994; **72** (suppl 1): 89.

Effects on the nervous system. See under Precautions, below.

Effects on respiration. See under Precautions, below.

Hypersensitivity. Anaphylactic reactions associated with polyethoxylated castor oil used in propofol preparations had prompted a change to the use of soya oil and egg phosphatide in the formulation. A group of workers have reported a patient who experienced anaphylactic shock when given the reformulated emulsion.[1] A possible case of anaphylaxis to this formulation has also been reported in a child with allergies to egg and peanut oil.[2]

1. Laxenaire MC, *et al.* Anaphylactic shock due to propofol. *Lancet* 1988; **ii:** 739–40.
2. Hofer KN, *et al.* Possible anaphylaxis after propofol in a child with food allergy. *Ann Pharmacother* 2003; **37:** 398–401.

Infection. Between June 1990 and February 1993 62 cases of postsurgical infections identified in 7 hospitals in the USA were attributed to improper handling of propofol.[1] The infusion was not prepared aseptically and the syringes used in the infusion pumps were reused for several patients. Propofol is formulated as a soybean fat emulsion and the injection contains no antimicrobial preservative although, in the USA, the formulation now contains the microbial-retarding agent, disodium edetate (see under Administration, below). However, either formulation still has the potential to support microbial growth. UK and US licensed product information now warns of the importance of aseptic technique in the preparation and use of propofol. Microbial multiplication did not appear to be clinically significant when propofol infusions were prepared and given using conventional aseptic techniques.[2]

1. Bennett SN, *et al.* Postoperative infections traced to contamination of an intravenous anesthetic, propofol. *N Engl J Med* 1995; **333:** 147–54.
2. Farrington M, *et al.* Do infusions of midazolam and propofol pose an infection risk to critically ill patients? *Br J Anaesth* 1994; **72:** 415–17.

Malignant hyperthermia. From an *in-vitro* study it was concluded that propofol does not trigger malignant hyperthermia.[1] There is a report of the safe use of propofol in 19 patients considered susceptible to malignant hyperthermia.[2]

1. Denborough M, Hopkinson KC. Propofol and malignant hyperpyrexia. *Lancet* 1988; **i:** 191.
2. Harrison GG. Propofol in malignant hyperthermia. *Lancet* 1991; **337:** 503.

Pain on injection. Product information suggests the use of lidocaine or alfentanil to reduce the pain associated with injection of conventional formulations of propofol (see Administration, below); alternatively, the larger veins in the forearm and antecubital fossa can be used. Studies indicate that metoclopramide[1] might also be effective. The pain is thought to be caused by the proportion of the propofol dose that is present in the aqueous rather than the oily phase of the emulsion. It has been suggested[2] that the analgesic effect of lidocaine, and possibly metoclopramide, is due to a pH-lowering effect, causing more propofol to be present in the oily phase, but a study showing that lidocaine given by iontophoresis also reduces pain[3] suggests this is not the only mechanism. In another attempt to reduce pain by decreasing the amount of aqueous propofol, a formulation containing a mixture of medium-chain and long-chain triglycerides (*Propofol-Lipuro*), assumed to improve distribution into the lipid phase, has been introduced in a number of countries. However, studies in adults[4] and children[5] suggest that the reduction in pain with the newer formulation is not as great as that achieved by mixing lidocaine with the conventional long-chain formulation.

Urine discoloration. A case report of dark green urine in a 16-year-old during a prolonged infusion of propofol.[1]

1. Bodenham A, *et al.* Propofol infusion and green urine. *Lancet* 1987; **ii:** 740.

Precautions

Propofol should not be given to patients known to be allergic to it. Propofol should be used with caution in patients with hypovolaemia, epilepsy, or lipid metabolism disorders, and in the elderly. Since there have been reports of delayed convulsions associated with the use of propofol it is recommended that special care should be taken when propofol is used for day-case surgery. When used in patients with increased intracranial pressure it should be given slowly to avoid a substantial decrease in mean arterial pressure and a resultant decrease in cerebral perfusion pressure. It is also recommended that propofol should not be used with ECT. Premedication with an antimuscarinic may be advisable since propofol does not cause vagal inhibition.

Propofol is used to provide continuous sedation for ventilated adult patients under intensive care. Account should be taken of increasing the patient's lipid load. If the duration of sedation is in excess of 3 days, lipid concentrations should be monitored. Children aged 16 years or less should not be sedated in this manner with propofol (see Incidence of Adverse Effects, above). Propofol is not recommended for use in obstetrics including caesarean section. See also Precautions for General Anaesthetics, p.1779.

For the need for aseptic handling of propofol see Administration, below.

Abuse. References to the abuse of propofol.

CNS effects. Epileptic activity was seen[1] on the EEGs of 3 patients given propofol and it was suggested that it might be useful in ECT, but others[2,3] found that the duration of seizures was less with propofol anaesthesia than with methohexital anaesthesia. It has been suggested that propofol should not be used with ECT[4] and this is the advice in UK licensed product information.

Some consider that abnormal movements induced by propofol are not associated with cortical seizure activity.[5,6] These appear to be more frequent with low doses of propofol[6] and can be abolished in children by increasing the induction dose of propofol from 3 to 5 mg/kg.

Impaired respiration. The manufacturer has stated[1] that some patients who have received propofol for sedation in regional anaesthesia have experienced bradypnoea or hypoxaemia, or both. A reduction in oxygen saturation has also been noted in other patients sedated for endoscopy.[2] UK product information therefore recommends that oxygen saturation should be monitored and that oxygen supplementation should be readily available.

Interactions

The use of propofol with other CNS depressants, including those used in premedication, may increase the sedative, anaesthetic, and cardiorespiratory depressant effects of propofol. It is recommended that propofol is given after opioids so that the dose of propofol can be carefully titrated against the response. The dosage of propofol should be reduced if used with nitrous oxide or halogenated anaesthetics. Although propofol does not potentiate the effects of neuromuscular blockers, bradycardia and asystole have occurred after use of propofol with atracurium or suxamethonium (but see under Adverse Effects, above for the effects of propofol itself on the cardiovascular system).

See also Interactions of General Anaesthetics, p.1779.

Benzodiazepines. Propofol and *midazolam* have been reported to act synergistically.[1-3]

1. Short TG, Chui PT. Propofol and midazolam act synergistically in combination. *Br J Anaesth* 1991; **67:** 539–45.
2. McClune S, *et al.* Synergistic interaction between midazolam and propofol. *Br J Anaesth* 1992; **69:** 240–5.
3. Teh J, *et al.* Pharmacokinetic interactions between midazolam and propofol: an infusion study. *Br J Anaesth* 1994; **72:** 62–5.

Clonidine. Premedication with clonidine has been reported[1] to reduce intraoperative requirements of propofol.

1. Guglielminotti J, *et al.* Effects of premedication on dose requirements for propofol: comparison of clonidine and hydroxyzine. *Br J Anaesth* 1998; **80:** 733–6.

Gastrointestinal drugs. The dose of propofol required for induction is reduced in patients given *metoclopramide*.[1]

1. Page VJ, Chhipa JH. Metoclopramide reduces the induction dose of propofol. *Acta Anaesthesiol Scand* 1997; **41:** 256–9.

General anaesthetics. Use with *halothane* or *isoflurane* has been reported to increase serum concentrations of propofol.[1] Synergy has been reported between propofol and *etomidate*.[2]

1. Grundmann U, *et al.* Propofol and volatile anaesthetics. *Br J Anaesth* 1994; **72** (suppl 1): 88.
2. Drummond GB, Cairns DT. Do propofol and etomidate interact kinetically during induction of anaesthesia? *Br J Anaesth* 1994; **73:** 272P.

Local anaesthetics. A reduction in the amount of propofol required to provide adequate hypnosis[1] or sedation[2] has been reported after *bupivacaine*[1] or *lidocaine*.[1,2] However, lidocaine is often added to propofol emulsions to reduce the pain of injection, see under Administration, below.

1. Ben-Shlomo I, *et al.* Hypnotic effect of iv propofol is enhanced by im administration of either lignocaine or bupivacaine. *Br J Anaesth* 1997; **78:** 375–7.
2. Mallick A, *et al.* Local anaesthesia to the airway reduces sedation requirements in patients undergoing artificial ventilation. *Br J Anaesth* 1996; **77:** 731–4.

Opioids. In a study mean blood concentrations of propofol were higher in patients pretreated with *fentanyl* compared with patients maintained only on nitrous oxide.[1] However, others[2] were unable to confirm this interaction.

1. Cockshott ID, *et al.* Pharmacokinetics of propofol in female patients. *Br J Anaesth* 1987; **59:** 1103–10.
2. Dixon J, *et al.* Study of the possible interaction between fentanyl and propofol using a computer-controlled infusion of propofol. *Br J Anaesth* 1990; **64:** 142–7.

Pharmacokinetics

The pharmacokinetics of propofol are best described by a 3-compartment model. After a single bolus dose, two distribution phases are seen. The first phase has a half-life of 2 to 4 minutes. This is followed by a slow distribution phase with a half-life of 30 to 60 minutes. Significant metabolism of propofol occurs during the second phase. The termination of anaesthetic effect after a single intravenous bolus or maintenance infusion is due to extensive redistribution from the brain to other tissues and to metabolic clearance. Propofol is over 95% bound to plasma proteins. It undergoes extensive hepatic metabolism to conjugates which are eliminated in the urine. The terminal half-life ranges from 3 to 12 hours; with prolonged use, the terminal half-life may be longer. The pharmacokinetics of propofol do not appear to be altered by gender, chronic hepatic cirrhosis, or chronic renal impairment. Propofol crosses the placental barrier and is distributed into breast milk.

Uses and Administration

Propofol is a short-acting anaesthetic given intravenously for the induction and maintenance of general anaesthesia (p.1780). It is also used for sedation (p.956) in adult patients undergoing diagnostic procedures, in those undergoing surgery with local or regional anaesthesia, and in ventilated adult patients under intensive care. When used for anaesthesia, induction is rapid, as is recovery. Propofol has no analgesic activity and supplementary analgesia may be required.

Propofol is available as a 1 or 2% emulsion. The 1% emulsion may be given by intravenous injection or infusion, but the 2% emulsion is for infusion only. Infusions and injections should be prepared using aseptic techniques, see Administration, below.

Induction of **anaesthesia** is generally carried out by giving propofol by injection or infusion at a rate of 40 mg every 10 seconds; a rate of 20 mg every 10 seconds may be used in high-risk patients including elderly, neurosurgical, and debilitated patients. Most *adults* under 55 years of age can be anaesthetised by a dose of 1.5 to 2.5 mg/kg; high-risk patients usually require a dose of 1 to 1.5 mg/kg.

When used for maintenance propofol is infused at a rate of between 4 to 12 mg/kg per hour (or 3 to 6 mg/kg per hour for elderly and debilitated patients); alternatively intermittent bolus injections of 20 to 50 mg may be given; rapid bolus doses should be avoided in high-risk patients.

A novel delivery system is also available for the induction and maintenance of anaesthesia in adults. The Diprifusor target-controlled infusion system allows the speed of induction and depth of anaesthesia to be controlled by specifying target blood concentrations of propofol. Initial target concentrations for induction range from 4 to 8 micrograms/mL for patients under 55 years of age; lower initial target concentrations should be used in older and debilitated patients and should be increased gradually thereafter in steps of 0.5 to 1 microgram/mL at intervals of 1 minute to achieve a gradual induction of anaesthesia. Target concentrations for maintenance are 3 to 6 micrograms/mL.

In the UK, *children* aged 1 month and over may be given propofol for the induction and maintenance of anaesthesia. The dose should be adjusted for weight and age and administered slowly until the onset of anaesthesia. Most children aged over 8 years require an induction dose of 2.5 mg/kg; younger children may require a higher dose within the range of 2.5 to 4 mg/kg. Doses of 9 to 15 mg/kg per hour by intravenous infusion or intermittent bolus injections are suitable for maintenance. The 2% emulsion formulation of propofol should only be used in children aged over 3 years. In the USA, children aged 3 years and over may be given propofol for the induction of anaesthesia; those aged 2 months and over may receive propofol for maintenance of anaesthesia. Doses are similar to those used in the UK.

For **sedation** in diagnostic and surgical procedures in *adults* an initial infusion of 6 to 9 mg/kg per hour may be given for 3 to 5 minutes; alternatively 0.5 to 1 mg/kg may be injected slowly over 1 to 5 minutes. An infusion of 1.5 to 4.5 mg/kg per hour may be used for maintenance of sedation. High-risk patients usually require a 20% reduction in the maintenance dose.

For the sedation of ventilated adults propofol can be given by intravenous infusion in a dose of 0.3 to 4 mg/kg per hour. If the duration of sedation is in excess of 3 days, lipid concentrations should be monitored.

Propofol is contra-indicated for sedation in *children* aged 16 years or less.

Administration. Propofol is formulated as an oil-in-water emulsion for injection. Strict aseptic techniques must be maintained when handling propofol as, in some countries (including the UK), the parenteral product contains no antimicrobial preservatives and the vehicle can support rapid growth of microorganisms. Aseptic techniques must also be applied to formulations, such as those available in the USA, that contain the microbial-retarding agent disodium edetate, as microbial growth is still possible. An emulsion containing 1% of propofol may be diluted with glucose 5% immediately before use but it should not be diluted to a concentration of less than 2 mg/mL. An emulsion containing 2 % of propofol should not be diluted. The use of a 5-micron filter needle to withdraw propofol emulsion from an ampoule does not cause significant loss of drug.[1] A reduction in concentration of propofol can occur when the diluted emulsion is run through polyvinyl chloride intravenous tubing.[1] Propofol 1 or 2% may be given into a running intravenous infusion through a Y-site close to the injection site and under these circumstances it is compatible with glucose 5%, sodium chloride 0.9%, and glucose with sodium chloride intravenous solutions.

Because injection of propofol can be painful, it may be mixed with alfentanil or lidocaine before use. UK licensed product information advises mixing lidocaine 0.5 or 1% injection (without preservatives) in a ratio of 1:20 with propofol injection 1% immediately before use; similarly, alfentanil injection 500 micrograms/mL may be mixed in a ratio of 1:20 to 1:50 with propofol 1%. It advises against mixing the 2% emulsion of propofol with other drugs.

Nausea and vomiting. It is commonly believed that propofol is associated with less postoperative nausea and vomiting than some other anaesthetics.[1,2] However, a review[3] concluded that any reduction in nausea and vomiting when using propofol anaesthesia may be short term and clinically relevant only for maintenance anaesthesia in procedures with an inherent risk of nausea and vomiting.

There are also reports[4-8] indicating that propofol may have some intrinsic antiemetic action when used in sub-hypnotic doses although a study[9] of the effect of sedative and non-sedative (subhypnotic) doses against apomorphine-induced vomiting has suggested that any antiemetic effect is probably due to sedation.

Pruritus. Propofol is one of many drugs that have been tried in the management of pruritus (p.1582). Sub-hypnotic doses of propofol appear to have an antipruritic action. It has produced conflicting results in the treatment and prophylaxis of pruritus associated with epidural and intrathecal morphine[1-4] although it appears to be able to relieve cholestasis-associated pruritus.[5] It has been suggested that propofol might act by suppression of the spinal transmission of pruritic signals.

Status epilepticus. General anaesthesia may be used to control refractory tonic-clonic status epilepticus (p.469). A short-acting barbiturate such as thiopental is usually used. Propofol is also used[1-4] although good controlled studies of its effectiveness are lacking; in addition, it has caused seizures when used in anaesthesia (see CNS Effects, under Precautions, above) and should be given with caution to patients with epilepsy. The risks of respiratory and cerebral depression, as well as of lipid overload with prolonged therapy, should also be borne in mind. It may induce involuntary movements and care is required to distinguish these from seizures. Nonetheless, it has a rapid onset of action and its effects are maintained while the infusion is maintained; recovery is rapid on stopping. A suggested regimen for management[2] is an initial intravenous bolus of 1 to 2 mg/kg followed by an infusion of 2 to 10 mg/kg per hour guided by EEG monitoring. The dose should be gradually reduced and the infusion tapered 12 hours after seizure activity is halted. Lower doses should be used in the elderly. A study[5] comparing propofol with high-dose barbiturates in patients with refractory status epilepticus concluded that recurrent seizures were common when propofol infusions were suddenly stopped but not when the infusions were gradually tapered.

Sevoflurane *(BAN, USAN, rINN)*

BAX-3084; MR-654; Sevofluraani; Sevofluran; Sévoflurane; Sevoflurano; Sevofluranum. Fluoromethyl 2,2,2-trifluoro-1-(trifluoromethyl)ethyl ether; 1,1,1,3,3,3-Hexafluoro-2-(fluoromethoxy)-propane.

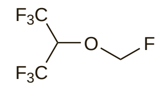
Севофлуран

$C_4H_3F_7O$ = 200.1.

CAS — 28523-86-6.

ATC — N01AB08.

ATC Vet — QN01AB08.



Pharmacopoeias. In *US.*

USP 31 (Sevoflurane). A clear, colourless, volatile, non-flammable liquid. Slightly soluble in water; miscible with alcohol, with chloroform, and with ether. Store in airtight containers at a temperature of 20° to 25°, excursions permitted between 15° and 30°. Protect from light.

Adverse Effects

As with other halogenated anaesthetics sevoflurane may cause cardiorespiratory depression, hypotension, and malignant hyperthermia. However, the effects of sevoflurane on heart rate have only been seen at higher concentrations and it appears to have little effect on heart rhythm in comparison to other halogenated anaesthetics. Sevoflurane appears to sensitise the myocardium to sympathomimetics to a lesser extent than halothane or enflurane. Other effects seen with sevoflurane include agitation, especially in children, laryngospasm, and increased cough and salivation. Acute renal failure has also been noted. Shivering, nausea, and vomiting have been reported in the postoperative period.

See also Adverse Effects of General Anaesthetics, p.1779.

Effects on the cardiovascular system. The cardiovascular effects of sevoflurane are similar to those of isoflurane (see p.1786) but it does not produce coronary steal. Also sevoflurane produces less tachycardia than isoflurane suggesting that it may be preferable in those predisposed to myocardial ischaemia.

Effects on the kidneys. Investigations[1] of the nephrotoxic potential of sevoflurane have found no evidence of renal function impairment despite peak plasma-fluoride ion concentrations greater than 50 nanomol/mL (a level considered to be nephrotoxic) being recorded in some patients at the end of sevoflurane anaesthesia,[2] and clinical experience would tend to support this.[3] The lack of renal toxicity with sevoflurane may be due to low concentrations of intrarenally generated fluoride ions;[4] in comparison, methoxyflurane defluorination in the kidney is much greater and may contribute to its known nephrotoxicity.

Compound A, formed by the breakdown of sevoflurane by carbon dioxide absorbents (see under Precautions, below), is nephrotoxic in *rats.*[1] However, studies in humans undergoing sevoflurane anaesthesia have detected no renal impairment postoperatively even when compound A was detected in the anaesthetic circuits.

2. Kobayashi Y, *et al.* Serum and urinary inorganic fluoride concentrations after prolonged inhalation of sevoflurane in humans. *Anesth Analg* 1992; **74:** 753–7.
3. Gentz BA, Malan TP. Renal toxicity with sevoflurane: a storm in a teacup? *Drugs* 2001; **61:** 2155–62.
4. Kharasch ED, *et al.* Human kidney methoxyflurane and sevoflurane metabolism: intrarenal fluoride production as a possible mechanism of methoxyflurane nephrotoxicity. *Anesthesiology* 1995; **82:** 689–99.

Effects on the liver. There have been signs of hepatotoxicity in *animal* studies but in studies in humans, markers for hepatocellular dysfunction were no greater after sevoflurane anaesthesia than those after isoflurane.[1] UK licensed product information also states that there have only been rare postmarketing reports of hepatic failure and necrosis for which causality has not been established. The metabolism of sevoflurane differs from other halogenated anaesthetics in such a way that metabolites implicated in liver toxicity are not formed (see Pharmacokinetics, below).

1. Darling JR, *et al.* Comparison of the effects of sevoflurane with those of isoflurane on hepatic glutathione-S-transferase concentrations after body surface surgery. *Br J Anaesth* 1994; **73:** 268P.

Effects on the nervous system. Clonic and tonic seizure-like movements of the extremities have been reported[1] in a child during induction of anaesthesia using sevoflurane. It was considered that this might have been a result of seizure activity in the CNS or due to myoclonus of the extremities.

1. Adachi M, *et al.* Seizure-like movements during induction of anaesthesia with sevoflurane. *Br J Anaesth* 1992; **68:** 214–15.

Precautions

As with other halogenated anaesthetics, patients with known or suspected susceptibility to malignant hyperthermia should not be anaesthetised with sevoflurane. Although the effects of sevoflurane on cerebral pressure are minimal in normal patients, safety in those with raised intracranial pressure has not been established and therefore sevoflurane should be used with caution. As emergence and recovery are particularly rapid with sevoflurane patients may require early postoperative pain relief.

See also Precautions for General Anaesthetics, p.1779.

Carbon dioxide absorbents. The breakdown of sevoflurane by carbon dioxide absorbents (such as soda lime) results in the formation of pentafluoroisopropenyl fluoromethyl ether (PIFE; compound A), and trace amounts of pentafluoromethoxy isopropyl fluoromethyl ether (PMFE; Compound B). Compound A has been shown to be nephrotoxic in *rats* (see under Effects on the Kidneys, above). Even during short exposure times, as required for induction of anaesthesia, use of moist soda lime is important to minimise sevoflurane degradation, which is aggravated by a high potassium hydroxide content of the soda lime.[1]

Licensed product information states that increased amounts of compound A may be formed if barium hydroxide lime is used as a carbon dioxide absorbent rather than soda lime.

The use of desiccated carbon dioxide absorbents with sevoflurane has also been associated with rare cases of extreme heat and smoke or fire developing in the anaesthetic apparatus.[2]

2. Abbott Laboratories, Canada. Important safety information regarding the use of Sevorane AF (sevoflurane) in conjunction with anesthesia machines. Available at: http://www.hc-sc.gc.ca/dhp-mps/alt_formats/hpfb-dgpsa/pdf/medeff/sevorane_hpc-cps-eng.pdf (accessed 08/08/08)

Interactions

Care is advised if adrenaline or other sympathomimetics are given during sevoflurane anaesthesia. The effects of competitive neuromuscular blockers such as atracurium are enhanced by sevoflurane (see p.1904). The metabolism, and hence toxicity, of sevoflurane may be increased by drugs or compounds that induce cytochrome P450 isoenzyme CYP2E1 including isoniazid and alcohol.

See also Interactions of General Anaesthetics, p.1779.

◊ References.

1. Dale O. Drug interactions in anaesthesia: focus on desflurane and sevoflurane. *Baillieres Clin Anaesthesiol* 1995; **9:** 105–17.

Pharmacokinetics

Sevoflurane is absorbed on inhalation. The blood/gas partition coefficient is low. Up to 5% of the absorbed dose of sevoflurane is metabolised in the liver by the cytochrome P450 isoenzyme CYP2E1 and defluorinated to its major metabolites hexafluoroisopropanol (HFIP), inorganic fluoride, and carbon dioxide. HFIP is rapidly conjugated with glucuronic acid and eliminated in the urine. Sevoflurane crosses the placenta.

◊ References.

Uses and Administration

Sevoflurane is a volatile halogenated anaesthetic given by inhalation. It has a minimum alveolar concentration (MAC) value (see Uses of General Anaesthetics, p.1779) ranging from 1.4% in the elderly to 3.3% in neonates. It is used for the induction and maintenance of general anaesthesia (p.1780). It is non-flammable. Sevoflurane has a nonpungent odour and does not cause respiratory irritation. It also has muscle relaxant properties which may be sufficient for some surgical procedures to be performed without a neuromuscular blocker. However, it possesses no analgesic properties.

Sevoflurane is given using a calibrated vaporiser. For induction, sevoflurane is given in concentrations of up to 5% v/v in adults, with oxygen or a mixture of oxygen and nitrous oxide. Concentrations of up to 7% v/v may be used in children. A short-acting barbiturate or other intravenous induction agent may be given before inhaling sevoflurane. Induction with sevoflurane is rapid (surgical anaesthesia in less than 2 minutes) and smooth because of its nonpungent odour. Maintenance of anaesthesia is achieved with a concentration of 0.5 to 3% v/v with or without nitrous oxide.

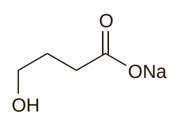
Sodium Oxybate *(USAN)*

NSC-84223; Oxibato sódico; Sodium Gamma-hydroxybutyrate; Wy-3478. Sodium 4-hydroxybutyrate.

$C_4H_7NaO_3$ = 126.1.

CAS — 502-85-2.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of sodium oxybate or gamma-hydroxybutyrate:

Blue nitro; Blue verve; Caps; Cherry Meth; Date rape drug; Drogue Du Cambriolage Sexuel Parfait; Easy lay; Everclear; EZLay; Fantasy; G; Gamma Oh; Gamma-OH; GBH; Georgia home boy; GHB; Goop; Great hormones at bedtime; Grievous bodily harm; G-riffic; Jib; Liquid E; Liquid ecstacy; Liquid ecstasy; Liquid G; Liquid X; Organic quaalude; Salty water; Scoop; Sleep; Sleep-500; Soap; Somatomax; Somatomax PM; Vita-G; Water.

Pharmacopoeias. In *Chin.*

Adverse Effects

When used in general anaesthesia adverse effects with sodium oxybate include abnormal muscle movements during the induction period and nausea and vomiting. Occasional emergence delirium has been reported. Bradycardia frequently occurs. Respiration may be slowed and hypokalaemia has been reported.

The most common adverse reactions seen in patients taking sodium oxybate orally for the management of narcolepsy are dizziness, headache, and, particularly in women, nausea. Other common reactions include anorexia, vomiting, diarrhoea, peripheral oedema, abnormal dreams and nightmares, sleepwalking, confusion, depression, anxiety, insomnia, paraesthesia, somnolence, tremor, amnesia, blurred vision, sweating, muscle cramps, nocturnal enuresis, urinary incontinence, asthenia, and fatigue. Blood pressure may also be increased. Psychosis, convulsions, hallucinations, agitation, hypersensitivity, and faecal incontinence are less common; rarely, respiratory depression has been reported.

See also Adverse Effects of General Anaesthetics, p.1779.

Effects on electrolyte balance. A report of severe metabolic disorders occurring during therapy with sodium oxybate and tetracosactide in 4 patients with severe head injuries.[1] The disorders consisted of hypernatraemia, hypokalaemia, and metabolic acidosis.

1. Béal JL, *et al.* Troubles métaboliques induits par l'association gamma-hydroxy butyrate de sodium et tétracosactide chez le traumatisé crânien. *Therapie* 1983; **38:** 569–71.

Precautions

In general anaesthesia, sodium oxybate should not be given to patients with severe hypertension, bradycardia, conditions associated with defects of cardiac conduction, epilepsy, eclampsia, renal impairment, or alcohol abuse.

Treatment with oral sodium oxybate is contra-indicated in patients with succinic semialdehyde dehydrogenase deficiency, an enzyme involved in its metabolism to succinic acid. Its use is also contra-indicated in patients with epilepsy as safety and efficacy have not been established; convulsions have been reported with sodium oxybate use.

Patients with a history of depression or suicide attempt should be carefully monitored for depressive symptoms while taking sodium oxybate. The high sodium content of sodium oxybate (0.75 g of sodium in a 4.5 g daily dose) should be considered in patients with heart failure, hypertension, or impaired renal function.

Rebound symptoms with an increased frequency of cataplexy may be seen when sodium oxybate is stopped. There has also been rare reports of withdrawal symptoms such as insomnia, headache, dizziness, anxiety, hallucinations, and psychotic disorders following the illicit use of sodium oxybate (see Abuse, below).

See also Precautions for General Anaesthetics, p.1779.

Abuse. Reports[1] of acute poisoning with sodium oxybate following illicit use led the FDA to issue warnings[2] about its potential for abuse. It is usually supplied illicitly as the sodium salt under a variety of names (see above) and has been promoted for body building, weight loss, as a psychedelic substance, and as a sleep aid. Adverse effects include vomiting, drowsiness, amnesia, hypotonia, vertigo, respiratory depression, and involuntary movements. Seizure-like activity, bradycardia, hypotension, and respiratory arrest have also been reported. Resolution of symptoms occurs spontaneously over 2 to 96 hours. However, some patients have required hospitalisation and respiratory support and deaths have been reported in several countries.[3-5] Severity of symptoms depends on the dose of sodium oxybate and the presence of other drugs such as alcohol, benzodiazepines, cannabis, or amfetamines. Prolonged use of large doses may lead to a withdrawal syndrome on discontinuation.[6-8]

There is also a report of CNS depression after ingestion of a chemical derivative, gamma-butyrolactone (GBL).[9] Another derivative, 1,4-butanediol is abused similarly.[7] Withdrawal symptoms have also been associated with discontinuation of these 2 substances in abusers.[8]

Porphyria. Sodium oxybate is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals* or *in-vitro* systems.

Interactions

In anaesthesia, sodium oxybate enhances the effects of opioid analgesics, barbiturates, and competitive neuromuscular blockers. The CNS depressant effects of sodium oxybate may be potentiated by alcohol, sedative-hypnotics, and other CNS depressants. The risk of respiratory depression may also be increased by benzodiazepines.

See also Interactions of General Anaesthetics, p.1779.

Pharmacokinetics

After oral doses sodium oxybate is rapidly but incompletely absorbed from the gastrointestinal tract; absolute bioavailability is about 25%. Peak concentrations are reached within 0.5 to 2 hours. Absorption may be delayed and decreased following a high fat meal. Protein binding is less than 1%. Sodium oxybate is metabolised in the liver via GHB dehydrogenase to succinic semialdehyde, which is then converted to succinic acid via another enzyme, succinic semialdehyde dehydrogenase. Succinic acid enters the Krebs cycle and is metabolised to carbon dioxide, which is expired, and water. Less than 5% of unchanged drug appears in the urine; faecal excretion is also negligible.

2. Scharf MB, *et al.* Pharmacokinetics of gammahydroxybutyrate (GHB) in narcoleptic patients. *Sleep* 1998; **21:** 507–14.

Uses and Administration

Sodium oxybate has hypnotic properties and, in its endogenous form, gamma-hydroxybutyrate (a catabolite of gamma-aminobutyric acid), increases dopamine concentrations in the brain. It is given intravenously usually with an opioid analgesic and a neuroleptic to produce general anaesthesia (p.1780). Skeletal muscle relaxants may also be necessary. Sodium oxybate given orally is used in the treatment of cataplexy in patients with narcolepsy; in the USA it is also indicated for the excessive daytime sleepiness associated with narcolepsy.

In general anaesthesia a solution of sodium oxybate equivalent to 20% of the acid is given slowly by intravenous injection, usually in a dose of 60 mg/kg; further smaller doses may be required in long procedures. In children 100 mg/kg may be used.

For the management of narcolepsy in adults, sodium oxybate is given in initial oral doses of 4.5 g daily, as two equally-divided doses. The first dose should be taken at bedtime while in bed and at least 2 to 3 hours after food; the second dose should be taken 2.5 to 4 hours later also while sitting in bed. Both doses should be prepared before going to bed: each dose should be diluted with 60 mL of water. The initial dose may be increased in steps of 1.5 g (0.75 g per dose) every 1 to 2 weeks to a maximum dose of 9 g daily. If therapy has been stopped for more than 14 consecutive days, titration should be restarted at the lowest dose. Reduced doses are recommended in patients with hepatic impairment (see below).

Administration in hepatic impairment. The recommended initial oral dose of sodium oxybate (see above) should be halved in patients with hepatic impairment. Subsequent increases should be monitored against effect.

Alcohol withdrawal syndrome. Gamma-hydroxybutyric acid has been reported[1] to be effective in reducing symptoms of alcohol withdrawal (p.1626) and to be of use as an aid in the maintenance of abstinence.[2,3] However, following reports of CNS toxicity associated with abuse of gamma-hydroxybutyric acid its role in the treatment of substance abuse disorders appears questionable.[4]

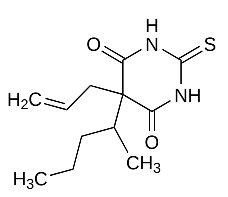
Thiamylal Sodium

Tiamilal sódico. Sodium 5-allyl-5-(1-methylbutyl)-2-thiobarbiturate.

$C_{12}H_{17}N_2NaO_2S = 276.3.$

CAS — 77-27-0 (thiamylal); 337-47-3 (thiamylal sodium).



(thiamylal)

Pharmacopoeias. In *Jpn.*

Profile

Thiamylal sodium is a short-acting intravenous barbiturate anaesthetic. It is possibly slightly more potent than thiopental sodium (p.1796) and has similar actions and uses. It has been used for the production of complete anaesthesia of short duration, for the induction of general anaesthesia, or for inducing a hypnotic state.

Thiopental Sodium *(BANM, rINN)*

Natrium Isopentylaethylthiobarbituricum (cum Natrio Carbonico); Penthiobarbital Sodique; Sodyum Tiopental; Sodyum Tiopenton; Soluble Thiopentone; Thiomebumalnatrium cum Natrii Carbonate; Thiopental et carbonate sodiques; Thiopental Sodique; Thiopental Sodium and Sodium Carbonate; Thiopental sodná sůl a uhličitan sodný; Thiopentalum Natricum; Thiopentalum natricum et natrii carbonas; Thiopentobarbitalum Solubile; Thiopentone Sodium; Tiopentaalinatrium; Tiopentaalinatrium ja natriumkarbonaatti; Tiopental sódico; Tiopentalio natrio druska ir natrio karbonatas; Tiopentalnatrium; Tiopentál-nátrium és nátrium-karbonát; Tiopentalnatrium och natriumkarbonat. Sodium 5-ethyl-5-(1-methylbutyl)-2-thiobarbiturate.

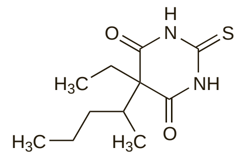
Тиопентал Натрий

$C_{11}H_{17}N_2NaO_2S = 264.3.$

CAS — 76-75-5 (thiopental); 71-73-8 (thiopental sodium).

ATC — N01AF03; N05CA19.

ATC Vet — QN01AF03; QN05CA19.



(thiopental)

NOTE. The name thiobarbital has been applied to thiopental and has also been used to describe a barbiturate of different composition.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.* Some include thiopental sodium with, some without, anhydrous sodium carbonate; some only include a sterile mixture for injection.

Ph. Eur. 6.2 (Thiopental Sodium and Sodium Carbonate; Thiopental Sodium BP 2008). A yellowish-white hygroscopic powder. It contains 84 to 87% thiopental and 10.2 to 11.2% sodium. Freely soluble in water; partly soluble in dehydrated alcohol. Store in airtight containers. Protect from light.

USP 31 (Thiopental Sodium). A white to off-white crystalline powder, or yellowish-white to pale greenish-yellow hygroscopic powder. May have a disagreeable odour. Its solutions are alkaline to litmus, decompose on standing, and on boiling, precipitation occurs. Soluble in water and in alcohol; insoluble in ether, in petroleum spirit, and in benzene. Store in airtight containers.

Incompatibility. Solutions of thiopental sodium are incompatible with acidic and oxidising substances including some antibacterials, neuromuscular blockers and analgesics. Compounds commonly listed as incompatible include amikacin sulfate, benzylpenicillin salts, cefapirin sodium, codeine phosphate, ephedrine sulfate, fentanyl citrate, glycopyrronium bromide, morphine sulfate, pentazocine lactate, prochlorperazine edisilate, suxamethonium salts, and tubocurarine chloride. Solutions decompose on standing and precipitation occurs on boiling.

Stability. Loss of thiopental in PVC and cellulose propionate delivery systems has been reported,[1,2] but in another study,[3] no loss of potency was noted. Adsorption has been reported[4] not to occur in polyolefin infusion bags.

4. Trissel LA, *et al.* Drug compatibility with new polyolefin infusion solution containers. *Am J Health-Syst Pharm* 2006; **63:** 2379–82.

Adverse Effects and Treatment

As for Phenobarbital, p.492.

Excitatory phenomena such as coughing, hiccuping, sneezing, and muscle twitching or jerking may occur with any of the barbiturate anaesthetics, particularly during induction, but they occur more frequently with methohexital than with thiopental. Cough, sneezing, and laryngeal spasm or bronchospasm may also occur during induction. The intravenous injection of concentrated solutions of thiopental sodium such as 5% may result in thrombophlebitis. Extravasation of barbiturate anaesthetics may cause tissue necrosis. Intra-arterial injection causes severe arterial spasm with burning pain and may cause prolonged blanching of the forearm and hand and gangrene of digits. Hypersensitivity reactions have been reported. Barbiturate anaesthetics can cause respiratory depression. They depress cardiac output and often cause an initial fall in blood pressure, and overdosage may result in circulatory failure. Arrhythmias may occur. Postoperative vomiting is infrequent but shivering may occur and there may be persistent drowsiness, confusion, and amnesia. Headache has also been reported.

See also under Adverse Effects of General Anaesthetics, p.1779.

Hypersensitivity. Anaphylactic reactions to thiopental have been reported[1,2] although such reactions are rare. There has also been a report of haemolytic anaemia and renal failure in association with the development of an anti-thiopental antibody in a patient who had undergone general anaesthesia induced by thiopental.[3]

1. Westacott P, *et al.* Anaphylactic reaction to thiopentone: a case report. *Can Anaesth Soc J* 1984; **31:** 434–8.
2. Moneret-Vautrin DA, *et al.* Simultaneous anaphylaxis to thiopentone and a neuromuscular blocker: a study of two cases. *Br J Anaesth* 1990; **64:** 743–5.
3. Habibi B, *et al.* Thiopental-related immune hemolytic anemia and renal failure: specific involvement of red-cell antigen I. *N Engl J Med* 1985; **312:** 353–5. Correction. *ibid.*; 1136.

Intra-arterial injection. Accidental intra-arterial injection of thiopental sodium produces severe arterial spasm with intense burning pain. Anaesthesia, paresis, paralysis, and gangrene may occur. Therapy has concentrated on dilution of injected thiopental, prevention and treatment of arterial spasm, prophylaxis of thrombosis, thrombectomy and other measures to sustain good blood flow. There has been a report[1] of the successful use of urokinase intra-arterially in the management of one patient accidentally given thiopental intra-arterially.

1. Vangerven M, *et al.* A new therapeutic approach to accidental intra-arterial injection of thiopentone. *Br J Anaesth* 1989; **62:** 98–100.

Precautions

Barbiturate anaesthetics are contra-indicated when there is dyspnoea or respiratory obstruction such as in acute severe asthma or when maintenance of an airway cannot be guaranteed.

Barbiturate anaesthetics should be used with caution in shock and dehydration, hypovolaemia, severe anaemia, hyperkalaemia, toxaemia, myasthenia gravis, myxoedema and other metabolic disorders, or in severe renal disease. Caution is also required in patients with cardiovascular disease, muscular dystrophies, adrenocortical insufficiency, or with increased intracranial pressure. Reduced doses are required in the elderly and in severe hepatic disease.

See also Precautions for General Anaesthetics, p.1779.

Breast feeding. No adverse effects have been seen in breast-fed infants whose mothers received thiopental, and the American Academy of Pediatrics[1] considers that it is therefore usually compatible with breast feeding.

In two groups of 8 women undergoing induction with thiopental, the milk-to-plasma ratio was less than 1 in both groups and it was considered that the effects of thiopental on breast-fed infants would be negligible.[2]

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 26/05/04)
2. Andersen LW, *et al.* Concentrations of thiopentone in mature breast milk and colostrum following an induction dose. *Acta Anaesthesiol Scand* 1987; **31:** 30–2.

Porphyria. Barbiturates including thiopental sodium have been associated with acute attacks of porphyria and are considered unsafe in porphyric patients.

Interactions

Difficulty may be experienced in producing anaesthesia with the usual dose of barbiturate anaesthetics in patients accustomed to taking alcohol or other CNS depressants; additional anaesthetics may be necessary. Patients being treated with phenothiazine antipsychotics may experience increased hypotension. Some phenothiazines, especially promethazine, may also increase the incidence of excitatory phenomena produced by barbiturate anaesthetics; cyclizine may possibly have a similar effect. Opioid analgesics can potentiate the respiratory depressant effect of barbiturate anaesthetics and the dose of the anaesthetic may need to be reduced. Use with nitrous oxide greatly reduces the dose of barbiturate anaesthetics required for anaesthesia. Reduced doses of thiopental may be required in patients receiving sulfafurazole.

See also Interactions of General Anaesthetics, p.1779.

Antidepressants. Potentiation of barbiturate anaesthesia may be expected in patients receiving *tricyclic antidepressants* or *MAOIs* (see Anaesthesia under Precautions of Amitriptyline, p.378 and for Phenelzine, p.417, respectively).

Antipsychotics. For mention of the effect of *droperidol* on thiopental see Gastrointestinal Drugs, below.

Aspirin. Pretreatment with aspirin, a highly protein-bound drug, has been shown to potentiate thiopental anaesthesia.[1]

1. Dundee JW, *et al.* Aspirin and probenecid pretreatment influences the potency of thiopentone and the onset of action of midazolam. *Eur J Anaesthesiol* 1986; **3:** 247–51.

Gastrointestinal drugs. *Metoclopramide* profoundly reduced the dose of thiopental required to produce hypnosis in female patients; *droperidol* had a similar effect.[1]

1. Mehta D, *et al.* Metoclopramide decreases thiopental hypnotic requirement. *Anesth Analg* 1993; **77:** 784–7.

Probenecid. Pretreatment with probenecid, a highly protein-bound drug, has been shown to potentiate thiopental anaesthesia.[1]

1. Dundee JW, *et al.* Aspirin and probenecid pretreatment influences the potency of thiopentone and the onset of action of midazolam. *Eur J Anaesthesiol* 1986; **3:** 247–51.

Pharmacokinetics

Thiopental is highly lipid soluble and when it is given intravenously as the sodium salt, concentrations sufficient to produce unconsciousness are achieved in the brain within 30 seconds. Onset of action occurs within 8 to 10 minutes when thiopental sodium is given rectally but absorption may be unpredictable if a suspension rather than a solution is used. Recovery from anaesthesia is also rapid due to redistribution to other tissues, particularly fat. About 80% of thiopental may be bound to plasma proteins, although reports show a wide range of figures. Thiopental is metabolised almost entirely in the liver, but as it is only released slowly from lipid stores this occurs at a very slow rate.

It is mostly metabolised to inactive metabolites but a small amount is desulfurated to pentobarbital. Repeated or continuous use can lead to accumulation of thiopental in fatty tissue and this can result in prolonged anaesthesia and respiratory and cardiovascular depression. Elimination of thiopental after bolus injection can be described by a triexponential curve. The terminal elimination half-life has been reported to be 10 to 12 hours in adults and about 6 hours in children. However, values of 26 to 28 hours have been reported in obese patients and pregnant patients at term. Thiopental readily diffuses across the placenta and is distributed into breast milk.

Uses and Administration

Thiopental is a short-acting barbiturate anaesthetic. It is given intravenously, usually for the induction of general anaesthesia (p.1780), but may be used as the sole anaesthetic to maintain anaesthesia for short procedures with minimal painful stimuli. It is also used in anaesthesia as a supplement to other anaesthetics and as a hypnotic in balanced anaesthesia. Thiopental sodium may also be used intravenously in the control of refractory tonic-clonic status epilepticus and in neurosurgical patients to reduce increased intracranial pressure. It has also been given rectally for basal anaesthesia or basal narcosis.

Thiopental does not usually produce excitation and induction of anaesthesia is usually smooth. It has poor muscle relaxant properties and a muscle relaxant must be given before intubation is attempted. Thiopental also has poor analgesic properties and small doses may even lower the pain threshold. Recovery from moderate doses usually occurs within 10 to 30 minutes, but the patient may remain sleepy or confused for several hours. Large doses, repeated smaller doses, or continuous use may markedly delay recovery.

In **anaesthesia**, the dosage of thiopental varies greatly according to the state of the patient and the nature of other drugs being used concurrently (see under Precautions above and Interactions above for further details). Thiopental is usually given intravenously as the sodium salt as a 2.5% solution but a 5% solution is occasionally used. UK licensed product information states that a typical dose for inducing anaesthesia is 100 to 150 mg injected over 10 to 15 seconds, repeated after 30 to 60 seconds according to response. It also recommends that the total dosage used should not exceed 500 mg; in pregnant patients the total maximum dose is 250 mg. In some other countries, it is recommended that induction begin with a test dose of 25 to 75 mg; thereafter, a dose of 50 to 75 mg may be given at intervals of 20 to 40 seconds according to response. Once anaesthesia has been established, additional doses of 25 to 50 mg may be given as necessary. When thiopental is used as the sole anaesthetic, anaesthesia can be maintained by repeat doses as needed or by continuous intravenous infusion of a 0.2 or 0.4% solution.

To **reduce elevations of intracranial pressure** in neurological patients, thiopental sodium is licensed for use as intermittent bolus injections of 1.5 to 3 mg/kg if adequate ventilation is provided (but see also Cerebrovascular Disorders, below). Higher doses have been tried.

For suggested doses in refractory tonic-clonic **status epilepticus** see Status Epilepticus, below.

For dosage in *children* and the *elderly*, also see below.

◊ References.

1. Russo H, Bressolle F. Pharmacodynamics and pharmacokinetics of thiopental. *Clin Pharmacokinet* 1998; **35:** 95–134.

Administration in children. For the *induction of anaesthesia* in children, UK licensed product information recommends that thiopental sodium is given by slow intravenous injection (over 10 to 15 seconds) in a dose of 2 to 7 mg/kg; the dose may be repeated after 1 minute.

In the treatment of prolonged *status epilepticus* (see below), the *BNFC* recommends an initial dose of up to 2 mg/kg in neonates or up to 4 mg/kg in children aged 1 month and over, given as a slow intravenous injection; for all patients, this should then be followed by a continuous intravenous infusion of up to 8 mg/kg per hour, adjusted according to response.

Intravenous injections are normally given as a 2.5% solution; the *BNFC* recommends that intravenous infusions are given as a 0.25% solution.

Administration in the elderly. It is usually recommended that the dosage of barbiturate anaesthetics is reduced in the elderly. A study[1] in elderly patients demonstrated that although reducing the rate of intravenous injection reduced the speed of induction, the dosage required was also reduced. Giving thiopental sodium 2.5% solution at a rate of 125 mg/minute induced anaesthesia in a mean of 90.8 seconds and required a mean dose of 2.8 mg/kg. Corresponding values for a rate of 500 mg/minute were 40.8 seconds and 5 mg/kg, respectively.

Anaesthesia. Some of the adverse effects of the neuromuscular blocker suxamethonium may be reduced when thiopental is used as part of the anaesthetic regimen. For a suggestion that thiopental may help to counteract the rise in intra-ocular pressure associated with the use of suxamethonium for intubation, see under Anaesthesia, p.1900.

Cerebrovascular disorders. Barbiturates are considered to be suitable anaesthetics for use in patients with or at risk of raised intracranial pressure. Barbiturate-induced coma (commonly with pentobarbital or thiopental) has been used, both therapeutically and prophylactically, to protect the brain from ischaemia resulting from neurological insults including head injury, stroke, Reye's syndrome, and hepatic encephalopathy.[1-3] Rationale includes the ability of barbiturates to reduce intracranial pressure and to reduce metabolic demands of cerebral tissues. Although thiopental protected patients against the neuropsychiatric complications of cardiopulmonary bypass,[4] the Brain Resuscitation Clinical Trial I Study Group[5] found no cerebral benefit from thiopental in comatose survivors of cardiac arrest. Nor did others[6] observe any benefit from thiopental-induced coma in infants with severe birth asphyxia. A review in 1989 considered that there was no convincing evidence of improvement in neurological outcome to justify the risks of the procedure in conditions causing global ischaemia, although use of barbiturates without necessarily inducing coma might have a limited role in reduction of raised intracranial pressure refractory to other therapy. Use of barbiturates in the setting of regional cerebral ischaemia, including use during cardiopulmonary bypass to prevent focal neurological complications, remained controversial.[1] A systematic review[7] came to similar conclusions, pointing out that although the barbiturates may reduce intracranial pressure their hypotensive effects are likely to offset any beneficial action on cerebral perfusion, perhaps accounting for the lack of evidence for any clinical benefit.

For a discussion of the treatment of raised intracranial pressure, including a mention of the use of barbiturates, see p.1181.

Status epilepticus. General anaesthesia may be used to control refractory tonic-clonic status epilepticus (p.469). A short-acting barbiturate such as thiopental is usually used.

Doses of thiopental sodium in the treatment of status epilepticus appear to vary widely and may be defined by local clinical protocols. Licensed product information and the *BNF* recommend a dose of 75 to 125 mg intravenously as a 2.5% solution. Other regimens advocate an initial loading dose followed by further intermittent doses or a continuous infusion. One high dose regimen suggests an intravenous loading dose of 5 mg/kg followed after 30 minutes by an infusion given at a rate of 1 to 3 mg/kg per hour and adjusted to maintain a maximum blood concentration of 60 to 100 micrograms/mL.[1] It has been recommended that dosage should be continued for at least 12 hours after seizure activity has ceased and then slowly stopped.[2] Recovery may be prolonged.[3]

For the dose of thiopental in children see Administration in Children, above.

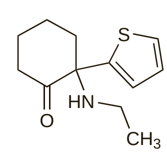
Tiletamine Hydrochloride *(BANM, USAN, rINNM)*

CI-634; CL-399; CN-54521-2; Hidrocloruro de tiletamina; Tilétamine, Chlorhydrate de; Tiletamini Hydrochloridum. 2-Ethylamino-2-(2-thienyl)cyclohexanone hydrochloride.

Тилетамина Гидрохлорид

$C_{12}H_{17}NOS,HCl = 259.8.$

CAS — 14176-49-9 (tiletamine); 14176-50-2 (tiletamine hydrochloride).



(tiletamine)

Pharmacopoeias. In *US* for veterinary use only.

USP 31 (Tiletamine Hydrochloride). A white to off-white crystalline powder. Freely soluble in water; slightly soluble in chloroform; practically insoluble in ether; soluble in methyl alcohol;

freely soluble in 0.1N hydrochloric acid. pH of a 10% solution in water is between 3.0 and 5.0. Store in airtight containers.

Profile

Tiletamine has similar properties to ketamine (p.1787). It is used as the hydrochloride with zolazepam (p.1037) for general anaesthesia in veterinary medicine.

Trichloroethylene *(rINN)*

Trichlorethylene; Trichlorethylenum; Trichloroethene; Trichloroéthylène; Trichloroethylenum; Trichloroetylen; Tricloroetileno.

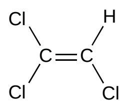
Трихлороэтилен

$CHCl{:}CCl_2$ = 131.4.

CAS — 79-01-6.

ATC — N01AB05.

ATC Vet — QN01AB05.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of trichloroethylene: Trichlo.

Stability. NOTE. Trichloroethylene used for anaesthetic purposes contains thymol 0.01% w/v as a stabiliser and is coloured blue for identification. It is non-flammable.

Adverse Effects and Precautions

Trichloroethylene increases the rate and decreases the depth of respiration and may be followed by apnoea. The sensitivity of the heart to beta-adrenergic activity may increase, possibly with ventricular arrhythmias.

Acute exposure to trichloroethylene may be followed by dizziness, lightheadedness, lethargy, nausea, and vomiting; hepatic and renal dysfunction may follow. Fatalities have occurred, although temporary unconsciousness is a more common manifestation.

Chronic poisoning may result in visual disturbances, intolerance to alcohol as manifested by transient redness of the face and neck (degreasers' or trichloroethylene flush), impairment of performance, hearing defects, neuralgia, and mild liver dysfunction. Prolonged contact with trichloroethylene can cause dermatitis, eczema, burns, and conjunctivitis.

Dependence has been reported in medical personnel and factory workers who regularly inhale trichloroethylene vapour.

If trichloroethylene is used as an anaesthetic it should not be used in closed-circuit apparatus since there is a reaction with soda lime to produce a toxic end product that may cause cranial nerve paralysis and possibly death.

See also Adverse Effects and Precautions for General Anaesthetics, p.1779.

3. Davidson IWF, Beliles RP. Consideration of the target organ toxicity of trichloroethylene in terms of metabolite toxicity and pharmacokinetics. *Drug Metab Rev* 1991; **23:** 493–599.

Abuse. Toxicity associated with inhalation of volatile substances including trichloroethylene has been reviewed.[1,2] Trichloroethylene can damage the kidney, liver, heart, and lung. However, in young healthy subjects, organ toxicity becomes apparent only with intensive and protracted abuse of volatile substances.

2. Anonymous. Solvent abuse: little progress after 20 years. *BMJ* 1990; **300:** 135–6.

Carcinogenicity. The use of trichloroethylene in foods, drugs, and cosmetics was banned by the FDA after studies demonstrating that hepatocellular carcinomas could be induced in *mice* by chronic exposure to very high doses. However, similar effects have not been found in *rats* and larger species and several epidemiologic studies have failed to demonstrate an increased incidence of liver tumours, total mortality or mortality due to cancer in workers exposed to trichloroethylene. Suggestions that the carcinogenicity of trichloroethylene is due to one of its intermediate metabolites, cloral hydrate, have raised concern over the continuing use of cloral hydrate as a medicine. For further details, see p.979.

Effects on the liver. References[1,2] to hepatotoxicity after occupational exposure to trichloroethylene. See also Carcinogenicity, above.

Effects on the skin. A report[1] of scleroderma in 3 patients occupationally exposed to trichloroethylene and, in 2 cases, also to trichloroethane.

1. Flindt-Hansen H, Isager H. Scleroderma after occupational exposure to trichlorethylene and trichlorethane. *Acta Derm Venereol (Stockh)* 1987; **67:** 263–4.

Interactions

The arrhythmogenic effects of trichloroethylene may be potentiated by sympathomimetics such as adrenaline. Alcohol consumption after chronic exposure to trichloroethylene may result in a reddening of the skin (see Adverse Effects and Precautions, above).

See also Interactions of General Anaesthetics, p.1779.

Pharmacokinetics

Trichloroethylene is rapidly absorbed by inhalation and ingestion. Percutaneous absorption can occur. Some of the inhaled trichloroethylene is slowly eliminated through the lungs; trichloroethylene is metabolised primarily in the liver, cloral hydrate (see p.979) being the first stable major metabolite formed; most is then metabolised to trichloroethanol and trichloroacetic acid which are excreted in the urine. The latter may be used as an indicator of industrial exposure. Trichloroethylene diffuses across the placenta.

Uses and Administration

Trichloroethylene is a volatile halogenated anaesthetic given by inhalation. It has been used in some countries for the maintenance of light anaesthesia (p.1780) but it has weak anaesthetic properties compared to other halogenated anaesthetics and poor muscle relaxant activity, and safer anaesthetics are generally preferred. It has also been used to supplement anaesthesia with nitrous oxide-oxygen or halothane. Trichloroethylene is a potent analgesic and has been used in subanaesthetic concentrations to provide analgesia for obstetrics, emergency management of trauma, and other acutely painful procedures.

Trichloroethylene is used in industry as a solvent for oils and fats, for degreasing metals, and for dry cleaning. It has also been used in type correction fluids but is no longer included in most brands.

Xenon

Ksenon; Xénon; Xenón; Xenonum.

Xe = 131.293.

ATC — N01AX15.

ATC Vet — QN01AX15.

Profile

Xenon is a non-explosive gas. Mixtures of 60 or 70% v/v xenon with oxygen have been tried as a general anaesthetic.

Growth Hormone and its Modulators

Human growth is under a complex system of hormonal controls. Growth hormone is produced by specialised cells (somatotropes) in the anterior pituitary; production and secretion are under a system of double regulation by a release-inhibiting hormone, somatostatin, and a growth hormone-releasing hormone, somatorelin, both produced in the hypothalamus. These in turn are modulated by various stimuli: dopamine, serotonin, hypoglycaemia, stress or emotional excitement, and ingestion of protein-rich meals all stimulate growth hormone release, whereas glucose, free fatty acids, insulin-like growth factor and growth hormone itself all suppress it.

The effects of growth hormone in the body rely on its interaction with a distinct growth hormone receptor; some effects, such as stimulation of lipolysis and gluconeogenesis, are direct but others, including its anabolic and growth-promoting effects, are mediated by induction of insulin-like growth factors (somatomedins).

Included in this chapter are growth hormone itself, now generally given as recombinant somatropin (p.1799) or its synthetic methionyl analogue somatrem (p.1799), and somatomedins such as mecasermin (p.1807). Also included are the hypothalamic releasing hormone, somatorelin (p.1808), and its analogue sermorelin (p.1808); the hypothalamic inhibiting hormone, somatostatin (p.1809), and its analogues such as lanreotide (p.1803) and octreotide (p.1803); the growth hormone release stimulant pralmorelin (p.1807); and the growth hormone-receptor antagonist pegvisomant (p.1807). Their use in acromegaly and growth retardation is discussed in more detail below.

Acromegaly and gigantism

Acromegaly and gigantism are syndromes of excess growth hormone secretion, usually associated with a secretory pituitary adenoma (somatropinoma).

Excessive growth hormone secretion in childhood, while the epiphyses of the long bones are open, results in **gigantism**,[1] with a proportional growth spurt and skeletal enlargement. Other common features include obesity, coarse facial features, and disproportionately large hands and feet with thick fingers and toes. Puberty, with the increase in sex hormone secretion that leads to epiphyseal fusion, may be delayed by concomitant hypogonadism, leading to attainment of an even greater ultimate height. If growth hormone excess persists into adulthood, features of acromegaly may be superimposed on gigantism.

When excess growth hormone secretion develops first in adulthood the condition is known as **acromegaly**. Signs and symptoms tend to develop slowly and may be missed, sometimes for years. Growth hormone concentrations, and hence those of insulin-like growth factor I (IGF-I), which is produced in the liver in response to growth hormone, are elevated, sometimes markedly. The facial features become coarser, the jaw enlarges (prognathism), and hands and feet become enlarged. Peripheral neuropathy and carpal tunnel syndrome due to nerve entrapment, arthropathy, osteoarthritis, and muscle weakness, abnormal glucose tolerance, hypertension and left ventricular hypertrophy are all common, as is nodular goitre. Daytime somnolence may occur due to sleep apnoea. Acromegalics have an increased mortality if left untreated, largely due to cardiovascular disease.

Treatment. The biochemical goal of treatment is to normalise growth hormone and IGF-I concentrations in order to reduce some of the signs and symptoms of acromegaly and to reverse the increased risk of mortality.[2] Growth hormone is usually measured after an oral glucose tolerance test (OGTT); this suppresses growth hormone concentrations in healthy subjects, but not in patients with acromegaly. A growth hormone concentration below 1 microgram/litre after an OGTT may be used to exclude acromegaly at the initial diagnosis, and as a target in the assessment of treatment efficacy in acromegaly. Growth hormone concentrations taken as random samples or as mean 24-hour measures may also be used during the long-term monitoring of patients treated for acromegaly; in such circumstances a target concentration below 2.5 micrograms/litre is often used.[3] However, the target concentrations that have been suggested have changed over time with the development of more sensitive assays, and results must be interpreted in the context of the method used.[4] Random IGF-I concentrations should be reduced to normal for age and sex.[3,5]

As for most pituitary tumours, **surgery** is the mainstay of treatment.[2,5] The success rate depends on surgical expertise and the size and extension of the mass, with success rates higher for microadenomas (about 80%) than macroadenomas (less than 50%) depending on criteria.[3,6]

Drug therapy for acromegaly is indicated for patients who refuse surgery, are at increased risk from surgery, have active disease after surgery, or are awaiting the effects of radiotherapy (see below).[2] The somatostatin analogues, octreotide and lanreotide, reduce growth hormone secretion in most patients, but not all will have persistent suppression and normalisation of growth hormone levels.[7,8] Reported response rates vary, but effective growth hormone suppression occurs in about 50 to 55% of patients, and IGF-I is normalised in about 50 to 65%. Somatostatin analogues also produce tumour shrinkage, reducing tumour size by 20 to 50% in about 30% of patients, and improve signs and symptoms of acromegaly, including improvements in cardiac structure and function. Octreotide and lanreotide are given as sustained-release intramuscular injections.[7] Octreotide may be more effective than lanreotide, but not all formulations have been compared.[8] Octreotide can also be given by subcutaneous injection, but must be given three times daily, making it less attractive for long-term therapy. There have been some promising reports of the use of somatostatin analogues for primary therapy, but when there is visual or neurological compromise then surgery is preferred because drug therapy may not provide enough tumour shrinkage to relieve pressure on the optic chiasm.[7,9] There is some data to suggest that pre-operative use of somatostatin analogues could improve cardiovascular, respiratory, and metabolic functions and hence reduce morbidity associated with surgery, and improve remission rates, but further study is needed.[7,8,10] Dopaminergics can produce a paradoxical reduction in growth hormone secretion in some patients with acromegaly, providing symptomatic relief. Bromocriptine produces acceptable suppression of growth hormone secretion in less than 20% of patients.[9] A small study of quinagolide reported the normalisation of hormonal values in about 44% of patients, which was better than the poor responses to a depot preparation of bromocriptine, or cabergoline.[11] A later, open study, however, found that cabergoline produced a good response in about 40% of patients.[12] Dopaminergics are generally added to somatostatin analogue therapy[5] and may be most useful in patients with associated hyperprolactinaemia.[2,5,8] Pegvisomant is a growth hormone-receptor antagonist that may be used when other therapies have failed or are inappropriate.[2,8,13] It is reported[14,15] to lower IGF-I concentrations, improve signs and symptoms of acromegaly, and be well tolerated. Pegvisomant does not reduce growth hormone concentrations so these patients must be monitored by IGF-I measurement.[4] The addition of pegvisomant has also been reported to normalise IGF-I concentrations in patients with persistently elevated levels during somatostatin analogue therapy.[16]

Tumour regression induced by **radiotherapy** is a possible alternative when surgery cannot be performed, there is residual pituitary disease after surgery, or medical therapy has failed.[2,5,6] Although it reduces growth hormone concentrations in about 90% of patients[3] and tumour recurrence is rare[5] its effects are slow and it often produces hypopituitarism. Some consider these to be disadvantages and prefer to use drug treatment for management of tumours that persist after surgery.[5] Since it may take several years for growth hormone concentrations to fall, drug therapy is also given until the effects of radiation therapy are satisfactory.[2,5]

Growth retardation

Stature follows a normal (bell-shaped) distribution within the population. Short stature has been defined as a height more than 2 standard deviations below the population mean, but there may be some difficulty in deciding at what point short stature becomes abnormal and to some extent this is determined by cultural as well as physiological norms. However, certain disorders are associated with well-defined deficiencies of growth which may be severe enough to warrant the description dwarfism. Some forms are associated with disorders of bone or cartilage growth (skeletal dysplasias), and many of these result additionally in disproportionate growth, as in the short-limbs and large head characteristic of achondroplasia. Other important causes of dwarfism include inadequate production of growth hormone (idiopathic growth hormone deficiency), either alone (isolated growth hormone deficiency) or combined with other pituitary hormone deficiencies as part of hypopituitarism; resistance to circulating growth hormone, as in Laron-type dwarfism, where there is a mutation of the growth hormone receptor; or defects in somatomedin synthesis. Some other endocrine causes of short stature include hypothyroidism, Cushing's syndrome, and Turner's syndrome. Severe chronic disease in childhood such as asthma, chronic renal failure, or liver disorders can result in some growth retardation as can inadequate nutrition due to malabsorption syndromes such as coeliac disease.

Endocrine causes of growth retardation are significant because they may be treatable by appropriate replacement therapy. Isolated growth hormone deficiency, or growth hormone and gonadotrophin deficiencies, are the commonest congenital forms of hypopituitarism. The deficiency is rarely complete, and since most children with short stature will not have growth hormone deficiency care is required in its diagnosis. Although provocative growth hormone tests, which use non-physiological means to stimulate growth hormone secretion, have long been considered the gold standard for diagnosis of growth hormone deficiency they have a number of limitations and some consider measurement of circulating somatomedins (insulin-like growth factors; IGFs) or their binding proteins to be more useful.[1] Different assays may give different results, and it has been advised that therapeutic decisions should be based on a combination of comprehensive clinical and height assessments, biochemical tests, and radiological evaluation.[2,3]

In children with confirmed growth hormone deficiency replacement therapy is appropriate, and is given by subcutaneous injections of synthetic human growth hormone (somatropin) or its methionyl analogue (somatrem). Treatment improves bone density[4,5] and growth velocity;[6,7] final adult height is also increased but the extent of the benefit is unclear. A cohort study of French children registered to receive growth hormone between 1973 and 1993 suggested that the eventual outcome was not as good as expected, and treated individuals remained short.[8] However, a large American cohort that included more than 11 000 growth-hormone deficient patients found that although treated patients remained below target heights, many did achieve heights within the normal range for chronological age.[9] Maximum growth rates occurred in the first year of treatment and fell progressively thereafter, with no significant difference between growth rates after 4 years compared with pretreatment rates. A further cohort study[10] from the same French register for 1987 to 1996 found that adult heights were similar whether patients completed treatment or stopped before reaching adult height, and that patients with severe growth hormone deficiency may respond better than those with less severe deficiency. Growth hormone treatment regimens have changed over the years, and it appears that with optimal treatment it may be possible for some growth-hormone deficient children to achieve their genetic height potential.[7] An important prognostic factor is age, and for optimum results treatment should be started as early as possible in an attempt to maximise height before the onset of puberty.[2,7]

In patients with multiple pituitary hormone deficiencies, genetic defects in growth hormone synthesis, or severe organic growth hormone deficiency, growth hormone therapy should be continued into adulthood. In other patients, growth hormone deficiency may or may not persist into adult life, and retesting should be done after the patient reaches adult height and after 1 to 3 months without therapy.[2,11] In those patients who need continued treatment, the dose of growth hormone should be gradually reduced in order to maintain IGF-I concentrations within the normal range.[11]

Somatorelin (growth hormone-releasing hormone) or its analogue sermorelin have also been tried to boost growth hormone secretion in patients with growth hormone deficiency. Although there have been reports of improved growth rates, there are limited data directly comparing these with growth hormone. One large study[12] of sermorelin found that, compared with results generally reported for growth hormone therapy, fewer patients responded over a 12-month period and growth responses were poorer. Pralmorelin is a small synthetic growth hormone-releasing peptide that is also under investigation.[13,14]

In patients with Laron dwarfism (growth hormone resistance or insensitivity), conventional growth hormone therapy is ineffective because of defects in the growth hormone receptors. However, replacement therapy with mecasermin, the recombinant form of insulin-like growth factor-I, may be of substantial benefit in the treatment of this disorder.[15]

The use of growth hormone in short stature other than that due to indisputable growth hormone deficiency is controversial. Benefit has been reported from growth hormone therapy in children with chronic renal failure,[16,17] in girls with Turner's syndrome (but see p.2081), in young children (6 months to 3 years of age) with Down's syndrome,[18,19] and in Prader-Willi syndrome[20] (p.2149), all of which are associated with marked growth retardation. However, many commentators see such interventions as essentially cosmetic. The treatment of idiopathic short stature in particular, for which no underlying disorder can be identified, in particular, poses problems as the risks and also the benefits in terms of final height are uncertain.[21] Children who are born small for gestational age usually experience catch-up growth by 2 years of age. In those who do not achieve this, growth hormone therapy can induce catch-up growth and improve childhood height scores; data on adult height are limited, however.[22] Guidelines suggest that therapy is justifiable in chronic renal insufficiency,[3,6,23] Turner's syndrome,[3,6,23] Prader-Willi syndrome,[3,23] and for children born small for gestational age.[3] However, sufficient evidence of benefit is lacking for other disorders including non-growth hormone deficient short stature and growth retardation associated with Down's syndrome, and some[6] consider that growth hormone should not be given to children with constitutional delay of growth. More recently, growth hormone therapy has improved growth rate and height in children with SHOX (short stature homeobox-containing gene) deficiency.[24] Mutations and deletions of the SHOX gene, a gene involved in bone and cartilage formation, are associated with various short stature conditions such as Léri-Weill dyschondrosteosis, and are now understood to play a role in the short stature of Turner's syndrome and in some cases of idiopathic short stature.

Although sex hormones have effects on growth they may also cause premature closure of the epiphyses when given to prepubertal or pubertal children, and this has limited their use. Nonetheless, anabolic drugs such as testosterone and oxandrolone have been used in boys, and oestrogen in girls, who have constitutional delay of growth associated with delayed puberty (see p.2079). Oestrogens are not generally used for growth promotion in girls with Turner's syndrome, but as replacement therapy to promote puberty when a satisfactory height has been reached (see p.2081).

A number of other drugs have been investigated in growth retardation. Clonidine, which can promote growth hormone-releasing hormone release, has been given to children with growth hormone deficiency as well as to short children without proven deficiency, but results have been contradictory and largely unsatisfactory.[25-27] Gonadorelin analogues have also been given with growth hormone to short girls without growth hormone deficiency, in an attempt to slow bone maturation and delay puberty, thereby improving adult height.[28] However, a decrease in bone mineral density may outweigh any modest increase in height.[29] Where growth retardation is associated with zinc deficiency, zinc supplementation may be useful (see p.2000).

ATC — H01AC02.

ATC Vet — QH01AC02.

Description. Somatrem is an analogue of somatropin containing an additional (methionyl) amino-acid residue. It may be produced in bacteria from recombinant DNA.

Sometribove (*BAN*) is methionyl bovine growth hormone.

Sometripor (*BAN*) is methionyl porcine growth hormone.

Somatropin *(BAN, USAN, rINN)* ⊗

CB-311; HGH; Human Growth Hormone; LY-137998; Somatropiini; Somatropina; Somatropinas; Somatropine; Somatropinum; Szomatropin.

$C_{990}H_{1528}N_{262}O_{300}S_7$ = 22 125.

CAS — 12629-01-5.

ATC — H01AC01.

ATC Vet — QH01AC01.

Description. Somatropin is synthetic human growth hormone having the normal structure of the major (22K) component of natural human pituitary growth hormone. It consists of a single polypeptide chain of 191 amino acids with disulfide linkages between positions 53 and 165 and between 182 and 189. For labelling purposes, the name may carry in parentheses an approved code in lower case letters indicative of the method of production: (epr) indicates production by enzymatic conversion of a precursor produced by a bacterium genetically modified by recombinant DNA technology; (rbe) indicates production from bacteria genetically modified by recombinant DNA technology; (rmc) indicates production from genetically engineered and transformed mammalian (mouse) cells.
