Management. Therapy for ARDS is essentially supportive. Mechanical ventilation is necessary in most cases, and circulatory support may require fluids, cardiac inotropes, and vasodilators. Optimum management may include diuretics and fluid restriction provided that cardiac output and oxygen delivery are maintained.[6] Because of the association with sepsis antibacterial therapy may be important, but studies of anti-endotoxin antibodies have produced disappointing results.[3] Improvements in supportive care and mechanical ventilation are considered to have reduced the mortality rate.[1,7] Partial liquid ventilation with perfluorocarbons has been tried, but good evidence to support this intervention is not available.[8]

Numerous drugs have been proposed for the management of ARDS, but, although case reports are often encouraging, none has been conclusively shown to improve mortality in controlled trials,[9] or in systematic review.[10] Corticosteroids do not appear to reduce acute mortality,[3,5] although they may be tried in the later phases of the syndrome (5 or more days from onset) to try to prevent fibroproliferative lung changes.[1,11,12] Good results have been reported with inhaled epoprostenol,[13,14] but these results await confirmation from larger controlled studies.

There is evidence that ketoconazole may prevent development of ARDS in patients considered at risk,[15,16] but it does not appear to be effective as a treatment for ARDS or acute lung injury.[17] Among the drugs that have proved disappointing are acetylcysteine,[18,19] alprostadil,[20,21] and nitric oxide[22] (which may, however, improve oxygenation to some degree). Studies[23,24] of pulmonary surfactants in ARDS have generally shown no survival benefit; however, calfactant significantly decreased mortality when given to infants, children, and adolescents.[25]

A high-fat, low-carbohydrate diet has been advocated for patients with ARDS. Supplementation with eicosapentaenoic acid and gamolenic acid has been reported to benefit oxygenation, but with no significant effect on mortality.[7,12]

Adrenal hyperplasia, congenital

See Congenital Adrenal Hyperplasia, below.

Adrenocortical insufficiency

The major function of the adrenal cortex is the production of glucocorticoid and mineralocorticoid hormones, of which cortisol (hydrocortisone) and aldosterone respectively are the most important. Glucocorticoid production is regulated by the hypothalamic-pituitary-adrenal axis, being stimulated by the release of ACTH (adrenocorticotrophic hormone; corticotropin) from the pituitary, while mineralocorticoid production is primarily controlled by the renin-angiotensin system.

Adrenocortical insufficiency is defined as inadequate production of endogenous corticosteroids. It may be primary (Addison's disease), due to destruction of the adrenal cortex; or secondary, due to hypothalamic or pituitary disease, or corticosteroid therapy which suppresses ACTH release.[1] Diagnosis can be difficult, even with the aid of hormone tests such as the tetracosactide stimulation test.[2]

Clinical manifestations of adrenocortical insufficiency are usually seen once about 90% of the adrenal cortex is destroyed. Weight loss, anorexia, weakness, and fatigue may be accompanied by gastrointestinal symptoms such as abdominal pain, nausea, vomiting, and diarrhoea, as well as electrolyte abnormalities (hyponatraemia, hyperkalaemia), salt craving, and orthostatic hypotension. In acute cases, abdominal pain and rigidity, fever, volume depletion, hypotension, and shock may occur. Hyperpigmentation, especially of skin creases, exposed areas, and scars is a distinguishing feature of primary, but not secondary, insufficiency. Hypoglycaemia is more likely in secondary deficiency due to lack of growth hormone, and failure of other pituitary hormones usually accompanies secondary adrenocortical insufficiency.

Treatment for acute insufficiency should be with intravenous hydrocortisone as the sodium succinate, sodium phosphate or other readily soluble ester: the usual dose is the equivalent of 100 mg every 6 to 8 hours for 24 hours. Volume depletion, dehydration, hypotension and hypoglycaemia should be corrected with intravenous saline and glucose, and precipitating factors, such as infection, should be dealt with appropriately. Provided no complications occur, the dosage of hydrocortisone can be tapered over 4 or 5 days to oral maintenance therapy.

For chronic insufficiency the usual oral dosage of **maintenance** or **replacement therapy** is hydrocortisone 20 to 30 mg, preferably divided unequally, e.g. 30 mg as 20 mg in the morning and 10 mg in the evening, in an attempt to mimic the natural pattern of secretion. Other corticosteroids have been used, including cortisone acetate, prednisolone, prednisone, and dexamethasone, but offer no advantage over hydrocortisone. Patients with primary insufficiency also require additional mineralocorticoid replacement with fludrocortisone, usually in a dose of 100 micrograms daily. Mineralocorticoid replacement is not usually necessary in secondary insufficiency. There has been some evidence of benefit from studies of adjunctive oral use of prasterone, another steroidal compound secreted by the adrenal glands, in patients with primary or secondary adrenal insufficiency.

Corticosteroid cover. An increase in replacement therapy is required during periods of stress. In mild infection, a doubling of the maintenance dose of hydrocortisone may be appropriate but for major infection, or severe stress such as surgery, parenteral therapy is required. It is generally considered safer to overestimate rather than underestimate the appropriate cover. For regimens used to provide cover in patients with secondary insufficiency due to corticosteroid therapy see Uses and Administration of Hydrocortisone, p.1536.

AIDS

For the use of corticosteroids in AIDS patients with pneumocystis pneumonia, see p.1510.

Alopecia

The management of alopecia (p.1577) is often difficult. In alopecia areata intralesional corticosteroids, most commonly triamcinolone, will induce hair growth although they are not suitable when more than 50% of the scalp is involved.[1] Regrowth is confined to the site of injection and therefore patchy, although soon concealed by spontaneous growth from uninjected regions. Some atrophy of the scalp is inevitable. Topical corticosteroids are mostly reported to be ineffective although some consider them beneficial; the use of systemic corticosteroids is controversial, given their adverse effects and a lack of evidence that they alter the long-term prognosis.

1. Meidan VM, Touitou E. Treatments for androgenetic alopecia and alopecia areata: current options and future prospects. *Drugs* 2001; **61:** 53–69.

Anaemias

For the use of corticosteroids in haemolytic anaemias, including cold haemagglutinin disease, see p.1043.

Anaphylaxis

For the use of corticosteroids in the management of anaphylaxis, see p.1205. Intravenous corticosteroids are given after initial treatment with adrenaline as part of the management of anaphylaxis; their effects are delayed, and they are not suited for immediate relief, but early use may help prevent deterioration after primary treatment has been given.

Aspiration syndromes

For a review of the management of aspiration syndromes, including reference to the probable lack of value of corticosteroids, see p.1693.

Asthma

The cornerstones of current asthma therapy, as discussed in more detail on p.1108, are the beta$_2$-adrenoceptor agonists and the corticosteroids. Drug therapy for **chronic asthma** is managed by a stepwise approach. Patients requiring only occasional relief from symptoms may be managed with an inhaled short-acting beta$_2$ agonist as required. An inhaled corticosteroid such as beclometasone dipropionate, budesonide, or fluticasone may be added to therapy if symptomatic relief is needed more than two or three times a week but regular use is important since corticosteroids take several hours to exert an effect in asthma. If control is still inadequate, a long-acting beta$_2$ agonist is added. The dose of inhaled corticosteroid may be increased if further control is needed, and other additional therapies include anti-leukotrienes or theophylline. Severe asthma requires regular bronchodilator therapy as well as high-dose inhaled corticosteroids, while in the most severe cases, regular oral corticosteroids may also be required. A short 'rescue' course of oral corticosteroid may be needed at any stage for an acute exacerbation. Corticosteroids should be used cautiously in children because of possible adverse effects on growth.

Guidelines vary slightly in their definition of low, moderate and high inhaled corticosteroid doses. ***UK*** guidelines use beclometasone dipropionate (p.1516) given via a chlorofluorocarbon (CFC)-containing metered-dose inhaler (MDI) as the reference inhaled corticosteroid. Although now almost phased out, this is the formulation used in most of the evidence-base that supports current asthma management. Adjustments to doses will be required for other formulations and corticosteroids. Differences in CFC-free beclometasone dipropionate formulations available in the UK mean they are not dose equivalent (see Reformulation, under Beclometasone Dipropionate, p.1517).

- For **adults**, doses in the range 200 to 800 micrograms daily of beclometasone dipropionate via a CFC-containing MDI are considered *low* initial doses, with 400 micrograms daily being an appropriate starting dose for most patients
- a dose of 800 micrograms daily is considered *moderate*
- doses greater than 800 up to 2000 micrograms daily are *high*
- For **children** under 12 years, doses in the range 200 to 400 micrograms daily are considered *low* initial doses, with 200 micrograms daily being an appropriate starting dose for most patients
- a dose of 400 micrograms daily is considered *moderate*
- doses of more than 400 up to 800 microgram daily are *high*

The definition in ***global*** guidelines vary slightly.

- For **adults**, doses in the range 200 to 500 micrograms daily of beclometasone dipropionate via a CFC-containing MDI are considered *low* initial doses
- 500 to 1000 micrograms daily are considered *moderate*
- 1000 to 2000 microgram daily doses are *high*
- For **children**, doses in the range 100 to 200 micrograms daily are considered *low* initial doses
- doses from over 200 up to 400 micrograms daily are considered *moderate*
- doses more than 400 micrograms are *high*

In the ***USA*** CFC-containing beclometasone dipropionate MDIs have been phased out and replaced with MDIs containing hydrofluoroalkane (HFA). The recommended US dose of beclometasone dipropionate HFA MDI, relative to a CFC-containing MDI formulation, is lower due to differences in delivery characteristics between the products; however, a definitive comparative therapeutic ratio has not been demonstrated. In addition, doses are given as the amount delivered *from* the mouthpiece in the USA, instead of the amount delivered *into* the mouthpiece. For one product, Qvar (*Teva, USA*), each 100 micrograms of beclometasone dipropionate delivered *into* the mouthpiece equates to 80 micrograms delivered *from* the mouthpiece. Doses in the US guidelines will therefore seem somewhat lower, although in practical terms there is probably little difference.

- For **adults**, US guidelines consider doses in the range 80 to 240 micrograms daily of beclometasone dipropionate via a HFA-containing MDI to be *low* initial doses
- doses greater than 240 up to 480 micrograms daily are considered *moderate*
- doses above 480 micrograms daily are *high*
- For **children** 5 years and over, doses in the range 80 to 160 micrograms daily are considered *low* initial doses
- doses greater than 160 up to 320 micrograms are considered *moderate*
- doses above 320 micrograms are considered *high*

Acute severe asthma (status asthmaticus) is potentially life-threatening and is treated with inhaled oxygen and beta$_2$ agonists, as well as systemic corticosteroids; inhaled ipratropium bromide, and intravenous magnesium sulfate, xanthine, or beta$_2$ agonist may need to be added. Once lung function is stabilised the patient can be discharged on a regimen of oral and inhaled corticosteroids, and bronchodilators.

Behçet's syndrome

Behçet's syndrome (or Behçet's disease) is a recurrent multifocal disorder most prevalent in the Far East and countries of the Mediterranean and Middle East.

The clinical features include oral and genital ulceration, skin lesions, arthritis, vasculitis leading to thromboembolic disorders and aneurysms, ocular lesions (including uveitis, hypopyon, and iridocyclitis leading eventually to blindness), and CNS involvement (meningomyelitis, dementia, extrapyramidal symptoms, and paralysis, sometimes fatal). Gastrointestinal disturbances and involvement of other body systems have been reported. However, the complete gamut of symptoms is unlikely in a single patient, and the disease has been classified into mucocutaneous, arthritic, neurological, and ocular forms depending on the predominant symptoms. Diagnosis can be difficult, but oral ulceration, with recurrent genital ulceration, ocular involvement, and skin lesions or a positive pathergy test are considered the major diagnostic criteria.[1,2]

Treatment of Behçet's syndrome is essentially symptomatic and empirical. Controlled studies are mostly lacking, which has hindered meta-analysis.[3] Where possible, topical treatment of **mucocutaneous** lesions should be attempted before embarking on systemic therapy. Topical application of a potent corticosteroid, such as triamcinolone acetonide, or a tetracycline solution may be tried for oral ulceration.[1,2] Genital ulcers can be treated topically with betamethasone ointment.[2] Sucralfate suspension used topically has also been reported to be effective in oral and genital ulceration,[4] and topical mesalazine has been tried.[5] Systemically, colchicine is reportedly beneficial in the treatment of mucocutaneous lesions,[1,2] although a review failed to find any evidence of benefit from colchicine treatment.[3] Systemic corticosteroids are advocated for severe mucocutaneous disease;[4] oral prednisolone has been given for erythema nodosum.[1,2] Thalidomide is also effective for mucocutaneous symptoms,[2,4] although relapses occur on cessation of therapy. Other drugs with reported efficacy for mucocutaneous symptoms include azathioprine,[4] benzathine benzylpenicillin (sometimes with colchicine),[4] dapsone,[1,2,4,6] interferon alfa,[4,6] levamisole,[4] pentoxifylline,[1] and rebamipide.[4,6]

The use of NSAIDs in the treatment of **arthritis** in patients with Behçet's disease is controversial,[4] although indometacin is used.[2] Colchicine is also used,[2,4] and sulfasalazine may be beneficial in patients who do not respond to NSAIDs.[1] Corticosteroids used with azathioprine are effective,[2,4] as are interferon alfa,[1,2,4] and benzathine benzylpenicillin.[3]

Short courses of intravenous methylprednisolone or high-dose oral prednisolone with subsequent tapering are used in the acute phase of **neurological** involvement, and may be followed by chlorambucil, cyclophosphamide, or methotrexate.[2] Chronic CNS disease is generally resistant to therapy.[2]

Ocular involvement in Behçet's disease leads to blindness in about a quarter of patients.[1,2] For acute attacks of anterior uveitis, topical mydriatics such as tropicamide, or corticosteroid drops may be sufficient. Local injections of corticosteroids are used to treat acute attacks of posterior uveitis, and systemic use may also be required.[2] Oral corticosteroid therapy does not improve visual prognosis, however, and may lead to secondary retinal thrombosis or cataracts;[2] good evidence of its benefit is lacking.[3] Colchicine is used for prophylaxis of both anterior and posterior uveitis;[2] ciclosporin is considered more effective at controlling acute ocular attacks[1] but its efficacy appears to gradually decline.[2,4] Other drugs deemed effective in preventing ocular inflammation include azathioprine,[1-4] chlorambucil,[2,4] and cyclophosphamide.[2,4] There are reports of benefit with benzathine benzylpenicillin, interferon alfa, levamisole, methotrexate, pentoxifylline, sulfasalazine, and thalidomide.[4] Tacrolimus has also been beneficial in cases of refractory uveitis.[1,4] Combinations of the above drugs are also used, such as corticosteroids with immunosuppressants, or corticosteroids with cytotoxics.[4]

In patients with **vasculitis**, arteritis is treated with systemic corticosteroids and cyclophosphamide, either orally or pulsed monthly boluses.[1,2] Deep-vein thrombosis has been treated with anticoagulants, such as warfarin or heparin, but caution is advised in those with pulmonary arteritis because of the risk of potentially fatal haemoptysis,[2] and their use is generally not recommended.[1,4] Aspirin is used with immunosuppressants, particularly azathioprine.[4] Stanozolol has also been used to treat the vascular symptoms of Behçet's disease.

Corticosteroids and sulfasalazine are the main drugs used for **gastrointestinal** lesions;[2] thalidomide has also been beneficial.[1]

Infliximab has been found to reduce acute ocular inflammation,[7] and heal gastrointestinal ulceration;[8] it has also proved effective in controlling neurological manifestations of the disease.[9]

Bell's palsy

Bell's palsy is a condition that may be caused[1,2] by herpes simplex virus 1. It affects the facial nerves and results in facial muscle weakness and paralysis. It is often accompanied by pain and lachrymation. Untreated, over 80% of all patients recover completely or almost so, while in a smaller number facial weakness persists; complete failure of motor recovery is very rare.

Corticosteroids dramatically relieve pain associated with Bell's palsy,[3] and their use in treatment is widely accepted.[4] The suggested oral dose of prednisone for adults is 1 mg/kg daily in divided doses morning and evening; if the paralysis remains incomplete after 5 or 6 days the prednisone is gradually withdrawn over the next 5 days but if the paralysis is complete the initial dosage should be continued for another 10 days and then gradually withdrawn.[3] While a review of 4 studies in 1996 suggested an increased rate of complete recovery with corticosteroid treatment,[5] and others consider treatment to decrease the incidence of permanent facial paralysis,[2] not all studies have shown such benefits.[2,6] The original review included a study in which a large number of patients were lost to follow-up, and a more recent review concluded that available evidence does not show significant benefit from corticosteroid therapy,[6] although their anti-inflammatory effects might prevent nerve damage. There is some suggestion that addition of aciclovir or valaciclovir to corticosteroid treatment may improve outcome,[4,7] although again substantive evidence is lacking.[2,8]

Bites and stings

Corticosteroids (prednisone 100 mg daily) have been recommended for the stabilisation of erythrocyte membranes in the management of systemic envenomation by the brown recluse spider (*Loxosceles reclusa*).[1] They have also been given after stings by some species of scorpion, although their value is not certain.[1] Corticosteroids are considered to have no place in snake venom poisoning.[2] Topical corticosteroids may be useful for mild itching of healing skin after some types of jelly fish sting, while systemic corticosteroids have been used for delayed hypersensitivity reactions.[3]

Bone cysts

Intralesional corticosteroid injection (usually methylprednisolone) has been used as an alternative to surgical or other methods for the treatment of bone cysts.[1-6] An early report indicated that methylprednisolone acetate 40 to 200 mg injected into unicameral bone cysts under brief general anaesthesia stimulated bone formation to obliterate the cyst or promoted sufficient healing to prevent further fractures.[1] A single injection was sufficient for healing in 10 to 25% of cysts; only rarely were more than 4 injections needed. Treatment of an aneurysmal bone cyst with methylprednisolone and calcitonin has also been reported.[7] (Systemic corticosteroids are, of course, generally associated with bone loss rather than bone formation—see Effects on the Bones and Joints, p.1491).

Brain injury

See Spinal Cord and Head Injury, p.1513.

Bronchiolitis

Acute bronchiolitis is usually caused by RSV infection (p.860) in infants and young children, and may contribute to the subsequent development of asthma. Supportive therapy, where necessary, may involve the use of oxygen and bronchodilators (see also p.1134). Numerous studies have failed to show a benefit from corticosteroid therapy, and it has generally been considered that corticosteroids have no role in the management of the condition.[1] Although one study did find that oral prednisolone might be of benefit,[2] it was suggested that the results might be due to inclusion of children with asthma among the study population.[3] A systematic review[4] found little benefit in terms of length of hospital stay or admission rate and no evidence of improvement in clinical scores, respiratory rate, or oxygen saturation when compared with placebo. However, a study[5] found that a 3-day course of oral prednisolone given to children aged 6 to 35 months with respiratory distress reduced disease severity, length of hospital stay, and the duration of symptoms. Inhaled corticosteroids seem to be of little value[6] and a systematic review concluded that they did not prevent post-bronchiolitic wheezing when given during the initial acute phase of bronchiolitis.[7]

Bronchopulmonary dysplasia

Bronchopulmonary dysplasia is the major cause of chronic lung disease (defined as the need for supplementary oxygen more than 28 days after birth) in neonates. It has also been defined as oxygen dependency beyond a corrected gestational age of 36 weeks.[1] It is considered to comprise 4 radiographically distinct stages, of which stage 1 is effectively indistinguishable from neonatal respiratory distress syndrome (see p.1508), with which it is usually associated. A 'bubbly' appearance of the lung is seen in radiographs of advanced disease. Bronchopulmonary dysplasia is invariably associated with prolonged mechanical ventilation, but it is uncertain whether it plays a causative role, or whether the disease develops anyway in infants with respiratory failure severe enough to need prolonged ventilation.[2] Other risk factors include prematurity, low birthweight, pulmonary oedema, inflammation due to infection or other causes, and adrenal insufficiency.[1]

Treatment. Corticosteroids, usually in the form of systemic dexamethasone, have been widely used in premature infants with bronchopulmonary dysplasia,[1] or who are considered to be at high risk of it (the borderline between treatment and prophylaxis in studies in these mechanically ventilated infants is not always clear[3]). Dexamethasone has been reported to improve pulmonary outcome, allowing more rapid weaning from mechanical ventilation, and in some studies was reported to improve neurological outcome as well.[4] However, some investigators consider its benefits in the long term inadequately established.[3,5,6]

There also remains some concern about possible adverse effects of dexamethasone, especially on long-term development.[1,7,8] One meta-analysis suggested that use was associated with a high incidence of cerebral palsy and neurodevelopmental impairment, and should be abandoned.[9] Infants requiring mechanical ventilation and given intravenous dexamethasone or placebo in a trial were followed up about 8 years later. Children in the dexamethasone group were shorter, had smaller head circumferences, poorer motor skills and coordination, lower IQ scores, and a higher frequency of clinically significant disabilities.[10] However, a 15-year follow-up of preterm infants given dexamethasone at 2 weeks of age, showed that those given a 42-day course had significantly better neurological outcomes than those given an 18-day course, or saline placebo.[11]

Many studies have favoured an initial dexamethasone dose of 500 micrograms/kg daily intravenously, tapered over a period of days to weeks, but it is not always clear if this is expressed in terms of the base or one of its esters,[12] and in any case regimens have varied between studies. Despite suggestions that beginning therapy shortly after birth might minimise lung injury, evidence suggests that early therapy offers no advantage,[6,13] and may be more hazardous.[6,8,14-16] Meta-analysis has suggested that while beginning dexamethasone at any time between birth and 14 days of age reduced the risk of chronic lung disease, mortality was only reduced in the group who began treatment between 7 and 14 days of age.[17] However, a subsequent systematic review concluded that the benefits of therapy started between 7 to 14 days may not outweigh the adverse effects.[15]

In an attempt to propose guidelines, a review of the available evidence concluded that there was no role for corticosteroid use in the first 4 days of life and that use should be limited to exceptional clinical circumstances such as ventilator dependency in an infant after the second week of life. When used, the lowest effective dose was recommended for the shortest possible duration; dexamethasone 200 micrograms/kg daily (in two divided doses) for 3 days, then 100 micrograms/kg daily for 3 days, then 50 micrograms/kg daily for 3 days was suggested.[1]

Inhaled corticosteroids have also been investigated. A systematic review did not demonstrate any reduction in the incidence of chronic lung disease or the need for systemic corticosteroids.[18] Another systematic review of controlled studies found that inhaled corticosteroids may improve the rate of extubation in infants.[19]

Additional therapy is essentially supportive, including fluid restriction, nutritional supplementation, bronchodilators, and diuretics. Routine use of bronchodilators for prevention of bronchopulmonary dysplasia is not recommended, and studies of use in treatment are limited.[2] UK guidelines (issued in 1998 but not subsequently updated) considered that diuretics were indicated for episodes of associated cardiac failure but their long-term value was uncertain; if used, consideration should be given to a calcium-sparing regimen.[20] Improved pulmonary status has been reported with furosemide in established dysplasia,[21,22] although routine or sustained use cannot be recommended at present. Results with hydrochlorothiazide and spironolactone are more ambiguous.[23,24] Anaemia in infants with bronchopulmonary dysplasia has benefited from erythropoietin.[25] Although vitamin A deficiency has been implicated in the pathogenesis of bronchopulmonary dysplasia, trials of vitamin A supplementation have produced conflicting results. However, differences in patient population, postnatal therapies, and dosage of vitamin A could explain these results,[26] and some recommend supplementation to reduce the incidence of chronic lung disease.[2,26] Despite promising preliminary results,[27] treatment with alpha$_1$-proteinase inhibitor has not been shown to reduce the incidence of chronic lung disease.[2] Similarly, although there is evidence suggesting that early use of sudismase may reduce development of chronic lung disease (but not bronchopulmonary dysplasia),[28] routine use is not recommended.[2]

Cachexia

For mention of the use of corticosteroids in cancer-related cachexia see under Uses and Administration of Megestrol, p.2115.

Cardiac arrhythmias

Atrial fibrillation (see Cardiac Arrhythmias, p.1160) is common after cardiothoracic surgery, and although it is usually self-limiting, it may be associated with increased morbidity and mortality. Cardiopulmonary bypass used during surgery provokes an inflammatory response that may contribute to atrial fibrillation, and there has been some investigation of the effect of prophylactic corticosteroids. Dexamethasone, hydrocortisone, methylprednisolone, and prednisolone have been tried, in single doses or short courses; studies have been small and results mixed.[1-3] A systematic review[3] of 9 studies found that corticosteroids may reduce the incidence of atrial fibrillation and shorten hospital stay, but the effect may depend on the dose, and larger studies are required.

Cerebral oedema

Corticosteroids (usually dexamethasone) play an important role in the treatment of cerebral oedema caused by malignancy and dexamethasone is advocated for the cerebral oedema associated with high-altitude disorders (see p.1168). The management of raised intracranial pressure and the usual drugs used to treat it are discussed on p.1181.

Corticosteroids have also been used for the management of raised intracranial pressure in patients with head injuries or stroke, but despite earlier small studies showing them to be beneficial in some patients, current opinion is that corticosteroids are not useful in head injuries (see Spinal Cord and Head Injury, p.1513) or stroke, and that their adverse effects may outweigh any possible benefit.

Chronic active hepatitis

Chronic hepatitis is characterised by liver cell necrosis and inflammation that persists for more than 6 to 12 months. Probably the most serious form is chronic active hepatitis in which inflammatory infiltrates (mononuclear and plasma cells) are found within and around the portal areas, with piecemeal necrosis of adjacent liver cells, and in severe cases bands of necrotic tissue between portal tracts or to the central vein (bridging necrosis). Symptoms are essentially non-specific and include fatigue, malaise, fever, anorexia, jaundice, and raised serum aminotransferase values; biopsy is required for accurate diagnosis. The causes of chronic active hepatitis vary and may include: infection with hepatitis viruses; adverse effects of drugs such as isoniazid, methyldopa, or nitrofurantoin; or, particularly in women, an apparently idiopathic form, auto-immune hepatitis.

Treatment with corticosteroids is widely used in patients with auto-immune hepatitis.[1,2] A moderate initial oral dose of 20 to 30 mg of prednisolone or prednisone daily or a higher dose of 60 mg daily may be used,[3-5] and is then slowly tapered over several months to the minimum required for maintenance. Daily maintenance therapy appears more effective than alternate-day regimens. Patients who respond (as shown by a return of serum aminotransferase values to the normal or near normal range and a reduction in the inflammatory processes on biopsy) usually require prolonged treatment; although some patients remain in remission for months to years after withdrawal, relapse generally occurs, and therapy should be reinstated when the disease becomes active again.[1]

Combined treatment including azathioprine is frequently given and may be the preferred initial treatment in some patients;[4,5] such treatment is at least as effective as a corticosteroid alone,[2] can produce[6,7] and maintain[8,9] remission, and permits a reduction in corticosteroid dosage in a group of patients who will require long-term drug treatment.[1] There has been some dispute about the value of azathioprine alone, but combined therapy has generally been found to be superior.[6] However, azathioprine has been used alone in high doses to maintain remission.[5,9]

In contrast to the fairly extensive experience with azathioprine, ciclosporin is little used in this condition; once started it appears to be required indefinitely.[4] It may be an alternative in severe disease where corticosteroids alone or with azathioprine cannot suffice. Mycophenolate mofetil may offer an alternative to azathioprine.[5] Some investigators have also used cyclophosphamide successfully,[3] and tacrolimus has been reported to be of benefit.[10]

Penicillamine has been tried as an alternative to prolonged use of corticosteroid maintenance therapy, the dose of penicillamine being gradually increased over several months to a suitable maintenance dose as the dosage of corticosteroid is tapered off.

It is generally agreed that immunosuppression is not suitable in patients with viral chronic active hepatitis.[11] However, combination therapy has been reported to produce benefit in patients positive for HBsAg,[6] and it has been reported[12] that patients with chronic active hepatitis of unknown cause, at least some of whom may have hepatitis C,[11] respond as well to corticosteroids or combined therapy as patients with proven auto-immune disease. Liver transplantation (p.1815) may be necessary in patients who are refractory to or intolerant of immunosuppressive therapy, and in whom end-stage liver disease develops.[1]

Chronic obstructive pulmonary disease

Corticosteroids play some part in the symptomatic and palliative management of chronic obstructive pulmonary disease (COPD—p.1112), although there is controversy as to their value. It remains to be confirmed whether corticosteroids slow the deterioration rate and improve long-term outcome in COPD, regardless of corticosteroid responsiveness. Some studies have suggested that inhaled corticosteroids might reduce the number of acute exacerbations and slow the decline in lung function,[1-3] whereas others found no, or limited, benefit.[4-7] Some commentators have therefore cautioned against the routine use of corticosteroids in patients with COPD;[8] certain subgroups of patients, however, may benefit from corticosteroid therapy,[8,9] and reviews[10,11] have concluded that inhaled corticosteroids were beneficial in reducing COPD exacerbation rates. Official guidelines generally recommend the use of inhaled corticosteroids in patients with severe disease and repeated exacerbations (see p.1112).

A large randomised study[12] found that combination therapy with fluticasone and salmeterol reduced exacerbation rate compared with placebo, and improved lung function significantly more than treatment with either drug alone. However, there is some uncertainty as to the degree of clinical benefit.[13]

Short courses of systemic corticosteroids are commonly used for acute exacerbations of COPD, despite limited evidence of clinical benefit. However, a systematic review[14] concluded that the benefit from corticosteroid therapy is evident within the first day and lasts for at least 5 days of therapy, although there is no evidence suggesting advantage to courses for longer than 2 weeks. Dose-dependent deleterious effects on bone mineral density may occur.

Churg-Strauss syndrome

The Churg-Strauss syndrome is sometimes classified with polyarteritis nodosa (see p.1510), although, unlike the latter, pulmonary manifestations are relatively common in Churg-Strauss syndrome. Patients commonly have a history of allergic disease (rhinitis, sinusitis, and asthma); intractable asthma and eosinophilia with granulomatous vasculitis characterise the syndrome.

Treatment is similar to that of polyarteritis nodosa, being based on systemic corticosteroids and, where necessary, cyclophosphamide.[1-4] When cyclophosphamide is used, intravenous pulse therapy is often preferred to continuous oral dosage,[2,4] as it has been shown to reduce adverse effects and allows for a lower total dose.[3,4] Substitution of cyclophosphamide with azathioprine or mycophenolate mofetil after 4 to 6 months can also allow for reduced overall doses of cyclophosphamide to be given,[3,4] although azathioprine is not as effective as cyclophosphamide for primary treatment.[3] In patients with haemorrhagic cystitis, there is some suggestion that mycophenolate mofetil may be more effective than azathioprine.[3] Interferon alfa may also be of benefit.[4,5] In patients refractory to corticosteroids and cyclophosphamide, there are reports of benefit with antilymphocyte immunoglobulins or intravenous immunoglobulins.[3]

Cogan's syndrome

Corticosteroids are useful in the treatment of Cogan's syndrome, a condition characterised by non-syphilitic interstitial keratitis and audiovestibular symptoms including deafness.[1-3] The deafness, although often irreversible, may respond to systemic corticosteroids begun within 2 weeks of onset of symptoms (prednisolone or prednisone, at least 1.5 mg/kg daily for 2 weeks is advised) and ocular involvement benefits from topical corticosteroid therapy (e.g. prednisolone 1% at a rate of 1 drop every hour for 1 to 2 weeks).[3] Improvement in ocular symptoms has also been seen with sodium cromoglicate eye drops.[4] For patients with severe Cogan's syndrome including large-vessel vasculitis, corticosteroids have been used with other immunosuppressants such as azathioprine, ciclosporin and cyclophosphamide.[5] Methotrexate has also been tried.[6]

Congenital adrenal hyperplasia

Congenital adrenal hyperplasia comprises a heterogeneous group of disorders due to inherited defects of steroid synthesis in the adrenal gland, the most frequent of which are defects involving 21-hydroxylase or 11-β-hydroxylase. Defective enzyme production blocks the formation of cortisol and aldosterone; the pituitary produces increased amounts of ACTH in an attempt to compensate, but this results in excessive adrenal androgen production. Presentation varies from virilisation and abnormal genital formation at birth to mild cryptic forms that may be detected only later in life. Salt-losing forms (due to lack of aldosterone or the accumulation of precursors with antagonist activity) may lead to hyperkalaemia, acidosis, and dehydration. Patients with 11-β-hydroxylase defect are also prone to hypertension.

Neonates with **salt-losing forms** of congenital adrenal hyperplasia require urgent treatment. Treatment usually consists of a mineralocorticoid, fludrocortisone, and a glucocorticoid (usually hydrocortisone) in regimens similar to those for adrenocortical insufficiency (see p.1498).[1-5] Saline infusion or addition of salt to the feed is required initially.

Even where salt-losing symptoms are not overt or marked, control is reportedly better with a mineralocorticoid added to therapy, rather than with hydrocortisone alone,[4] and it has been recommended that children with salt-losing congenital adrenal hyperplasia should continue to receive combined therapy at least until adult life.[1] Careful titration of dosage is important to avoid growth retardation and toxicity, and potent synthetic glucocorticoids such as betamethasone and dexamethasone may be inappropriate in infants and children with the condition, even in the non-salt-losing form. An alternative approach is the use of flutamide and testolactone to block androgenic effects, with a reduced dose of hydrocortisone.[4,6] However, studies suggest that normal growth is possible with regular glucocorticoid therapy.[7,8]

Patients with **non-salt-losing congenital adrenal hyperplasia** may be adequately managed with glucocorticoids alone, and in mild late-onset forms a single dose daily in the late evening (when its suppressive effect on ACTH production is greatest) may be sufficient. In adults who do not require mineralocorticoid treatment betamethasone or dexamethasone may be useful because of their lack of mineralocorticoid actions.

Surgical correction may be necessary in females with masculinised external genitalia. Giving a glucocorticoid to pregnant women whose offspring are considered at risk has been tried in an attempt to prevent virilisation:[3] dexamethasone is preferred to hydrocortisone because of a lack of placental degradation.[4]

Corneal graft rejection

Corticosteroids are the mainstay of postoperative prophylaxis and treatment of corneal graft rejection.[1] Topical and subconjunctival corticosteroids are widely used, but in acute rejection episodes involving the endothelium systemic therapy is usually necessary. A single 500-mg intravenous pulse of methylprednisolone appears to be as effective as up to 2 weeks of treatment with oral prednisolone 60 to 80 mg daily for the management of severe endothelial rejection.[2] However, another study found that addition of a single intravenous pulse of 500 mg methylprednisolone to local corticosteroid treatment with betamethasone and dexamethasone gave no benefit over local therapy alone.[3]

In high-risk patients corticosteroids alone provide insufficient immunosuppression and systemic immunosuppression has been tried, although the evidence base is limited,[1] mainly relating to the use of ciclosporin, and with inconsistent results. Mycophenolate mofetil has also been tried,[1,4] and has been reported to be as effective as ciclosporin in preventing acute rejection after high-risk corneal transplantation.[4] However, because most patients are healthy and transplantation is not life-saving, the risks of systemic immunosuppression may be hard to justify.[1] Topical ciclosporin has also been investigated.[5]

Corticosteroids have also been used to reduce inflammation after corneal reconstruction using tissue engineered from autologous oral mucosal epithelium.[6]

For discussions of the role of corticosteroids in other forms of organ and tissue grafting, see Organ and Tissue Transplantation, p.1810.

Croup

Croup is an acute childhood syndrome of upper respiratory tract inflammation (laryngotracheobronchitis) associated with viral infection, usually by parainfluenza virus although other viruses may also produce the syndrome. It is characterised by harsh, barking cough, stridor, and hoarseness, most usually occurring at night.[1-3]

Traditional home management has revolved around the inhalation of steam, despite a lack of evidence for effectiveness, but symptoms may be sufficiently alarming to result in presentation to a hospital.

In severe croup there is clear evidence that treatment with a systemic corticosteroid reduces symptoms and decreases the need for intubation.[4-6] Oral dexamethasone is as effective as intramuscular,[7] and while dexamethasone 600 micrograms/kg is commonly prescribed, lower doses of 300 micrograms/kg and 150 micrograms/kg appear to be equally effective.[2] Nebulised budesonide has also been reported to be effective,[8-10] and of similar efficacy to inhalation of nebulised adrenaline.[11] However despite the theoretical attraction of this route, studies have failed to find any significant difference in effectiveness between nebulised budesonide 2 mg and oral dexamethasone 600 micrograms/kg,[12] or combination therapy with both,[13] and another study found 600 micrograms/kg of dexamethasone given intramuscularly to be more effective than 4 mg of nebulised budesonide.[14] In contrast, others have found that addition of nebulised budesonide to oral dexamethasone produced more rapid improvement than the latter alone.[15] Studies have also shown a significant benefit from corticosteroids in children with mild to moderate croup,[12,16-18] and although the use of such potent drugs in children with a mild, largely self-limiting condition has been questioned,[19] a review of the risks and benefits concluded that oral dexamethasone 150 micrograms/kg, or nebulised budesonide 2 mg were the treatment of choice in mild to moderate croup while oral prednisolone 1 mg/kg should be given for croup requiring intubation.[1] However, nebulised adrenaline is probably the initial drug of choice where rapid relief of obstructive symptoms is required.[2,3] Oxygen is given to those children with upper airway obstruction and significant oxygen desaturation.[3] Heliox, a mixture of helium and oxygen, may be used as adjunctive therapy to glucocorticoids, for short-term treatment of refractory croup.[2]

Cystic fibrosis

Corticosteroids have been used orally or by inhalation in the management of the inflammatory response of the lungs in cystic fibrosis (see p.166) but do not form part of standard management.

Deafness

For references to the use of corticosteroids in the treatment of deafness associated with Cogan's syndrome, see above.

Dermatomyositis

For references to the treatment of dermatomyositis with corticosteroids, see Polymyositis and Dermatomyositis, p.1510.

Diffuse parenchymal lung disease

Diffuse parenchymal lung disease (DPLD; interstitial lung disease) represents a large and heterogeneous group of inflammatory disorders that have in common a thickening of the interstitial walls between alveoli. In some cases, particularly in the early stages, this is due to accumulation of inflammatory cells in the interstitium, and control of inflammation can reverse the changes; however, when fibrotic changes to the alveolar walls take place these are usually irreversible. The causes of chronic DPLD are numerous and include pneumoconioses due to inhalation of inorganic dusts (as in asbestosis and silicosis); extrinsic allergic alveolitis due to inhalation of, usually, organic antigens (as in farmers' lung, bird fanciers' lung, and many similar occupational disorders); cryptogenic fibrosing alveolitis (idiopathic pulmonary fibrosis); adverse effects of drugs such as bleomycin; sarcoidosis; lung disease associated with collagen vascular disorders such as rheumatoid arthritis and SLE, or with the vasculitides; histiocytic syndromes; and pulmonary eosinophilic syndromes. Cryptogenic fibrosing alveolitis (below) and sarcoidosis (p.1512) are probably the most common chronic DPLDs.[1]

The symptoms of DPLD are usually insidious and non-specific, and may include dyspnoea of varying severity, usually first noticed on exertion, cough, and fatigue; fine crackling sounds (rales) on breathing and finger clubbing occur in some forms. If the disease progresses, respiratory failure becomes more severe, and eventually may prove fatal.

Where a causative agent can be identified, initial treatment is to prevent exposure but where inflammation persists, or where the causation is uncertain, corticosteroids are the mainstay of treatment (despite a lack of controlled trials for efficacy),[2] in an attempt to control inflammation and preserve as much normal tissue as possible. The management of cryptogenic fibrosing alveolitis is discussed in more detail below.

Cryptogenic fibrosing alveolitis (idiopathic pulmonary fibrosis) is a form of DPLD of uncertain origin, associated with alveolitis and thickening of the interstitial walls by oedema, cellular exudate, and fibrosis. The clinical course is variable but the mean survival is only 3 to 5 years.[3] Cryptogenic fibrosing alveolitis itself appears to represent a spectrum of disorders; some have advocated that usual interstitial pneumonia (the most common form) should be distinguished from forms such as non-specific, or desquamative interstitial pneumonia, or cryptogenic organising pneumonia (bronchiolitis obliterans organising pneumonia), which differ in prognosis and may respond better to corticosteroid therapy.[4-9]

Treatment of cryptogenic fibrosing alveolitis is highly controversial, with no proven benefit from conventional therapy with corticosteroids, immunosuppressants, and cytotoxics.[9] The British[1] and American[8] Thoracic Societies have recommended that where therapy is considered appropriate initial treatment should be with oral prednisone or prednisolone 500 micrograms/kg daily plus azathioprine. Azathioprine may be used alone where corticosteroid therapy is problematic, or cyclophosphamide may be given with the corticosteroid if azathioprine is not tolerated. About 50% of patients with cryptogenic fibrosing alveolitis show a symptomatic response to corticosteroids and about 25% show an improvement in lung function.[1] However, in the absence of placebo-controlled trials there is no clear evidence that treatment improves survival.[1,7,9] Survival does seem to be improved after treatment with corticosteroids plus azathioprine, compared with corticosteroids alone.[1] It should also be borne in mind that patients defined as having cryptogenic fibrosing alveolitis are a heterogeneous group, with some forms appearing to respond better to treatment than others, which makes comparison of studies difficult.[5] If the condition stabilises, the dose of corticosteroid may be reduced gradually for maintenance. Corticosteroid therapy is usually continued lifelong; attempts at withdrawal should be gradual and cautious. Relapse or clinical deterioration may warrant an increased dose of corticosteroid, or addition of an immunosuppressant.[8]

Many other drugs have been tried in patients with cryptogenic fibrosing alveolitis.[1,5,8-11] Ciclosporin has been used adjunctively and also as a corticosteroid-sparing treatment;[11] some benefit has been reported,[1] but data are too limited to support its use.[8,9,11] Colchicine has been suggested to be as effective as corticosteroids, and some consider it for first-line therapy or for patients refractory to corticosteroids, either alone or with immunosuppressants.[8] However, studies have generally shown no evidence of survival benefit, and others do not recommend its use.[9] There are reports of response to penicillamine, but controlled studies are lacking, and in view of its adverse effects, its use is generally not recommended.[8,9,11] Toxicity has limited the use of chlorambucil and methotrexate,[8] and there is no evidence to support the use of vincristine or mercaptopurine.[11] Despite promising preliminary results, a controlled trial of interferon gamma found no significant effects on mortality compared with placebo.[9] Early trials of pirfenidone have shown improvements in pulmonary function;[9] further studies are underway. Acetylcysteine is also under investigation.[9,12] Experimental strategies include the use of relaxin, suramin, endothelin-1 inhibitors, angiotensin II receptor antagonists, and gene therapy.[8,9,11]

In patients in whom other options fail, lung transplantation (p.1815) should be considered.[1,5,8,10,11]

Eaton-Lambert myasthenic syndrome

Corticosteroids have been tried in the treatment of Eaton-Lambert myasthenic syndrome (p.629).

Eczema

Topical corticosteroids have an important role in the management of atopic eczema (p.1579). The least potent preparation that is effective should be used, combined with regular use of an emollient; in mild to moderate disease the topical corticosteroid is only given for 1 to 2 weeks at a time. Most patients with mild to moderate eczema respond to treatment with a mildly potent preparation such as 1% hydrocortisone ointment. For older children and adults with refractory disease, a more potent topical corticosteroid should be considered for long enough to bring the disease under control, followed by a weaker preparation as the condition improves.

The use of systemic corticosteroids is a treatment of last resort in resistant severe eczema, usually for short periods to control the disease, and very rarely for maintenance.

Epidermolysis bullosa

High-dose oral corticosteroids may be tried to control blistering in severe forms of epidermolysis bullosa (p.1579).

Epilepsy

Corticosteroids and corticotropin have been commonly used to treat **infantile spasms,** which are generally unresponsive to conventional antiepileptics. There is, however, limited evidence for the efficacy of oral corticosteroids.[1] Corticotropin appears to be effective for short-term treatment, and one study[2] indicated that high-dose corticotropin was preferable to prednisone, but the optimum dose and duration of therapy have not been determined.[1,3] In addition, corticotropin and corticosteroids are associated with frequent and severe adverse effects, and as discussed on p.465, some now prefer newer antiepileptics such as vigabatrin. A short-term study of infants with spasms of non-tuberous sclerosis origin found that tetracosactide or prednisolone were superior to vigabatrin.[4] However, vigabatrin is preferred for the treatment of spasms due to tuberous sclerosis,[3,4] and data are insufficient for recommendations regarding the use of any drug to improve the long-term outcome of children with infantile spasms.[1,3]

Erythema multiforme

In the management of erythema multiforme (p.1580) systemic corticosteroids may be considered in severe reactions but there has been controversy about their value.

Giant cell arteritis

Giant cell arteritis (temporal arteritis; cranial arteritis) is a vasculitic disorder that is frequently associated with polymyalgia rheumatica (p.1510). It occurs mainly in persons over 50 years of age of European, particularly Scandinavian, extraction and is more common in women than men. It is characterised by inflammatory, granulomatous lesions with giant mononuclear cell infiltrates affecting large and medium sized arteries, particularly those supplying the neck and extracranial structures of head and arms. Symptoms vary but may include headache, scalp tenderness, claudication of the jaw, swelling and absence of pulse in the temporal artery, fever, weight loss, malaise, anaemia, visual disturbances, and irreversible blindness. About a third of all patients also exhibit polymyalgia rheumatica.

Treatment is with corticosteroids,[1-8] and early diagnosis and treatment is desirable to reduce the risk of sudden blindness. Most regimens have involved high initial doses of corticosteroid to control the disease followed by reduction to a maintenance dose, but both initial and maintenance doses have varied considerably. Prednisone or prednisolone 40 to 60 mg daily by mouth initially is generally considered adequate in uncomplicated cases without visual symptoms;[1,4-6] this can then be reduced gradually according to the patient's response. Some, however, recommend[3] lower initial doses of about 20 mg daily.

While it is suggested that patients presenting with visual symptoms should receive 80 mg daily or 1 mg/kg daily of prednisone or prednisolone,[3,7,8] some ophthalmologists[9] recommend that all patients with giant cell arteritis receive these doses, as visual loss may be sudden and profound. Initial 1-g doses of pulsed intravenous methylprednisolone have also been used.[2,5,8,9]

Maintenance treatment is usually required and while a small number require indefinite treatment, most patients should be able to stop treatment within 5 years; however, relapses are not uncommon.[7]

Because of the need for prolonged corticosteroid therapy, adverse effects are common,[7] and their management difficult. Azathioprine has been added to corticosteroid therapy for its modest 'steroid-sparing' effect,[10] whereas results with methotrexate have been conflicting.[4,6,11] Other immunosuppressants have been tried,[4,6] but are not routinely used. Dapsone has been reported to be of benefit, but its use is limited by haematological toxicity.[4] Infliximab has been tried.[8]

The prognosis is excellent in adequately-treated patients, as the life expectancy of patients with giant cell arteritis is the same as the general population.[12]

Glomerular kidney disease

Glomerular disease accounts for a considerable proportion of all kidney disease. Various forms of primary glomerular disease (glomerulopathy) are known, and are discussed below; in addition, numerous systemic diseases (connective tissue disorders such as SLE as well as malignancy and conditions such as diabetes), may result in secondary glomerular disorders. Despite the various potential causes it is thought that many of these diseases act by common immunological mechanisms to damage the glomerulus, either by accumulation of antigen-antibody complexes (immune-complex nephritis) or more rarely by the formation of antibodies to the glomerular basement membrane (anti-GBM nephritis).[1]

Since the kidney can respond in only a limited number of ways to glomerular damage, certain common presentations are seen regardless of aetiology, including **acute glomerulonephritis** (acute nephritis syndrome), which is marked by haematuria and proteinuria of abrupt onset, usually with renal impairment (a decrease in glomerular filtration rate), salt and water retention, and hypertension; and the **nephrotic syndrome**, which is marked by severe proteinuria, hypoalbuminaemia, and oedema. Other, less dramatic presentations of glomerular disease are asymptomatic proteinuria or microscopic haematuria; alternatively, glomerular disease may be one of the many potential causes of chronic renal failure. Appropriate management of these conditions depends to a considerable extent on the underlying disease.

• MANAGEMENT OF PRIMARY GLOMERULAR DISEASE.

Minimal change nephropathy (MCN; minimal change disease). This condition occurs mainly in children, the highest incidence being at 2 to 4 years, and is the main cause of childhood nephrotic syndrome. It also accounts for about 20% of adult cases of nephrotic syndrome.[2] It is treated with a corticosteroid. Regimens vary somewhat but a suggested oral regimen for adults has been 60 mg prednisolone daily for 4 days, reduced to 40 mg daily until remission occurs (which in 90% of patients will be within 3 weeks) and then tapered off.[2] In children, initial doses of 60 mg/m^2 of prednisolone or prednisone daily have been used,[3] which may be given for 4 weeks before switching to 40 mg/m^2 given on alternate days for a further 4 weeks, and then tapered off.[4] Lower relapse rates have been reported with 60 mg/m^2 prednisone given daily for 6 weeks, followed by 40 mg/m^2 on alternate days for 6 weeks; this 12-week course may be preferable to the standard 8-week course.[3] A modification to the children's dose is to give 60 mg/m^2 of prednisolone daily until there is a response when the dose is reduced to 40 mg/m^2 on alternate days for the next 4 weeks. If there is no response within 4 weeks of treatment with the 60 mg/m^2 dose then the drug should be withdrawn and the child considered to be corticosteroid resistant.[5] A systematic review of treatment regimens found that children with their first episode of nephropathy should be treated with prednisone for at least 3 months, and possibly up to 7, to reduce the risk of relapse.[6]

Relapse is common and occurs in about 60% of cases; relapses usually respond to a further course of corticosteroids, but if a third relapse occurs cyclophosphamide 2 to 3 mg/kg daily for 8 to 12 weeks may be added to a course of corticosteroid therapy.[2,3] Deflazacort may also be effective in corticosteroid-sensitive patients who do not respond to prednisone.[6] Cytotoxics or immunosuppressants are reserved for frequently relapsing or corticosteroid-dependent cases because of their potential for severe toxicity, including carcinogenesis; cyclophosphamide appears to be preferred to chlorambucil because it is perceived as entailing a somewhat lower risk, although both are effective.[3,7] Ciclosporin has been used long-term to achieve and maintain remission, although renal biopsies are advised to screen for nephrotoxicity.[3,7] Levamisole has also been reported to be of benefit.[3,7]

Focal glomerulosclerosis. Focal glomerulosclerosis is a sclerosing lesion affecting parts of the glomeruli which occurs in some patients who otherwise have symptoms characteristic of minimal change nephropathy, and some authorities do not regard it as a distinct disease. It is common in abusers of diamorphine and has also been linked with the nephropathy that can occur in patients with AIDS. Treatment is similar to that for minimal change nephropathy but only about 20% of cases respond to corticosteroids; addition of a cytotoxic immunosuppressant such as cyclophosphamide may improve the prospect of remission. Responses to ciclosporin have been seen in both adults and children with corticosteroid-resistant disease.[3,8] Prolonged treatment may be necessary and relapse is common when ciclosporin is stopped.[7] Tacrolimus has been reported to be successful after ciclosporin failure,[3,8] and mycophenolate mofetil has been tried with conflicting results.[8] High-dose pulsed methylprednisolone, given in a tapering schedule over 6 years, has been reported to show high response rates in focal glomerulosclerosis.[3] In patients who fail to respond, progression to renal failure may occur over several years, but renal transplantation may not be helpful as disease can recur in the transplanted kidney.

Membranous nephropathy (membranous glomerulonephritis). This is a disease mainly of adults, in whom it is the single most important cause of the nephrotic syndrome, accounting for about 50% of cases. It is characterised by diffuse thickening of the glomerular basement membrane after subepithelial deposition of immune complexes. The course of disease is variable and often slow, with some spontaneous remissions, which makes the benefits of treatment difficult to demonstrate and the use of potentially toxic drugs difficult to justify. Cyclophosphamide or chlorambucil combined with a corticosteroid appear to produce some clinical improvement, and stabilisation of progressive disease, but corticosteroids alone do not appear to be of benefit.[9-11] Cyclophosphamide may be preferred as it seems to be better tolerated.[11] Ciclosporin is an alternative but therapy may need to be continued for 6 months or more before remission occurs[9,10] and a systematic review found it to be no better than placebo.[11] Other immunosuppressants under investigation in this condition include mycophenolate mofetil[10] and rituximab. Recent studies have also emphasised the control of blood pressure and proteinuria using ACE inhibitors and angiotensin II receptor antagonists.[10]

Mesangiocapillary glomerulonephritis (MCGN; membranoproliferative glomerulonephritis; MPGN). Mesangiocapillary glomerulonephritis comprises 2 separate diseases, known as type I and type II, which both occur in children and young adults and usually result in nephrotic syndrome, although about 20% of cases present with acute glomerulonephritis. Both forms show proliferation of mesangial cells and thickening of glomerular walls with formation of deposits (in type I disease due to immune complexes) in capillary walls and basement membranes. There is no established treatment regimen: some improvement or stabilisation of renal function may occur with corticosteroids and cytotoxic immunosuppressants, but about half of all patients develop end-stage renal failure within 15 to 20 years (type I disease) or 6 to 10 years (type II disease). Antiplatelet drugs and anticoagulants have also been tried but as with other therapies there is little evidence of benefit, and some centres do not recommend any specific therapy, although prednisolone and cyclophosphamide may be offered to those with a rapidly progressive course.[12]

IgA nephropathy (Berger's disease) is the commonest cause of primary glomerular disease, and is most common in young men. It results in focal, segmental proliferative glomerulonephritis associated with mesangial formation of immune deposits largely composed of IgA. The usual presentation is acute glomerulonephritis with gross haematuria, often during or just after viral upper-respiratory-tract infection. Some patients develop rapidly progressive disease similar to idiopathic rapidly progressive glomerulonephritis, with renal failure within 6 months, but in many others the syndrome is benign, and requires only observation. No form of therapy has been unequivocally shown to be of value, but control of associated hypertension, usually with ACE inhibitors, is considered important. Corticosteroids and cytotoxic immunosuppressants may be tried in severe rapidly progressive disease.[13-17] Promising results have been seen with the use of n-3 fatty acids from fish oil, and there are also reports of benefit with normal immunoglobulin, and mycophenolate mofetil.[16]

Idiopathic rapidly progressive glomerulonephritis (RPGN). Although rapidly progressive glomerulonephritis (crescentic glomerulonephritis) may be a feature of other forms of glomerular disease such as IgA nephropathy (see above) or Goodpasture's syndrome (see below) it also occurs in an idiopathic form. The disease is characterised by the formation of glomerular crescents associated with leakage of fibrin from damaged capillaries, and loss of renal function is very rapid, sometimes with renal failure within weeks. Oral corticosteroids are of little value alone, but pulsed intravenous methylprednisolone followed by oral prednisone or prednisone and cyclophosphamide over several months has produced some impressive responses;[18,19] an alternative is the use of intensive plasma exchange with a corticosteroid and cytotoxic immunosuppressants.[20] Controlled trials of these therapies are mostly lacking, although a small prospective study[21] found lymphocytapheresis to be more effective than pulsed methylprednisolone as an addition to prednisolone and cyclophosphamide therapy for reduction of glomerular injury.

Goodpasture's syndrome. Goodpasture's syndrome is a form of anti-GBM nephritis in which rapidly progressive glomerulonephritis is accompanied by pulmonary haemorrhage (because the antibody responsible for the renal symptoms also reacts with the membranes of the alveoli). It is a disease mainly of young males. Pulmonary haemorrhage responds to high dose oral prednisolone or prednisone, or pulsed intravenous methylprednisolone, but corticosteroids are of little value in controlling renal lesions, which requires vigorous plasma exchange therapy with corticosteroids and cyclophosphamide on a daily or alternate-day basis for several weeks, until antibody is no longer detectable and disease progression has halted; it is important to begin therapy before renal damage becomes irreversible.[22]

• MANAGEMENT OF SECONDARY GLOMERULAR DISEASE.

Post-infectious glomerulonephritis. The classical form of post-infectious glomerulonephritis is post-streptococcal glomerulonephritis, which produces an immune-complex-mediated acute glomerulonephritis, but glomerular disease may follow other bacterial infections, as well as protozoal infections such as malaria (malaria-associated nephrotic syndrome is familiar in endemic regions) and viral infections such as AIDS (see Focal Glomerulosclerosis, above). In most cases no additional treatment beyond appropriate management of infection and general supportive care is warranted, and corticosteroids and cytotoxic immunosuppressants are not generally used and may in some cases be harmful.[23] Nonetheless, delayed progressive renal disease may occur in a minority of patients, and has prompted efforts to treat.[22]

Other secondary glomerulopathies. Where glomerular disease is secondary to other diseases (connective tissue disorders such as SLE, the vasculitides, Henoch-Schönlein purpura, thrombotic thrombocytopenic purpura, or others such as rheumatoid arthritis, amyloidosis, neoplasia, sickle-cell disease, gout, or diabetes mellitus) most treatment is directed at the underlying disease. In addition, symptomatic management such as the use of sodium restriction for the oedema of nephrotic syndrome may be appropriate; diuretics should be used cautiously because of the risk of hypovolaemia.[24] Proteinuria of various causes may respond to the use of ACE inhibitors or NSAIDs,[2,24] although care is required in patients with renal artery stenosis or renal failure respectively. Associated hypertension and hypercholesterolaemia should be treated, and anticoagulants such as heparin may be required for associated coagulation disorders.[24] Renal toxicity can arise from various drug treatments and this should also be treated symptomatically.

Graves' ophthalmopathy

Patients with moderate to severe ophthalmopathy as a result of hyperthyroidism (p.2165) may be treated with corticosteroids or with orbital radiotherapy. There is evidence of a synergistic effect when these therapies are combined. If orbital radiotherapy is contra-indicated, glucocorticoids may be combined with ciclosporin. There is some suggestion that intravenous pulse therapy is more effective than oral glucocorticoids.[1] Giving a corticosteroid with radioiodine therapy may prevent transient exacerbation of Graves' ophthalmopathy.[2]

Haemangioma

Haemangiomas are benign vascular neoplasms of the skin that may enlarge dramatically before regressing spontaneously. Although no treatment is normally required, occasional complications due to ocular or visceral involvement, or associated thrombocytopenia due to platelet trapping (the Kasabach-Merritt syndrome), may merit treatment, generally with corticosteroids. Oral prednisone or prednisolone is usually given; intravenous high-dose methylprednisolone has been used for life-threatening haemangiomas.[1] Response is variable.[1-3] Another common technique is intralesional injection of a mixture of triamcinolone with betamethasone.[4] There has been a report of 2 infants responding to vincristine after corticosteroids had failed.[5] Interferon alfa has been used for corticosteroid-refractory lesions.[1] Phototherapy with a pulsed dye laser has also been reported to be effective;[6] a randomised study of this method found no benefit compared with observation only,[7] but treatment is still recommended by some[8] for problematic lesions.

Headache

Corticosteroids have a limited role in the management of some types of headache. Although their long-term use is not considered desirable, short courses of prednisolone or prednisone in doses of 20 to 40 mg daily can be an effective alternative to standard drugs such as ergotamine in the prevention of cluster headache attacks during cluster periods (p.616). Corticosteroids have also been used for the emergency treatment of prolonged severe attacks of migraine (status migrainosus) (p.616) refractory to other drugs.

Herpes infections

Although corticosteroids alone are contra-indicated for most forms of ocular herpes simplex infection (p.854), which should be treated with a topical antiviral, a combination of corticosteroid and antiviral may be indicated for herpes simplex stromal keratitis. For discussion of the use of corticosteroids in Bell's palsy, which may be associated with herpes simplex virus, see p.1499, and for discussion of their role in postherpetic neuralgia, see p.9.

Hypercalcaemia

For a description of the treatment of hypercalcaemia, including the specific role of corticosteroids, see p.1668, and p.1083.

Hypersensitivity vasculitis

Hypersensitivity vasculitis is usually associated with an antigenic stimulus, either exogenous (e.g. a drug[1] or microbe), or endogenous (e.g. an immune complex associated with connective tissue disease). The term covers a heterogeneous group of disorders, many of which are associated with some underlying disease process (including infections, malignant neoplasms and disorders such as rheumatoid arthritis or SLE), as well as vasculitis of less clear aetiology such as Henoch-Schönlein purpura, a disease typically seen in prepubertal males. There is a suggestion that such a broad grouping is inappropriate, and that the term 'hypersensitivity vasculitis' should not be used;[2] however, it continues to be found in the literature.

Hypersensitivity vasculitis is characterised by small vessel involvement (arterioles and venules), particularly of the skin, and skin manifestations such as purpura, rashes, and urticaria predominate. Neutrophil debris is typically present around the vessel (**leucocytoclastic vasculitis**). However other organ systems may also be involved: in **Henoch-Schönlein purpura**, the skin lesions are associated with arthralgia, abdominal pain and other gastrointestinal symptoms, and glomerulonephritis.[3] Although not always immediately apparent, renal impairment may be delayed, and progress to end-stage renal failure.[4]

The prognosis is typically much better in hypersensitivity vasculitis than in the other major vasculitic syndromes, and most cases resolve spontaneously. Where a recognised antigenic stimulus is present it should be removed if possible, e.g. by withdrawal of a drug[1] or by appropriate therapy of infection. Hypersensitivity vasculitis generally responds less well to conventional drug therapy than other vasculitic syndromes. Nonetheless, where disease persists or results in organ dysfunction, a corticosteroid should be given, typically oral prednisone or prednisolone 60 mg, or 1 mg/kg daily, tapered rapidly until therapy can be stopped. Plasmapheresis has also been used, but the use of cytotoxic immunosuppressants is less well established. However azathioprine[4] and cyclophosphamide[5] have been used successfully with corticosteroids. Anecdotal reports of excellent responses to dapsone in Henoch-Schönlein purpura exist.[6] Other drugs that have been tried include danazol,[7] pentoxifylline,[8] the latter sometimes with dapsone,[8] and normal immunoglobulin.[9]

Idiopathic thrombocytopenic purpura

Idiopathic thrombocytopenic purpura (ITP; sometimes referred to as auto-immune thrombocytopenic purpura[1]) is an auto-immune bleeding disorder characterised by the development of antibodies to the body's own platelets, with consequent sequestration and destruction of platelets. Both acute and chronic forms are seen; the acute form, which is usually self-limiting and follows viral or other infection, is the usual form in children, whereas chronic and sometimes more serious disease is more likely in adults, particularly young or middle-aged women. Patients develop petechiae, ecchymoses, and epistaxis, and women may develop menorrhagia; death due to haemorrhage is not unknown.

Treatment. For both adults and children with mild thrombocytopenia (counts of 20 000 to 30 000 cells/mm^3 or more) and no severe bruising or haemorrhage, no treatment is required.[2-8] American guidelines[7] recommend treatment for children with platelet counts below 10 000 cells/mm^3 and minor bruising; British guidelines[6] recommend that clinical severity also be considered before treating, as even pronounced bruising does not necessarily indicate a serious bleeding risk. In many cases the platelet count will return to normal or remain in a safe range despite the lack of therapy, and spontaneous remission can occur, even after a period of years.[9]

Where treatment is required in chronic disease, corticosteroids are the mainstay of therapy in adults.[8,10,11] Prednisolone or prednisone 1 mg/kg daily is used, usually for 2 to 4 weeks,[6,7] and then tapered down.[6,8] Most responses occur within the first 3 weeks, but there is no consensus as to appropriate duration of treatment.[5,11] Response rates vary widely, but most patients will relapse when the drug is withdrawn.[6] Good responses have also been reported with the use of high-dose oral or intravenous methylprednisolone for 3 to 7 days.[12-15] This has also been tried in children with the acute form[16] although controlled studies in children[17] and adults[18] found intravenous normal immunoglobulin to be more effective. Pulsed high-dose dexamethasone at 40 mg daily for 4 days has produced promising results,[3,19,20] although it is not clear how great the benefits will be in children.[21-23]

Use of corticosteroids for acute or chronic ITP in children is in any case controversial. Some consider low daily doses of prednisolone (250 micrograms/kg daily for 21 days) to be effective, while others have used high doses (prednisone 4 mg/kg daily for 7 days, then tapered).[6,7] Generally, lower doses of prednisone or prednisolone 1 to 2 mg/kg daily should not be used for longer than 2 to 3 weeks in children with ITP, and higher doses of 4 mg/kg daily are to be used for a maximum of 4 to 7 days, and tapered off as necessary.[6,7] Some centres consider that corticosteroids are of at best temporary benefit in children.[24]

In patients with chronic disease and symptoms of bleeding who fail to respond to first-line therapy, splenectomy should be considered.[2,3,5-8,10,24] About 70% of patients will respond but the operative and postoperative risks (notably of sepsis) must be considered, particularly in children.

Responses can also be achieved with intravenous normal immunoglobulin, which in practice is often preferred to corticosteroids for initial drug therapy of acute ITP in children,[4,25] and appears to be more effective in increasing platelet counts.[26] Although the effect may be transient, an increase in platelet count is achievable with doses of 400 mg/kg daily for 5 days;[6,7] single doses of 800 mg/kg or 1 g/kg are equally effective. Response is often achievable even in patients refractory to other therapies,[2,3] but treatment must be repeated periodically. It is perhaps most useful when acute symptoms supervene, because of its rapid activity, and it is recommended that it be reserved for patients with acute severe bleeding, as pre-operative prophylaxis in patients with severe thrombocytopenia, or for patients with bleeding symptoms refractory to corticosteroids.[2,3,6-8] A response to normal immunoglobulin has been reported to be a good predictor of benefit from splenectomy.[27,28] An alternative to normal immunoglobulin in rhesus-positive patients may be the use of anti-D immunoglobulin,[4,5,8,29] although there are conflicting views as to its effectiveness,[10,29-33] and it has been associated with haemoglobinuria and haemoglobinaemia.[34]

Other second-line drugs have been tried in the minority of patients with refractory chronic disease, but few have been well evaluated. Generally,[35-39] but not universally,[8,40] good results have been reported with danazol, particularly in older patients. Since response may be delayed, therapy should be continued for at least 6 months, and preferably for 1 year if no adverse effects occur.[8]It may have advantages for long-term maintenance, and is a potential alternative to splenectomy, at least in selected patients.[37,38] It can be used as a 'steroid-sparing' drug, permitting reduction in corticosteroid maintenance doses.[5,37] Dapsone may also elicit responses in patients with chronic ITP,[41] but is less effective in severe cases.[6]

Antineoplastic and immunosuppressive drugs have been tried in refractory disease, but their potential toxicity has meant that they have often been reserved for older patients, as a treatment of last resort. Oral cyclophosphamide 1 to 2 mg/kg or azathioprine 1 to 4 mg/kg have been given daily[5,8] to adults; responses to cyclophosphamide generally occur within 8 weeks but for azathioprine several months of treatment is generally necessary before response can be assessed.[3,6] High-dose cyclophosphamide has also been tried in refractory, life-threatening disease.[3] Although some patients have responded to intravenous injection of vincristine, responses have tended to be partial and inadequate, and somewhat better results have been achieved with infusions of platelets incubated with vinblastine or vincristine to encourage binding and permit selective drug delivery to the macrophages responsible for platelet destruction.[42-44] Although the developers of this technique have reported long-lasting remission in 38% of patients,[44] enthusiasm elsewhere appears to be muted.[5,45] Combination chemotherapy (cyclophosphamide and prednisone plus vincristine, vincristine and procarbazine, or etoposide) has produced prolonged remission in a few patients,[3,8,46,47] but such aggressive treatment would be difficult to justify in most cases. Ciclosporin may be a reasonable salvage treatment in refractory ITP,[8,48] and mycophenolate mofetil has been reported to be of benefit in small numbers of patients.[6] Rituximab[49,50] may also be a useful alternative, and alemtuzumab has been well tolerated.[6]

Other reports of benefit exist for colchicine,[51-53] heparin,[54] and ascorbic acid,[55] the latter having at least the advantage that it is relatively non-toxic, but such therapies remain experimental.

Thrombopoietin may offer a future new approach to treatment.[5,8,56] Other compounds that stimulate platelet production are also under investigation, including eltrombopag[57] and romiplostim,[58] which act on the thrombopoietin receptor.

Tranexamic acid may be helpful in the symptomatic management of menorrhagia, although hysterectomy is occasionally necessary.

In pregnancy. Particular problems arise in the management of ITP in pregnancy, since antiplatelet antibodies can cross the placenta and produce thrombocytopenia in the fetus. The risk is greater when disease exists before pregnancy than when it develops in the course of pregnancy.

If therapy is considered necessary the mother may be given corticosteroids or normal immunoglobulin, with platelet infusions for more serious, unresponsive symptoms.[6,7] Treatment may be required for the neonate[5] if there are complications or the platelet count falls below 30 000 cells/mm^3. The risk of intracranial haemorrhage is not necessarily reduced by caesarean section,[5] and the mode of delivery should be determined by obstetric indications.[6]

Infections

Although long-term corticosteroid therapy has an adverse effect on the body's response to infection (see Effects on Immune Response, under Adverse Effects, p.1492), the judicious use of corticosteroids, usually on a short-term basis, with appropriate anti-infective drugs, may have a beneficial effect on the symptoms of selected acute infections, and may on occasions be life-saving. Guidelines have been published concerning a number of infections and whether corticosteroids should be used or not.[1]

For further comment on the use of corticosteroids in ocular herpes infections, infectious mononucleosis, leishmaniasis, leprosy, meningitis, pneumocystis pneumonia in AIDS patients, septic shock, and tuberculosis, see under the relevant headings in this section.

1. McGowan JE, *et al.* Report by the Working Group on Steroid Use, Antimicrobial Agents Committee, Infectious Diseases Society of America: Guidelines for the use of systemic glucocorticoids in the management of selected infections. *J Infect Dis* 1992; **165:** 1–13.

Infectious mononucleosis

Discussions on the use of corticosteroids in infectious mononucleosis (glandular fever—see Epstein-Barr Virus Infections, p.854) usually consider that although all cases would respond promptly to therapy, only patients with an unduly prolonged infection and those with an exceptionally severe sore throat that interferes with respiratory function should be treated with a corticosteroid.[1,2] Some may consider using corticosteroids in patients with aplastic anaemia, thrombocytopenia, haemolytic anaemia, encephalitis, pericarditis, or myocarditis associated with infection by the Epstein-Barr virus. The corticosteroid used, dosage, route, and duration of treatment is variable. Dexamethasone, methylprednisolone, and prednisolone have all been tried in infectious mononucleosis. While corticosteroid treatment is considered relatively safe in infectious mononucleosis, impaired immunity might theoretically increase the risk of Epstein-Barr virus-related tumours in later life.

Inflammatory bowel disease

Corticosteroids with aminosalicylates form the mainstay of treatment for active ulcerative colitis and Crohn's disease (see Inflammatory Bowel Disease, p.1697). In moderate to severe acute disease systemic corticosteroids are indicated for initial management, either orally or in the most severe cases intravenously. Doses are high initially and are gradually reduced as symptoms resolve. In patients with disease confined to the distal colon or rectum, local topical therapy with suppositories, rectal foams, or enemas of corticosteroids may be appropriate. Oral or rectal formulations of poorly absorbed or rapidly metabolised corticosteroids such as beclometasone, budesonide, or tixocortol have been developed in the hope of producing local improvement without systemic effects.

Leishmaniasis

Corticosteroids may be required to control severe inflammation in patients with mucocutaneous leishmaniasis (p.824), although pentavalent antimony is usually the drug used for initial treatment.

Leprosy

Type I lepra (reversal) reactions in patients with leprosy (p.176) frequently respond to high-dose corticosteroids (for example 40 to 60 mg of prednisolone daily) started immediately and given for several days.[1] Doses may be reduced over several weeks or months. Corticosteroids may also be used for type II reactions.

It has been considered that corticosteroid treatment of nerve function impairment should be started within 6 months of onset, as the earlier that treatment was started, the more likely it was that function would be restored. A standardised regimen in which the usual adult dose was 40 mg daily of prednisolone for 4 weeks, tapered over the next 12 weeks, has been reported to be successful in the field management of acute nerve function impairment,[2] as has a regimen consisting of 30 mg of prednisone for 2 weeks tapered down with a minimum duration of 10 weeks.[3] However, a subsequent study[4] in patients with mild nerve impairment for less than 6 months, and another in patients with established sensory impairment[5] both failed to show any benefit from a tapered corticosteroid regimen. There was evidence that sensory impairment may undergo some degree of spontaneous recovery, which casts doubt on previous reports of benefit from uncontrolled studies of corticosteroids. The use of a lower dose prophylactic regimen has also been studied, starting with prednisolone 20 mg daily for 3 months then tapering in the fourth month.[6] Although the incidence of new leprosy-related reactions and associated nerve function impairment in all patients was reduced during corticosteroid treatment, there appeared to be a rebound after this was stopped and the initial beneficial effect was not sustained at 1 year. Interestingly, however, subgroup analysis suggested that existing nerve function impairment at diagnosis may affect the outcome; after 4 months of prophylaxis, a significant reduction in acute reactions or new nerve function impairment was seen only in those without initial evidence of impairment although, as before, this was not sustained.

Lichen

Lichen planus (p.1580) is generally controlled with corticosteroids applied topically or, occasionally, injected intralesionally; systemic corticosteroids (usually prednisone or prednisolone) are used for severe erosive lichen planus, generalised cutaneous disease, and acute exacerbations.[1,2] Prednisone has generally been used in oral doses of 30 to 60 mg daily, for courses of 4 to 6 weeks.[1] Shorter courses may be of value: prednisolone (30 mg daily for 10 days) was reported to be effective and safe for mild or moderately severe lichen planus.[3]

The use of topically applied corticosteroids in the treatment of lichen sclerosus (p.1580) has been discussed.[4,5] Relief from vulvar pruritus is obtained in most cases with a potent corticosteroid preparation, such as clobetasol propionate, applied twice daily for up to 3 months before tapering the dose.[4]

Liver disorders

Corticosteroids are considered to be useful in chronic active hepatitis (p.1501). There is some disagreement over the benefit from corticosteroid therapy in alcoholic liver disease with hepatic encephalopathy,[1-4] and they do not appear to be of benefit in acute hepatic failure.[5] Corticosteroid therapy may however be of benefit in sclerosing cholangitis.[6]

No treatment has proven unequivocally successful in the management of primary biliary cirrhosis (p.2408). Corticosteroids are one of a number of drugs for which reports of benefit exist, but their use has been restricted as they may exacerbate bone disease.

Male infertility

Immunosuppressive treatment with corticosteroids has been given for male infertility (p.2080) due to low-grade auto-immune orchitis.[1] Corticosteroids have also been used in men with autoantibodies to spermatozoa. Various regimens have been tried, such as giving the man a corticosteroid for a set number of days during the partner's menstrual cycle, or giving a continuous low-dose for several months.[2] However, there is a lack of evidence of benefit from substantial controlled trials and the use of corticosteroids is not generally recommended. They might, however, be considered for men with autoantibodies who have failed assisted reproductive techniques.[1]

2. Lombardo F, *et al.* Antisperm immunity in natural and assisted reproduction. *Hum Reprod Update* 2001; **7:** 450–6.

Malignant neoplasms

Corticosteroids are extensively prescribed in malignant disease for the relief of pain, nerve compression, or raised intracranial pressure; to alleviate dyspnoea, effusion, or hypercalcaemia; to counteract adverse effects of other therapies such as antineoplastic-induced nausea and vomiting or radiation-induced inflammation; and in the management of cachexia and to improve mood and sense of well-being.[1] In addition they form an important part of multidrug anticancer regimens used for various haematological malignancies such as acute lymphoblastic leukaemia (p.651) and Hodgkin's disease (p.655). In contrast, it has been postulated that the use of corticosteroids in patients with solid, non-haematological tumours might induce resistance in cancer cells to cytotoxic therapy, and increase the risk of treatment failure, although clinical evidence for this is lacking.[2]

1. Twycross R. The risks and benefits of corticosteroids in advanced cancer. *Drug Safety* 1994; **11:** 163–78.
2. Rutz HP. Effects of corticosteroid use on treatment of solid tumours. *Lancet* 2002; **360:** 1969–70.

Meningitis

Corticosteroids may be given as adjuncts to antibacterial therapy in bacterial meningitis (p.178), in the hope of moderating any neurological sequelae; there is some evidence that dexamethasone, especially if given early, may reduce the risk of deafness in children and reduce mortality in adults.

Mouth ulceration

Local treatment of mouth ulcers (p.1700) often involves a topical corticosteroid for symptomatic relief. Systemic corticosteroids have occasionally been given where there is severe underlying disease.

Multiple sclerosis

Corticosteroids are often used in the management of multiple sclerosis (p.892). Corticosteroid therapy reduces the duration of the relapse and accelerates recovery, but it is not known whether it alters the course of the disease in the long term.[1,2] Methylprednisolone has superseded corticotropin and prednisolone as the drug of choice. Methylprednisolone is usually given intravenously in high doses (typically 1 g daily) for 3 to 5 days, sometimes followed by a tapering dose of oral prednisolone. Doses of up to 2 g of methylprednisolone daily have been tried.[3] In patients with acute optic neuritis (frequently the first manifestation of multiple sclerosis), methylprednisolone delayed the onset of other symptoms of multiple sclerosis[4] although the effect was not sustained beyond 2 years.[5] Beneficial responses have also been reported with oral methylprednisolone at doses including 500 mg once daily for 5 days followed by a tapering dose over 10 days[6] and 48 mg once daily for 7 days followed by a tapering dose over 14 days.[7]

In patients with primary progressive disease, the benefits of short-course methylprednisolone lasted no longer than 3 months[8] although, in patients with secondary progressive disease, a preliminary study has suggested that progression may be delayed by intermittent high-dose methylprednisolone therapy.[9]

Muscular dystrophies

Muscular dystrophies are a range of inherited myopathies in which there is progressive degeneration of muscle fibres and associated muscle weakness. They may be classified according to the mode of inheritance. The most common type is the fatal recessive X-linked **Duchenne muscular dystrophy** (DMD) in which there is a deficiency in the structural muscle protein dystrophin. There is no effective therapy that affects the ultimate outcome of the various muscular dystrophies. Management is mainly through the use of physiotherapy, supports, and surgery. Drug treatment has been tried for symptomatic management, but generally the number of patients studied has been small. However, corticosteroids have been shown to be effective in increasing muscle strength and function in children for 6 months to 2 years;[1] prednisone or prednisolone 750 micrograms/kg daily is considered to be the most effective dose,[1-3] with gradual tapering to doses as low as 300 micrograms/kg daily if necessary.[2] Improvement does not appear to be sustained to the same degree with alternate-day therapy;[4] some benefit in terms of motor function preservation has been reported with intermittent prednisone (750 micrograms/kg daily for 10 days of each month).[5] Benefit has also been seen with deflazacort[1-3,6] in doses of 900 micrograms/kg daily. It has been suggested that the failure of azathioprine to produce any beneficial effect when used alone or added to prednisone treatment might indicate that prednisone's effectiveness is not due to immunosuppression.[7] There have also been reports of benefit in small numbers of patients given ciclosporin or oxandrolone; evidence to support the use of most other drugs (e.g. allopurinol) is either conflicting or unconvincing. A small trial found that supplementation with creatine monohydrate (100 micrograms/kg daily) significantly increased handgrip strength in the dominant hand compared with placebo; results were independent of corticosteroid use.[8] Future prospects for treatment include gene therapy, haematopoietic stem-cell therapy, or upregulation of the protein utrophin (related to dystrophin) to try to ameliorate the dystrophy.[9,10]

Myasthenia gravis

Corticosteroids are the main immunosuppressants used in the management of myasthenia gravis (p.629).

Nasal polyps

Nasal polyps[1-3] are outgrowths of the nasal mucosa, typically pale, smooth, translucent, and round or pear-shaped. They are often associated with a history of rhinitis or asthma; the triad of nasal polyps, asthma, and hypersensitivity to aspirin may occur. Patients typically present with obstruction, loss of smell, and often rhinorrhoea and postnasal drip.

Corticosteroids are extremely effective in reducing polyp size, either by the intranasal[4,5] or systemic route.[5] In the former case beginning with betamethasone sodium phosphate nasal drops, and then maintaining the reduction with an intranasal spray such as beclometasone, budesonide, or fluticasone, has been suggested.[1] Alternatively prednisone, prednisolone, or dexamethasone can be given orally: suggested regimens have included prednisone 60 mg daily, tapered over 10 or 14 days and followed by intranasal corticosteroids,[2] or dexamethasone 12, 8, and 4 mg daily, each for 3 days.[1] Surgery may be necessary where there is marked obstruction, and most patients require it at some point,[1] although polyps usually recur. Pre-operative use of systemic corticosteroids may help reduce recurrence.[2] Continued use of topical corticosteroids may reduce the frequency of relapses.[4] Antibacterials may be indicated for superimposed bacterial infection. Antihistamines, although not extensively studied, have been reported to be of benefit in nasal obstruction. Leukotriene antagonists have shown promising results, although large-scale trials are lacking; they may be indicated in patients with aspirin hypersensitivity.[5]

Nausea and vomiting

Corticosteroids, usually in the form of dexamethasone, play an important role in antiemetic regimens (see p.1700) used to combat the effects of moderately to severely emetogenic cancer chemotherapy: they have been shown to enhance the effects of both metoclopramide- and 5-HT_3 antagonist-based regimens. Dexamethasone is a well-established treatment for delayed emesis. It is also used in palliative care and in the prophylaxis of postoperative nausea and vomiting. A study of corticosteroid treatment in refractory hyperemesis gravidarum showed improvements in appetite, weight gain, and well-being, and suggested that corticosteroids might improve nausea and vomiting but was too small to provide conclusive evidence.[1]

1. Nelson-Piercy C, *et al.* Randomised, double-blind, placebo-controlled trial of corticosteroids for the treatment of hyperemesis gravidarum. *Br J Obstet Gynaecol* 2001; **108:** 9–15.

Neonatal intraventricular haemorrhage

For the suggestion that antenatal corticosteroids may reduce the incidence of intraventricular haemorrhage in neonates, see p.1050.

Neonatal respiratory distress syndrome

Neonatal respiratory distress syndrome is a condition of increasing respiratory distress occurring at, or shortly after, birth. It is marked by cyanosis, tachypnoea, expiratory grunting and sternal retraction. Symptoms increase in severity with progressive collapse of the lung (atelectasis), leakage of plasma into alveolar spaces, and the formation of hyaline membranes, until death occurs or slow recovery takes place from about the 2nd to 4th day. The syndrome affects primarily premature infants and its incidence increases with the degree of prematurity; severe problems are most likely in those delivered before 30 weeks of gestation. Symptoms are thought to be at least partly due to inadequate amounts of surfactant in the premature lung resulting in high internal surface tension and increased risk of alveolar collapse, but in very immature infants other factors, possibly including impaired sodium and fluid absorption from the lung, may play a role.[1]

Treatment. The optimum treatment is prevention, and previous[2] and more recent[3] UK guidelines recommend betamethasone 12 mg daily by intramuscular injection for 2 days in women in whom delivery before 34 weeks of gestation is likely. Similar recommendations apply elsewhere. In the USA, for example, antenatal corticosteroid treatment (with betamethasone or dexamethasone) is recommended for women between 24 and 34 weeks of pregnancy who show signs of premature delivery.[4] Results from a large trial suggest that babies born after 37 weeks by elective caesarean section also benefit from antenatal betamethasone.[5] Betamethasone may be preferable to dexamethasone, as the latter appears to have a deleterious effect on neurodevelopment.[6] Long-term follow-up of those exposed antenatally to betamethasone showed no deleterious effects on psychological functioning[7] or on cardiovascular risk factors;[8] however, small increases in insulin resistance, albeit clinically insignificant, were noted in those exposed to the glucocorticoid. An overview of studies of antenatal corticosteroid therapy suggests that it may reduce the risk of respiratory distress syndrome by about 50% overall;[9] the risk of death, and of periventricular haemorrhage and necrotising enterocolitis is also reduced. Whether repeat courses should be considered is uncertain, although the practice has become widespread. A systematic review[10] indicated that repeat doses did reduce the occurrence and severity of neonatal lung disease and risk of serious health problems in the first few weeks of life. However, these benefits were associated with a reduction in some measures of weight and head circumference at birth and there was insufficient evidence on the long-term benefits and risks. Some have recommended that repeat doses be restricted to patients in clinical studies.[6,11] While repeat doses of corticosteroids may reduce the development of severe respiratory distress syndrome, especially among neonates of less than 28 weeks of gestation, weekly courses of betamethasone or dexamethasone did not reduce neonatal morbidity compared with a single course of treatment.[12] Delaying delivery with a tocolytic (see Premature Labour, p.2003) may be considered to increase the time available for management with antenatal corticosteroids.[2,3] Reported benefit from adding protirelin to antenatal corticosteroids has not been borne out by 2 large multicentre studies.[13-15] The earlier of these studies actually found neonatal outcome and maternal morbidity to be worse in those who also received protirelin,[13,14] but this conclusion has been questioned.[16,17]

In infants born with the syndrome rapid supportive care is required, which may include correction of metabolic acidosis, circulatory support, oxygen supplementation, and assisted ventilation, although there has been a lack of consensus about the most appropriate method for these.[2] Ventilation using a helium-oxygen mixture may give better results than a nitrogen-oxygen mix.[18] Another alternative is the use of partial liquid ventilation with the fluorocarbon compound perflubron.[19] Meta-analysis suggests that inhaled nitric oxide improves outcomes in infants born at or near term who are hypoxaemic,[20] but evidence of benefit in preterm infants has not been shown.[21] The majority of infants survive the acute episode with careful management, although associated complications may subsequently develop, including bronchopulmonary dysplasia (p.1500), retinopathy of prematurity (p.1994), and cerebral palsy. There is evidence that supplementation with inositol can significantly reduce the incidence of adverse outcomes in preterm infants.[22]

Since deficiency of surfactant is considered to play an important role in the neonatal respiratory distress syndrome, the use of surfactant replacement therapy has been intensively investigated, and is now accepted as reducing the risk of death from the disease and the development of pneumothorax and other lung complications.[2,23,24] Both natural and synthetic surfactants have been used and although both are effective results have tended to be better with the preparations of natural origin.[25-27] Natural surfactants of differing origins may also vary in their properties: poractant,[28] or calfactant,[29] have both been reported to give better responses than beractant. Surfactant is given as a suspension by endotracheal tube directly into the infant's lung, although other devices, such as nebulisers, have been investigated. Most surfactants are given in recommended doses of 100 to 200 mg/kg phospholipids. Repeat doses may be given if necessary, and a meta-analysis[30] of data from two randomised controlled trials using preparations of natural surfactant extract in neonates with established disease found a more favourable clinical outcome, including a decreased risk of pneumothorax, with multiple rather than single doses. However, in clinical practice the number of doses and the dosage interval varies. One large study[31] found that a dose of 100 mg/kg, repeated twice, was as effective as 200 mg/kg followed by up to four further doses of 100 mg/kg. Another found that 3 doses, given at 12-hour intervals with the first dose shortly after birth were more effective than the first dose alone in improving physiological findings and mortality rates in low birth-weight infants.[32] One large multicentre randomised controlled trial[33] investigated the difference between giving repeat doses of a surfactant (calfactant) at a low threshold of respiratory support, as recommended by the manufacturer, versus a higher threshold. The conclusion was that efficacy was not compromised by delaying surfactant re-treatment in infants with uncomplicated respiratory distress syndrome until they had reached a higher level of respiratory support than is currently recommended, but infants with complications should continue to be treated by the currently recommended low-threshold strategy.

There has been debate whether 'prophylactic' early therapy, given immediately after birth to all infants deemed at risk of the syndrome, or delayed therapy given 2 or more hours after birth to intubated infants who have developed symptoms, is the more appropriate,[34] but the large OSIRIS study,[35] and later systematic reviews,[36-38] found in favour of early intervention, and this strategy is recommended in the UK guidelines.[2,3]

Optic neuropathies

Causes of optic neuropathies are diverse, and they may be classified by their aetiology.[1,2] Ischaemic optic neuropathies, of which the acute anterior form is most common, may be caused by vasculitic syndromes (p.1515) such as giant cell arteritis (p.1503).[3] Inflammatory optic neuropathies (optic neuritis) may be caused by infectious disease, immune-mediated disorders such as Behçet's disease (p.1499), sarcoidosis (p.1512), or demyelination of the optic nerve such as occurs with multiple sclerosis (p.892).[4,5] Other causes include hereditary disorders, trauma, or compression. Vitamin or nutritional deficiency (often due to alcohol abuse) or toxicity (due to drugs such as amiodarone, digoxin, or isoniazid) may also lead to optic neuropathy.[1,2] Clinical features such as pattern of visual field loss and pain can aid diagnosis.[2]

Management will depend on the type of neuropathy and any underlying disease. Individual studies have reported benefit with corticosteroids. Improvement in vision was reported in patients with auto-immune optic neuropathy after 5 to 7 days of treatment with high doses of intravenous methylprednisolone (1 to 2 g daily) or oral prednisolone (80 to 400 mg daily).[6] In some patients, recurrent visual loss required repeated high-dose intravenous methylprednisolone, an increase in oral prednisolone dosage, or additional immunosuppressants, but in many patients visual benefits were maintained even when treatment was withdrawn. Visual recovery has also been reported in patients with optic neuritis of unknown aetiology given intravenous methylprednisolone 250 or 500 mg every 6 hours for 3 to 7 days.[7] Another study found oral prednisone alone (1 mg/kg daily for 14 days) to be ineffective whereas intravenous methylprednisolone (1 g daily for 3 days) followed by oral prednisone (1 mg/kg daily for 11 days) was beneficial in the treatment of acute optic neuritis.[8] A review of corticosteroid use in optic neuritis concluded that high-dose oral or parenteral methylprednisolone, or corticotropin, were of value in the treatment of acute disease. However, their long-term benefit could not be determined.[9] In contrast, a systematic review of 5 studies found no evidence of benefit from intravenous or oral corticosteroid therapy at the doses used.[10]

Organ and tissue transplantation

For a discussion of organ and tissue transplantation, including the role of corticosteroids, see p.1810.

Osteoarthritis

Systemic corticosteroids are not considered to have a place in the management of osteoarthritis (p.11); however, intra-articular injection may be useful for acute exacerbations of joint pain and inflammation. Such injections should be given only infrequently and as adjunctive therapy.

Osteopetrosis

Osteopetrosis is a rare set of heterogeneous disorders characterised by an increase in bone density, generally due to a failure of the osteoclasts to resorb mineralised bone. In the severe infantile malignant form there is reduction in the bone marrow space, leading to anaemia, hepatosplenomegaly, and nerve compression that may produce blindness and deafness; early death often results. The adult form is benign; patients typically present with fractures, back and bone pain, but no haematological abnormalities, and generally have a full life expectancy.[1]

Bone marrow transplantation may be curative for the infantile malignant form if a suitable donor can be found.[1,2] Corticosteroids are used palliatively. Benefit has been reported in 3 of 4 children treated with oral prednisone 1 mg/kg daily, with phosphate supplements and a low-calcium diet.[3] Some patients have also benefited from the use of high-dose calcitriol, again with a low-calcium diet.[4]

Another study, in 14 patients, found that treatment with interferon gamma-1b increased bone resorption.[5] In 11 who received this treatment for 18 months there was stabilisation or improvement in clinical condition and a reduction in the frequency of serious infection.

Pain

Corticosteroids have produced improvement, often substantial, in neuropathic pain, including pain due to nerve damage and sympathetically maintained pain, and are widely used in conditions such as cancer pain. Dexamethasone, methylprednisolone, and prednisolone have been used for pain management, sometimes in the form of long-acting depot injections administered locally. The exact mechanism of action of corticosteroids in analgesia is not clear but may involve relief of pressure on nervous tissue by reduction of inflammation and oedema.

For discussions of pain and its management, see p.2.

Pancreatitis

Corticosteroids are generally ineffective for pancreatitis (p.2361), but a response has been reported[1,2] in patients with acute episodes caused by sarcoidosis (p.1512).

Pemphigus and pemphigoid

Systemic corticosteroids are the mainstay of management of pemphigus and pemphigoid (p.1582). Initially, high doses are used to control blistering, which may take weeks. The optimum dose has not yet been established and suggestions have varied enormously; very high doses of oral prednisolone have been used in the past. The usual starting dose for widespread disease is about 1 mg/kg daily of prednisolone, continued until new blisters stop forming, then gradually decreased. However, doses above 750 micrograms/kg daily may have no additional benefit in bullous pemphigoid, and lower starting doses have been suggested for some patients: 300 micrograms/kg daily in localised or mild disease, 600 micrograms/kg daily in moderate disease, and 0.75 to 1 mg/kg daily in severe disease.[1] Doses of 40 to 60 mg daily for mild pemphigus vulgaris and 60 to 100 mg daily for more severe disease have been recommended.[2] Pulsed intravenous corticosteroids such as methylprednisolone (250 to 1000 mg given for up to 5 consecutive days) may be considered for severe or refractory disease, particularly if there has been no response to high oral doses.[2] Other immunosuppressants may be added once remission is achieved and the condition has stabilised, with the aim of tapering the corticosteroid and eventually withdrawing treatment. Maintenance treatment must be individualised; one suggested regimen for tapering the corticosteroid is to reduce the dose of prednisolone by 50% every 2 weeks; alternatively, the dose is reduced by 5 to 10 mg weekly then more slowly below 20 mg daily.[2]

A very potent topical corticosteroid such as clobetasol propionate can be sufficient to control localised or mild to moderate disease in some patients, particularly in bullous pemphigoid, and can be a useful adjunct to systemic treatment in pemphigus and pemphigoid.[1,2] A large randomised study[3] found that topical application of 40 g of clobetasol propionate cream 0.05% daily to the entire body had a similar efficacy to oral prednisone 500 micrograms/kg daily for moderate bullous pemphigoid and was better than 1 mg/kg daily for severe disease. Blistering and ulceration of the oral mucous membranes may be treated with topical corticosteroid preparations such as mouthwashes, adhesive pastes, lozenges, or aerosols.[2,4] Intralesional injections have also been used for isolated lesions of the oral mucosa.[4] Topical corticosteroids do not control ocular disease on their own but may be added to initial systemic therapy to control acute ocular inflammation; they should not be used as long-term therapy.[5]

Pneumocystis pneumonia

The management of pneumocystis pneumonia (p.521) is primarily with co-trimoxazole. In patients with severe infection who are hypoxic, adjuvant therapy with high-dose oral or intravenous corticosteroids reduces both the risk of respiratory failure and the risk of death.[1,2] Concerns about the potential for further immunosuppression with such adjuvant therapy in patients with HIV infection[3] do not seem to have been borne out: a comparative study noted no increase in mortality or the risk of developing other opportunistic infections.[4]

Polyarteritis nodosa and microscopic polyangiitis

Polyarteritis nodosa is considered the prototype of systemic necrotising vasculitis. It may occur at any age but is more common in white patients and in men. It is characterised by inflammation throughout the arterial wall with fibrinoid necrosis of the arterial media, particularly in medium-sized vessels, partial occlusion of the vessel due to proliferation of the intima (possibly leading to thrombosis and infarction), fibrosis, and the formation of aneurysms. Microscopic polyangiitis, in which small vessels are primarily involved, with frequent renal and pulmonary involvement, has been seen as part of the spectrum of polyarteritis nodosa but is now considered an entity in its own right, although patients may have features of both. Antineutrophil cytoplasmic antibodies (ANCA) are common in patients with microscopic polyangiitis, which has many similarities to Wegener's granulomatosis (p.1515), but not in classic polyarteritis nodosa.

Symptoms depend on the vessels affected but most patients have fever, weight loss, myalgia, and arthralgia. Those associated with gastrointestinal involvement include mouth ulceration, diarrhoea, visceral pain, haemorrhage, or sometimes infarction of the bowel, while involvement of liver can lead to hepatomegaly or hepatic necrosis and pancreatic involvement may simulate pancreatitis. Renal involvement may present as acute glomerulonephritis and renal failure or as nephrotic syndrome; like pulmonary involvement it is a feature particularly of microscopic polyangiitis, and associated with a poor prognosis. Skin lesions, peripheral neuropathies, alterations in mental function, convulsions, episcleritis or scleritis and retinal vasculitis, ischaemic heart disease, heart failure, Raynaud's phenomenon, and hypertension are among other potential symptoms. If untreated, death, usually due to renal or cardiac involvement, occurs in about 90% of patients within 5 years.

Classic polyarteritis nodosa may respond to treatment with a corticosteroid given alone, typically prednisone or prednisolone in a dose of 40 to 60 mg daily; however, although the benefits of adding a cytotoxic to the regimen have been queried,[1,2] a combined regimen with cyclophosphamide is often preferred.[1,3-5] Some reserve combined therapy for patients with evidence of more severe disease.[6] In patients with microscopic polyangiitis a combined regimen is recommended.[6,7] One suggested oral regimen is prednisone or prednisolone 1 mg/kg with cyclophosphamide 2 mg/kg, both daily, for initial induction of remission.[8] Pulsed intravenous methylprednisolone has also been used, followed by a tapering dose of corticosteroid. There is a trend towards giving shorter courses of cyclophosphamide, and to using intravenous pulsed cyclophosphamide rather than oral dosage, in an attempt to reduce adverse effects.[5,8,9] Treatment with corticosteroids and cyclophosphamide should not exceed 1 year.[9] Azathioprine has been substituted for cyclophosphamide to maintain remission, and mycophenolate mofetil has been tried in a few patients as an alternative to cyclophosphamide in combination therapy after initial induction.[6,10]

Polyarteritis nodosa may be associated with hepatitis B infection; the vasculitis responds in most cases to treatment with antiviral drugs and plasma exchange.[3,9] Prolonged treatment with corticosteroids and cyclophosphamide should be avoided in these patients because of the risks of enhanced viral replication. However, corticosteroids may be given initially to rapidly control severe life-threatening vasculitis. The corticosteroid is stopped abruptly after 2 weeks to enhance immunological clearance of hepatocytes infected by hepatitis B virus and to favour seroconversion, and plasma exchange and antiviral drug therapy are started.[5]

Plasma exchange with cyclophosphamide may also be useful in patients with microscopic polyangiitis, particularly those with acute renal failure or severe pulmonary haemorrhage.[7] Another therapy that has been tried in this group, but with ambiguous results, is high dose intravenous normal immunoglobulin.[8]

Vasodilators such as calcium-channel blockers, inhibitors of platelet activation, or drugs that improve blood flow may be useful to improve local ischaemia.[11] Skin lesions in a patient with cutaneous polyarteritis nodosa have reportedly responded to oral pentoxifylline.[12]

Polychondritis

Relapsing polychondritis is a rare systemic disease that results in inflammation and destruction of cartilage in various parts of the body, most seriously in the respiratory system (e.g. nose, larynx, and trachea). Airway narrowing and obstruction due to loss of cartilaginous support results, and may be complicated by pneumonia; fatalities have resulted. Cardiovascular involvement, ocular manifestations, skin disorders, and renal disease may occur; it may also be associated with other diseases such as the vasculitic syndromes. Mild inflammation is usually treated with dapsone, colchicine, or NSAIDs. Relatively high doses of corticosteroid may improve symptoms in active disease, but do not appear to retard progression. Acute airway obstruction may be treated with high-dose intravenous pulse corticosteroids.[1,2] Methotrexate,[3] azathioprine,[1] or ciclosporin[2] may be of value in reducing corticosteroid requirements. CD4 antibodies have also been tried in refractory disease but did not prove particularly useful in clinical practice.[2] Newer biological therapies such as infliximab or etanercept have been reported to be of benefit in a few cases, but their role in the management of the disease remains to be determined.[2]

Polymyalgia rheumatica

Polymyalgia rheumatica is a rheumatic disorder of uncertain aetiology. It occurs mainly in persons over 50 years of age of European, especially Scandinavian, extraction and is more common in women than in men. The disease is characterised by myalgia and severe morning stiffness in the neck and shoulder girdle and in the hips and pelvic girdle, which may spread in more advanced cases to the muscles of the thighs, chest, and arms. Stiffness and pain are worse after periods of inactivity. There may be some joint involvement; other symptoms include fatigue, weight loss, and fever, and anaemia and raised erythrocyte sedimentation rate are seen. In some patients polymyalgia rheumatica is associated with giant cell arteritis (p.1503).

Treatment. Although NSAIDs may improve the symptoms of polymyalgia rheumatica they do not control the disease process, and corticosteroids are preferred;[1-5] in particular, corticosteroid therapy is essential where giant cell arteritis is present.

The usual initial oral dose is prednisolone or prednisone 10 to 20 mg daily, depending on the severity of symptoms; higher doses are needed where giant cell arteritis is also present, particularly if there are ophthalmic symptoms.[4,6] After 1 to 2 months a reduction in dosage is usually possible provided symptoms are well controlled. Dosage reduction should be gradual;[4,5] mean maintenance dose at one year is about 6 mg daily.[1,5]

Maintenance therapy may need to be prolonged. Although about a third to a half of all patients may be able to have corticosteroids withdrawn within about 2 years,[2] maintenance can be required for considerably longer periods.[5] Intramuscular methylprednisolone has also been found to be effective in polymyalgia rheumatica; because the cumulative dose with prolonged therapy is lower it has been suggested that this has advantages over the use of oral corticosteroids.[7] Intravenous pulse methylprednisolone has also been used.[5] Relapse is not uncommon and is most likely within one year of corticosteroid withdrawal.[2,3,5] It may be associated with arteritic symptoms, but arteritic relapses are unusual in patients whose original presentation was pure polymyalgia.[2] Methotrexate or azathioprine may be used for their corticosteroid-sparing effect in patients in whom withdrawal is difficult.[2-4]

Polymyositis and dermatomyositis

The term polymyositis has been used to describe several types of rare idiopathic inflammatory muscle disorders (myopathies).

The cardinal symptom of polymyositis is symmetrical progressive muscle weakness, usually starting in the shoulder girdle and neck, and pelvic girdle. Onset is usually gradual over a period of months, and accompanied by mild pain and tenderness, although more rapidly evolving disease with intense muscle pain is known. With progression, weakness may prevent the patient from moving their limbs, and muscle atrophy and contracture can develop. Dysphagia, pulmonary aspiration, and hypoventilation may occur, and some patients develop fibrosing alveolitis; pulmonary involvement, especially aspiration pneumonia, can be fatal. ECG abnormalities, usually asymptomatic, are common, and some patients develop Raynaud's syndrome. Primary disease may be associated with skin rashes, in which case it is known as dermatomyositis. Purplish scaly rashes on knees, elbows, and knuckles, and a characteristic purplish ('heliotrope') coloration and oedema of the eyelids may occur. A childhood form known as juvenile dermatomyositis exists, in which additional signs include vasculitis and subcutaneous calcium deposition (calcinosis cutis), and gastrointestinal haemorrhage and perforation may occur.

Treatment. Patients with active disease require bed rest, with the head elevated in patients at risk of aspiration. Physiotherapy to maintain muscle tone and avoid the development of contractures may be required.

Initial drug therapy is based on corticosteroids.[1-5] The usual choice is oral prednisone or prednisolone 40 to 60 mg or more, or 1 to 2 mg/kg daily. This usually produces improvement within 1 to 2 months. The dose may then be gradually tapered off to the minimum required for disease control;[1-3] some patients with well controlled disease may be satisfactorily maintained on an alternate-day regimen.[2,3] In patients with severe disease or extramuscular manifestations such as lung involvement, pulse intravenous methylprednisolone may be preferred initially, to gain more rapid disease control.[1,2,4] Maintenance therapy may need to be prolonged and a reduction in corticosteroid dosage to the minimum is therefore desirable, but too early or too rapid a reduction may lead to relapse.

Up to 30% of patients do not respond to corticosteroids,[2] or develop unacceptable adverse effects, and in these cases the second-line drugs are cytotoxic immunosuppressants.[1-3] There is considerable experience with the use of methotrexate, by mouth, subcutaneously, intramuscularly, or intravenously, usually at weekly intervals; it may be used with corticosteroids, permitting a reduction in their dose. Azathioprine may also be given with corticosteroids, again permitting a reduction in corticosteroid dosage, and the combination has also been shown to be superior to a corticosteroid alone for long-term maintenance (although this was only apparent after more than a year of therapy).[6] There is some evidence that methotrexate may be superior to azathioprine in patients unresponsive to prednisone alone.[7] Combining methotrexate and azathioprine has also been suggested.[2,4]

Some consider that corticosteroid therapy should be combined with a cytotoxic immunosuppressant such as azathioprine or methotrexate from the outset of treatment.

The role of other drugs is less well defined. Cyclophosphamide may be of use in patients with lung disease,[1,3,5] while chlorambucil and tacrolimus have produced benefit in individual cases but have not been formally assessed.[4] There have been reports of ciclosporin producing a response in refractory disease.[2,4] Normal immunoglobulin has also produced responses; it is usually reserved for refractory cases, or as an add-on therapy in patients inadequately controlled on corticosteroids and immunosuppressants, or for whom immunosuppressants are contra-indicated.[2,3] Promising results have been obtained with fludarabine[1] and mycophenolate mofetil;[2,3] there are preliminary reports of success with etanercept, and infliximab, and interferon beta has been investigated.[2]

Cutaneous symptoms in patients with dermatomyositis do not always respond satisfactorily to corticosteroids, but hydroxychloroquine is reputed to be of benefit in patients with rash,[8] probably due to a photoprotective effect.[9] Calcinosis, which can cause considerable morbidity, is particularly difficult to treat but some cases have responded to treatment with aluminium hydroxide, alendronate, diltiazem, or magnesium sulfate.[4] Warfarin therapy has been used,[10,11] but its value for calcinosis is disputed.[12]

Polyneuropathies

Ten patients with subacute demyelinating polyneuropathy obtained a beneficial response to corticosteroid therapy.[1] In one patient the response was initially slight, but became dramatic when azathioprine was added. Prednisone was given in initial single daily doses of 40 to 150 mg, until definite clinical improvement was obtained, and followed by a single-dose alternate-day regimen. Corticosteroids are generally considered to be of little use in Guillain-Barré syndrome (p.2228), which usually occurs due to an acute inflammatory polyradiculoneuropathy.[2] In chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), corticosteroids are reported to be beneficial,[1,3] although a review[3] found weak evidence to support this. Subacute demyelinating neuropathy appeared to be a distinct and clinically identifiable entity in which corticosteroid therapy is indicated.[1]

Postoperative ocular inflammation

Corticosteroid eye drops are used to control the inflammatory response commonly seen after cataract surgery; prednisolone is usually used but dexamethasone may be necessary if the inflammation is severe.

Corticosteroids should only be used with care and for short periods for topical control of postoperative ocular inflammation, as discussed on p.100.

Pregnancy

Although some adverse effects have been recorded and certain precautions need to be observed, the use of corticosteroids during pregnancy (see under Precautions, p.1494) is appropriate to promote fetal maturation where there is a risk of premature delivery (see Neonatal Respiratory Distress Syndrome, above). In addition, in those maternal conditions serious enough to require systemic corticosteroids the risk to both mother and offspring of discontinuing therapy is often greater than that of corticosteroid use during pregnancy.

Psoriasis

Reviews of psoriasis (p.1583) and its management[1-3] include topical corticosteroids among first-line treatments. Combination therapy using corticosteroids with other topical treatments, such as calcipotriol or tazarotene, may be used to reduce adverse effects and improve efficacy of both drugs.[4]

Intralesional injection of corticosteroids has been used for small, localised, recalcitrant plaques of psoriasis but caution is required to avoid skin atrophy or depigmentation.[1] Systemic corticosteroids are not generally recommended, but have been used for short periods in extreme or rare cases; there is a risk of systemic adverse effects and of rebound psoriasis occurring on stopping therapy.

Topical corticosteroids remain the mainstay of treatment in scalp psoriasis, although long-term treatment is not recommended; the more potent corticosteroids are reserved for adult use.[5]

Pyoderma gangrenosum

A systemic corticosteroid is one of the treatments that is usually tried in pyoderma gangrenosum (p.1583). High-dose oral treatment or intravenous pulse therapy may be needed initially to induce remission.[1,2] Response is usually rapid, but maintenance doses vary considerably. Healing of superficial granulomatous pyoderma has occurred after intralesional injection of triamcinolone,[3,4] oral doses of prednisolone,[3,4] and after long-term topical corticosteroids.[4]

Respiratory disorders

Although corticosteroids have been used in the management of many forms of respiratory disorder, this use has frequently been on an empirical and uncontrolled basis, and evidence of benefit is often somewhat mixed. Thus, while an established role exists for corticosteroids in the management of asthma (p.1108), the antenatal prevention of neonatal respiratory distress syndrome (p.1508), and probably in croup (p.1502) they are no longer used in aspiration syndromes (p.1693) and their role in diffuse parenchymal lung disorders (see p.1502 and under Sarcoidosis, below) and in acute respiratory distress syndrome (p.1498) is uncertain. Other disorders in which they have been tried with varying success include bronchiolitis (p.1500), chronic obstructive pulmonary disease (see p.1501), fat embolism syndrome,[1] acute eosinophilic pneumonia[2] and pulmonary eosinophilia,[3] diffuse alveolar haemorrhage,[4] and 'ice hockey lung' (due to nitrogen dioxide).[5]

Retinal vasculitis

Inflammation of the retinal blood vessels (retinal vasculitis) usually occurs as a feature of ocular disorders such as Eales disease; systemic inflammatory conditions such as Behçet's disease (p.1499), sarcoidosis (p.1512), and multiple sclerosis (p.892); or infections such as herpes (p.854), tuberculosis (p.196), syphilis (p.192), and toxoplasmosis (p.826). Vascular sheathing, occlusion, macular oedema, and retinal haemorrhage can occur, and symptoms of retinal vasculitis include painless loss of vision, blurred vision, floaters, and scotoma.[1,2]

In the treatment of non-infectious retinal vasculitis, corticosteroids are used to control inflammation and prevent long-term vision loss. Local treatment by periocular injection may be used in unilateral disease or moderate inflammation; improvement usually occurs in 2 to 3 weeks and may last for up to 3 months. Oral corticosteroids may be required for moderate to severe bilateral disease with a marked reduction in visual acuity, and improvement may take 3 to 4 weeks to appear.[1] Other immunosuppressants may be needed for vasculitis that is unresponsive or inadequately controlled by corticosteroids, and may be used for their corticosteroid-sparing effect when long-term therapy is required. Azathioprine and ciclosporin are most commonly used, but cyclophosphamide, methotrexate, and mycophenolate have also been tried.[1,2] Appropriate anti-infective therapy can clear retinal vasculitis associated with infection, but corticosteroids may be needed where there is residual vasculitis.[1]

Rheumatoid arthritis

Systemic corticosteroids can play an important role in the management of juvenile idiopathic arthritis (p.10); they may be given by intra-articular injection in oligoarthritis, and to control disease flares, or systemically in more widespread and severe disease.

Similarly, in adult rheumatoid arthritis (p.11). corticosteroids may be added to DMARD therapy to control synovitis or provide cover when changing therapies, since they provide rapid symptomatic control. They have been shown to reduce the development of joint erosions, and in the short-term this beneficial effect outweighs their adverse effects on bone. Short- to moderate-term use of systemic corticosteroids (in doses not exceeding the equivalent of 15 mg of prednisolone daily) is therefore considered valuable. However, their adverse effects mean that longer term use cannot be justified. Intra-articular injection is recommended for acute disease flares, particularly when combined with aggressive DMARD therapy.

Rhinitis

For a brief description of rhinitis and a discussion of its management including the use of corticosteroids, see p.565. Reviews[1,2] including a systematic review,[1] found that intranasal corticosteroids produced greater relief of the nasal symptoms of allergic rhinitis than oral antihistamines, and there was no difference between the two treatments in relief of eye symptoms. Commonly used nasal sprays appear to have similar efficacy and adverse effect profiles,[3] and choice of therapy is probably influenced by other factors including cost[3] and patient preference.[4]

Sarcoidosis

Sarcoidosis is a disorder involving the development of multiple granulomas in a variety of organs, which may subsequently resolve or progress to chronic fibrosis.[1] The disease is frequently asymptomatic, and since it usually regresses spontaneously estimating the incidence is difficult, but it appears to vary considerably in different countries. It is most often seen in young adults and is slightly more common in female than male and in black than white patients.

Almost any organ can be affected, but manifestations in lymph nodes, lungs, skin, joints, and eyes are common. Lymphadenopathy, some decrease in pulmonary function, dyspnoea, and cough may mark lung and lymph node involvement. Skin manifestations include erythema nodosum, macular or papular lesions due to granuloma formation in the skin, and violaceous plaques on fingers, nose, ears, and cheeks known as lupus pernio. Arthropathy, with painful joint swellings, may be associated with erythema nodosum and fever in acute presentations; bone lesions are most common in fingers and toes. Involvement of the nervous system may be particularly difficult to diagnose because of its protean manifestations. Involvement of the eyes is usually manifest as uveitis although other symptoms include keratoconjunctivitis sicca. Symptomatic disease involving the gastrointestinal tract, liver, pancreas, heart, or kidneys is rare, although asymptomatic involvement may occur.

In addition to symptoms directly due to the disease, sarcoidosis is often associated with hypercalcaemia (p.1668) and hypersensitivity to the effects of vitamin D. Other biochemical abnormalities include raised serum concentrations of angiotensin-converting enzyme (ACE), and there are abnormalities of some aspects of immune function.

Diagnosis of sarcoidosis is problematic because of its multiple manifestations and the fact that it is so often clinically silent. It is often detected by accident, when radiography is performed for other reasons, but biopsy is often needed to help confirm the disease. The Kveim test, in which an antigen derived from patients with sarcoidosis (see p.2329) is given intradermally and produces a delayed reaction in patients with the disease, is now rarely used because of its perceived lack of precision, although some still consider it useful.[2]

Treatment. Asymptomatic disease requires no therapy, and since spontaneous remission can occur, corticosteroids, which are the usual therapy,[1] are generally reserved for patients in whom the disease affects the function of a vital organ or for patients with hypercalcaemia. NSAIDs alone may be adequate to control the fever and arthropathy of acute disease. Where corticosteroids are called for a typical oral regimen is prednisolone or prednisone 30 to 40 mg daily, the dose being reduced after several weeks as the patient improves.[3-5] Therapy should be continued (at the minimum effective maintenance dose) for 12 to 18 months before any attempt is made to withdraw it.[3] Alternate-day dosage has been suggested, with 40 mg every other day as initial therapy,[6] and 5 to 10 mg every other day as maintenance.[7] There is some evidence[8] that relapse may be more likely after withdrawal of corticosteroids than in patients who do not receive corticosteroid therapy, but this may simply reflect the natural course of disease in this group. Higher initial doses of 60 to 80 mg daily of prednisone are generally used in cardiac sarcoidosis, although controversy exists as to the clinical efficacy and optimal dose and duration of corticosteroids. Treatment halts progression and improves survival, but it does not reduce the incidence of ventricular arrhythmias.[9] There also remains some dispute about the value of oral corticosteroids in pulmonary disease: although they are useful in the short term their long-term benefits are more uncertain.[10] Inhaled corticosteroids have also been investigated in pulmonary sarcoidosis; they appear less reliable than oral therapy for primary treatment, but may have a role as maintenance therapy.[5,11] In patients with ocular disease corticosteroid drops and ointment are used for anterior uveitis; resistant cases, or patients with posterior uveitis, require systemic corticosteroids.[1] Skin lesions usually respond to corticosteroids but the high doses that may be required for suppression of lupus pernio may produce changes in appearance as disfiguring as the disease.[3]

Other drugs have occasionally been used in sarcoidosis but are very much second-line. In patients in whom corticosteroids are not effective or not tolerated cytotoxic immunosuppressants have been given, with variable results.[1,3,5,7] Methotrexate has perhaps been most useful, having been found to be effective in low oral doses (up to 15 mg weekly) in refractory disease;[1,12] corticosteroid-sparing effects may be evident after 6 months.[7] Azathioprine has been used for severe refractory cases.[5] Results with ciclosporin have been variable,[7] although there are reports of response in refractory skin lesions and optic neuropathy.[1] Toxicity and concerns about carcinogenesis limit the use of chlorambucil and cyclophosphamide.[1,5] The antimalarials have also been tried as adjuncts or alternatives to corticosteroid therapy,[5] and may be useful for skin disease and hypercalcaemia.[7] Potential ocular toxicity is a concern, however, and although hydroxychloroquine may be less oculotoxic than chloroquine,[7] regular ophthalmological assessment is recommended.[5] Other reports of benefit in cutaneous sarcoidosis have involved allopurinol,[13] thalidomide,[14] and tranilast,[15] while there is report of response to melatonin in 2 patients with refractory sarcoidosis.[16] Infliximab and pentoxifylline have also shown promising results.[7]

Sciatica

For mention of the use of epidural corticosteroid injections to treat sciatica, and doubts about the extent of benefit, see Administration, Epidural Route, p.1496.

Scleritis

Scleritis and episcleritis are inflammatory diseases of the sclera often associated with various systemic diseases. Episcleritis tends to be a benign superficial condition but treatment can be difficult and it tends to recur. The use of topical corticosteroids and topical NSAIDs are sometimes of temporary benefit. Scleritis is a rarer more deep-seated inflammation. Initial treatment of non-necrotising scleritis is with NSAIDs; high dose systemic corticosteroids (usually oral prednisone or prednisolone 60 to 80 mg daily) have been used successfully in many patients unresponsive to NSAIDs.[1,2] If necessary, to reduce any attendant adverse effects, corticosteroids have been given by orbital floor injection (methylprednisolone acetate 40 mg)[1] or at a reduced systemic dosage with an additional immunosuppressant such as ciclosporin, methotrexate, cyclophosphamide, or azathioprine.[3] Immunosuppressants may also be of value alone in severe or unresponsive disease.[4] It has been suggested that immunosuppressant therapy should be the initial choice in necrotising scleritis, as therapeutic failure is very common with less aggressive regimens.[4]

Scleroderma

Corticosteroids may be useful for the management of scleroderma (p.1817), but must be used with care because of the risk of exacerbating renal and other problems.

Seborrhoeic dermatitis

Topical corticosteroids are used with an imidazole antifungal in the management of seborrhoeic dermatitis (p.1584).

Septic shock

The role of corticosteroids in septic shock (see under Septicaemia, p.190) has been controversial. Early studies reported both beneficial[1] and detrimental[2] effects, but corticosteroids were considered ineffective[2,3] and likely to worsen secondary infection.[4-7] More recently, supplemental corticosteroids have been suggested to be beneficial in patients with established septic shock who exhibit adrenal insufficiency.[8] However, their routine use in septic shock is not recommended[9] and a systematic review[10] concluded that short-course high-dose corticosteroids did not alter mortality rates in severe sepsis and septic shock, and that current evidence did not support their use. However, meta-analyses[10,11] and a review[12] suggest that longer courses (5 to 11 days) of low-dose corticosteroids might reduce mortality especially in those with vasopressor-dependent septic shock.

Sickle-cell disease

A study[1] has suggested that a short course of high-dose methylprednisolone might be a useful adjunct in controlling pain in sickle-cell crisis (p.9). However, the use of corticosteroids in sickle-cell disease is problematic; apart from the usual adverse effects, including the risk of exacerbating underlying infection, corticosteroid therapy has been reported to provoke sickle-cell crisis in patients with sickle C disease—see under Precautions, p.1494.

1. Griffin TC, *et al.* High-dose intravenous methylprednisolone therapy for pain in children and adolescents with sickle cell disease. *N Engl J Med* 1994; **330:** 733–7.

Skin disorders

For some guidelines to the use of topical application of corticosteroids in skin disorders, see under Administration, p.1497. For discussion of the use of corticosteroids in individual skin disorders see under the relevant headings in this section.

Soft-tissue rheumatism

Soft-tissue rheumatism (p.13) includes a number of conditions affecting tendons, ligaments, muscles, fascia, and joint capsules; some lesions may respond to local injections of corticosteroid, often given with a local anaesthetic. In the treatment of shoulder pain, intra-articular injection of triamcinolone acetonide was considered to be superior to physiotherapy for reducing pain in the short-term.[1] Injection of corticosteroids below the point where the clavicle joins the shoulder blade (subacromial injection) may be superior to placebo for rotator cuff disease, as may intra-articular injection for adhesive capsulitis.[2] One meta-analysis[3] found that subacromial injection produced dose dependent benefit for up to 9 months in shoulder pain associated with rotator cuff tendinitis, with a number-needed-to-treat of between 1.4 and 2.2; there was some evidence that higher doses (50 mg equivalent of prednisone or greater) were more effective. However, there has been concern over accuracy of needle placement, and the scanty evidence to guide treatment.[2,4] There is also limited evidence that oral corticosteroids may produce improvement in pain and mobility in patients with adhesive capsulitis (frozen shoulder), but this improvement may not last beyond 6 weeks.[5] In lateral epicondylitis (tennis elbow), local injections of triamcinolone acetonide with local anaesthetic improved short-term outcomes such as pain and disability, although long-term results favoured physiotherapy.[6] Another study found that short-term benefit with corticosteroid injection for epicondylitis was paradoxically reversed after 6 weeks, implying the need for caution.[7] Evidence appears to support the use of corticosteroids such as betamethasone and methylprednisolone, with local anaesthetic, in trigger finger.[4] In contrast, no benefit has been found in Achilles' tendinopathy.[4] In carpal tunnel syndrome, injection of corticosteroids produces short term benefit but has not been shown to produce better results than other treatments such as splinting in the longer term.[8] Concerns have been expressed about the lack of good studies to support the use of corticosteroids,[2,4] and some have suggested that in tendinopathies, they be reserved for chronic injuries, and that short- or moderate-acting, soluble preparations be used.[4] Tendon rupture after local corticosteroid injection may occur.[4]

Spinal cord and head injury

Spinal cord injury usually causes significant disability arising from either partial or total paralysis. The degree of disability and organ dysfunction is determined by the spinal level of the injury, and whether severance of the cord is complete or not. Patients with lesions at the level of the fourth cervical vertebra and above will almost certainly have respiratory problems or diaphragm paralysis, requiring ventilation. Spinal shock occurs almost invariably, resulting in hypotension and reduced renal perfusion, which may cause renal failure. Patients are also at risk for acute respiratory distress syndrome (p.1498) and thromboembolism (p.1187). Lesions above the fifth thoracic vertebra may cause autonomic dysreflexia which results in a potentially life-threatening rise in blood pressure, requiring the use of antihypertensives.[1]

Neural tissue in the spinal cord cannot regenerate and damage is considered permanent; however, some lessening of disability is possible with rehabilitation. One of the main aims in the management of spinal cord injuries is to minimise secondary damage from hypoxia, hypoperfusion and inflammation. Results of a multicentre placebo-controlled study in the USA[2] indicated that high-dose intravenous corticosteroids resulted in improvements in neurological function if given within 8 hours of spinal cord injury. Methylprednisolone was given in an initial dose of 30 mg/kg followed by 5.4 mg/kg per hour for 23 hours. A subsequent study found that although this regimen was adequate if begun within 3 hours of injury, better results were obtained by continuing methylprednisolone for 48 hours in patients in whom therapy commenced 3 to 8 hours after injury.[3,4] The lazaroid tirilazad, given for 48 hours, had some benefit in this study, although it was less effective than 48 hours of treatment with methylprednisolone in the doses used. In contrast, a systematic review found that high-dose methylprednisolone did not improve neurological function in patients, and might potentially have a deleterious effect.[5] Another review failed to find any benefit from the use of gangliosides.[6]

The longer-term management of spinal cord injuries has been reviewed.[7]

Management of traumatic head injury poses similar problems and risks to those of spinal cord trauma. The effects of corticosteroids on mortality in acute traumatic head injury had been unclear, until an international randomised trial in 10 008 adults found that the risk of death from all causes within 2 weeks[8] or 6 months[9] of significant head injury was higher in the group given methylprednisolone compared with placebo. There is little evidence that tirilazad is of any value in acute traumatic brain injury,[10,11] nor for other interventions that have been suggested for this, including barbiturates,[12] calcium-channel blockers such as nimodipine (other than perhaps in a subgroup of patients with subarachnoid haemorrhage—see also p.1357),[13] central stimulants such as methylphenidate or the amfetamines,[14] inhibitors of glutamate neurotransmission,[15] or hyperventilation or hyperbaric oxygen therapy.[16,17] Mannitol is widely used after severe head injury to reduce intracranial pressure (p.1181), but evidence from randomised studies is limited and it is unclear whether mannitol therapy has any effect on death or disability.[18]

Spondyloarthropathies

Intra-articular injections of corticosteroids have been given in ankylosing spondylitis (see Spondyloarthropathies, p.13).

Systemic lupus erythematosus

Systemic lupus erythematosus (SLE) is an auto-immune disease of complex aetiology characterised by autoantibodies that participate in the mediation of tissue damage affecting joints, skin, kidney, CNS, and other organs. It is far more common in women than in men, the evidence suggesting that male hormones have a protective effect, and peak onset is usually in women in their 20s and 30s.

The commonest symptom in patients with SLE is arthralgia or arthritis; fatigue, fever, weight loss, rashes (characteristically a so-called 'butterfly rash' on the cheeks and bridge of the nose), CNS involvement including personality changes, anaemia, nephritis, and pulmonary symptoms (notably pleurisy) are also frequent, while other symptoms include myalgia, alopecia, Raynaud's syndrome, convulsions, coma, stroke, pneumonitis, pericarditis, myocarditis with tachycardia, leucopenia, thrombocytopenia, coagulation disorders (both thrombosis and haemorrhage), hepatomegaly, splenomegaly, and lymphadenopathy. Thrombotic symptoms and recurrent miscarriage may represent an 'antiphospholipid antibody syndrome' due to antibodies against phospholipids, which occurs in about a third of all patients with SLE but may also occur independently.[1]

Management. SLE is characterised by exacerbation and remission so individualised management with careful monitoring and appropriate and timely symptomatic treatment is required. Treatment is largely empirical and there have been few controlled studies.

In addition to any specific treatment, patients require emotional support, extensive rest, and avoidance where possible of stimuli that may provoke disease exacerbation, including ultraviolet light, certain drugs or foods rich in psoralens, infections, and psychological stress.

Mild disease may require no treatment, or may be managed simply with NSAIDs for muscular and joint symptoms.[2] In more severe, but non-life-threatening disease chloroquine or, more often, hydroxychloroquine is effective, particularly for cutaneous and joint manifestations,[3-5] although disease flare may occur on withdrawal.[6] Retinoids such as acitretin have also been shown to be of use in some patients.[7]

Many patients require treatment with corticosteroids at some point, although in such patients they can be a major cause of morbidity.[3,8] It is usual to use a corticosteroid when treatment with NSAIDs or antimalarials has failed, or when life or vital organs are threatened.[2] They are usually given in high doses (1 mg/kg or more of prednisone or prednisolone daily, sometimes preceded by a course of intravenous methylprednisolone)[2] for life-threatening manifestations such as high fever, severe thrombocytopenia, coma, seizures, or involvement of a major organ such as the kidney (see also Lupus Nephritis, below). Non-life-threatening symptoms that fail to respond to other measures will usually respond to lower corticosteroid doses (not more than 500 micrograms/kg daily of prednisolone or prednisone).[2] Once a response is achieved the dose should be tapered to the lowest required to control symptoms, sometimes in the form of alternate-day dosage, although disease may relapse.[2] Complete withdrawal is optimal, although some patients may need long-term maintenance on about 5 mg daily.[2] One study found that raising the maintenance corticosteroid dose temporarily to counteract any increases in the concentration of antibodies to double-stranded DNA may reduce the number of relapses,[9] but the design and conclusions of this study are open to criticism.

Prolonged corticosteroid therapy, particularly at the higher doses, is associated with adverse effects such as aseptic bone necrosis and an increased susceptibility to infection, and other drugs have been added to corticosteroid therapy in an attempt to lower the corticosteroid dose but maintain disease control. In particular the immunosuppressant azathioprine has been used for its corticosteroid-sparing effect.[2] Oral or intravenous pulse cyclophosphamide has been used with some success to treat severe organ involvement although toxicity may be of concern.[2,3] Low-dose weekly methotrexate may also be helpful in patients with cutaneous or joint involvement.[10] The antimalarials may also be combined with corticosteroid therapy, and in addition to a corticosteroid-sparing effect there is a suggestion that hydroxychloroquine may counter the adverse effects of corticosteroids on serum-lipid profiles.[2,11] Prasterone is under investigation for the treatment of severe disease.[12] Thalidomide has been investigated for treating cutaneous manifestations of SLE.[13] Remission has been reported in a few patients with refractory disease given rituximab.[5]

Thrombotic symptoms due to antiphospholipid antibodies require adequate long-term anticoagulation with warfarin or low-dose aspirin, and it should be borne in mind that stroke and related CNS symptoms will not respond to corticosteroids. In patients with other severe CNS symptoms that fail to respond to corticosteroids intravenous cyclophosphamide may be helpful,[14,15] but response is unpredictable. Intravenous immunoglobulin has been used as an adjunct in CNS lupus,[5] although its role is unclear; it may also be used in the management of thrombocytopenic symptoms.[16]

In patients with severe and potentially fatal symptoms plasma exchange may provide temporary benefit by removing circulating antibodies.

Lupus nephritis. Renal disease is probably the best studied symptom of SLE. Almost all patients develop some renal involvement,[17] with clinical nephritis in up to 50%.[18,19] Usual manifestations of renal disease include hypertension, oedema, proteinuria or frank nephrotic syndrome, and oliguria; more severe disease is usually associated with focal or diffuse proliferative glomerulonephritis on biopsy.[18,19]

Patients with active disease (worsening renal function, proteinuria, and urinary sediment) require aggressive treatment to prevent irreversible renal damage. It is generally accepted that the use of a cytotoxic immunosuppressant with a corticosteroid is more effective than the use of corticosteroids alone in controlling nephritis and the risk of end-stage renal failure,[17,18] although corticosteroids alone may be used for less severe disease.[16]

One suggested outline for treatment in severe active disease is to begin with pulsed intravenous methylprednisolone as 3 doses of 1g daily, or prednisone or prednisolone orally (initially 0.5 to 1 mg/kg daily, gradually reduced) accompanied if necessary by cyclophosphamide or azathioprine.[19] An alternative approach is to begin therapy with intermittent intravenous cyclophosphamide,[20] which appears to be more effective than pulsed methylprednisolone[21,22] and then to maintain patients with low-dose oral prednisone plus pulsed intravenous cyclophosphamide. Azathioprine may be a useful alternative for patients who cannot tolerate cyclophosphamide;[18,19] it may be used as maintenance after cyclophosphamide induction in an attempt to reduce toxicity.[17,19] Ciclosporin has also been investigated, with preliminary results suggestive of benefit,[23,24] but has been viewed with caution because of its nephrotoxicity.[18,19] Mycophenolate mofetil has shown promising results;[25,26] some suggest it may come to replace cyclophosphamide.[5] Abetimus is under investigation,[18] and other drugs that have been reported to be of benefit include intravenous immunoglobulins,[18] cladribine, and fludarabine.[17] Autologous haematopoietic stem-cell transplantation (p.1811) is considered feasible in SLE.[18,27]

Pregnancy. Although symptoms of SLE do not appear to be exacerbated in most patients during pregnancy,[28,29] it is considered advisable that pregnancy be deferred until the disease is in remission or controlled by therapy, since complications are more likely in active disease.[13,28] Cyclophosphamide or methotrexate are contra-indicated in pregnancy because of the risk of teratogenesis but corticosteroids, azathioprine, and hydroxychloroquine may be used if necessary:[2-4,30] the risks of miscarriage, still-birth, growth retardation, or preterm delivery due to the disease are considered greater than the risks to the fetus of continued therapy. The use of low-dose aspirin (75 mg daily) has been recommended in women with renal involvement or a history of pre-eclampsia or fetal growth retardation;[30] in women with antiphospholipid antibodies, low-dose aspirin with subcutaneous heparin or low-molecular-weight heparin markedly improves the live birth rate.[1,13,31] The use of high-dose prednisone, with or without aspirin, to suppress antiphospholipid antibodies, while reportedly effective in some women with bad obstetric histories,[32,33] has been found by others to be of no benefit,[34] and is associated with unacceptable maternal morbidity.[35] Warfarin prophylaxis, which appears effective in other patients with the antiphospholipid antibody syndrome,[36] is unsuited to pregnant women because of the teratogenic effects of warfarin.[37]

Postpartum exacerbation is well recognised,[28,30] and some workers favour prophylactic corticosteroid cover during the puerperium. A small proportion of neonates born to mothers with lupus exhibit a neonatal lupus syndrome,[38] manifesting most seriously as heart block which may require a permanent pacemaker.

Takayasu's arteritis

Takayasu's arteritis is a vasculitis of the aorta and its branches seen particularly in young women and in Oriental patients. It is characterised by vasculitis followed by fibrosis, leading to stenosis or occlusion of the vessel. Symptoms vary depending on the anatomical site, but include constitutional symptoms such as fever, malaise, and arthralgia, syncope, dyspnoea, palpitations, loss of pulses, intermittent claudication, and visual disturbances.

Active inflammatory disease may respond to corticosteroids: doses of 1 mg/kg daily of prednisone or prednisolone, tapered after one month in patients who respond, have been suggested.[1,2] In patients who do not respond, azathioprine, cyclophosphamide, or methotrexate have been added, although opinions vary as to the necessity of cytotoxic agents in these patients.[1-3] Ciclosporin[4] and mycophenolate mofetil[5] have also been used. A preliminary report[6] suggests that the use of etanercept or infliximab to inhibit the actions of tumour necrosis factor may be useful in patients who are refractory to other treatments. Widely varying estimates of mortality and aggressiveness exist for Takayasu's arteritis, and in the absence of large controlled studies it is difficult to assess the benefits of drug therapy. The course may be very prolonged, and minimising the maintenance dosage (e.g. by alternate-day corticosteroid therapy) is important to avoid adverse effects.[7]

Surgical reconstruction of affected vessels has been carried out in patients at risk of ischaemic compromise.[8] Angioplasty has been tried.

Tuberculosis

The use of corticosteroids in tuberculosis (p.196) is controversial.[1-3] They should never be given to patients with active disease without protective chemotherapy cover, and must be used with caution in patients with dormant disease as it may be reactivated. Use of corticosteroids in pulmonary tuberculosis is to be avoided except in life-threatening disease. WHO suggests that corticosteroids may be useful adjuvants to antituberculous therapy in selected conditions including tuberculous meningitis, pericarditis, pleural effusion, or laryngitis, or tuberculosis of the renal tract, adrenocortical insufficiency due to adrenal gland tuberculosis, massive lymph node enlargement, or to control drug hypersensitivity. They are also likely to be of benefit in patients with HIV infection and the above conditions.[4] Similar recommendations have been made by NICE with regard to tuberculous meningitis and pericarditis.[5] However, systematic reviews of tuberculous pleurisy[6] and pericarditis[7] have concluded that there is insufficient evidence to support the use of corticosteroids in these conditions.

Urticaria and angioedema

Oral antihistamines are the mainstay of treatment for urticaria (p.1584). Severe attacks refractory to standard therapy may require a short course of oral corticosteroid therapy.

When angioedema affecting the larynx (laryngeal oedema) is present, the patients should be treated with adrenaline as an allergic emergency (see Anaphylaxis and Anaphylactic Shock, p.1205).

Uveitis

Uveitis is inflammation of the uveal tract of the eye, which comprises the choroid, ciliary body, and the iris. It is usually idiopathic but may be secondary to infection, allergy, or inflammatory disorders with an auto-immune component.

In anterior uveitis, also referred to as iridocyclitis, there is inflammation of the iris (iritis) and the ciliary body (cyclitis). It tends to be acute and self-limiting and is likely to be associated with infection. The iris becomes spongy and hyperaemic and exudates may result in adhesions between the iris and the lens (posterior synechiae). Chronic anterior uveitis is associated with formation of cataracts and glaucoma. Posterior uveitis can be acute or chronic and may just affect the choroid (choroiditis) or may also involve the retina (chorioretinitis). It is more likely to be an auto-immune condition.

The treatment of uveitis has been reviewed.[1-4]

Corticosteroids given topically and, when necessary, systemically are the mainstay of treatment for acute anterior uveitis.[5] Cycloplegics and mydriatics such as atropine, cyclopentolate, and homatropine are used adjunctively to rest the ciliary body and iris, diminish hyperaemia, and to prevent the formation of posterior synechiae. Antibacterials should be used to treat any infection. In children with chronic anterior uveitis associated with juvenile idiopathic arthritis, corticosteroids are supplemented with chronic use of an oral NSAID if inflammation persists after 90 days of treatment and attempted corticosteroid withdrawal.[6] In the 30% or so of cases that do not respond to corticosteroids and NSAIDs, low-dose weekly methotrexate (with folic acid supplements daily) is advocated, with other immunosuppressants being substituted or used adjunctively when methotrexate fails or is not tolerated.

Treatment of posterior uveitis is less satisfactory than that of acute anterior uveitis since gross damage to the retina often occurs before the condition can be controlled. Corticosteroids are usually required given either as periocular injections or as high-dose systemic therapy.[5] A suggested protocol[2] involves the use of high-dose systemic corticosteroids to control active disease; long-term control is then maintained primarily with low-dose ciclosporin, corticosteroids being tapered to a low dose or eventually withdrawn. Certain patients may require an additional immunosuppressant, usually azathioprine, although methotrexate, cyclophosphamide, ciclosporin, or chlorambucil may be considered. Other immunosuppressants being studied include tacrolimus, and there are reports of improvement with mycophenolate mofetil.[4,5]

Visual impairment in chronic uveitis is often the result of macular oedema and is not necessarily prevented by immunosuppressants. Short-term treatment with acetazolamide is considered to have produced some encouraging results in reducing chronic uveitic macular oedema but its long-term efficacy or efficacy with low-dose corticosteroids remains to be determined.[7] Although systemic and topical NSAIDs have been shown to reduce cystoid macular oedema in post cataract extraction (see Postoperative Inflammatory Ocular Disorders, p.100) their role in the treatment of macular oedema associated with uveitis is less clear.

Vasculitic syndromes

Vasculitis may be defined as inflammation of the blood vessel wall, and the term has been applied in describing a wide range of diseases involving blood vessels of various sizes and types. Vasculitis may occur as part of a systemic disease such as rheumatoid arthritis or SLE, or may itself be the primary disorder, and symptoms may vary from superficial cutaneous disease, with purpura and urticaria, to progressive and fatal systemic vasculitides such as Wegener's granulomatosis. In some forms of vasculitis, such as giant cell arteritis, mononuclear giant cells may be seen, while in granulomatous vasculitis the mononuclear cells form granulomata adjacent to the damaged vessel wall. Necrotising vasculitis is used to describe inflammation associated with necrosis of the media, the middle part of the vessel wall, while polyarteritis implies inflammation of the full thickness of an arterial wall.

Because of the heterogeneous nature of this group of diseases and the degree of overlap which exists between some of them, and between them and other diseases, classification has been difficult. Classification has often been based on the size of the affected vessel, as well as the presence or absence of granulomata and antineutrophil cytoplasmic antibodies (ANCA), and whether the vasculitis is primary or secondary. Of the major primary vasculitic syndromes, giant cell arteritis (p.1503) and Takayasu's arteritis (p.1514) are examples of large vessel disease; classic polyarteritis nodosa (p.1510) affects medium-sized vessels; Churg-Strauss syndrome (p.1501), microscopic polyangiitis (p.1510), and Wegener's granulomatosis (below) are diseases of small or medium-sized vessels; the so-called 'hypersensitivity vasculitides' (p.1505), including Henoch-Schönlein purpura, are small vessel diseases, though usually limited in extent.

Treatment depends on the type of vasculitis, its severity, and prognosis. Treatment of the systemic vasculitides has revolved around corticosteroids and cyclophosphamide; other cytotoxic immunosuppressants, normal immunoglobulins, NSAIDs, anticoagulants, dapsone, and colchicine have been tried in various forms of disease.

Vitiligo

Topical corticosteroids are sometimes effective in inducing repigmentation in patients with vitiligo (p.1582 under Pigmentation Disorders).

Wegener's granulomatosis

Wegener's granulomatosis is a form of granulomatous vasculitis that occurs more frequently in men and in white patients. It is characterised by necrotising vasculitis of small arteries and veins, accompanied by granuloma formation, and affecting particularly the respiratory tract and kidneys. It is usually associated with antineutrophil cytoplasmic antibodies (ANCA). Symptoms include rhinorrhoea, sinusitis, cough and dyspnoea (signs of pulmonary infiltration which is seen in the majority of patients at presentation); renal manifestations include haematuria, proteinuria, uraemia, and oedema of the lower limbs due to a focal glomerulonephritis which can progress to crescentic glomerulonephritis and rapidly progressive renal failure. Other organ systems may be involved, with effects similar to those of microscopic polyangiitis (see p.1510). If untreated, the disease is fatal.

Treatment is with a combination regimen based on cyclophosphamide with a corticosteroid. A standard regimen has been low-dose (1 to 2 mg/kg daily) oral cyclophosphamide, with prednisolone or prednisone 1 mg/kg daily by mouth initially, subsequently tapered to an alternate-day regimen and eventually stopped.[1-3] Cyclophosphamide is usually continued for at least a year before considering gradual withdrawal but there is a trend in Europe towards the use of shorter courses of cyclophosphamide.[4] Standard treatment regimens produce improvement or remissions in about 90% of patients.[1,5] Relapses may subsequently occur in about half, and require re-treatment; prompt intensification of treatment when serum ANCA concentrations begin to rise may avert relapse.[6] There is evidence from one controlled study that addition of co-trimoxazole to maintenance regimens reduces the incidence of relapse,[7] although another suggested that it might actually increase the risk of relapse.[8]

Despite the success of regimens based on low-dose oral cyclophosphamide there is considerable concern about their toxicity, particularly since prolonged use may be necessary. Intermittent high-dose intravenous ('pulse') cyclophosphamide has been suggested as an alternative to the oral regimen with fewer adverse effects,[9] but results in practice seem to have been variable.[10,11] Regimens similar to the standard regimen, but substituting azathioprine for cyclophosphamide once remission is achieved (usually after 3 to 6 months) and continuing with low-dose corticosteroids concomitantly have been used.[12] Other drugs, such as methotrexate, have been tried and addition of low-dose weekly methotrexate to a corticosteroid may be a possible treatment option.[8,13-15] Ciclosporin has been reported to reverse acute renal failure in 2 patients with Wegener's granulomatosis, as well as controlling fulminant symptoms unresponsive to cyclophosphamide and corticosteroids in one of them,[16] but others have found ciclosporin plus a corticosteroid to be ineffective in suppressing disease activity.[17] Etoposide[18] and infliximab[19] have also been successfully used to induce remission in cyclophosphamide-resistant disease, but etanercept has proved ineffective in maintaining remission.[20] Other drugs that have been investigated include high-dose intravenous immunoglobulin,[21] mycophenolate mofetil,[22] and rituximab,[23] while anti-CD4 monoclonal antibodies have proved useful in patients with microscopic polyangiitis, which has some similarities to Wegener's granulomatosis, but the role of such investigational regimens remains to be determined.

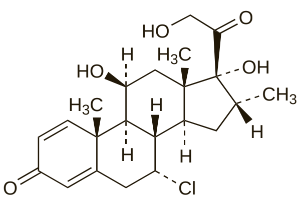
$C_{28}H_{37}ClO_7$ = 521.0.

CAS — 67452-97-5 (alclometasone); 66734-13-2 (alclometasone dipropionate).

ATC — D07AB10; S01BA10.

ATC Vet — QD07AB10; QS01BA10.



(alclometasone)

Pharmacopoeias. In *US.*

USP 31 (Alclometasone Dipropionate). Store in airtight containers.

Profile

Alclometasone dipropionate is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream or ointment containing 0.05%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see Topical Application, p.1497.

Preparations

USP 31: Alclometasone Dipropionate Cream; Alclometasone Dipropionate Ointment.

Proprietary Preparations (details are given in Part 3)
Austral.: Logoderm†; ***Chile:*** Logoderm†; ***Cz.:*** Afloderm; ***Denm.:*** Legederm†; ***Fin.:*** Legederm†; ***Ger.:*** Delonal; ***Gr.:*** Lomesone; ***Hong Kong:*** Perderm; ***Hung.:*** Perderm†; ***Indon.:*** Cloderm; Perderm; ***Irl.:*** Modrasone; ***Ital.:*** Legederm; ***Malaysia:*** Perderm†; ***Mex.:*** Logoderm; ***Neth.:*** Aclosone; ***NZ:*** Logoderm†; ***Port.:*** Miloderme; ***Rus.:*** Afloderm (Афлодерм); ***Singapore:*** Perderm†; ***Swed.:*** Legederm†; ***Switz.:*** Delonal†; ***UK:*** Modrasone; ***USA:*** Aclovate; ***Venez.:*** Demiderm.

Aldosterone *(BAN, rINN)*

Aldosteron; Aldosterona; Aldostérone; Aldosteroni; Aldosteronum; Electrocortin. 11β,18-Epoxy-18,21-dihydroxypregn-4-ene-3,20-dione.

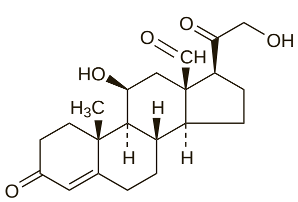
Альдостерон

$C_{21}H_{28}O_5$ = 360.4.

CAS — 52-39-1.

ATC — H02AA01.

ATC Vet — QH02AA01.



Adverse Effects

Aldosterone has very pronounced mineralocorticoid actions and little effect on carbohydrate metabolism. It may therefore exhibit the mineralocorticoid adverse effects described for the corticosteroids in general (p.1490).

Uses and Administration

Aldosterone is the main mineralocorticoid (p.1490) secreted by the adrenal cortex. It has no significant glucocorticoid (anti-inflammatory) properties.

Aldosterone has been given by intramuscular or intravenous injection, with a glucocorticoid, in the treatment of primary adrenocortical insufficiency (p.1498) but synthetic mineralocorticoids such as fludrocortisone (p.1530), which can be given orally, are usually preferred. It has also been used as the sodium succinate.

Amcinonide *(BAN, USAN, rINN)* ⊗

Amcinónida; Amcinonidum; Amcinopol; CL-34699. 16α,17α-Cyclopentylidenedioxy-9α-fluoro-11β,21-dihydroxypregna-1,4-diene-3,20-dione 21-acetate.

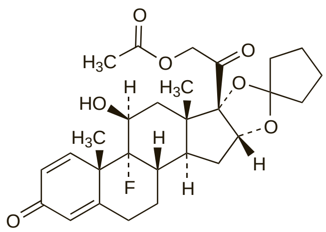
Амцинонид

$C_{28}H_{35}FO_7$ = 502.6.

CAS — 51022-69-6.

ATC — D07AC11.

ATC Vet — QD07AC11.



Pharmacopoeias. In *US.*

Profile

Amcinonide is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream, lotion, or ointment containing 0.1%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

(beclometasone)

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.*, and *Jpn. US* allows either the anhydrous or monohydrate form. *Eur.* also includes a separate monograph for the monohydrate.

Ph. Eur. 6.2 (Beclometasone Dipropionate, Anhydrous). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone. Protect from light.

Ph. Eur. 6.2 (Beclometasone Dipropionate Monohydrate). A white or almost white powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone. Protect from light.

USP 31 (Beclomethasone Dipropionate). It is anhydrous or contains one molecule of water of hydration. A white to cream white, odourless powder. Very slightly soluble in water; freely soluble in alcohol and in acetone; very soluble in chloroform.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (p.1490).

Adrenal suppression may occur in some patients treated with high-dose long-term inhalation therapy for asthma. It has been stated that in the majority of patients no significant suppression is likely to occur when total daily doses of less than 1.5 mg are used (but see Adrenal Suppression, below).

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Systemic absorption may also follow nasal use, particularly after high doses or prolonged treatment.

Adrenal suppression. The problem of adrenal suppression with corticosteroids is discussed on p.1491. Listed below are some references and correspondence concerning adrenal suppression due to beclometasone inhalation therapy,[1-8] in some cases occurring with doses below 1.5 mg daily.[6] However, one study found that function of the hypothalamic-pituitary-adrenal axis remained normal in most patients at beclometasone doses below 3 mg daily.[9]

Candidiasis. Results of a study involving 229 asthmatic children indicated that the presence of a sore throat or a hoarse voice was not related to the presence of *Candida* or to treatment with inhaled beclometasone.[1] The occurrence of only one clinical case of oral candidiasis in 129 of the children receiving beclometasone confirmed previous observations that it is an uncommon finding in children compared with the reported incidence of between 4.5 and 13% in adults. The incidence of colonisation with *Candida* was greater in those children who received corticosteroids than in those who did not but was not affected by either the dose or type of inhaler used.

Effects on the bones. The adverse effects of corticosteroids in general on bones are discussed on p.1491.

Studies in healthy subjects have shown that inhaled beclometasone dipropionate can suppress bone metabolism.[1-3] These studies measured biochemical markers such as serum-osteocalcin concentrations, serum alkaline phosphatase activity, and urinary hydroxyproline-creatinine ratio, over short periods of time. Another study found that markers of collagen turnover, but not osteocalcin, were reduced by beclometasone or budesonide 800 micrograms daily in mildly asthmatic children.[4] Results are difficult to interpret since osteocalcin concentrations are reduced in patients with asthma regardless of treatment,[5] and it is uncertain whether significant bone loss does occur in practice. One 12-month study[6] in adults with asthma found that biochemical markers showed suppressed bone formation from inhaled beclometasone, and that there was some loss of bone mineral density from the hip. This study also found that inhaled fluticasone, in equivalent therapeutic doses, may have less adverse effect on bone. Another, smaller, study[7] found no adverse effects from beclometasone or fluticasone on bone mass or metabolism. In a study[8] of asthmatic children, comparing those treated with inhaled budesonide with those who received no corticosteroids, an average daily dose of about 500 micrograms budesonide for 3 to 6 years did not adversely affect bone density and mineral measures.

Effects on growth. Meta-analysis of 3 eligible studies (out of 92 examined) concluded that inhaled beclometasone therapy at a dose of 400 micrograms daily may cause a 1.54 cm/year decrease in growth in children with mild to moderate asthma.[1] The long-term effects of treatment are unknown, and therefore it is not clear whether catch-up growth will occur on stopping therapy. The lowest possible dose of corticosteroid therapy should be used in asthma, and growth should be monitored.[1] There is also evidence[2] that long-term intranasal beclometasone for the treatment of allergic rhinitis can slow growth in children; the effect on final height is unknown. For further details of the effects of corticosteroids on growth, see p.1492.

Reformulation. Reformulation of some metered-dose inhalers to use a chlorofluorocarbon (CFC)-free propellant has resulted in a change of efficacy. One CFC-free product (*Qvar, UK*) is reported to be effective at about half the dose[1] required with the standard product (see Uses and Administration, below) and the UK CSM has issued a reminder of the need for dosage reduction when converting from the conventional formulation to this product.[2] An open-label, crossover study in healthy subjects also found higher beclometasone plasma concentrations after use of another brand (*Beclozone, Eire*) of CFC-free product.[3] However, this dose reduction does not apply to all CFC-free formulations of beclometasone. A review[4] concluded that good studies on the bioequivalence between the reference beclometasone preparation and the newer CFC-free formulations are not available.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495. Beclometasone is stated to be readily absorbed from sites of local application, and rapidly distributed to all body tissues. It is metabolised principally in the liver, but also in other tissues including gastrointestinal tract and lung; enzymatic hydrolysis rapidly produces the monopropionate (which has some glucocorticoid activity), and, more slowly, the free alcohol, which is virtually devoid of activity. Only a small proportion of an absorbed dose is excreted in urine, the remainder being excreted in the faeces mainly as metabolites.

Uses and Administration

Beclometasone dipropionate is a corticosteroid with mainly glucocorticoid activity (p.1490) that is stated to exert a topical effect on the lungs without significant systemic activity at recommended doses (but see Adrenal Suppression under Adverse Effects, above). It is used by inhalation, generally from a metered-dose aerosol, for the prophylaxis of asthma (see below).

Many formulations are now available, with differing dosage regimens, and the appropriate product literature should be consulted before starting therapy or changing to another formulation. Furthermore in the UK the doses of beclometasone dipropionate for asthma and rhinitis are expressed in units of 50 micrograms or multiples thereof (dose supplied into the mouthpiece per actuation) whereas in the USA the dose-unit is 42 micrograms or multiples thereof (dose emitted from the mouthpiece); recommended doses therefore appear somewhat lower in the USA than the UK doses given below, although in practical terms there is probably no difference.

In the UK the adult dosage of the **conventional aerosol** and some dry powder inhalers is usually 400 micrograms daily, inhaled in 2 to 4 divided doses for maintenance treatment; if necessary, 600 to 800 micrograms may be inhaled daily initially, subsequently adjusted according to the patient's response. In patients with severe asthma or in those showing only a partial response to standard inhalation doses, high-dose inhalation therapy may be considered; doses of 1 mg daily (250 micrograms four times daily or 500 micrograms twice daily) may be used and may be increased to 1.5 to 2 mg daily (500 micrograms three or four times daily) if necessary; a maximum of 2 mg daily should not be exceeded. In children, 50 or 100 micrograms may be inhaled 2 to 4 times daily according to the response or alternatively, 100 or 200 micrograms may be inhaled twice daily.

Although beclometasone dipropionate is generally inhaled in aerosol form, **inhalation capsules** or **discs** containing powder for inhalation are available for patients who experience difficulty in using the aerosol. Owing to differences in the relative bioavailability to the lungs a 100-microgram dose from an inhalation capsule or disc is approximately equivalent in activity to a 50-microgram dose from a conventional aerosol. Recommended maintenance doses of beclometasone dipropionate from inhalation capsules or discs are therefore *higher*: 200 micrograms inhaled 3 or 4 times daily or 400 micrograms inhaled twice daily for adults, and 100 micrograms inhaled 2 to 4 times daily or 200 micrograms inhaled twice daily for children. Up to 800 micrograms twice daily may be inhaled if necessary in adults requiring high-dose therapy.

In some countries beclometasone dipropionate is now available as a **CFC-free aerosol**. Because of changes in particle size the dose required from some such inhalers may be *lower* than that from a conventional aerosol: typical UK doses for one product (*Qvar*) range from 100 to 200 micrograms daily in mild asthma to 400 to 800 micrograms daily in severe asthma, given as 2 divided doses.

Inhalation of **nebulised** beclometasone dipropionate has also been used in the management of asthma in children.

Beclometasone dipropionate is also used as a **nasal spray** in the prophylaxis and treatment of allergic and non-allergic rhinitis (p.565). Usual doses are 100 micrograms in each nostril twice daily or 50 micrograms in each nostril 3 or 4 times daily; a total of 400 micrograms daily should not generally be exceeded. A dose of 50 micrograms in each nostril twice daily may be sufficient for prophylaxis. The nasal spray is also used to prevent recurrence of nasal polyps after surgical removal (p.1508).

Beclometasone dipropionate is also used **topically** in the treatment of various skin disorders. It is generally applied as a cream or ointment containing 0.025%. Beclometasone salicylate has also been used topically. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Adenoidal hypertrophy. Although normally managed by surgery (or if less severe simply by symptomatic relief) adenoidal hypertrophy in children was reported to respond to aqueous nasal beclometasone 336 micrograms daily in an 8-week crossover study.[1] Improvements in adenoidal obstruction and symptom scores were enhanced in a subsequent 16-week follow-on study using 168 micrograms daily. Another similar study,[2] of an initial 4-week crossover period followed by 24 weeks of open-label treatment, found symptomatic improvements in about half of the patients, and at 100 weeks there was a decrease in the rate of adenotonsillectomy in children who had responded to beclometasone compared with nonresponders.

Asthma. Corticosteroids and beta$_2$-adrenoceptor agonists form the cornerstone of the management of asthma (p.1108). Patients requiring only occasional relief from symptoms may be managed with an inhaled short-acting beta$_2$ agonist, and an inhaled corticosteroid such as beclometasone is added if symptomatic relief is needed more than once daily. In more severe asthma other drugs may be added (combination with a long-acting beta$_2$ agonist may have synergistic benefits), or the dose of inhaled corticosteroid may be increased.

High-dose regimens may pose problems of compliance if beclometasone must be inhaled several times daily. However, one study[1] found once-daily inhalation to be as effective as the same dose divided into 2 daily inhalations in short-term control of moderate asthma. Also there have been doubts that increasing the dose of inhaled beclometasone brings about increased benefits,[2] but guidelines and clinical practice suggest that improved control can often be achieved by increasing the dose. A systematic review[3] noted that while there was little evidence of an effect of dose titration above 400 micrograms daily in those with mild to moderate asthma, evidence was lacking in patients with more severe disease (who are more likely to be given high-dose therapy), and studies were needed to resolve the question.

Inhalation of beclometasone dipropionate as a nebulised solution has been found to be useful in the management of severe asthma in children aged 2 years or under previously unresponsive to other drugs.[4] Nebulised beclometasone dipropionate was also effective in the management of recurrent episodes of bronchopulmonary obstruction following bronchiolitis in children under 2 years of age.[5] However, in other reports nebulised beclometasone dipropionate, although more effective than saline in pre-school children, produced a response less than that usually observed with inhalation of beclometasone from an aerosol or capsules,[6] or no benefit at all.[7] This may have been due to beclometasone somehow failing to reach the lungs.[8] In pre-school children able to use a spacer device with a metered aerosol, intermittent therapy with high-dose beclometasone dipropionate, given at the first sign of symptoms, reduced the severity of acute episodic asthma.[9]

Chronic obstructive pulmonary disease. For discussion of the value of inhaled corticosteroids in chronic obstructive pulmonary disease, see p.1501.

Cough. In children with recurrent cough inhalation of beclometasone 200 micrograms twice daily from a conventional aerosol or salbutamol 200 micrograms twice daily had no effect on cough frequency or severity.[1] However, in another study of 200 adults, use of beclometasone, salbutamol, or sodium cromoglicate (all in aerosol formulation) given 15 minutes before anaesthesia, significantly decreased coughing caused by fentanyl when compared with placebo. Of the 50 patients given beclometasone, none experienced coughing.[2]

Graft-versus-host disease. Beclometasone is under investigation for its topical effect in the treatment of intestinal graft-versus-host disease (GVHD). A study[1] in patients with acute intestinal GVHD after bone marrow transplantation (see Haematopoietic Stem Cell Transplantation, p.1811) found that addition of oral beclometasone to prednisolone therapy was associated with a greater proportion of durable responses after 30 days. Repeated courses may be needed in some patients to achieve and maintain response, but prolonged therapy appears to be feasible.[2]

2. Iyer RV, *et al.* Long-term use of oral beclomethasone dipropionate for the treatment of gastrointestinal graft-versus-host disease. *Biol Blood Marrow Transplant* 2005; **11:** 587–92.

Inflammatory bowel disease. Beclometasone 500 micrograms given nightly as an enema was as effective as betamethasone 5 mg enemas in the treatment of acute attacks of distal ulcerative colitis.[1] Although betamethasone produced slightly superior histological improvement and faster disappearance of blood from the stools, systemic adverse effects observed with betamethasone therapy were absent in patients treated with beclometasone.

Comparisons of beclometasone dipropionate enemas (3 mg) with prednisolone sodium phosphate enemas[2] (30 mg) or mesalazine enemas[3] (1 g) found them to be equally effective. Treatment was well tolerated. Beclometasone dipropionate has also been investigated for the oral treatment of ulcerative colitis.[4,5]

For a review of the management of inflammatory bowel disease, including the role of corticosteroids, see p.1697.

Betamethasone *(BAN, USAN, rINN)* ⊗

Beetametasoni; Betadexamethasone; Betametason; Betametasona; Betametazon; Betametazonas; Betamethason; Bétaméthasone; Betamethasonum; Flubenisolone; Flubenisolonum; 9α-Fluoro-16β-methylprednisolone; β-Methasone; NSC-39470; Sch-4831. 9α-Fluoro-11β,17α,21-trihydroxy-16β-methylpregna-1,4-diene-3,20-dione.

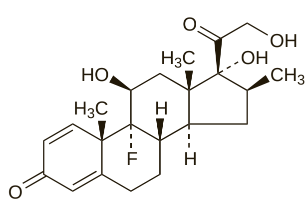
Бетаметазон

$C_{22}H_{29}FO_5$ = 392.5.

CAS — 378-44-9.

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QD07XC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS01CB04; QS02BA07; QS03BA03.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Betamethasone). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in dehydrated alcohol; very slightly soluble in dichloromethane. Protect from light.

USP 31 (Betamethasone). A white to practically white, odourless, crystalline powder. Soluble 1 in 5300 of water, 1 in 65 of alcohol, 1 in 15 of warm alcohol, 1 in 325 of chloroform, and 1 in 3 of methyl alcohol; sparingly soluble in acetone and in dioxan; very slightly soluble in ether. Store in airtight containers at a temperature between 2° and 30°.

Betamethasone Acetate *(BANM, rINNM)* ⊗

Acetato de betametasona; Beetametasoniasetaatti; Betametasonacetat; Betametazon Asetat; Betametazon-acetát; Betametazono acetatas; Betamethason-acetát; Bétaméthasone, acétate de; Betamethasoni acetas. Betamethasone 21-acetate.

Бетаметазона Ацетат

$C_{24}H_{31}FO_6$ = 434.5.

CAS — 987-24-6.

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS02BA07; QS03BA03.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Betamethasone Acetate). A white or almost white, crystalline powder. Practically insoluble in water; soluble in alcohol and in dichloromethane; freely soluble in acetone. It shows polymorphism. Protect from light.

USP 31 (Betamethasone Acetate). A white to creamy-white, odourless powder. Soluble 1 in 2000 of water, 1 in 9 of alcohol, and 1 in 16 of chloroform; freely soluble in acetone. Store in airtight containers at a temperature between 2° and 30°.

Betamethasone Benzoate *(BANM, USAN, rINNM)* ⊗

Benzoato de betametasona; Bétaméthasone, Benzoate de; Betamethasoni Benzoas; W-5975. Betamethasone 17α-benzoate.

Бетаметазона Бензоат

$C_{29}H_{33}FO_6$ = 496.6.

CAS — 22298-29-9.

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS02BA07; QS03BA03.

Pharmacopoeias. In *US.*

USP 31 (Betamethasone Benzoate). A white to practically white, practically odourless, powder. Insoluble in water; soluble in alcohol, in chloroform, and in methyl alcohol. Store in airtight containers at a temperature between 2° and 30°.

Betamethasone Dipropionate

(BANM, USAN, rINNM) ⊗

Beetametasonidipropionaatti; Betametasondipropionat; Betametazon Dipropiyonat; Betametazon-dipropionát; Betametazono dipropionatas; Betametazonu dipropionian; Betamethason-dipropionát; Bétaméthasone, dipropionate de; Betamethasoni dipropionas; Dipropionato de betametasona; Sch-11460. Betamethasone 17α,21-dipropionate.

Бетаметазона Дипропионат

$C_{28}H_{37}FO_7$ = 504.6.

CAS — 5593-20-4.

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS02BA07; QS03BA03.

NOTE. Compounded preparations of betamethasone dipropionate may be represented by the following names:

- Co-climasone (*PEN*)—clotrimazole and betamethasone dipropionate.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Betamethasone Dipropionate). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone and in dichloromethane. Protect from light.

USP 31 (Betamethasone Dipropionate). A white to cream-white, odourless powder. Insoluble in water; sparingly soluble in alcohol; freely soluble in acetone and in chloroform. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°.

Betamethasone Sodium Phosphate

(BANM, rINNM) ⊗

Beetametasoninatriumfosfaatti; Betametasonnatrifosfatum; Betametazon Disodyum Fosfat; Betametazon-nátrium-foszfát; Betametazono natrio fosfatas; Betamethasone Disodium Phosphate; Bétaméthasone, phosphate sodique de; Betamethason-fosfát sodná sůl; Betamethasoni natrii phosphas; Fosfato sódico de betametasona; Natrii Betamethasoni Phosphas. Betamethasone 21-(disodium phosphate).

Натрия Бетаметазона Фосфат

$C_{22}H_{28}FNa_2O_8P$ = 516.4.

CAS — 360-63-4 (betamethasone phosphate); 151-73-5 (betamethasone sodium phosphate).

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS02BA07; QS03BA03.

NOTE. BET is a code approved by the BP 2008 for use on single unit doses of eye drops containing betamethasone sodium phosphate where the individual container may be too small to bear all the appropriate labelling information.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Betamethasone Sodium Phosphate). A white or almost white, very hygroscopic, powder. Freely soluble in water; slightly soluble in alcohol; practically insoluble in dichloromethane. A 1% solution in water has a pH of 7.5 to 9.0. Store in airtight containers. Protect from light.

USP 31 (Betamethasone Sodium Phosphate). A white to practically white, odourless, hygroscopic, powder. Soluble 1 in 2 of water and 1 in 470 of alcohol; freely soluble in methyl alcohol; practically insoluble in acetone and in chloroform. Store in airtight containers.

Betamethasone Valerate (*BANM, USAN, rINNM*) ⊗

Beetametasonivaleraatti; Betametasonvalerat; Betametazon Valerat; Betametazono valeratas; Betametazonu walerianian; Betametazon-valerát; Bétaméthasone, valérate de; Betamethasoni valeras; Betamethason-valerát; Valerato de betametasona. Betamethasone 17α-valerate.

Бетаметазона Валерат

$C_{27}H_{37}FO_6$ = 476.6.

CAS — 2152-44-5.

ATC — A07EA04; C05AA05; D07AC01; H02AB01; R01AD06; R03BA04; S01BA06; S02BA07; S03BA03.

ATC Vet — QA07EA04; QC05AA05; QD07AC01; QH02AB01; QR01AD06; QR03BA04; QS01BA06; QS02BA07; QS03BA03.

Pharmacopoeias. In *Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Betamethasone Valerate). A white or almost white, crystalline powder. Practically insoluble in water; soluble in alcohol; freely soluble in acetone and in dichloromethane. Protect from light.

USP 31 (Betamethasone Valerate). A white to practically white, odourless, powder. Practically insoluble in water; soluble 1 in 16 of alcohol, 1 in less than 10 of chloroform, and 1 in 400 of ether; freely soluble in acetone; slightly soluble in benzene. Store in airtight containers.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Betamethasone has little or no effect on sodium and water retention.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or when given intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Anosmia. Complete anosmia was reported in 2 patients after the use of nasal drops containing betamethasone and neomycin sulfate[1] and, in one patient, showed no sign of resolving 1 year later. The reaction was thought to be due to the preservative thiomersal present in the drops, although it was noted that neomycin could exert a toxic effect on the olfactory mucosa and that there have been several reports of anosmia associated with the use of betamethasone alone.

1. Whittet HB, *et al.* Anosmia due to nasal administration of corticosteroid. *BMJ* 1991; **303:** 651.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495. Betamethasone crosses the placenta.

Uses and Administration

Betamethasone is a corticosteroid with mainly glucocorticoid activity (p.1490); the anti-inflammatory activity of 750 micrograms of betamethasone is equivalent to about 5 mg of prednisolone. It has been used, either in the form of the free alcohol or in one of the esterified forms, in the treatment of conditions for which corticosteroid therapy is indicated (p.1495), except adrenal-deficiency states for which hydrocortisone with supplementary fludrocortisone is preferred. Its virtual lack of mineralocorticoid properties makes betamethasone particularly suitable for treating conditions in which water retention would be a disadvantage.

The dose is usually expressed in terms of the base, and the following are each equivalent to about 1 mg of betamethasone:

- betamethasone acetate 1.1 mg
- betamethasone benzoate 1.3 mg
- betamethasone dipropionate 1.3 mg
- betamethasone sodium phosphate 1.3 mg
- betamethasone valerate 1.2 mg

When given orally betamethasone or betamethasone sodium phosphate are used; the usual dose, expressed in terms of betamethasone, ranges from 0.5 to 5 mg daily.

For parenteral use the sodium phosphate ester may be given intravenously by injection or infusion or intramuscularly by injection in doses equivalent to 4 to 20 mg of betamethasone. It may also be given by local injection into soft tissues in doses equivalent to 4 to 8 mg of betamethasone. Doses in children, as a slow intravenous injection, are:

- infants aged up to 1 year: the equivalent of 1 mg of betamethasone
- 1 to 5 years: 2 mg
- 6 to 12 years: 4 mg

Doses may be repeated 3 or 4 times in 24 hours if necessary, depending on the condition being treated and the clinical response. The sodium phosphate ester is also sometimes used with the acetate or dipropionate esters, which have a slower and more prolonged action.

Betamethasone sodium phosphate is also used in the topical treatment of allergic and inflammatory conditions of the eyes, ears, or nose, usually as drops or ointment containing 0.1%.

For topical application in the treatment of various skin disorders the dipropionate and valerate esters of betamethasone are extensively used; the usual concentrations available are the equivalent of 0.05% of betamethasone as the dipropionate, and 0.025 or 0.1% as the valerate. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Betamethasone valerate has also been used by inhalation for the prophylaxis of asthma.

Other esters of betamethasone which have occasionally been used include the benzoate, butyrate propionate, phosphate, salicylate (cortobenzolone), and valeroacetate.

Betamethasone adamantoate has been used in veterinary practice.

Haemangioma. For reference to the use of a mixture of betamethasone and triamcinolone for the intralesional injection of haemangiomas, see p.1505.

Inflammatory bowel disease. For a comparison of betamethasone and beclometasone enemas in the treatment of ulcerative colitis, see under Beclometasone, p.1518. Corticosteroids are one of the mainstays of treatment of inflammatory bowel disease, the general management of which is discussed on p.1697.

Neonatal respiratory distress syndrome. For a discussion on the antenatal use of betamethasone to prevent neonatal respiratory distress syndrome, see p.1508.

Preparations

BP 2008: Betamethasone and Clioquinol Cream; Betamethasone and Clioquinol Ointment; Betamethasone Eye Drops; Betamethasone Injection; Betamethasone Sodium Phosphate Tablets; Betamethasone Tablets; Betamethasone Valerate Cream; Betamethasone Valerate Lotion; Betamethasone Valerate Ointment; Betamethasone Valerate Scalp Application;

USP 31: Betamethasone Benzoate Gel; Betamethasone Cream; Betamethasone Dipropionate Cream; Betamethasone Dipropionate Lotion; Betamethasone Dipropionate Ointment; Betamethasone Dipropionate Topical Aerosol; Betamethasone Sodium Phosphate and Betamethasone Acetate Injectable Suspension; Betamethasone Sodium Phosphate Injection; Betamethasone Syrup; Betamethasone Tablets; Betamethasone Valerate Cream; Betamethasone Valerate Lotion; Betamethasone Valerate Ointment; Clotrimazole and Betamethasone Dipropionate Cream.

Proprietary Preparations (details are given in Part 3)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Budesonide). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in dichloromethane.

USP 31 (Budesonide). A white to off-white, odourless, crystalline powder. Practically insoluble in water and in heptane; sparingly soluble in alcohol; freely soluble in chloroform. Store in airtight containers at a temperature of 20° to 25°, excursions permitted between 15° and 30°. Protect from light.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Inhalation of high doses of budesonide is associated with some adrenal suppression. Systemic absorption may follow nasal use, particularly after high doses or prolonged treatment. The dose of oral budesonide may need to be reduced in hepatic impairment (see also Administration in Hepatic Impairment, below).

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or when given intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects.

Effects on the bones. For mention of the effects of inhaled budesonide on markers of collagen turnover and bone density in asthmatic children, see under Adverse Effects of Beclometasone, p.1516. For the suggestion that inhalation once-daily in the morning may have less marked effects on growth and collagen turnover than twice-daily inhalation, see Administration, below.

Effects on the nervous system. Psychotic behaviour has been reported after use of inhaled budesonide.[1-3]

1. Lewis LD, Cochrane GM. Psychosis in a child inhaling budesonide. *Lancet* 1983; **ii:** 634.
2. Meyboom RHB, de Graff-Breederveld N. Budesonide and psychic side effects. *Ann Intern Med* 1988; **109:** 683.
3. Connett G, Lenney W. Inhaled budesonide and behavioural disturbances. *Lancet* 1991; **338:** 634–5.

Hypersensitivity. Contact dermatitis has been reported to topical or intranasal budesonide.[1] An anaphylactoid reaction occurred 5 minutes after the first dose of oral budesonide in a patient who had previously reacted in a similar way to mesalazine.[2]

1. Quintiliani R. Hypersensitivity and adverse reactions associated with the use of newer intranasal corticosteroids for allergic rhinitis. *Curr Ther Res* 1996; **57:** 478–88.
2. Heeringa M, *et al.* Anaphylactic-like reaction associated with oral budesonide. *BMJ* 2000; **321:** 927.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495. Budesonide is rapidly and almost completely absorbed after oral administration, but has poor systemic availability (about 10%) due to extensive first-pass metabolism in the liver, mainly by the cytochrome P450 isoenzyme CYP3A4. The major metabolites, 6-β-hydroxybudesonide and 16-α-hydroxyprednisolone have less than 1% of the glucocorticoid activity of unchanged budesonide. Budesonide is reported to have a terminal half-life of about 2 to 4 hours.

Uses and Administration

Budesonide is a corticosteroid with mainly glucocorticoid activity (p.1490). It is used by inhalation in the management of **asthma**, in usual doses of 400 micrograms daily in 2 divided doses from a metered-dose aerosol; in severe asthma the dosage may be increased up to a total of 1.6 mg daily, and guidelines for the management of asthma permit up to 2 mg daily (see p.1108). Maintenance doses may be less than 400 micrograms daily but should not be below 200 micrograms daily. A dose for children is 50 to 400 micrograms inhaled twice daily. Budesonide is also available for the management of asthma in the form of a dry powder inhaler; doses are 200 to 800 micrograms daily, as 2 divided doses or a single daily dose; up to 800 micrograms twice daily may be given to adults if necessary. Patients for whom budesonide from a pressurised inhaler or dry powder formulation is unsatisfactory may use a nebulised solution. The usual adult dosage by this method is 1 to 2 mg inhaled twice daily. This may be increased if asthma is severe. Maintenance doses are 0.5 to 1 mg inhaled twice daily. For children between 3 months and 12 years of age, an initial dose is 0.5 to 1 mg twice daily with a maintenance dose of 0.25 to 0.5 mg twice daily.

Budesonide is also given by inhalation as a nebulised solution in the management of childhood **croup** (p.1502). The usual dose is 2 mg, as a single inhaled dose or 2 doses of 1 mg, given 30 minutes apart.

Budesonide is used topically in the treatment of various **skin disorders**, as a cream, lotion, or ointment containing 0.025%. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Budesonide is also used intranasally for the prophylaxis and treatment of **rhinitis** (p.565). In the UK, two nasal spray preparations are available, one containing 100 micrograms per metered spray, and one containing 64 micrograms per metered spray. The initial recommended dose for adults and children over 12 years is either 2 sprays into each nostril once daily in the morning, or 1 spray into each nostril twice daily. This may be subsequently reduced to 1 spray into each nostril once daily; treatment can be continued for up to 3 months. In the USA and some other countries, a nasal spray and a nasal inhaler are available. The intranasal dose may be expressed in multiples of 32 micrograms, which is the quantity of budesonide delivered from the nasal adaptor. When given from a nasal inhaler, the recommended initial dose for adults and children over 6 years is 4 sprays into each nostril in the morning, or 2 sprays into each nostril twice daily, to give a total daily dose of 256 micrograms daily. This is reduced to the lowest dose adequate to control symptoms. If no benefit is seen after 3 weeks of treatment, budesonide should be stopped. When given as an aqueous nasal spray, the recommended initial dose for adults and children over 6 years is 1 spray into each nostril once daily (64 micrograms daily), increasing as necessary up to a maximum of 256 micrograms daily for adults and 128 micrograms daily for children aged less than 12 years. Budesonide is also used as a nasal spray in the management of **nasal polyps** (p.1508). In the UK, for adults and children over 12 years, 1 spray (containing 64 or 100 micrograms, as above) is given into each nostril twice daily for up to 3 months.

Local formulations of budesonide are used in the management of **inflammatory bowel disease** (see below). In mild to moderate Crohn's disease affecting the ileum or ascending colon it is given orally as modified-release capsules intended for a topical effect on the gastrointestinal tract. The recommended dose is 9 mg daily for active disease, as either a single dose before breakfast or in 3 divided doses about 30 minutes before meals, depending on the preparation. Treatment is given for up to 8 weeks, and the dosage should be reduced 2 to 4 weeks before discontinuing therapy. For recurring episodes of active Crohn's disease, an 8-week course may be repeated. After an 8-week course for active disease, budesonide 6 mg once daily is recommended for maintenance of clinical remission, for up to 3 months; thereafter, doses are tapered and therapy stopped, as continued treatment has not shown substantial clinical benefit. There is some absorption of budesonide from the gastrointestinal tract, and the dose may need to be reduced in patients with hepatic impairment, especially those with cirrhosis (see also Administration in Hepatic Impairment, below). Ulcerative colitis affecting the rectum and sigmoid colon may be treated locally with budesonide. A retention enema providing a dose of 2 mg in 100 mL is given daily at bedtime for 4 weeks, which may be extended to 8 weeks if the patient is not in remission after the initial 4-week course. Alternatively, a rectal foam can be used in a dose of 2 mg once daily, usually for 6 to 8 weeks. The dose may be given in the morning or the evening, but treatment is more effective if the bowel is emptied before a dose is given.

Local formulations of budesonide are also used in the management of **collagenous colitis** (see below). It is given orally as modified-release capsules in a dose of 3 mg three times daily for up to 8 weeks. The dosage should be reduced gradually during the last 2 weeks of therapy.

Administration. *INHALATIONAL ROUTE.* One study in 6 children aged up to 30 months found that about 75% of the nominal dose of nebulised budesonide was deposited in the nebuliser system,[1] while a study in 126 older children indicated that maintenance doses of budesonide could be halved when the dose was given by dry powder inhaler rather than nebuliser, without any loss of asthma control.[2] Although oropharyngeal deposition is thought to play a role in the systemic effects of inhaled corticosteroids, another study[3] indicated that only about 20% of the systemically available drug appeared to be derived from oropharyngeal deposition after inhalation from a dry powder inhaler.

There is evidence that the timing of inhaled therapy might influence some systemic effects. A study[4] in children with mild asthma found that 800 micrograms of budesonide inhaled in the morning had less effect on measurements of short-term growth and collagen turnover than inhalation of 400 micrograms twice daily.

Administration in hepatic impairment. In a study[1] of patients with primary biliary cirrhosis the clearance of oral budesonide was significantly reduced in those with cirrhosis (stage IV) compared with milder disease (stage I/II). Elevated budesonide concentrations were sufficient to suppress cortisol production, and believed to be associated with the development of portal vein thrombosis in 2 cirrhotic patients.

Collagenous colitis. Budesonide has been used in a few small controlled studies[1-5] of the management of collagenous colitis (see Microscopic Colitis, p.1700). Treatment courses given orally for 6 or 8 weeks were found to improve symptoms and histology, and the short-term benefits have been confirmed by meta-analysis,[6] although high rates of relapse after stopping treatment have been reported.[3,5]

Cystic fibrosis. Cystic fibrosis (p.166) is associated with bronchial hyper-responsiveness; a small study[1] has suggested that inhalation of budesonide 1.6 mg daily for 6 weeks improves hyper-responsiveness slightly and leads to improvement in cough and dyspnoea. A larger study[2] of budesonide given for two successive 3-month treatment periods found improved hyper-responsiveness and a trend towards slower decline in lung function.

Inflammatory bowel disease. Budesonide has been given as an enema for the treatment of distal ulcerative colitis, in which context its potency and low systemic availability are advantageous.[1] A rectal foam has also been developed, which may be easier to use, and retain in the bowel, than an enema.[2] Budesonide is available as a modified-release oral dosage form for the management of active Crohn's disease.[1,3] Ileal-release preparations of budesonide have been indicated as first-line therapy in the treatment of mild to moderate ileal and right-sided colonic Crohn's disease.[4] Systematic review[5] has suggested that it is slightly less effective than conventional corticosteroid therapy, but is associated with fewer adverse effects. Budesonide has also been effective in delaying relapse in quiescent disease.[6-8] However, the benefit appears to be short-term (3 months)[4] and it has been concluded that oral modified-release budesonide is not effective in long-term (12 months) maintenance of remission.[4,9] Similarly, oral budesonide was ineffective in preventing postoperative recurrence after resection for Crohn's disease.[10]

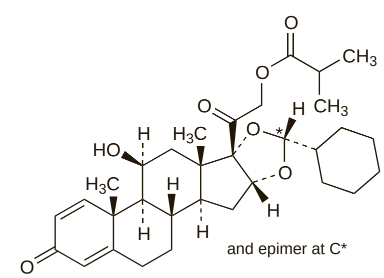
CAS — 126544-47-6; 141845-82-1.

ATC — R03BA08.

ATC Vet — QR03BA08.



and epimer at C*

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Systemic absorption may follow inhalation of ciclesonide, particularly if high doses are used for prolonged periods.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495. Ciclesonide is hydrolysed to its biologically active metabolite by esterase enzymes in the lung and nasal mucosa; the systemic bioavailability for the active metabolite is reported to be more than 50% when ciclesonide is given by metered-dose inhaler.

Oral bioavailability is less than 1%. Ciclesonide and its active metabolite are extensively bound to plasma proteins. It is further metabolised to inactive metabolites via the cytochrome P450 isoenzyme CYP3A4. After oral or intravenous dosage, ciclesonide is mainly excreted via the faeces.

Uses and Administration

Ciclesonide is a corticosteroid with glucocorticoid activity (p.1490). It is used by inhalation in the management of asthma (p.1108) in adults and adolescents aged 12 years and older. The usual dose is 160 micrograms once daily from a metered-dose aerosol; the dose may be reduced to 80 micrograms once daily for maintenance. It is preferably given in the evening. Ciclesonide is given intranasally for the treatment of seasonal and perennial allergic rhinitis (p.565) in adults and adolescents 12 years of age and older; children 6 years of age and older may be treated for seasonal allergic rhinitis. A dose of 200 micrograms once daily is given as 2 sprays of 50 micrograms into each nostril.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Clobetasol Propionate). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone. Protect from light.

USP 31 (Clobetasol Propionate). A white to cream crystalline powder. Practically insoluble in water; sparingly soluble in dehydrated alcohol; soluble in acetone, in chloroform, in dimethyl sulfoxide, in dioxan, and in methyl alcohol; slightly soluble in benzene and in ether. Store in airtight containers. Protect from light.

Profile

Clobetasol propionate is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream, ointment, gel, scalp application, or foam containing 0.05%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

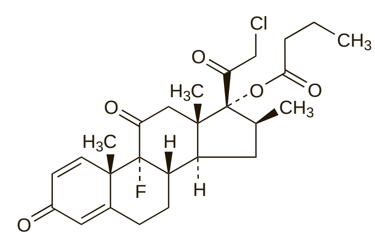
ATC — D07AB01; S01BA09.

ATC Vet — QD07AB01; QS01BA09.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Clobetasone Butyrate). A white or almost white powder. Practically insoluble in water; slightly soluble in alcohol; freely soluble in acetone and in dichloromethane. Protect from light.

Profile

Clobetasone butyrate is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream or ointment containing 0.05%. When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Clobetasone butyrate is also used for inflammatory eye disorders, as eye drops containing 0.1%. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intraocular pressure and reduced visual function.

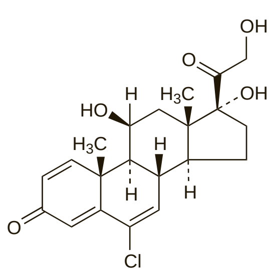
Cloprednol (BAN, USAN, rINN) ⊗

Cloprednolum; RS-4691. 6-Chloro-11β,17α,21-trihydroxypregna-1,4,6-triene-3,20-dione.

Клопреднол

$C_{21}H_{25}ClO_5$ = 392.9.
CAS — 5251-34-3.
ATC — H02AB14.
ATC Vet — QH02AB14.



Profile

Cloprednol is a corticosteroid with mainly glucocorticoid activity (p.1490); the anti-inflammatory activity of 2.5 mg of clopredнol is equivalent to about 5 mg of prednisolone. Cloprednol is given orally in various disorders for which corticosteroid therapy is helpful (p.1495), in usual doses ranging from 1.25 to 12.5 mg daily.

Preparations

Proprietary Preparations (details are given in Part 3)

CAS — 121249-14-7 (corticorelin ovine triflutate).
ATC — V04CD04.
ATC Vet — QV04CD04.

NOTE. Corticorelin Ovine Triflutate is *USAN.*

Adverse Effects

Flushing of the face, neck, and upper chest, and mild dyspnoea may follow intravenous injection of corticorelin, and last for about 3 to 5 minutes. Prolonged flushing, tachycardia, hypotension, and chest tightness have been reported after large doses.

Effects on the cardiovascular system. Loss of consciousness, lasting for 10 seconds to 5 minutes, occurred in 3 patients, 2 of whom had Cushing's disease and one who had secondary adrenal insufficiency, after intravenous injection of corticorelin 200 micrograms.[1] The 2 patients with Cushing's disease had a slight accompanying fall in blood pressure. In a fourth patient, receiving corticosteroid and thyroid hormone replacement therapy, injection of corticorelin was associated with a sharp fall in systolic blood pressure and subsequent asystole. These serious adverse effects were not noted by others[2,3] and were variously attributed to impurities,[2] high dosage,[2] vasovagal syncope,[3] or to the fact that the corticorelin used in the study was of ovine rather than human origin.[3] The authors of the original study[1] have since stated[4] that lowering of the dose from 200 micrograms given intravenously over 10 seconds to 100 micrograms over 60 seconds has stopped serious adverse effects but that ovine corticorelin was still preferred because of its longer duration of action and lower incidence of hypotensive adverse effects. There has, however, been a further report of chest pain accompanied by a fall in blood pressure in a patient receiving corticorelin at a dose of 100 micrograms.[5]

5. Paloma VC, *et al.* Chest pain after intravenous corticotropin-releasing hormone. *Lancet* 1989; **i:** 222.

Uses and Administration

Corticorelin is a polypeptide hypothalamic releasing hormone that stimulates the release of corticotropin (p.1523) from the anterior pituitary. It is used in the differential diagnosis of Cushing's syndrome (p.2344) and other adrenal disorders. Corticorelin is usually given as the triflutate, but doses are expressed in terms of corticorelin (human or ovine). A single dose of 100 micrograms, or of 1 microgram/kg, is given by intravenous injection over 30 seconds. Higher and more rapid doses have been used but may be associated with an increased risk of adverse effects (see above).

Corticorelin acetate is under investigation in cerebral oedema.

Administration. Corticorelin was well absorbed after subcutaneous injection and bioavailability was calculated to be about 60 to 70%; absorption was slower with high doses, suggesting that it may be a saturable process. Given the retention of bioactivity, the subcutaneous route was considered an attractive alternative to intravenous use.[1]

1. Angst MS, *et al.* Pharmacokinetics, cortisol release, and hemodynamics after intravenous and subcutaneous injection of human corticotropin-releasing factor in humans. *Clin Pharmacol Ther* 1998; **64:** 499–510.

Diagnosis and testing. Corticorelin may be used in the diagnosis of adrenal disorders including Cushing's syndrome (p.2344). In the initial diagnosis of Cushing's syndrome, a dexamethasone-corticorelin test may be used to identify pseudo-Cushing's conditions such as depression or alcoholism in patients with mild hypercortisolism and equivocal results on other diagnostic tests. This combination is reportedly more accurate than either alone,[1] but it is cumbersome and difficult to carry out on an ambulatory basis.[2]

When a diagnosis of ACTH-dependent Cushing's syndrome has been established, corticorelin may be used for differential diagnosis of the subtype. Patients with pituitary Cushing's syndrome have an exaggerated increase in plasma-corticotropin and plasma-cortisol concentrations in response to corticorelin, whereas those with adrenal or ectopic syndrome generally have no response.[3,4] The corticorelin stimulation test is of comparable diagnostic efficacy to the dexamethasone suppression test,[5,6] although false results have been obtained with both tests.[2,5,7] Again, a combination of the dexamethasone and corticorelin tests is reportedly more accurate than either alone.[6] The most reliable test to distinguish between pituitary and nonpituitary forms of Cushing's syndrome is to measure the difference between central and peripheral concentrations of ACTH after giving corticorelin.[2] However, this requires sampling of central (petrosal) venous blood, an invasive procedure needing considerable expertise.

Кортикотропин

CAS — 9002-60-2 (corticotropin); 9050-75-3 (corticotropin zinc hydroxide); 8049-55-6 (corticotropin zinc hydroxide).
ATC — H01AA01.
ATC Vet — QH01AA01.

Pharmacopoeias. In *US* as preparations for injection.

Units

5 units of porcine corticotropin for bioassay are contained in about 50 micrograms (with lactose 5 mg) in one ampoule of the third International Standard (1962).

Adverse Effects

Corticotropin stimulates the adrenals to produce cortisol (hydrocortisone) and mineralocorticoids; it therefore has the potential to produce similar adverse glucocorticoid and mineralocorticoid effects to those of the corticosteroids (see p.1490). In particular, its mineralocorticoid properties can produce marked sodium and water retention; considerable potassium loss may also occur.

Corticotropin can induce sensitisation, and severe hypersensitivity reactions, including anaphylaxis, may occur. This is generally considered to be due to the porcine component of the peptide.

Whereas corticosteroids replace endogenous cortisol (hydrocortisone) and thereby induce adrenal atrophy, corticotropin's stimulant effect induces hypertrophy. Nevertheless, the ability of the hypothalamic-pituitary-adrenal axis to respond to stress is still reduced, and abrupt withdrawal of corticotropin may result in symptoms of adrenal insufficiency (see Withdrawal, below).

◊ Reports of adverse effects in children given corticotropin for infantile spasms.

2. Hanefeld F, *et al.* Renal and pancreatic calcification during treatment of infantile spasms with ACTH. *Lancet* 1984; **i:** 901.
3. Riikonen R, *et al.* Disturbed calcium and phosphate homeostasis during treatment with ACTH of infantile spasms. *Arch Dis Child* 1986; **61:** 671–6.
4. Perheentupa J, *et al.* Adrenocortical hyporesponsiveness after treatment with ACTH of infantile spasms. *Arch Dis Child* 1986; **61:** 750–3.

Withdrawal

Corticotropin use may depress the hypothalamic-pituitary-adrenal axis. Abrupt withdrawal of corticotropin may therefore produce adrenocortical and pituitary unresponsiveness, and therapy should be stopped gradually. An increase in corticosteroid requirements associated with the stress of infection, or accidental or surgical trauma, may also precipitate acute adrenocortical insufficiency. See also Withdrawal under Corticosteroids, p.1493.

Precautions

As for Corticosteroids, p.1493.

Phaeochromocytoma. A hypertensive crisis in a patient given intravenous tetracosactide led to the discovery of an adrenaline-secreting phaeochromocytoma in a patient.[1] It was suggested that caution should be observed when using corticotropin in patients with orthostatic hypotension in whom the diagnosis of phaeochromocytoma has not been excluded.

1. Jan T, *et al.* Epinephrine-producing pheochromocytoma with hypertensive crisis after corticotropin injection. *Am J Med* 1990; **89:** 824–5.

Interactions

Interactions seen with corticotropin are liable to be similar to those with corticosteroids (p.1494).

Uses and Administration

Corticotropin is a naturally occurring hormone of the anterior lobe of the pituitary gland. It stimulates the adrenal glands to secrete adrenocortical hormones, especially cortisol (hydrocortisone), some mineralocorticoids such as corticosterone, and, to a lesser extent, androgens. It has little effect on aldosterone secretion, which proceeds independently.

Secretion of corticotropin by the functioning pituitary gland is controlled by the release of corticorelin from the hypothalamus and is also regulated by a negative feedback mechanism involving concentrations of circulating glucocorticoids. Conditions of stress may also stimulate secretion.

Corticotropin may be used diagnostically to investigate adrenocortical insufficiency. It has also been used therapeutically in most of the conditions (with the exception of the adrenal deficiency states and adrenocortical overactivity) for which systemic corticosteroid therapy is indicated (p.1495). Such use is now fairly limited. However, corticotropin may be used in certain neurological disorders such as infantile spasms and multiple sclerosis. The synthetic polypeptide tetracosactide (p.1543), which has the same amino-acid sequence as the first 24 residues of human corticotropin, may be used as an alternative. Tosactide is another polypeptide analogue of corticotropin; it has the same sequence as the first 28 residues.

Corticotropin has been available for injection in two forms. One form is a plain injection that may be given by the subcutaneous, intramuscular, or intravenous routes. The other form is a long-acting depot preparation in which the viscosity is increased by the addition of gelatin, and which is given subcutaneously or intramuscularly; it must not be given intravenously. Individual responses to therapeutic corticotropin vary considerably and doses must be adjusted accordingly.

For *diagnostic purposes* the corticotropin test is based on the measurement of plasma-cortisol concentrations before and after injection. The plain preparation is used in doses of 10 to 25 units in 500 mL of glucose 5% infused intravenously over 8 hours.

For *therapeutic purposes* typical initial doses for the depot preparation have been about 20 to 80 units every 24 to 72 hours by the subcutaneous or the intramuscular route. As soon as possible the dosage should be reduced gradually to the minimum necessary to control symptoms.

A depot preparation of corticotropin combined with zinc hydroxide for intramuscular injection has been used in the past.

Epilepsy. The use of corticotropin in the management of infantile spasms is referred to under Epilepsy in Corticosteroids, p.1503.

Multiple sclerosis. Short-term courses of corticotropin have been used to speed recovery from acute exacerbations of multiple sclerosis (p.892) but corticosteroids, usually methylprednisolone, are now preferred.

Post-dural puncture headache. There are anecdotal reports of the relief of post-dural puncture headache by corticotropin or tetracosactide, but a controlled study of tetracosactide use found no benefit (see p.1544).

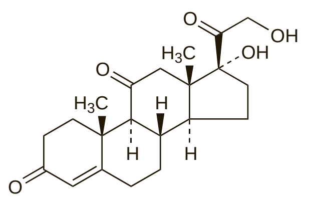
ATC Vet — QH02AB10; QS01BA03.



(cortisone)

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Cortisone Acetate). A white or almost white, crystalline powder. It shows polymorphism. Practically insoluble in water; slightly soluble in alcohol and in methyl alcohol; sparingly soluble in acetone; freely soluble in dichloromethane; soluble in dioxan. Protect from light.

USP 31 (Cortisone Acetate). A white or practically white, odourless, crystalline powder. Insoluble in water; soluble 1 in 350 of alcohol, 1 in 75 of acetone, 1 in 4 of chloroform, and 1 in 30 of dioxan. Store at a temperature of 25°, excursions permitted between 15° and 30°.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Cortisone acetate is readily absorbed from the gastrointestinal tract and the cortisone is rapidly converted in the liver to its active metabolite, hydrocortisone (cortisol). The biological half-life of cortisone itself is only about 30 minutes. Absorption of cortisone acetate from intramuscular sites is considerably slower than after oral doses.

Uses and Administration

Cortisone is a corticosteroid secreted by the adrenal cortex. It has glucocorticoid activity (p.1490), as well as appreciable mineralocorticoid activity; 25 mg of cortisone acetate is equivalent in anti-inflammatory activity to about 5 mg of prednisolone.

Cortisone acetate is rapidly effective when given orally, and more slowly by intramuscular injection.

Cortisone acetate has been used mainly for replacement therapy in adrenocortical insufficiency (p.1498), but hydrocortisone (p.1535) is generally preferred since cortisone itself is inactive and must be converted by the liver to hydrocortisone, its active metabolite; hence, in some liver disorders the activity of cortisone may be less reliable. Doses of cortisone acetate for oral replacement therapy are 12.5 to 37.5 mg daily in divided doses, with fludrocortisone if additional mineralocorticoid activity is required.

Cortisone acetate has been used in the treatment of many of the allergic and inflammatory disorders for which corticosteroid therapy is helpful (p.1495) but prednisolone or other synthetic glucocorticoids are generally preferred. Doses of cortisone acetate employed have generally ranged from about 25 to 300 mg daily by mouth or by intramuscular injection.

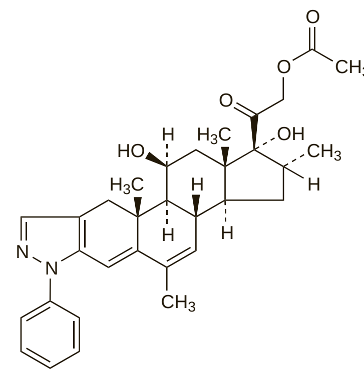
Кортивазол

$C_{32}H_{38}N_2O_5$ = 530.7.
CAS — 1110-40-3.
ATC — H02AB17.
ATC Vet — QH02AB17.



Profile

Cortivazol is a corticosteroid with mainly glucocorticoid activity (p.1490); 300 micrograms of cortivazol is equivalent in anti-inflammatory activity to about 5 mg of prednisolone. It is given in the treatment of musculoskeletal and joint disorders by intra-articular, periarticular, or epidural injection in doses of about 1.25 to 3.75 mg, according to the size of the joint, usually at intervals of 1 to 3 weeks. It has also been given by mouth.

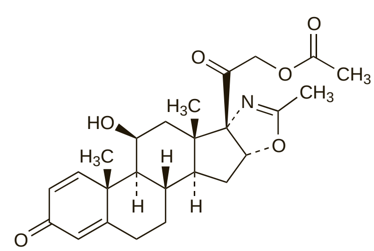
Дефлазакорт

$C_{25}H_{31}NO_6$ = 441.5.
CAS — 14484-47-0.
ATC — H02AB13.
ATC Vet — QH02AB13.



Profile

Deflazacort is a corticosteroid with mainly glucocorticoid activity (p.1490); 6 mg of deflazacort is reportedly equivalent in anti-inflammatory activity to about 5 mg of prednisolone (but see Action, below).

Deflazacort is used for its anti-inflammatory and immunosuppressant properties in conditions responsive to corticosteroid therapy (p.1495). It is given in initial oral doses of up to 120 mg daily; usual maintenance doses are 3 to 18 mg daily. Doses of 0.25 to 1.5 mg/kg daily have been used in children.

Action. Although it has been suggested that deflazacort produces fewer adverse effects than some conventional corticosteroids such as prednisolone, a study in healthy subjects found that the ratio of efficacy for deflazacort compared with prednisolone was higher than the 1.2 : 1 previously assumed,[1] implying that lower effective doses of deflazacort had been used in such comparisons. A review[2] of clinical studies of patients treated with deflazacort concluded that it was slightly less potent than prednisolone, and that many of the data on adverse effects were inconsistent. All systemic corticosteroids may produce clinically significant adverse reactions (see also p.1490) which are primarily dependent on dose and duration of use.

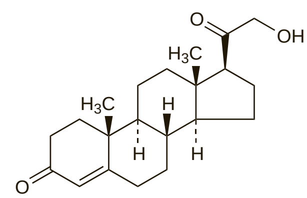
Desoxycortone *(BAN, rINN)*

Decortone; Deoxycortone; Desoksikortoni; Desoxicortona; Desoxikorton; Desoxycorticosterone; Désoxycortone; Desoxycortonum. 21-Hydroxypregn-4-ene-3,20-dione.

Дезоксикортон

$C_{21}H_{30}O_2$ = 314.5.
CAS — 64-85-7.
ATC — H02AA03.
ATC Vet — QH02AA03.



Desoxycortone Acetate *(BANM, rINNM)*

Acetato de desoxicortona; Cortin; Decortone Acetate; 11-Deoxycorticosterone Acetate; Deoxycortone Acetate; Desoksikortoniasetaatti; Desoxikortonacetat; Desoxycorticosterone Acetate; Désoxycortone, acétate de; Desoxycortoni acetas; Desoxykorton-acetát; Dezoksikortono acetatas; Dezoksykortonu octan; Dezoxikorton-acetát. Desoxycortone 21-acetate.

Дезоксикортона Ацетат

$C_{23}H_{32}O_4$ = 372.5.
CAS — 56-47-3.
ATC — H02AA03.
ATC Vet — QH02AA03.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Desoxycortone Acetate). A white or almost white, crystalline powder or colourless crystals. Practically insoluble in water; sparingly soluble in alcohol; soluble in acetone; freely soluble in dichloromethane; slightly soluble in propylene glycol and in fatty oils. Protect from light.

USP 31 (Desoxycorticosterone Acetate). A white or creamy-white, odourless, crystalline powder. Practically insoluble in water; sparingly soluble in alcohol, in acetone, and in dioxan; slightly soluble in vegetable oils. Store at a temperature of 25°, excursions permitted between 15° and 30°. Protect from light.

Desoxycortone Pivalate *(BANM, rINNM)*

Deoxycorticosterone Pivalate; Deoxycorticosterone Trimethylacetate; Deoxycortone Pivalate; Deoxycortone Trimethylacetate; Desoxycorticosterone Pivalate; Desoxycorticosterone Trimethylacetate; Désoxycortone, Pivalate de; Desoxycortoni Pivalas; Pivalato de desoxicortona. Desoxycortone 21-pivalate.

Дезоксикортона Пивалат

$C_{26}H_{38}O_4$ = 414.6.
CAS — 808-48-0.
ATC — H02AA03.
ATC Vet — QH02AA03.

Pharmacopoeias. In *US* for veterinary use only.

USP 31 (Desoxycorticosterone Pivalate). Store at a temperature of 25°, excursions permitted between 15° and 30°. Protect from light.

Profile

Desoxycortone is a corticosteroid secreted by the adrenal cortex and has primarily mineralocorticoid activity (p.1490). It has no significant glucocorticoid action.

Desoxycortone acetate has been used in the treatment of adrenocortical insufficiency (p.1498) as an adjunct to cortisone or hydrocortisone. For this purpose, however, fludrocortisone given orally is now usually preferred.

Desoxycortone acetate is given by intramuscular injection as an oily solution, in doses of up to 10 mg once or twice daily.

Desoxycortone has also been used as its enantate, phenylpropionate, and sodium hemisuccinate esters. Desoxycortone pivalate is used in veterinary medicine.

Preparations

USP 31: Desoxycorticosterone Acetate Injection; Desoxycorticosterone Acetate Pellets.

Proprietary Preparations (details are given in Part 3)

Fr.: Syncortyl; ***Ital.:*** Cortiron; ***Switz.:*** Cortisteron.

Dexamethasone *(BAN, rINN)* ⊗

Deksametasoni; Deksametazon; Deksametazonas; Desamethasone; Dexametason; Dexametasona; Dexametasone; Dexametazon; Dexamethason; Dexaméthasone; Dexamethasonum; 9α-Fluoro-16α-methylprednisolone; Hexadecadrol. 9α-Fluoro-11β,17α,21-trihydroxy-16α-methylpregna-1,4-diene-3,20-dione.

Дексаметазон

$C_{22}H_{29}FO_5$ = 392.5.

CAS — 50-02-2.

ATC — A01AC02; C05AA09; D07AB19; H02AB02; R01AD03; S01BA01; S02BA06; S03BA01.

NOTE. DSP is a code approved by the BP 2008 for use on single unit doses of eye drops containing dexamethasone sodium phosphate where the individual container may be too small to bear all the appropriate labelling information.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *US*, and *Viet.*

Ph. Eur. 6.2 (Dexamethasone Sodium Phosphate). A white or almost white, very hygroscopic, powder. It exhibits polymorphism. Freely soluble in water; slightly soluble in alcohol; practically insoluble in dichloromethane. A 1% solution in water has a pH of 7.5 to 9.5. Store in airtight containers. Protect from light.

USP 31 (Dexamethasone Sodium Phosphate). A white or slightly yellow, crystalline powder. Is odourless or has a slight odour of alcohol, and is exceedingly hygroscopic. Soluble 1 in 2 of water; slightly soluble in alcohol; insoluble in chloroform and in ether; very slightly soluble in dioxan. pH of a 1% solution in water is between 7.5 and 10.5. Store in airtight containers.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Dexamethasone has little or no effect on sodium and water retention.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or when given intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Effects on the neonate. The adverse effects of corticosteroids on the fetus are discussed under Pregnancy on p.1494.

Adverse effects noted in premature neonates with bronchopulmonary dysplasia (p.1500) receiving dexamethasone treatment to enable weaning from assisted ventilation have included hypertension[1-4] often accompanied by bradycardia,[1,2] gastroduodenal perforation,[4-6] ulceration and thinning of the gastric wall,[5] development of a catabolic state,[4,7] renal calcification,[8,9] and transient myocardial hypertrophy.[10-13] There is some evidence of a suppressive effect on motor activity and spontaneous movement.[14] It has been postulated that neonatal dexamethasone may both increase[15] and decrease[16] retinopathy of prematurity; its true effect is uncertain.[17]

There is also a concern that longer term development of the child may be adversely affected.[18,19] Although data are scanty, a meta-analysis[20] has concluded that postnatal use of corticosteroids to treat or prevent bronchopulmonary dysplasia is associated with dramatic increases in the incidence of cerebral palsy and neurodevelopmental impairment, and suggested that such use should be abandoned.

Pulsed dosage may reduce the adverse effects but may also reduce efficacy.[21]

Effects on the nervous system. Paraesthesia, usually localised to the perineum, has been associated with the intravenous use of dexamethasone sodium phosphate (see p.1492).

Interactions

The interactions of corticosteroids in general are described on p.1494. Various drugs may interfere with the dexamethasone suppression test.

Antiepileptics. As mentioned on p.499, dexamethasone may decrease or increase plasma concentrations of *phenytoin*. Like other enzyme-inducing drugs, phenytoin also has the potential to increase the metabolism of dexamethasone. There have been reports of false positive dexamethasone suppression tests (see Diagnosis and Testing, below) in patients taking *carbamazepine*.[1]

1. Ma RCW, *et al.* Carbamazepine and false positive dexamethasone suppression tests for Cushing's syndrome. *BMJ* 2005; **330:** 299–300.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Dexamethasone is readily absorbed from the gastrointestinal tract. Its biological half-life in plasma is about 190 minutes. Binding of dexamethasone to plasma proteins is about 77%, which is less than for most other corticosteroids. Up to 65% of a dose is excreted in urine within 24 hours. Clearance in premature neonates is reported to be proportional to gestational age, with a reduced elimination rate in the most premature. It readily crosses the placenta with minimal inactivation.

Uses and Administration

Dexamethasone is a corticosteroid with mainly glucocorticoid activity (p.1490); 750 micrograms of dexamethasone is equivalent in anti-inflammatory activity to about 5 mg of prednisolone.

It has been used, either in the form of the free alcohol or in one of the esterified forms, in the treatment of conditions for which corticosteroid therapy is indicated (p.1495), except adrenocortical insufficiency for which hydrocortisone with supplementary fludrocortisone is preferred. Its lack of mineralocorticoid properties makes dexamethasone particularly suitable for treating conditions where water retention would be a disadvantage.

The dose may be expressed in terms of the base, and the following are each equivalent to about 1 mg of dexamethasone:

- dexamethasone acetate 1.1 mg
- dexamethasone isonicotinate 1.3 mg
- dexamethasone phosphate 1.2 mg
- dexamethasone sodium metasulfobenzoate 1.5 mg
- dexamethasone sodium phosphate 1.3 mg

Dexamethasone sodium phosphate 1.1 mg is equivalent to about 1 mg of dexamethasone phosphate.

For **oral** administration dexamethasone is given in usual doses of 0.5 to 10 mg daily. Dexamethasone is also used orally in the dexamethasone suppression tests for the diagnosis of Cushing's syndrome (for further details see under Diagnosis and Testing, below).

For **parenteral administration** in **intensive therapy** or in **emergencies**, the sodium phosphate ester may be given intravenously by injection or infusion or intramuscularly by injection; doses are sometimes expressed in terms of the free alcohol, the phosphate, or the sodium phosphate and confusion has sometimes arisen in the literature because of these variations. Initial doses used, expressed in terms of dexamethasone phosphate, range from about 0.5 to 24 mg daily (about 0.4 to 20 mg of dexamethasone). Intravenous doses equivalent to 2 to 6 mg/kg of dexamethasone phosphate given slowly over a minimum period of several minutes have been suggested for the treatment of severe shock. These high doses may be repeated within 2 to 6 hours and this treatment should be continued only until the patient's condition is stable and usually for no longer than 48 to 72 hours. Alternatively, the initial intravenous injection may be followed by a continuous intravenous infusion of 3 mg/kg per 24 hours.

Dexamethasone sodium phosphate is also used in the treatment of **cerebral oedema** caused by malignancy. An initial intravenous dose equivalent to 10 mg of dexamethasone phosphate is usually given followed by 4 mg intramuscularly every 6 hours; a response is usually obtained after 12 to 24 hours and dosage may be reduced after 2 to 4 days, and gradually stopped over 5 to 7 days. A much higher dosage schedule has also been suggested for use in acute life-threatening cerebral oedema; initial doses equivalent to 50 mg of dexamethasone phosphate have been given intravenously on the first day together with 8 mg intravenously every 2 hours reduced gradually over 7 to 13 days. A maintenance dose of 2 mg two or three times daily has been used in patients with recurrent or inoperable neoplasms.

The sodium phosphate ester is given by **intra-articular, intralesional**, or **soft-tissue injection**. For intra-articular injection doses equivalent to 0.8 to 4 mg of dexamethasone phosphate are used depending upon the size of the joint. For soft-tissue injection doses of 2 to 6 mg are used. Injections are repeated every 3 to 5 days to every 2 to 3 weeks.

Dexamethasone acetate may be given by **intramuscular injection** in conditions where corticosteroid treatment is indicated but a prompt response of short duration is not required; doses are equivalent to 8 to 16 mg of dexamethasone, repeated, if necessary, every 1 to 3 weeks. The acetate may also be given locally by **intra-articular** or **soft-tissue injection** in doses equivalent to 4 to 16 mg of dexamethasone, repeated, if necessary, every 1 to 3 weeks, or by **intralesional injection** in doses equivalent to 0.8 to 1.6 mg.

For **ophthalmic disorders** or for topical application in the treatment of various skin disorders, either dexamethasone or its esters may be used; concentrations are often expressed in terms of dexamethasone or dexamethasone phosphate and are commonly 0.05 to 0.1% for eye or ear drops and ointments and 0.1% for topical skin preparations. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

For allergic rhinitis (p.565) and other allergic or inflammatory **nasal conditions**, a nasal spray containing dexamethasone isonicotinate is available; the acetate, phosphate, sodium phosphate, and sodium metasulfobenzoate have also been used.

Dexamethasone is given intravenously and orally for the prevention of **nausea and vomiting** induced by cancer chemotherapy (see below).

Other esters of dexamethasone that have occasionally been used include the hemisuccinate, linoleate, palmitate, pivalate, propionate, sodium succinate, tebutate, and valerate.

The phenpropionate and troxundate esters have been used in veterinary medicine.

Dexamethasone-releasing stents may be used to reduce restenosis after coronary artery stent placement.

Alcohol withdrawal syndrome. Dexamethasone was reported to be effective in a patient with benzodiazepine-resistant delirium tremens[1] and resolved symptoms of alcohol withdrawal syndrome resistant to other treatments in another 110 patients.[2] However, a subsequent small study found no evidence that dexamethasone was effective.[3]

3. Adinoff B, Pols B. Dexamethasone in the treatment of the alcohol withdrawal syndrome. *Am J Drug Alcohol Abuse* 1997; **23:** 615–22.

Amyloidosis. For mention of the use of dexamethasone in patients with amyloidosis, see p.743.

Blood disorders. High-dose pulsed dexamethasone therapy has been found useful in some patients with idiopathic thrombocytopenic purpura (p.1505), although results have been variable in children.

Cerebral oedema. Corticosteroids, usually dexamethasone, play an important role in the treatment of cerebral oedema in malignancy (see Raised Intracranial Pressure, p.1181), and dexamethasone is advocated for the cerebral oedema associated with high-altitude disorders (see below).

Congenital adrenal hyperplasia. Because of its lack of mineralocorticoid properties, dexamethasone has little advantage in the salt-losing form of congenital adrenal hyperplasia (p.1502), in which mineralocorticoid therapy must be given, and its potency means that dose titration to avoid toxicity can be difficult in infants and children, even with the non-salt-losing form. However, it may be useful in adults with forms of the syndrome that do not require mineralocorticoid replacement. It has also been given antenatally to the mother to prevent virilisation of female fetuses.

Diagnosis and testing. *CUSHING'S SYNDROME.* Dexamethasone has been used to differentiate Cushing's disease (adrenal hyperplasia caused by defects of pituitary origin) from other forms of Cushing's syndrome (caused by ectopic ACTH secretion from non-pituitary tumours or by cortisol secretion from adrenal tumours). The dexamethasone suppression test as first proposed[1] involved giving oral dexamethasone in low doses of 500 micrograms four times daily for 8 doses followed by higher doses of 2 mg four times daily for 8 doses. In the low-dose tests the urinary excretion of cortisol and 17-hydroxycorticosteroids is suppressed in healthy persons but not in patients and in the high-dose tests the excretion is still not suppressed in those with Cushing's syndrome but is partially suppressed in those with Cushing's disease. Because this test usually involves patients being admitted to hospital for urine collection over a number of days and because false-negative responses are reported to be fairly frequent, more rapid and reliable tests have been sought. The low-dose test plus measurement of serum-cortisol concentrations and the excretion of free cortisol in urine over 24 hours has been suggested[2] to be a reliable method for screening for Cushing's syndrome. In the UK a single dose of 1 mg of dexamethasone given at night is often used and is considered sufficient to inhibit corticotropin secretion for 24 hours in most subjects. In another variation[3] a single dose of dexamethasone 8 mg has been given at night and plasma-cortisol concentrations measured the next day; this test (known as the overnight high-dose dexamethasone suppression test) has again been said to be a practical and reliable alternative for the differential diagnosis of Cushing's syndrome.

Further variations in the dexamethasone suppression test have included giving a continuous intravenous infusion of dexamethasone at a rate of 1 mg/hour for 7 hours, with hourly measurement of blood-cortisol concentrations.[4] Initial results indicate that this variation produces a lower number of false-positive diagnoses than the test using oral dexamethasone. Other alternatives are a combined low-dose dexamethasone suppression test and corticotropin-releasing hormone (corticorelin) test,[5] or combination of a dexamethasone suppression test with a metyrapone test.[6]

Reviews[7,8] of diagnostic tests for Cushing's syndrome have outlined both the advantages and disadvantages of tests using dexamethasone. These suggested that where there is suspicion of Cushing's syndrome, the overnight low-dose dexamethasone suppression test may be used as part of a range of measures, and that the dexamethasone-corticorelin test may be useful when there are equivocal results from initial screening. In a study to assess the effectiveness of low-dose dexamethasone, some patients were found to suppress plasma or urinary steroid concentrations to levels previously thought to exclude a diagnosis of Cushing's syndrome. The authors concluded that these low-dose tests should not be used as the sole criterion for diagnosis, and that a much lower value for serum cortisol should be used to achieve adequate sensitivity.[9] In the differentiation of ACTH-dependent and ACTH-independent forms of Cushing's syndrome, one review[7] suggested that the high-dose dexamethasone suppression test cannot be recommended because of poor specificity.

For further discussion of the various methods used for the diagnosis of Cushing's syndrome and details of its management, see p.2344. Various drugs may interfere with the dexamethasone suppression test.

DEPRESSION. The Health and Public Policy Committee of the American College of Physicians noted that the dexamethasone suppression test for depression (p.373) was based on the premise that endogenously depressed patients have shown pituitary-adrenal axis abnormalities but had been found to have a low sensitivity for detecting depression. It was of unproven value and was not recommended as a screening test.[1] Nonetheless, interest remains; studies[2-6] have shown conflicting results.

High-altitude disorders. Dexamethasone is effective in the prevention of symptoms of acute mountain sickness (p.1168), for which mild cerebral oedema may be a contributing factor, but it is not generally considered suitable for routine prophylaxis because of concern about its adverse effects. In the treatment of acute severe mountain sickness, which may involve the development of pulmonary and cerebral oedema, the mandatory treatment is immediate descent, and drug therapy is primarily adjunctive, to facilitate descent or maintain the patient until descent is possible. Under these circumstances dexamethasone and oxygen form the mainstays of treatment.

Hirsutism. Unbound testosterone concentrations were consistently elevated in 32 hirsute women; when concentrations were suppressed to normal by dexamethasone 0.5 to 1 mg at night hirsutism was generally improved or ceased to progress after 8 to 10 months of treatment.[1] Other studies have shown only a modest improvement[2] or no improvement at all[3] in hirsutism when treated with dexamethasone. Addition of dexamethasone to anti-androgen therapy appeared to prolong the duration of remission in a later study.[4]

The mainstay of drug treatment for hirsutism tends to be an anti-androgen such as cyproterone or spironolactone (p.2089). Although low dose corticosteroids can suppress adrenal androgen production, careful consideration of the risks and benefits is advisable, especially since therapy for hirsutism may have to be given long-term.

Malaria. Corticosteroids, especially dexamethasone, have been used in cerebral malaria (p.594) in the belief that their anti-inflammatory effect would reduce cerebral oedema. However, studies have shown that cerebral oedema does not play a significant role in the pathophysiology of cerebral malaria and, indeed, double-blind studies using both moderate doses (2 mg/kg) and high doses (11 mg/kg) of dexamethasone intravenously over 48 hours found no reduction in death rates. Thus it is now considered that corticosteroids have no place in the treatment of cerebral malaria.[1]

1. Prasad K, Garner P. Steroids for treating cerebral malaria. Available in The Cochrane Database of Systematic Reviews; Issue 3. Chichester: John Wiley; 1999 (accessed 12/05/05).

Malignant neoplasms. Dexamethasone has been used in some regimens for the treatment of malignancy, for example in acute lymphoblastic leukaemia (p.651) and multiple myeloma (p.658).

Meningitis. The role of corticosteroids in the adjuvant treatment of bacterial meningitis (p.178) has been the subject of considerable debate. Studies have shown conflicting results.[1-3] However, a systematic review[4] concluded that there was evidence of benefit, particularly in reducing deafness in children in high-income countries, and in reducing mortality in adults. It has been suggested[4] that a 4-day regimen of dexamethasone be given to adults and in children in high-income countries, preferably before or with the first dose of antibacterial.

Nausea and vomiting. Dexamethasone has antiemetic properties, particularly against acute and delayed vomiting induced by cancer chemotherapy[1] (p.1700). It may be used alone for prevention of acute symptoms associated with moderately-emetogenic treatment and is combined with a 5-HT_3 antagonist for highly-emetogenic treatment. Typical dosage regimens have been dexamethasone 4 to 8 mg orally immediately before moderately-emetogenic chemotherapy and 20 mg by intravenous injection for more severely emetogenic chemotherapy. Dexamethasone is the drug of choice for prevention of delayed symptoms, given alone or with other antiemetics. A typical oral dose is 8 mg twice daily for 2 to 4 days. Dexamethasone is also effective for the prevention of postoperative nausea and vomiting,[2] and may be used to manage nausea and vomiting in palliative care.

1. Ioannidis JPA, *et al*. Contribution of dexamethasone to control of chemotherapy-induced nausea and vomiting: a meta-analysis of randomized evidence. *J Clin Oncol* 2000; **18:** 3409–22.
2. Henzi I, *et al*. Dexamethasone for the prevention of postoperative nausea and vomiting: a quantitative systematic review. *Anesth Analg* 2000; **90:** 186–94.

Opportunistic mycobacterial infections. Dexamethasone in doses of 1 to 4 mg daily was associated with weight gain, reduction in fever, and an improved sense of well-being in 5 patients with HIV and disseminated *Mycobacterium avium* complex infection.[1] Combination antimycobacterial therapy for nontuberculous mycobacterial infections (p.181) was also given. Similar results have been noted by others.[2]

1. Wormser GP, *et al*. Low-dose dexamethasone as adjunctive therapy for disseminated Mycobacterium avium complex infections in AIDS patients. *Antimicrob Agents Chemother* 1994; **38:** 2215–17.
2. Dorman SE, *et al*. Adjunctive corticosteroid therapy for patients whose treatment for disseminated Mycobacterium avium complex infection has failed. *Clin Infect Dis* 1998; **26:** 682–6.

Respiratory disorders. Corticosteroids such as dexamethasone have been given antenatally to mothers at risk of premature delivery in order to hasten fetal lung maturation and help prevent *neonatal respiratory distress syndrome* (p.1508) and *bronchopulmonary dysplasia* (p.1500). Neonatal dexamethasone has been reported to improve pulmonary outcome and assist weaning from mechanical ventilation in infants that have developed bronchopulmonary dysplasia.

Dexamethasone is also one of the drugs of choice for the management of severe *croup* (see p.1502). However, as with other corticosteroids (p.1500) it appears to be of little value in *bronchiolitis*.[1,2]

1. Roosevelt G, *et al*. Dexamethasone in bronchiolitis: a randomised controlled trial. *Lancet* 1996; **348:** 292–5.
2. Klassen TP, *et al*. Dexamethasone in salbutamol-treated inpatients with acute bronchiolitis: a randomized controlled trial. *J Pediatr* 1997; **130:** 191–6.

Retinopathy of prematurity. For a suggestion that antenatal dexamethasone might be helpful in the prophylaxis of retinopathy of prematurity, see p.1994. For mention of the uncertain effect of neonatal dexamethasone on retinopathy of prematurity, see Effects on the Neonate, under Adverse Effects above.

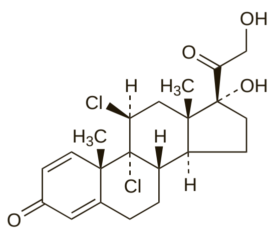
CAS — 7008-26-6 (dichlorisone); 79-61-8 (dichlorisone acetate).



(dichlorisone)

Profile

Dichlorisone acetate is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream containing 0.25 or 1%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (see p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, see p.1497.

Preparations

Proprietary Preparations (details are given in Part 3)

USP 31 (Diflorasone Diacetate). A white to pale yellow, crystalline powder. Insoluble in water; soluble in acetone and in methyl alcohol; very slightly soluble in ether; sparingly soluble in ethyl acetate; slightly soluble in toluene. Store in airtight containers.

Profile

Diflorasone diacetate is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream or ointment containing 0.05%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

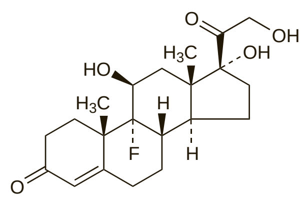
$C_{23}H_{31}FO_6$ = 422.5.

CAS — 127-31-1 (fludrocortisone); 514-36-3 (fludrocortisone acetate).

ATC — H02AA02.

ATC Vet — QH02AA02.



(fludrocortisone)

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Fludrocortisone Acetate). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in dehydrated alcohol.

USP 31 (Fludrocortisone Acetate). White to pale yellow, odourless or practically odourless, hygroscopic, crystals or crystalline powder. Insoluble in water; sparingly soluble in alcohol and in chloroform; slightly soluble in ether. Protect from light.

Adverse Effects, Treatment, Withdrawal, and Precautions

Fludrocortisone acetate has glucocorticoid actions about 10 times as potent as hydrocortisone and mineralocorticoid effects more than 100 times as potent. Adverse effects are mainly those due to mineralocorticoid activity, as described on p.1490.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Fludrocortisone is readily absorbed from the gastrointestinal tract. The plasma half-life is about 3.5 hours or more, but fludrocortisone exhibits a more prolonged biological half-life of 18 to 36 hours.

Uses and Administration

Fludrocortisone is a corticosteroid with glucocorticoid and highly potent mineralocorticoid activity (p.1490).

Fludrocortisone acetate is given orally to provide mineralocorticoid replacement in primary adrenocortical insufficiency (p.1498), with glucocorticoids. It is used in a dose range of 50 to 300 micrograms daily.

Fludrocortisone acetate may also be given with glucocorticoid therapy in doses of up to 200 micrograms daily in the salt-losing form of congenital adrenal hyperplasia (p.1502).

It is also given in the management of severe orthostatic hypotension (see below).

Fludrocortisone acetate is applied topically for its glucocorticoid actions in the treatment of various disorders. It is used as an ingredient of eye ointment or ear drops, usually in a concentration of 0.1%. Fludrocortisone acetate has also been included in topical preparations used for skin disorders. For recommendations concerning the correct use of corticosteroids on the skin, see p.1497.

Administration. A study of fludrocortisone requirements in 10 patients with Addison's disease indicated that dosage was often inadequate.[1] Nine were initially on fludrocortisone 50 to 100 micrograms daily in addition to cortisone or hydrocortisone; 5 were also taking levothyroxine for an associated auto-immune thyroid disease; one, who had detectable levels of aldosterone, was not initially receiving fludrocortisone. All the patients had evidence of sodium and water depletion and fludrocortisone was started at 300 micrograms daily, with downwards adjustments. Most patients required 200 micrograms daily; 2 patients elected to remain on 300 micrograms daily, but in most this dose caused pronounced sodium and water retention. The patient with detectable aldosterone levels required 50 micrograms daily. Eight of the 10 patients felt better on the higher fludrocortisone doses while 2 felt no change.

1. Smith SJ, *et al.* Evidence that patients with Addison's disease are undertreated with fludrocortisone. *Lancet* 1984; **i:** 11–14.

Neurally mediated hypotension. Fludrocortisone may be used in the management of neurally mediated hypotension in patients who require drug therapy (see p.1174) but there is limited evidence to support its use.

Orthostatic hypotension. Orthostatic (postural) hypotension[1-8] is a fall in blood pressure that occurs upon rising abruptly to an erect position, although it may also occur after a period of prolonged standing. Characteristic symptoms include lightheadedness, dizziness, blurred vision, weakness in the limbs, and syncope.

The causes of orthostatic hypotension are wide-ranging and include autonomic dysfunction, such as in the Shy-Drager syndrome, diabetes mellitus, and Parkinson's disease, circulating volume depletion, phaeochromocytoma, and Addison's disease. Orthostatic hypotension may also occur following a period of prolonged bed rest or after meals.

Orthostatic hypotension may result from the adverse effects of a range of drugs, such as antihypertensives, diuretics, tricyclic antidepressants, phenothiazines, and MAOIs.

In mild cases **nonpharmacological treatment** alone may be adequate. This includes increasing salt intake if not contra-indicated, maintaining adequate hydration, the use of elastic stockings to improve venous return and increase cardiac output, and elevating the head of the bed to reduce early morning symptoms. Drug-induced orthostatic hypotension should be treated by withdrawing the drug or by dose reduction.

Pharmacological treatment. No pharmacological treatment is entirely satisfactory: responses and tolerance vary greatly between patients. Fludrocortisone acetate is usually tried first; it increases sodium retention and thus plasma volume. Most reports indicate some response in about 80% of patients, but hypokalaemia, fluid retention, and supine hypertension may limit its use. In patients who fail to respond adequately an NSAID (usually indometacin) may be tried, alone or with fludrocortisone. In patients with overt autonomic failure a beta blocker with some partial agonist activity, such as pindolol, may be tried although they are potentially dangerous.

Sympathomimetics may be useful in some patients with autonomic failure; the direct acting drugs such as phenylephrine or midodrine are usually more consistently effective than the indirect such as ephedrine, but even so, responses tend to vary with the degree of denervation. Ambulatory noradrenaline infusion therapy is under investigation for severe refractory orthostatic hypotension. Patients with central neurological abnormalities may respond to desmopressin, while drugs such as ergotamine or dihydroergotamine may be useful for resistant disease.

Other drugs that have been tried include metoclopramide, which may be useful for autonomic symptoms in patients with diabetes mellitus, fluoxetine, octreotide, yohimbine, clonidine, and in patients with concurrent anaemia, erythropoietin. Caffeine has been tried in postprandial hypotension but its value in all but the mildest cases is dubious.[5] The use of MAOIs (which given alone can induce orthostatic hypotension) with a sympathomimetic to induce a pressor reaction is controversial. Most of these drugs have potentially serious adverse effects and few are well evaluated.

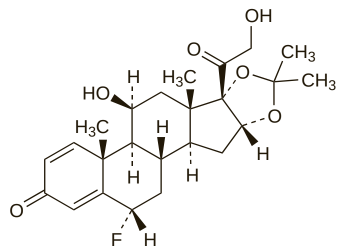
ATC — R01AD04; R03BA03.

ATC Vet — QR01AD04; QR03BA03.



Pharmacopoeias. In *US* which specifies the hemihydrate.

USP 31 (Flunisolide). A white to creamy-white crystalline powder. Practically insoluble in water; soluble in acetone; sparingly soluble in chloroform; slightly soluble in methyl alcohol.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495. Flunisolide is reported to undergo extensive first-pass metabolism, with only 20% of the dose available systemically if it is given by mouth. The major metabolite, 6β-hydroxyflunisolide has some glucocorticoid activity; it has a half-life of about 4 hours. Only small amounts of flunisolide are absorbed after intranasal doses.

◊ References.

2. Möllmann H, *et al.* Pharmacokinetic/pharmacodynamic evaluation of systemic effects of flunisolide after inhalation. *J Clin Pharmacol* 1997; **37:** 893–903.

Uses and Administration

Flunisolide is a corticosteroid with glucocorticoid activity (p.1490) used as a nasal spray for the prophylaxis and treatment of allergic rhinitis (p.565). In the UK a formulation containing 25 micrograms per metered spray is available, whereas in the USA each metered spray contains 29 micrograms flunisolide. In adults, the recommended starting dose is 2 sprays into each nostril twice daily, increased if necessary to three times daily, and then reduced for maintenance. In the USA a maximum dose of 8 sprays into each nostril daily has been established. For children aged from about 5 to 14 years, 1 spray into each nostril may be given up to 3 times daily; the USA also allows for an initial 2 sprays into each nostril twice daily (this is the recommended maximum of 4 sprays into each nostril daily).

Flunisolide is also used by inhalation from metered-dose aerosols in the management of asthma (p.1108). The usual adult dosage of flunisolide from an aerosol using chlorofluorocarbon (CFC) propellants is 500 micrograms inhaled twice daily. In severe asthma the dosage may be increased but should not exceed a total of 2 mg daily. A dose for children of 6 to 15 years of age is 500 micrograms inhaled twice daily, which should not be exceeded. A hydrofluoroalkane (CFC-free) aerosol, which is also available in some countries, has a lower dose because of different delivery characteristics. The usual adult dose, expressed as flunisolide hemihydrate, is 160 micrograms twice daily, which may be increased after 3 to 4 weeks but should not exceed 320 micrograms twice daily. In children aged 6 to 11 years of age a dose of 80 micrograms twice daily may be used, increased to a maximum of 160 micrograms twice daily if necessary.

Fluocinolone Acetonide *(BANM, USAN, rINN)* ⊗

Acetónido de fluocinolona; 6α,9α-Difluoro-16α-hydroxyprednisolone Acetonide; Fluocinolon acetonid; Fluocinolonacetonid; Fluocinolon-acetonid; Fluocinolone, acétonide de; Fluocinoloni acetonidum; Fluocinolono acetonidas; Fluocynolonu acetonid; Fluosinoloniasetonidi; NSC-92339. 6α,9α-Difluoro-11β,21-dihydroxy-16α,17α-isopropylidenedioxypregna-1,4-diene-3,20-dione.

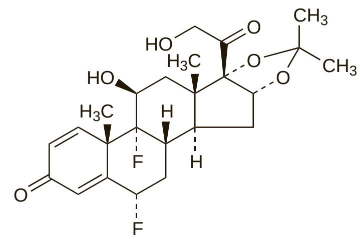
Флуоцинолона Ацетонид

$C_{24}H_{30}F_2O_6$ = 452.5.

CAS — 67-73-2.

ATC — C05AA10; D07AC04; S01BA15.

ATC Vet — QC05AA10; QD07AC04; QS01BA15.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *Viet. Br.* and *Viet.* have a separate monograph for the dihydrate; *US* allows either the anhydrous form or the dihydrate.

Ph. Eur. 6.2 (Fluocinolone Acetonide). A white or almost white, crystalline powder. It exhibits polymorphism. Practically insoluble in water; soluble in dehydrated alcohol and in acetone. Protect from light.

BP 2008 (Fluocinolone Acetonide Dihydrate). A white or almost white, crystalline powder. Practically insoluble in water and in hexane; soluble in dehydrated alcohol; freely soluble in acetone; sparingly soluble in dichloromethane and in methyl alcohol. Protect from light.

USP 31 (Fluocinolone Acetonide). It is anhydrous or contains two molecules of water of hydration. A white or practically white, odourless, crystalline powder. Insoluble in water; soluble 1 in 45 of alcohol, 1 in 25 of chloroform, and 1 in 350 of ether; soluble in methyl alcohol.

Profile

Fluocinolone acetonide is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream, gel, lotion, ointment, or scalp application; concentrations normally range from 0.0025 to 0.025% although higher-strength preparations may be available. When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Fluocinolone acetonide is also used topically with an antibacterial in the treatment of infective inflammatory eye, ear, and nose disorders.

A sterile implant of fluocinolone acetonide is used intravitreally for the treatment of chronic non-infectious posterior uveitis.

Formulation. The potency of fluocinolone acetonide varied with the formulation in a study[1] involving different *Synalar* topical preparations, the gel, ointment, and cream. The cream was the most potent followed by the gel, and then the ointment. A comparison of topical vasoconstrictor activity (used as an index of potency) unexpectedly found that the commercial dilutions of the cream (containing 0.00625% and 0.0025%) were indistinguishable in their effects from the full-strength (0.025%) cream.

1. Gao HY, Li Wan Po A. Topical formulations of fluocinolone acetonide: are creams, gels and ointments bioequivalent and does dilution affect activity? *Eur J Clin Pharmacol* 1994; **46:** 71–5.

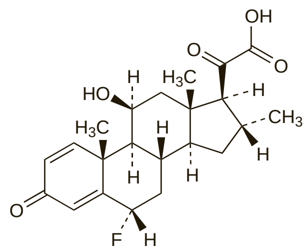
ATC — D07AB04.

ATC Vet — QD07AB04.



(fluocortin)

Profile

Fluocortin butyl is a corticosteroid that has been used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream or ointment containing 0.75%. When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Fluocortin butyl has also been used in the form of a dry powder nasal inhalation for the management of allergic rhinitis.

Флуокортолона Пивалат

$C_{27}H_{37}FO_5$ = 460.6.

CAS — 29205-06-9.

ATC — C05AA08; D07AC05; H02AB03.

ATC Vet — QC05AA08; QD07AC05; QH02AB03.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Fluocortolone Pivalate). A white or almost white crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in dichloromethane and in dioxan. Protect from light.

Profile

Fluocortolone and its esters are corticosteroids mainly used topically for their glucocorticoid activity (p.1490) in the treatment of various skin disorders. They are usually used as a cream or ointment; concentrations usually used are 0.25% of the caproate with 0.25% of either the free alcohol or pivalate ester. The pivalate and caproate esters have also been used together in ointments or suppositories for the treatment of anorectal disorders.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Fluocortolone free alcohol is sometimes given orally for its systemic effects in conditions for which corticosteroids are indicated (p.1495), in usual doses of 5 to 100 mg daily.

USP 31 (Fluorometholone Acetate).

Profile

Fluorometholone is a corticosteroid used for its glucocorticoid activity (p.1490), usually as eye drops containing 0.1%, in the treatment of allergic and inflammatory conditions of the eye. Fluorometholone acetate is used similarly.

Fluorometholone is also used topically in the treatment of various skin disorders.

Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function. When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, see p.1497.

Preparations

BP 2008: Fluorometholone Eye Drops;

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Fluticasone Propionate). A white or almost white powder. Practically insoluble in water; slightly soluble in alcohol; sparingly soluble in dichloromethane. Protect from light.

USP 31 (Fluticasone Propionate). Micronised fluticasone propionate is a fine white powder. Store in airtight containers at a temperature not exceeding 30°. Protect from light.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490). Hypersensitivity reactions have occurred. Eosinophilic conditions, including Churg-Strauss syndrome, have been reported rarely, in most cases after a transfer from oral corticosteroid therapy.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Inhalation or nasal use of large amounts of fluticasone may produce systemic effects also (see below).

Adrenal suppression. Despite the fact that inhaled fluticasone is generally thought to lack systemic effects at therapeutic doses, a study in 25 healthy subjects[1] indicated that fluticasone propionate as single inhaled doses of 250, 500, and 1000 micrograms did produce a reduction in plasma cortisol, indicating suppression of the hypothalamic-pituitary-adrenal axis to some degree. Others have also found evidence of adrenal suppression with fluticasone,[2-5] particularly at high doses and in children,[6] and the effect may be more marked with repeated than with single doses.[4,6-8] A number of cases of adrenal crisis have been associated with high-dose inhaled fluticasone,[9,10] including at least one fatality.[6] It has been recommended that children using inhaled fluticasone at doses above 400 micrograms daily should have adrenal function monitoring and a written plan for emergency corticosteroid replacement therapy.[6]

Effects on the bones. For studies of the effects on bone of inhaled fluticasone, compared with beclometasone, see p.1516.

Effects on the muscles. Proximal myopathy has been reported in children receiving high-dose inhaled fluticasone;[1] the patients recovered after replacement of fluticasone with alternative corticosteroid therapy.

1. De Swert LF, *et al.* Myopathy in children receiving high-dose inhaled fluticasone. *N Engl J Med* 2004; **350:** 1157–9.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Fluticasone propionate is poorly absorbed from the gastrointestinal tract and undergoes extensive first-pass metabolism; oral bioavailability is reported to be only about 1%.

Uses and Administration

Fluticasone is a corticosteroid with mainly glucocorticoid activity (p.1490).

Fluticasone propionate is stated to exert a topical effect on the lungs without significant systemic effects at usual doses, due to its low systemic bioavailability (but see Adrenal Suppression, above). It is used by powder or aerosol inhalation for the prophylaxis of **asthma**. Typical initial doses in the UK range from 100 to 250 micrograms twice daily in mild asthma up to 1 mg twice daily in severe asthma, adjusted according to response. Children over 4 years of age may be given initial doses of 50 to 100 micrograms twice daily, increased to 200 micrograms twice daily if necessary.

The drug may also be given via a nebuliser in severe chronic asthma. Usual adult doses are 0.5 to 2 mg twice daily. Children aged 4 to 16 years may be given 1 mg twice daily. In the USA, doses by powder inhalation are similar to that in the UK. The aerosol inhalation formulations contain 50, 125, or 250 micrograms of fluticasone propionate in each metered spray, which delivers 44, 110, or 220 micrograms, respectively from the actuator. Doses are therefore expressed in these units; dosage ranges from 88 micrograms twice daily to 880 micrograms twice daily, depending on previous therapy. Children aged 4 to 11 years are given 88 micrograms twice daily.

Fluticasone propionate is also available in some countries as a powder or aerosol inhalation for the treatment of **chronic obstructive pulmonary disease**, when it is given in doses of 500 micrograms twice daily.

Fluticasone is administered by nasal spray in the prophylaxis and treatment of **allergic rhinitis**. The usual dose of fluticasone propionate is 100 micrograms into each nostril once daily, increased if necessary to 100 micrograms into each nostril twice daily. Children over 4 years of age may be given half these doses. Fluticasone furoate is also used in the management of allergic rhinitis. This salt has enhanced affinity for the glucocorticoid receptor, and is given in a starting dose of 55 micrograms into each nostril once daily. When the maximum benefit has been achieved and symptoms controlled, the dose should be gradually reduced to the minimum effective dose; 27.5 micrograms into each nostril once daily may be sufficient to maintain control of symptoms. Children aged 2 years and over may be started on 27.5 micrograms into each nostril once daily, which may be increased to 55 micrograms into each nostril once daily if necessary to control symptoms.

Fluticasone propionate drops are used in the treatment of **nasal polyps**, 200 micrograms should be instilled into each nostril once or twice daily for at least 4 to 6 weeks.

Fluticasone propionate is applied topically in the treatment of various **skin disorders**. Creams and ointments containing 0.05% and 0.005%, respectively are available. For recommendations concerning the correct use of corticosteroids on the skin, see p.1497.

Asthma. Corticosteroids and beta$_2$-adrenoceptor agonists form the cornerstone of the management of asthma (p.1108). Patients requiring only occasional relief from symptoms may be managed with an inhaled short-acting beta$_2$ agonist, and an inhaled corticosteroid such as fluticasone is added if symptomatic relief is needed more than once daily. In more severe asthma other drugs may be added (combination with a long-acting beta$_2$ agonist may have synergistic benefits), or the dose of inhaled corticosteroid may be increased.

Some references to the use of fluticasone propionate for asthma are given below,[1-15] including one to a study indicating that increasing the dose of inhaled fluticasone did not produce increased benefit.[1]

Cough. A small study in children with persistent nocturnal cough compared fluticasone propionate 1 mg twice daily for 3 nights, followed by 500 micrograms twice daily for 11 nights, given by metered-dose inhaler, with placebo. Coughs reduced significantly by nights 15 and 16 in the children given the corticosteroid. However, both groups improved significantly compared to baseline, leading the authors to conclude that inhaled corticosteroids should not be given at the time of presentation of persistent nocturnal cough. If they are given, then a 2-week course of high dose corticosteroids may benefit some children.[1] In a controlled crossover study in adult patients with chronic cough, inhaled fluticasone 500 micrograms twice daily for 14 days significantly improved certain measurements of cough, although overall reduction in cough severity was modest.[2] In adults with a cough lasting more than 2 weeks, fluticasone 500 micrograms twice daily for 2 weeks decreased cough scores from day 5 onwards in non-smokers.[3]

Eczema. In a study in patients with moderate to severe eczema (p.1579), fluticasone propionate 0.05% cream or 0.005% ointment was applied once or twice daily for 4 weeks; if eczema stabilised, either the cream, the ointment, or an emollient placebo was then applied on 2 days per week, for up to 16 weeks. Fluticasone cream reduced the risk of relapse to about one-sixth of that of placebo, whereas the ointment formulation reduced the risk to about half; median times to relapse were similar for both fluticasone formulations. The formulations were originally expected to be of similar potency.[1] Others have commented[2] that caution should be exercised in generalising these results to primary care settings where most cases of eczema are likely to be mild, and relapses infrequent.

1. Berth-Jones J, *et al.* Twice weekly fluticasone propionate added to emollient maintenance treatment to reduce risk of relapse in atopic dermatitis: randomised, double blind, parallel group study. *BMJ* 2003; **326:** 1367.

Inflammatory bowel disease. Fluticasone propionate, given orally, has produced variable results in the treatment of Crohn's disease[1] and ulcerative colitis;[2,3] some benefit was also reported in coeliac disease.[4] The dose was 5 mg four times daily but some consider[2] higher doses necessary.

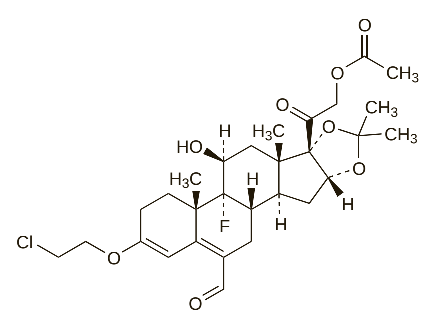
Fl-6341; Fluoroformylon; Formocortalum. 3-(2-Chloroethoxy)-9α-fluoro-11β,21-dihydroxy-16α,17α-isopropylidenedioxy-20-oxopregna-3,5-diene-6-carbaldehyde 21-acetate.

Формокортал

$C_{29}H_{38}ClFO_8$ = 569.1.
CAS — 2825-60-7.
ATC — S01BA12.
ATC Vet — QS01BA12.



Profile

Formocortal is a corticosteroid that is used for its glucocorticoid activity (see p.1490) in the treatment of inflammatory eye disorders as eye drops and eye ointments containing 0.05%.

Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Pharmacopoeias. In *Chin.* and *US.*

USP 31 (Halcinonide). A white to off-white, odourless, crystalline powder. Insoluble in water and in hexanes; slightly soluble in alcohol and in ether; soluble in acetone and in chloroform.

Profile

Halcinonide is a corticosteroid used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a 0.1% cream, lotion, or ointment.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Preparations

USP 31: Halcinonide Cream; Halcinonide Ointment; Halcinonide Topical Solution.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Hydrocortisone). A white or almost white, crystalline powder. It shows polymorphism. Practically insoluble in water; sparingly soluble in alcohol and in acetone; slightly soluble in dichloromethane. Protect from light.

USP 31 (Hydrocortisone). A white to practically white, odourless, crystalline powder. Very slightly soluble in water and in ether; soluble 1 in 40 of alcohol and 1 in 80 of acetone; slightly soluble in chloroform. Store at a temperature of 25°, excursions permitted between 15° and 30°.

Hydrocortisone Acetate *(BANM, rINNM)* ⊗

Acetato de hidrocortisona; Cortisol Acetate; Hidrokortizon Asetat; Hidrokortizon-acetát; Hidrokortizono acetatas; Hydrocortisone, acétate d'; Hydrocortisoni acetas; Hydrokortisonacetat; Hydrokortison-acetát; Hydrokortisoniasetaatti; Hydrokortyzonu octan. Hydrocortisone 21-acetate.

Гидрокортизона Ацетат

$C_{23}H_{32}O_6$ = 404.5.

CAS — 50-03-3.

ATC — A01AC03; A07EA02; C05AA01; D07AA02; H02AB09; S01BA02; S02BA01.

ATC Vet — QA01AC03; QA07EA02; QC05AA01; QD07AA02; QH02AB09; QS01BA02; QS02BA01.

NOTE. HCOR is a code approved by the BP 2008 for use on single unit doses of eye drops containing hydrocortisone acetate where the individual container may be too small to bear all the appropriate labelling information.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Hydrocortisone Acetate). A white or almost white, crystalline powder. Practically insoluble in water; slightly soluble in dehydrated alcohol and in dichloromethane. Protect from light.

USP 31 (Hydrocortisone Acetate). A white to practically white, odourless, crystalline powder. Insoluble in water; soluble 1 in 230 of alcohol and 1 in 200 of chloroform.

Hydrocortisone Buteprate *(BANM, rINNM)* ⊗

Buteprato de hidrocortisona; Hydrocortisone, Butéprate d'; Hydrocortisone Butyrate Propionate; Hydrocortisone Probutate *(USAN)*; Hydrocortisoni Butepras; TS-408. Hydrocortisone 17-butyrate 21-propionate.

Гидрокортизона Бутепрат

$C_{28}H_{40}O_7$ = 488.6.

CAS — 72590-77-3.

ATC — D07AB11.

ATC Vet — QD07AB11.

Hydrocortisone Butyrate *(BANM, USAN, rINNM)* ⊗

Butirato de hidrocortisona; Cortisol Butyrate; Hidrokortizon Bütirat; Hydrocortisone, Butyrate d'; Hydrocortisoni Butiras. Hydrocortisone 17α-butyrate.

Гидрокортизона Бутират

$C_{25}H_{36}O_6$ = 432.5.

CAS — 13609-67-1.

ATC — D07AB02.

ATC Vet — QD07AB02.

Pharmacopoeias. In *Chin., Jpn,* and *US.*

USP 31 (Hydrocortisone Butyrate). A white to practically white, practically odourless crystalline powder. Practically insoluble in water; soluble in alcohol, in acetone, and in methyl alcohol; freely soluble in chloroform; slightly soluble in ether.

Hydrocortisone Cipionate *(BANM, rINNM)* ⊗

Cipionato de hidrocortisona; Cortisol Cypionate; Hydrocortisone, Cipionate d'; Hydrocortisone Cyclopentylpropionate; Hydrocortisone Cypionate; Hydrocortisoni Cipionas. Hydrocortisone 21-(3-cyclopentylpropionate).

Гидрокортизона Ципионат

$C_{29}H_{42}O_6$ = 486.6.

CAS — 508-99-6.

ATC — A01AC03; A07EA02; C05AA01; D07AA02; H02AB09; S01BA02; S02BA01.

ATC Vet — QA01AC03; QA07EA02; QC05AA01; QD07AA02; QH02AB09; QS01BA02; QS02BA01.

Hydrocortisone Hydrogen Succinate *(BANM, rINNM)* ⊗

Cortisol Hemisuccinate; Hidrogenosuccinato de hidrocortisona; Hidrokortizon-hidrogén-szukcinát; Hidrokortizono hemisukcinatas; Hydrocortisone Hemisuccinate; Hydrocortisone, Hémisuccinate d'; Hydrocortisone, hydrogénosuccinate d'; Hydrocortisone Succinate; Hydrocortisoni Hemisuccinas; Hydrocortisoni hydrogenosuccinas; Hydrokortison-hydrogen-sukcinát; Hydrokortisonivetysuksinaatti; Hydrokortisonvätesuccinat. Hydrocortisone 21-(hydrogen succinate).

Гидрокортизона Гемисукцинат

$C_{25}H_{34}O_8$ = 462.5.

CAS — 2203-97-6 (anhydrous hydrocortisone hydrogen succinate); 83784-20-7 (hydrocortisone hydrogen succinate monohydrate).

ATC — A01AC03; A07EA02; C05AA01; D07AA02; H02AB09; S01BA02; S02BA01.

ATC Vet — QA01AC03; QA07EA02; QC05AA01; QD07AA02; QH02AB09; QS01BA02; QS02BA01.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn. US* allows the anhydrous form or the monohydrate.

Ph. Eur. 6.2 (Hydrocortisone Hydrogen Succinate). A white or almost white, hygroscopic powder. Practically insoluble in water; freely soluble in dehydrated alcohol and in acetone; dissolves in dilute solutions of alkali carbonates and alkali hydroxides. Store in airtight containers. Protect from light.

USP 31 (Hydrocortisone Hemisuccinate). It contains one molecule of water of hydration or is anhydrous. Store in airtight containers.

Hydrocortisone Sodium Phosphate *(BANM, rINNM)* ⊗

Cortisol Sodium Phosphate; Fosfato sódico de hidrocortisona; Hydrocortisone, Phosphate Sodique d'; Natrii Hydrocortisoni Phosphas. Hydrocortisone 21-(disodium orthophosphate).

Натрия Гидрокортизона Фосфат

$C_{21}H_{29}Na_2O_8P$ = 486.4.

CAS — 6000-74-4.

ATC — A01AC03; A07EA02; C05AA01; D07AA02; H02AB09; S01BA02; S02BA01.

ATC Vet — QA01AC03; QA07EA02; QC05AA01; QD07AA02; QH02AB09; QS01BA02; QS02BA01.

Pharmacopoeias. In *Br., Jpn,* and *US.*

BP 2008 (Hydrocortisone Sodium Phosphate). A white or almost white, hygroscopic powder. Freely soluble in water; practically insoluble in dehydrated alcohol and in chloroform. A 0.5% solution in water has a pH of 7.5 to 9.0. Protect from light.

USP 31 (Hydrocortisone Sodium Phosphate). A white to light yellow, odourless or practically odourless, exceedingly hygroscopic, powder. Soluble 1 in 1.5 of water; slightly soluble in alcohol; practically insoluble in chloroform, in dioxan, and in ether. Store in airtight containers.

Hydrocortisone Sodium Succinate

(BANM, rINNM) ⊗

Cortisol Sodium Succinate; Hydrocortisone, Succinate Sodique d'; Hydrocortisoni Natrii Succinas; Hydrokortyzonu bursztynianu sól sodowa; Succinato sódico de hidrocortisona. Hydrocortisone 21-(sodium succinate).

Гидрокортизона Натрия Сукцинат

$C_{25}H_{33}NaO_8$ = 484.5.

CAS — 125-04-2.

ATC — A01AC03; A07EA02; C05AA01; D07AA02; H02AB09; S01BA02; S02BA01.

ATC Vet — QA01AC03; QA07EA02; QC05AA01; QD07AA02; QH02AB09; QS01BA02; QS02BA01.

Pharmacopoeias. In *Chin., Int., It., Jpn., Pol.,* and *US.*

USP 31 (Hydrocortisone Sodium Succinate). A white or nearly white, odourless, hygroscopic, amorphous solid. Very soluble in water and in alcohol; very slightly soluble in acetone; insoluble in chloroform. Store in airtight containers. Protect from light.

Hydrocortisone Valerate *(BANM, USAN, rINNM)* ⊗

Cortisol Valerate; Hydrocortisone, Valérate d'; Hydrocortisoni Valeras; Valerato de hidrocortisona. Hydrocortisone 17-valerate.

Гидрокортизона Валерат

$C_{26}H_{38}O_6$ = 446.6.

CAS — 57524-89-7.

Pharmacopoeias. In *US.*

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Effects on fluid and electrolyte balance. A report of marked hypokalaemia and hypomagnesaemia associated with high-dose intravenous hydrocortisone therapy in an alcoholic patient with suspected immune thrombocytopenia.[1] Cardiac arrhythmias developed, and prolonged infusion of magnesium and potassium was required to restore normal plasma concentrations.

1. Ramsahoye BH, *et al.* The mineralocorticoid effects of high dose hydrocortisone. *BMJ* 1995; **310:** 656–7.

Effects on the nervous system. For reports and comments on paraesthesia or perineal irritation associated with hydrocortisone sodium phosphate given intravenously, see p.1492.

Hypersensitivity and anaphylaxis. References to hypersensitivity reactions and anaphylaxis associated with the intravenous use of hydrocortisone;[1-7] topical application can also result in hypersensitivity.[8]

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief account of the pharmacokinetics of corticosteroids, see p.1495.

Hydrocortisone is readily absorbed from the gastrointestinal tract and peak blood concentrations are attained in about an hour. The plasma half-life is about 100 minutes. It is more than 90% bound to plasma proteins. Following intramuscular injection, the absorption of the water-soluble sodium phosphate and sodium succinate esters is rapid, while absorption of hydrocortisone free alcohol and its lipid-soluble esters is slower. Absorption of hydrocortisone acetate after intra-articular or soft-tissue injection is also slow. Hydrocortisone is absorbed through the skin, particularly in denuded areas.

Hydrocortisone is metabolised in the liver and most body tissues to hydrogenated and degraded forms such as tetrahydrocortisone and tetrahydrocortisol. These are excreted in the urine, mainly conjugated as glucuronides, with a very small proportion of unchanged hydrocortisone. Hydrocortisone readily crosses the placenta.

Uses and Administration

Hydrocortisone is a corticosteroid with both glucocorticoid and to a lesser extent mineralocorticoid activity (p.1490). As cortisol it is the most important of the predominantly glucocorticoid steroids secreted by the adrenal cortex. Hydrocortisone is used, usually with a more potent mineralocorticoid, for replacement therapy in adrenocortical insufficiency (p.1498). It may also be used for its glucocorticoid properties in other conditions for which corticosteroid therapy is indicated (p.1495) but drugs with fewer mineralocorticoid effects tend to be preferred for the long-term systemic therapy of auto-immune and inflammatory disease.

The dose may be expressed in terms of the base, and the following are each equivalent to about 100 mg of hydrocortisone:

- hydrocortisone acetate 112 mg
- hydrocortisone buteprate 135 mg
- hydrocortisone butyrate 119 mg
- hydrocortisone cipionate 134 mg
- hydrocortisone hydrogen succinate 128 mg
- hydrocortisone sodium phosphate 134 mg
- hydrocortisone sodium succinate 134 mg
- hydrocortisone valerate 123 mg

However, esterification generally alters potency and compounds with equivalent hydrocortisone content may not have equivalent clinical effect.

When given **orally** hydrocortisone free alcohol is usually used; the cipionate ester is used in some formulations. For **replacement therapy** in acute or chronic adrenocortical insufficiency the normal requirement is 20 to 30 mg daily (usually taken in 2 doses, the larger in the morning and the smaller in the early evening, to mimic the circadian rhythm of the body). Children may be given 400 to 800 micrograms/kg daily in 2 or 3 divided doses, adjusted as needed. Additional sodium chloride may be required if there is defective aldosterone secretion, but mineralocorticoid activity is usually supplemented by fludrocortisone acetate orally. Similar regimens have also been used to correct glucocorticoid deficiency in the salt-losing form of congenital adrenal hyperplasia (p.1502).

Hydrocortisone may be given **intravenously**, by slow injection or infusion, in the form of a water-soluble derivative such as hydrocortisone sodium succinate or hydrocortisone sodium phosphate when a rapid effect is required in **emergencies**: such conditions are acute adrenocortical insufficiency caused by Addisonian or post-adrenalectomy crises, by the abrupt accidental withdrawal of therapy in corticosteroid-treated patients, or by the inability of the adrenal glands to cope with increased stress in such patients; certain allergic emergencies such as anaphylaxis; acute severe asthma (status asthmaticus—see also p.1108); and shock. The usual dose is the equivalent of 100 to 500 mg of hydrocortisone, repeated 3 or 4 times in 24 hours, according to the severity of the condition and the patient's response. Children up to 1 year of age may be given 25 mg, those aged 1 to 5 years 50 mg, and those aged 6 to 12 years 100 mg. Fluids and electrolytes should be given as necessary to correct any associated metabolic disorder. Similar doses to those specified above may also be given **intramuscularly** but the response is likely to be less rapid than that observed after intravenous doses. Corticosteroids are considered to be of secondary value in anaphylactic shock because of their relatively slow onset of action, but intravenous hydrocortisone may be a useful adjunct to adrenaline to prevent further deterioration in severely affected patients.

In patients with adrenal deficiency states supplementary corticosteroid therapy may be necessary during some **surgical operations** and hydrocortisone sodium succinate or sodium phosphate may be given intramuscularly or intravenously before surgery. Various regimens have been proposed (see also Surgery, p.1497). In patients taking more than 10 mg of oral prednisolone or its equivalent daily, the *BNF* recommends the following regimen:

- *minor surgery under general anaesthesia*, either the usual oral corticosteroid dose on the morning of surgery *or* hydrocortisone 25 to 50 mg (usually as the sodium succinate) intravenously at induction; the usual oral corticosteroid dose is resumed after surgery
- *moderate or major surgery*, the usual oral corticosteroid dose on the morning of surgery, *plus* hydrocortisone 25 to 50 mg intravenously at induction, and followed by similar doses of hydrocortisone 3 times daily, for 24 hours after moderate surgery and 48 to 72 hours after major surgery; the usual corticosteroid dose is resumed once hydrocortisone injections are stopped.

For **local injection** into soft tissues hydrocortisone is usually used in the form of the sodium phosphate or sodium succinate esters; doses in terms of hydrocortisone are usually 100 to 200 mg. For intra-articular injection hydrocortisone acetate is usually used in doses of 5 to 50 mg depending upon the size of the joint.

For **topical application** in the treatment of various skin disorders hydrocortisone and the acetate, buteprate, butyrate, and valerate esters are normally employed in creams, ointments, or lotions. Concentrations usually used have ranged from 0.1 to 2.5%. Although it is considered that hydrocortisone has fewer adverse effects on the skin and is less liable to cause adrenal suppression than the more potent topical corticosteroids (see p.1497 for a rough guide to the clinical potencies of topical corticosteroids), it should be borne in mind that this property may be considerably modified both by the type of formulation or vehicle used and by the type of esterification present; other factors that may also influence the degree of absorption include the site of application, use of an occlusive dressing, the degree of skin damage, and the size of the area to which the preparation is applied.

Hydrocortisone or its esters are also available in a variety of other dosage forms including those for ophthalmic, aural, dental, and rectal application, for use in allergic and inflammatory disorders.

Other esters of hydrocortisone that have occasionally been used include the aceponate, glycyrrhetinate, and propionate. Esters such as the aceponate may show modified topical activity.

Preparations

BP 2008: Gentamicin and Hydrocortisone Acetate Ear Drops; Hydrocortisone Acetate and Neomycin Ear Drops; Hydrocortisone Acetate and Neomycin Eye Drops; Hydrocortisone Acetate and Neomycin Eye Ointment; Hydrocortisone Acetate Cream; Hydrocortisone Acetate Injection; Hydrocortisone Acetate Ointment; Hydrocortisone and Clioquinol Cream; Hydrocortisone and Clioquinol Ointment; Hydrocortisone and Neomycin Cream; Hydrocortisone Cream; Hydrocortisone Ointment; Hydrocortisone Oromucosal Tablets; Hydrocortisone Sodium Phosphate Injection; Hydrocortisone Sodium Succinate Injection; Miconazole and Hydrocortisone Acetate Cream; Miconazole and Hydrocortisone Cream; Miconazole and Hydrocortisone Ointment;

USP 31: Chloramphenicol and Hydrocortisone Acetate for Ophthalmic Suspension; Chloramphenicol, Polymyxin B Sulfate, and Hydrocortisone Acetate Ophthalmic Ointment; Clioquinol and Hydrocortisone Cream; Clioquinol and Hydrocortisone Ointment; Colistin and Neomycin Sulfates and Hydrocortisone Acetate Otic Suspension; Hydrocortisone Acetate Cream; Hydrocortisone Acetate Injectable Suspension; Hydrocortisone Acetate Lotion; Hydrocortisone Acetate Ointment; Hydrocortisone Acetate Ophthalmic Ointment; Hydrocortisone Acetate Ophthalmic Suspension; Hydrocortisone and Acetic Acid Otic Solution; Hydrocortisone Butyrate Cream; Hydrocortisone Cream; Hydrocortisone Gel; Hydrocortisone Injectable Suspension; Hydrocortisone Lotion; Hydrocortisone Ointment; Hydrocortisone Rectal Suspension; Hydrocortisone Sodium Phosphate Injection; Hydrocortisone Sodium Succinate for Injection;

CAS — 129260-79-3 (loteprednol); 82034-46-6 (loteprednol etabonate).

ATC — S01BA14.

ATC Vet — QS01BA14.

Profile

Loteprednol etabonate is a corticosteroid used for its glucocorticoid activity (p.1490) in the topical management of inflammatory and allergic disorders of the eye. It is usually used as eye drops containing 0.2 or 0.5%.

Prolonged application to the eye of preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

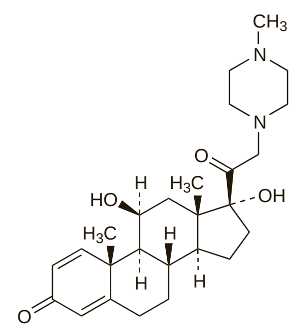
Мазипредон

$C_{26}H_{38}N_2O_4$ = 442.6.

CAS — 13085-08-0.



Profile

Mazipredone is a corticosteroid used topically for its glucocorticoid activity (p.1490). It is used as the hydrochloride with miconazole in the treatment of fungal infections of the skin.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, see p.1497.

Метилпреднизолона Натрия Сукцинат

$C_{26}H_{33}NaO_8$ = 496.5.
CAS — 2375-03-3.
ATC — D07AA01; H02AB04.
ATC Vet — QD07AA01; QH02AB04.

Pharmacopoeias. In *US.*

USP 31 (Methylprednisolone Sodium Succinate). A white or nearly white, odourless, hygroscopic, amorphous solid. Soluble 1 in 1.5 of water and 1 in 12 of alcohol; very slightly soluble in acetone; insoluble in chloroform and in ether. Store in airtight containers. Protect from light.

Stability. Methylprednisolone sodium succinate injection (*Solu-Medrol, USA*) was considered to be stable for 7 days when diluted in water for injection and stored in glass vials at 4°. When stored under similar conditions at 22°, it was considered to be stable for 24 hours.[1] The manufacturers state that the prepared solution should be stored at 20 to 25° and used within 48 hours of mixing.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490). Rapid intravenous injection of large doses has been associated with cardiovascular collapse.

Methylprednisolone may be slightly less likely than prednisolone to cause sodium and water retention.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects.

◊ References to various adverse effects associated with intravenous methylprednisolone in high-dose pulse therapy[1-11] and to adverse effects after intra-articular[12,13] and intranasal injection.[14] Epidural dosage (or more particularly inadvertent intrathecal dosage during attempted epidural placement) may be associated with serious adverse effects including arachnoiditis and aseptic meningitis, although the degree of risk is uncertain.[15]

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Methylprednisolone is fairly rapidly distributed after oral doses, with a plasma half-life of 3.5 hours or more. The tissue half-life is reported to range from 18 to 36 hours.

Methylprednisolone acetate is absorbed from joints over a week but is more slowly absorbed following deep intramuscular injection. The sodium succinate ester is rapidly absorbed after intramuscular doses, with peak plasma concentrations obtained in 2 hours.

Methylprednisolone crosses the placenta.

Uses and Administration

Methylprednisolone is a corticosteroid with mainly glucocorticoid activity (p.1490); 4 mg of methylprednisolone is equivalent in anti-inflammatory activity to about 5 mg of prednisolone.

It is used, either in the form of the free alcohol or in one of the esterified forms, in the treatment of conditions for which corticosteroid therapy is indicated (see p.1495) except adrenocortical-deficiency states, for which hydrocortisone with supplementary fludrocortisone is preferred.

The dose is usually expressed in terms of the base, and the following are each equivalent to about 40 mg of methylprednisolone:

- methylprednisolone acetate 44 mg
- methylprednisolone hydrogen succinate 51 mg
- methylprednisolone sodium succinate 53 mg

When given **orally**, methylprednisolone usually has an initial dosage range of 4 to 48 mg daily but higher initial doses of up to 100 mg or more daily may be used in acute severe disease.

For **parenteral use** in **intensive** or **emergency therapy**, methylprednisolone sodium succinate may be given by intramuscular or intravenous injection or by intravenous infusion. The intravenous route is preferred for its more rapid effect in emergency therapy. The usual initial intramuscular or intravenous dose ranges from the equivalent of 10 to 500 mg of methylprednisolone daily. Large intravenous doses (over 250 mg) should normally be given slowly over at least 30 minutes; doses up to 250 mg should be given over at least 5 minutes. High doses should generally not be given for prolonged periods; emergency treatment should only be used until the patient is stabilised. High doses given intermittently for a limited period have sometimes been known as 'pulse therapy' (see Administration, below) and in graft rejection (see Organ and Tissue Transplantation, p.1810) up to 1 g has been given daily for up to 3 days. In intensive therapy of acute spinal cord injury (p.1513) initial doses of the equivalent of up to 30 mg/kg of methylprednisolone have been given by bolus intravenous injection over 15 minutes and followed, after a 45-minute pause, by intravenous infusion of 5.4 mg/kg per hour over 24 hours or longer. For slow intravenous infusion methylprednisolone sodium succinate is dissolved in an appropriate volume of glucose 5% or sodium chloride 0.9% or sodium chloride 0.9% and glucose 5%.

Parenteral doses in children have varied considerably, depending on the condition: a range of 1 to 30 mg/kg of methylprednisolone daily has been given by the intravenous or intramuscular routes. A total dose of 1 g daily should not normally be exceeded.

Methylprednisolone acetate may be given by intramuscular injection for a prolonged systemic effect, the dose varying from 40 mg every 2 weeks to 120 mg weekly.

For **intra-articular injection** and for **injection into soft tissues** methylprednisolone acetate as an aqueous suspension is used. The dose by intra-articular injection varies from 4 to 80 mg according to the size of the affected joint. The acetate may also be given by intralesional injection in doses of 20 to 60 mg.

For use in the treatment of various skin disorders methylprednisolone acetate may be applied **topically**, usually in concentrations of 0.25%. The aceponate, which may exhibit modified topical activity, has also been applied as a 0.1% cream, lotion, or ointment. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Other esters of methylprednisolone that have occasionally been used include the cipionate and the suleptanate.

1. Cronstein BN. Clinical use of methylprednisolone sodium succinate: a review. *Curr Ther Res* 1995; **56:** 1–15.

Administration. For short-term intensive corticosteroid therapy or in certain emergency situations a technique known as 'pulse therapy' has been used. Methylprednisolone has often been used in this manner. Typically, high doses of about 1 g intravenously have been given, daily or on alternate days or weekly, for a limited number of doses; the most common regimen appears to be 1 g daily for 3 days.

Blood disorders. Methylprednisolone is one of the corticosteroids that have been used in the management of haemangioma (p.1505) and the Kasabach-Merritt syndrome.[1] There are also reports of benefit from very high-dose therapy in a few patients with refractory primary acquired pure red cell aplasia,[2] or aplasia due to Blackfan-Diamond anaemia.[3]

3. Bernini JC, *et al.* High-dose intravenous methylprednisolone therapy for patients with Diamond-Blackfan anemia refractory to conventional doses of prednisone. *J Pediatr* 1995; **127:** 654–9.

IDIOPATHIC THROMBOCYTOPENIC PURPURA. High-dose intravenous methylprednisolone may be used as part of the emergency management of acute idiopathic thrombocytopenic purpura (p.1505), for example when major acute bleeding or intracranial haemorrhage supervene. There is some evidence that methylprednisolone is less effective than normal immunoglobulins. Methylprednisolone has also been used by mouth or intravenously in the management of the chronic form, although prednisolone or prednisone are more frequently used for oral therapy and good controlled trials are scanty.

Rheumatoid arthritis. Methylprednisolone given in intravenous pulses has been reported[1-7] to be effective in the treatment of rheumatoid arthritis (p.11) including juvenile idiopathic arthritis. Some studies have shown this treatment to be of greatest benefit when given with a disease-modifying antirheumatic drug (DMARD),[1,2,4] although others showed the addition of methylprednisolone to existing therapy to have no extra benefit.[6] A comparatively low dose of 100 mg was found to be as effective as 1000 mg in one study.[3] Monthly doses of methylprednisolone by deep intramuscular injection were also an effective adjunct to gold therapy.[8]

A preliminary study in children has found intravenous pulses of methylprednisolone 30 mg/kg to be effective treatment for systemic flares of juvenile idiopathic arthritis.[7]

(mometasone)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Mometasone Furoate). A white or almost white powder. Practically insoluble in water; slightly soluble in alcohol; soluble in acetone and in dichloromethane.

USP 31 (Mometasone Furoate). A white to off-white powder. Soluble in acetone and in dichloromethane.

Profile

Mometasone furoate is a corticosteroid used topically for its glucocorticoid activity (see p.1490) in the treatment of various **skin disorders**. It is usually used as a cream, ointment, or lotion containing 0.1%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or when given intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (see p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

A nasal suspension of mometasone furoate 0.05%, as the monohydrate, is given in the treatment and prophylaxis of the symptoms of **allergic rhinitis** (p.565). The usual adult dose is the equivalent of 100 micrograms of mometasone furoate in each nostril once daily, increased if necessary to 200 micrograms in each nostril daily. Once symptoms are controlled a dose of 50 micrograms in each nostril daily may be effective for maintenance. In the UK, the dose for children aged between 6 and 11 years is the equivalent of 50 micrograms in each nostril once daily. In the USA, similar doses may be given to treat allergic rhinitis in children from 2 years of age.

The nasal suspension is also given for the treatment of **nasal polyps** in patients 18 years and older; the recommended initial dose in the UK is 100 micrograms into each nostril once daily, increased after 5 to 6 weeks to twice daily if needed. In the USA the recommended initial dose is 100 micrograms in each nostril twice daily, although once daily administration may be sufficient in some patients.

Mometasone furoate is used by dry powder inhaler for the prophylaxis of **asthma** (p.1108). Doses may differ between countries and dosage units may be expressed differently, as either the amount of drug released per actuation or the amount delivered from the mouthpiece. UK licensed product information includes an initial dose of 400 micrograms inhaled once daily in the evening for mild to moderate asthma in adults and adolescents aged 12 years and older. This may be adjusted to a maintenance dose of 200 micrograms once or twice daily. In severe asthma, an initial dose of 400 micrograms twice daily is used, then titrated to the lowest effective dose once symptoms are controlled. US doses are provided in terms of the amount of drug released per actuation (an actuation that releases 110 micrograms delivers 100 micrograms from the mouthpiece). An initial dose of 220 micrograms once daily in the evening is used in adults and adolescents, aged 12 years and older, who have been treated with inhaled therapy only (bronchodilators or corticosteroids); this may be increased to a maximum of 440 micrograms daily as a single dose or 2 divided doses. Patients receiving oral corticosteroids may be started on 440 micrograms twice daily. Children aged 4 to 11 years may be given 110 micrograms once daily in the evening, regardless of prior therapy; this is the maximum recommended daily dose.

Pharmacopoeias. In *US.*

USP 31 (Prednisolone Tebutate). A white to slightly yellow, hygroscopic, free-flowing powder, which may show some soft lumps. Is odourless or has not more than a moderate characteristic odour. Very slightly soluble in water; sparingly soluble in alcohol and in methyl alcohol; soluble in acetone; freely soluble in chloroform and in dioxan. Store in airtight containers sealed under nitrogen at a temperature not exceeding 8°.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490).

Owing to its less pronounced mineralocorticoid activity prednisolone is less likely than cortisone or hydrocortisone to cause sodium retention, electrolyte imbalance, and oedema. Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Breast feeding. Concentrations of prednisone and prednisolone in breast milk from one woman 120 minutes after prednisone 10 mg by mouth were found to be 26.7 nanograms and 1.6 nanograms/mL respectively.[1] In 7 similar women given a single 5-mg oral dose of tritium-labelled prednisolone, a mean of 0.14% of the radioactivity from the dose was recovered per litre of milk in the following 48 to 61 hours.[2] In a study of 3 women, only about 0.025% of a single intravenous dose of prednisolone phosphate 50 mg was recovered in breast milk over 6 hours.[3] During maintenance therapy with prednisolone in daily doses of 10 to 80 mg in 6 women, the milk to serum concentration ratio of prednisolone ranged from 0.2, for doses of 30 mg or more, to 0.1 for lower doses.[4] The authors estimated that the breast-fed infant would receive less than 0.1% of the maternal dose of prednisolone, and that this would be a negligible addition to the infant's endogenous cortisol production. They also concluded that exposure could be minimised by breast feeding at least 4 hours after the dose.

A review[5] by the UK CSM remarked that prednisolone was distributed into breast milk in small amounts and recommended that infants of mothers receiving 40 mg or more daily should be monitored for signs of adrenal suppression. The American Academy of Pediatrics considers[6] that the use of prednisone or prednisolone is usually compatible with breast feeding.

Hepatic impairment. Conversion of prednisone to prednisolone has been reported to be impaired in chronic active liver disease.[1,2] However, although plasma-prednisolone concentrations were found to be more predictable after prednisolone than prednisone in a group of healthy subjects,[3] no difference was noted in patients with chronic active hepatitis, in whom impaired elimination of prednisolone compensated for any impaired conversion of prednisone. A review of the pharmacokinetics of prednisone and prednisolone[4] concluded that fear of inadequate conversion of prednisone into prednisolone was not justified.

Inflammatory bowel disease. Symptoms recurred in a patient with Crohn's disease on changing from conventional to enteric-coated tablets of prednisolone.[1] This was not an isolated occurrence in the authors' unit, and it was advocated that only non-enteric-coated prednisolone tablets should be used in Crohn's disease, and that the enteric-coated form be used with caution in any condition characterised by diarrhoea or a rapid transit time.

Interactions

The interactions of corticosteroids in general are described on p.1494.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Prednisolone and prednisone are both readily absorbed from the gastrointestinal tract, but whereas prednisolone already exists in a metabolically active form, prednisone must be converted in the liver to its active metabolite, prednisolone. In general, this conversion is rapid so this difference is of little consequence when seen in the light of intersubject variation in the pharmacokinetics of prednisolone itself; bioavailability also depends on the dissolution rates of the tablet formulations. As discussed under Hepatic Impairment, above, reduced corticosteroid concentrations when giving prednisone to patients with liver disease do not seem to be a problem in practice. After intramuscular doses the sodium phosphate ester of prednisolone is rapidly absorbed whereas the acetate, in the suspension form, is only slowly absorbed.

Peak plasma concentrations of prednisolone are obtained 1 or 2 hours after an oral dose, and it has a usual plasma half-life of 2 to 4 hours. Its initial absorption, but not its overall bioavailability, is affected by food.

Prednisolone is extensively bound to plasma proteins, although less so than hydrocortisone (cortisol). The volume of distribution, and also the clearance are reported to increase with an increase from low to moderate doses; at very high doses, clearance appears to become saturated.

Prednisolone is excreted in the urine as free and conjugated metabolites, with an appreciable proportion of unchanged prednisolone. Prednisolone is largely inactivated as it crosses the placenta; small amounts are excreted in breast milk.

Prednisolone has a biological half-life lasting several hours, intermediate between those of hydrocortisone (cortisol) and the longer-acting glucocorticoids, such as dexamethasone. It is this intermediate duration of action that makes it suitable for the alternate-day dosage regimens which have been found to reduce the risk of adrenocortical insufficiency, yet provide adequate corticosteroid coverage in some disorders.

Uses and Administration

Prednisolone is a corticosteroid with mainly glucocorticoid activity (p.1490); 5 mg of prednisolone is equivalent in anti-inflammatory activity to about 25 mg of cortisone acetate. In general, prednisolone, either in the form of the free alcohol or in one of the esterified forms, is the drug of choice in the UK for conditions in which routine systemic corticosteroid therapy is indicated (see p.1495), except adrenocortical-deficiency states for which hydrocortisone with supplementary fludrocortisone is preferred. The more potent pituitary-suppressant properties of a glucocorticoid such as dexamethasone may, however, be required for the diagnosis and management of conditions associated with adrenal hyperplasia.

The dose may be expressed in terms of the base, and the following are each equivalent to about 100 mg of prednisolone:

- prednisolone acetate 110 mg
- prednisolone caproate 127 mg
- prednisolone hydrogen succinate 128 mg
- prednisolone metasulfobenzoate sodium 157 mg
- prednisolone pivalate 123 mg
- prednisolone sodium phosphate 135 mg
- prednisolone sodium succinate 134 mg
- prednisolone steaglate 190 mg
- prednisolone tebutate 132 mg

When given **orally** prednisolone is usually used although prednisolone sodium phosphate or prednisolone steaglate are also given; the usual dose, expressed in terms of prednisolone, is about 2.5 to 60 mg daily in divided doses, as a single daily dose after breakfast, or as a double dose on alternate days. Alternate-day early-morning dosage regimens produce less suppression of the hypothalamic-pituitary axis but may not always provide adequate control. Enteric-coated tablets of prednisolone are also available (for the view that these should not be used in patients with inflammatory bowel disease, see above).

For **parenteral use** the sodium phosphate ester is normally given, either intravenously by injection or infusion or intramuscularly by injection; doses appear to have been variously expressed in terms of prednisolone, prednisolone phosphate, or prednisolone sodium phosphate but are generally within the range of 4 to 60 mg daily. An aqueous suspension of prednisolone acetate is also used intramuscularly for a prolonged effect, in doses of 25 to 100 mg once or twice weekly. The sodium succinate ester has also been given parenterally.

For **intra-articular injection** the acetate, sodium phosphate, and tebutate esters are used. Suggested doses are 5 to 25 mg of prednisolone acetate, 2 to 30 mg of prednisolone phosphate (for the sodium phosphate ester), and 4 to 40 mg of prednisolone tebutate. The sodium phosphate and tebutate esters are also given by intralesional injection and by injection into soft tissue.

Prednisolone acetate and prednisolone sodium phosphate are also used in the **topical treatment** of allergic and inflammatory conditions of the eyes or ears, usually as drops containing 0.5 or 1%. Prednisolone has also been used topically as the free alcohol and as the hemisuccinate, pivalate, and metasulfobenzoate sodium esters.

For **rectal use** prednisolone metasulfobenzoate sodium or prednisolone sodium phosphate are often given. Retention enemas containing the equivalent of 20 mg of prednisolone per 100 mL, rectal foam containing the equivalent of 20 mg of prednisolone per dose, or suppositories containing the equivalent of 5 mg of prednisolone are available. Prednisolone has also been used rectally as the free alcohol and as the acetate and caproate esters.

Other esters of prednisolone that have occasionally been used include the farnesil, palmitate, sodium tetrahydrophthalate, and valeroacetate.

Preparations

BP 2008: Gastro-resistant Prednisolone Tablets; Prednisolone Enema; Prednisolone Sodium Phosphate Eye Drops; Prednisolone Tablets;

CAS — 125-10-0.

ATC — A07EA03; H02AB07.

ATC Vet — QA07EA03; QH02AB07.

Pharmacopoeias. In *Chin.* and *Pol.*

Profile

Prednisone is a biologically inert corticosteroid that is converted in the liver to the mainly glucocorticoid corticosteroid prednisolone. It has the same chemical relationship to prednisolone as cortisone has to hydrocortisone. The indications and dosage of prednisone for oral use are exactly the same as those for prednisolone (see p.1542, and the chapter introduction, p.1495).

In the UK prednisolone has historically been preferred to prednisone, on the grounds that it does not require conversion to the active substance, but in practice this is rarely significant (see Hepatic Impairment, under Prednisolone, p.1541), and in some countries, such as the USA, prednisone is the drug of choice for many of the conditions in which routine systemic corticosteroid therapy is indicated.

Preparations

USP 31: Prednisone Oral Solution; Prednisone Tablets.

Proprietary Preparations (details are given in Part 3)

Prednylidene *(BAN, rINN)* ⊗

16-Methyleneprednisolone; Prednilideeni; Prednilideno; Prednyliden; Prednylidène; Prednylidenum. 11β,17α,21-Trihydroxy-16-methylenepregna-1,4-diene-3,20-dione.

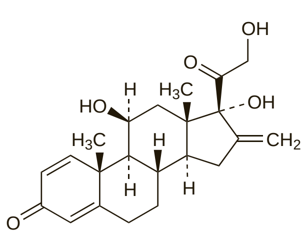
Преднилиден

$C_{22}H_{28}O_5$ = 372.5.

CAS — 599-33-7.

ATC — H02AB11.

ATC Vet — QH02AB11.



Profile

Prednylidene is a corticosteroid that has been used for its glucocorticoid activity similarly to prednisolone (see p.1540). It has been given orally as the free alcohol and by injection as the diethylaminoacetate hydrochloride.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Decortilen†.

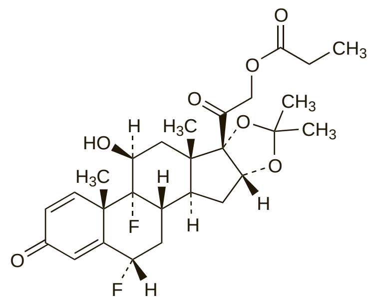
Procinonide *(USAN, rINN)* ⊗

Procinonida; Procinonidum; RS-2362. (6α,11β,16α)-6,9-Difluoro-11-hydroxy-16,17-[(1-methylethylidene)bis(oxy)]-21-(1-oxopropoxy)-pregna-1,4-diene-3,20-dione.

Процинонид

$C_{27}H_{34}F_2O_7$ = 508.6.

CAS — 58497-00-0.



Profile

Procinonide is a derivative of fluocinolone acetonide (p.1531) that has been applied topically with fluocinonide and ciprocinonide in the management of various skin disorders.

Resocortol Butyrate *(USAN, rINNM)* ⊗

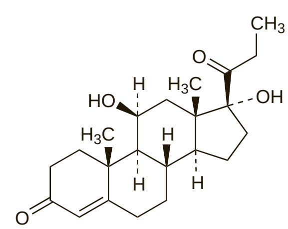
ALO-2184; Butirato de resocortol; Org-7417; Résocortol, Butyrate de; Resocortoli Butiras; Resocortoli Butyras; Resokortolbutyrat; Resokortolibutyraatti. 11β,17α-Dihydroxy-17-propionylandrost-4-en-3-one 17-butyrate.

Резокортола Бутират

$C_{26}H_{38}O_5$ = 430.6.

CAS — 76675-97-3 (resocortol); 76738-96-0 (resocortol butyrate).

ATC Vet — QD07AC90.



(resocortol)

Profile

Resocortol butyrate is a corticosteroid that is used topically in veterinary medicine.

Rimexolone *(BAN, USAN, rINN)* ⊗

Org-6216; Rimeksolon; Rimeksoloni; Rimexolon; Rimexolona; Rimexolonum; Trimexolone. 11β-Hydroxy-16α,17α-dimethyl-17β-propionylandrosta-1,4-dien-3-one.

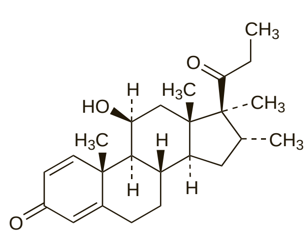
Римексолон

$C_{24}H_{34}O_3$ = 370.5.

CAS — 49697-38-3.

ATC — H02AB12; S01BA13.

ATC Vet — QH02AB12; QS01BA13.



Pharmacopoeias. In *US.*

USP 31 (Rimexolone). A white to off-white powder. Freely soluble in chloroform; sparingly soluble in methyl alcohol.

Profile

Rimexolone is a corticosteroid applied topically to the eye for its glucocorticoid activity (see p.1490) in the treatment of inflammatory eye disorders including uveitis (p.1515) and postoperative inflammation. It is used as a 1% suspension.

Prolonged use of ophthalmic preparations containing corticosteroids has caused raised intra-ocular pressure and reduced visual function.

Preparations

USP 31: Rimexolone Ophthalmic Suspension.

Proprietary Preparations (details are given in Part 3)

Suprarenal Cortex ⊗

Corteza suprarrenal.

Profile

Suprarenal cortex contains a number of steroid compounds the most active of which are corticosterone, dehydrocorticosterone, hydrocortisone, cortisone, and aldosterone. It has been prepared from the adrenal glands of oxen. Suprarenal cortex was formerly used intramuscularly for the treatment of adrenocortical insufficiency but it has been superseded by hydrocortisone and other corticosteroids (see p.1498).

Suprarenal cortex is an ingredient of a wide range of preparations, often with other organ extracts or vitamins, promoted for indications ranging from asthenia to liver disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austria:*** Mobilat; ***Belg.:*** Mobilat; ***Braz.:*** Broncopinol†; Mobilat; Suprasten†; ***Canad.:*** ratio-Heracline; ***Chile:*** Mobilat; ***Cz.:*** Mobilat; ***Fin.:*** Mobilat; ***Ger.:*** Arthrodeformat P†; Mobilat†; ***Hong Kong:*** Mobilat†; ***Philipp.:*** Mobilat; ***Pol.:*** Mobilat; ***Singapore:*** Mobilat†; ***Spain:*** Neurocatavin Dexa†; Pleocortex B6†; Rubrocortin†; ***Thai.:*** Mobilat.

Tetracosactide *(BAN, rINN)* ⊗

α^{1-24}-Corticotrophin; β^{1-24}-Corticotrophin; Cosyntropin *(USAN)*; Tetracosactida; Tétracosactide; Tetracosactido; Tetracosactidum; Tetracosactrin; Tetrakosaktid; Tetrakosaktidi; Tetrakosaktrin; Tetrakozaktidas. Corticotrophin-(1–24)-tetracosapeptide; Ser-Tyr-Ser-Met-Glu-His-Phe-Arg-Trp-Gly-Lys-Pro-Val-Gly-Lys-Lys-Arg-Arg-Pro-Val-Lys-Val-Tyr-Pro.

Тетракозактид

$C_{136}H_{210}N_{40}O_{31}S$ = 2933.4.

CAS — 16960-16-0 (tetracosactide); 22633-88-1 (tetracosactide hexaacetate); 60189-34-6 (tetracosactide x acetate).

ATC — H01AA02.

ATC Vet — QH01AA02.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Tetracosactide). A synthetic tetracosapeptide in which the sequence of amino acids is the same as that of the first 24 residues of human corticotropin. It is available as an acetate and contains water. It increases the rate at which corticoid hormones are secreted by the adrenal gland. The potency is not less than 800 units/mg. A white or yellow, amorphous powder. Sparingly soluble in water. Store under nitrogen at a temperature of 2° to 8°. Protect from light.

Adverse Effects, Withdrawal, and Precautions

As for Corticotropin, p.1523. Although hypersensitivity reactions, including anaphylaxis, may occur with the use of tetracosactide, it is reported to be less immunogenic than corticotropin; US licensed product information suggests that patients with a history of hypersensitivity to corticotropin may tolerate tetracosactide. In the UK, however, previous hypersensitivity to corticotropin or to tetracosactide is considered a contra-indication to tetracosactide use. Tetracosactide is also contra-indicated in patients with a history of allergic disorders such as asthma.

Since hypersensitivity reactions may occur up to 1 hour after injection, sufficient time should be allowed for recovery after use at the hospital or surgery. Self-administration is not recommended.

Interactions

As for Corticosteroids, p.1494.

Pharmacokinetics

On intravenous injection tetracosactide exhibits triphasic pharmacokinetics. It is rapidly eliminated from plasma, mostly by distribution to the adrenal glands and kidneys. It is metabolised by serum endopeptidases into inactive oligopeptides, and then by aminopeptidases into free amino acids. Most of a dose is excreted in urine within 24 hours. The terminal half-life of tetracosactide is about 3 hours.

Uses and Administration

Tetracosactide is a synthetic polypeptide with general properties similar to those of corticotropin (p.1524). Tetracosactide is used diagnostically to investigate adrenocortical insufficiency (p.1498).

Although tetracosactide, like corticotropin, has also been used therapeutically for most of the conditions in which systemic corticosteroid therapy is indicated, it is now rarely used for such indications.

Tetracosactide is usually used in the form of the acetate although doses are often expressed in terms of tetracosactide itself.

For diagnostic purposes tetracosactide acetate is used intramuscularly or intravenously as a plain injection in the first instance then, if results are inconclusive, intramuscularly as a long-acting depot injection. The initial test using the plain injection is based on the measurement of plasma-cortisol concentrations immediately before and exactly 30 minutes after an intramuscular or intravenous injection equivalent to 250 micrograms of tetracosactide; adrenocortical function may be regarded as normal if there is a rise in the cortisol concentration of at least 200 nanomoles/litre (70 micrograms/litre). A suggested intravenous dose in children has been 250 micrograms per 1.73 m^2.

If the results of this test are equivocal the long-acting depot preparation may be used, the adult dose being 1 mg of tetracosactide acetate given intramuscularly. Adrenocortical function is regarded as normal if plasma-cortisol concentrations have steadily increased to 1000 to 1800 nanomoles/litre 5 hours after the injection. A 3-day test, for example with 1 mg of the depot preparation given each morning, is also used to differentiate between primary and secondary adrenocortical insufficiency; this is preceded on the first day and followed on the fourth day by the test using the plain injection. A marked improvement in the second assessment suggests secondary adrenocortical insufficiency.

For therapeutic purposes tetracosactide acetate has been given by intramuscular injection as the long-acting depot preparation. The usual initial adult dose of tetracosactide acetate has been 1 mg daily (or 1 mg every 12 hours in acute cases), reduced after the acute symptoms have been controlled to 0.5 to 1 mg every 2 or 3 days or 1 mg weekly. For children aged 3 to 5 years, a dose of 250 to 500 micrograms intramuscularly has been given daily initially, and then every 2 to 8 days for maintenance. A dose of 0.25 to 1 mg has been used similarly in children aged 5 to 12 years.

Tetracosactide has also been used in children aged 1 month and older to manage infantile spasms in a dose of 500 micrograms by intramuscular injection given on alternate days and adjusted to response.

Post-dural puncture headache. There are anecdotal reports of the relief of post-dural puncture headache by corticotropin or, more recently, tetracosactide.[1-5] Intramuscular injection and intravenous infusion have both been used, but a controlled study[6] in 18 women found that a single intramuscular dose of tetracosactide 1 mg was no more beneficial than sodium chloride 0.9%. As discussed on p.1851, many patients respond to conservative measures.

Ph. Eur. 6.2 (Triamcinolone Hexacetonide). A white or almost white, crystalline powder. Practically insoluble in water; sparingly soluble in dehydrated alcohol and in methyl alcohol. Protect from light.

USP 31 (Triamcinolone Hexacetonide). A white to cream-coloured powder. Practically insoluble in water; soluble in chloroform; slightly soluble in methyl alcohol.

Adverse Effects, Treatment, Withdrawal, and Precautions

As for corticosteroids in general (see p.1490). High doses of triamcinolone may have a greater tendency to produce proximal myopathy. Its effects on sodium and water retention are less than those of prednisolone.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, or when given intranasally, corticosteroids may be absorbed in sufficient amounts to cause systemic effects.

Effects on the eye. For complications and precautions associated with intravitreal use of triamcinolone see under Eye Disorders, below.

Hypersensitivity. Local reactions to topical triamcinolone preparations have been attributed to the content of ethylenediamine.[1,2] However, there have also been reports of anaphylactic shock after intra-articular[3] or intramuscular[4] injection of triamcinolone acetonide.

4. Gonzalo FE, *et al.* Anaphylactic shock caused by triamcinolone acetonide. *Ann Pharmacother* 1994; **28:** 1310.

Pharmacokinetics

For a brief outline of the pharmacokinetics of corticosteroids, see p.1495.

Triamcinolone is reported to have a half-life in plasma of about 2 to over 5 hours. It is bound to plasma albumin to a much smaller extent than hydrocortisone.

The acetonide, diacetate, and hexacetonide esters of triamcinolone are only very slowly absorbed from injection sites.

Triamcinolone crosses the placenta.

Uses and Administration

Triamcinolone is a corticosteroid with mainly glucocorticoid activity (p.1490); 4 mg of triamcinolone is equivalent in anti-inflammatory activity to about 5 mg of prednisolone. It is used, either in the form of the free alcohol or in one of the esterified forms, in the treatment of conditions for which corticosteroid therapy is indicated (see p.1495), except adrenocortical insufficiency for which hydrocortisone with supplementary fludrocortisone is preferred.

For **oral dosage** triamcinolone is used in doses ranging from 4 to 48 mg daily.

For **parenteral use** the acetonide or diacetate esters are given in doses of about 40 mg by intramuscular injection. They are usually given as suspensions to provide a prolonged systemic effect. A dose of 40 to 100 mg of the acetonide may provide symptomatic control throughout the pollen season for hay fever sufferers (but see Rhinitis, below); for the diacetate, a 40-mg dose is given weekly.

For **intra-articular injection** triamcinolone acetonide, diacetate, and hexacetonide have all been used. Doses for these esters have typically been in the range of 2.5 to 40 mg, 3 to 48 mg, and 2 to 30 mg respectively, depending upon the size of the joint injected.

For **topical application** in the treatment of various skin disorders triamcinolone acetonide is used, usually in creams, lotions, or ointments containing 0.1% although concentrations ranging from 0.025 to 0.5% have been employed. Several topical preparations also contain an antimicrobial drug. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Triamcinolone esters are also commonly used by **intralesional** or **intradermal injection** in the treatment of some inflammatory skin disorders such as keloids. Suggested doses for the various esters have been:

- acetonide: 1 to 3 mg per site with no more than 5 mg injected into any one site or not more than 30 mg in total if several sites of injection are used
- diacetate: a total of 5 mg in divided doses into small lesions or up to a total of 48 mg in divided doses into large lesions with no more than 12.5 mg injected into any one site or 25 mg injected into any one lesion
- hexacetonide: up to 500 micrograms per square inch (about 80 micrograms/cm^2) of affected skin.

Triamcinolone acetonide is also used **by inhalation** for the control of asthma in a usual dose of about 150 micrograms by metered-dose inhaler three or four times daily, or 300 micrograms twice daily; the dose should not exceed 1200 micrograms daily. Children aged 6 to 12 years may be given 75 or 150 micrograms three or four times daily, or 150 to 300 micrograms twice daily; the daily dose should not exceed 900 micrograms.

In the prophylaxis and treatment of allergic rhinitis triamcinolone acetonide may be given by a **nasal spray** in a usual initial dose of 2 sprays (110 micrograms) into each nostril once daily, reduced to 1 spray (55 micrograms) when control is achieved. Children aged 6 to 12 years may be given 1 spray (55 micrograms) into each nostril once daily; in severe symptoms this may be increased to 220 micrograms daily.

A preservative-free suspension of triamcinolone acetonide 40 mg/mL is available for **intravitreal injection**. A dose of 4 mg is used for the treatment of sympathetic ophthalmia, temporal arteritis, uveitis, and ocular inflammatory conditions that are unresponsive to topical corticosteroids. Further doses may be given as needed during the course of treatment. A dose of 1 to 4 mg may be used for visualisation during vitrectomy.

Other esters of triamcinolone that have occasionally been used include the acetonide dipotassium phosphate, acetonide hemisuccinate, aminobenzal benzamidoisobutyrate, and benetonide. Flupamesone (triamcinolone acetonide metembonate) has also been used.

Asthma. Intramuscular triamcinolone acetonide has been reported to be more effective than oral low-dose prednisone in controlling exacerbations in patients with severe, chronic, life-threatening asthma,[1] although this conclusion is controversial.[2-7]

Corticosteroids and $beta_2$-adrenoceptor agonists form the cornerstone of the management of asthma (p.1108). Inhaled corticosteroids are added to therapy with a short-acting $beta_2$ agonist if symptom relief with the latter is needed more than once daily, although corticosteroids with reduced systemic activity are generally preferred to triamcinolone. Systemic corticosteroids are reserved for the most severe cases, and for the management of acute severe asthma attacks (status asthmaticus).

Chronic obstructive pulmonary disease. For discussion of the value of inhaled corticosteroids in chronic obstructive pulmonary disease, including reference to the use of triamcinolone acetonide, see p.1501.

Eye disorders. Intravitreal injection of triamcinolone acetonide has been tried in the management of eye disorders characterised by oedema and the abnormal proliferation of intra-ocular cells. Promising results have been reported in diabetic macular oedema,[1,2] cystoid macular oedema, and oedema associated with retinal vein occlusion.[2-5] It has also been used in age-related macular degeneration (p.785; better results being seen when it is combined with photodynamic therapy), in proliferative diabetic retinopathy, and in the management of some forms of cataract and non-infectious uveitis.[2,3] Complications of treatment may include raised intra-ocular pressure (IOP)[6] and both infectious and non-infectious endophthalmitis.[2] Patients with a baseline IOP greater than 16 mmHg or receiving a second injection should be carefully monitored, as they may be at greater risk of an increase; monitoring should continue beyond 6 months.[6]

Dissolved drugs are not retained in the eye for prolonged periods, and early studies and off-label treatment have used injectable suspensions to achieve long-lasting concentrations of triamcinolone in the vitreous body.[7] However, these commercial products were intended for intramuscular and intra-articular use and not licensed for intravitreal injection, and there has been concern about the potential ocular toxicity of their preservative, benzyl alcohol.[2,7] Various techniques, such as sedimentation, centrifugation, and filtration, have been used extemporaneously to reduce the benzyl alcohol content of such products, but the quantity of triamcinolone in the final preparation may be altered depending on the technique used.[8] More recently, a preservative-free product has been licensed in the USA for intravitreal use (*Triesence; Alcon, USA*—see Uses and Administration, above).

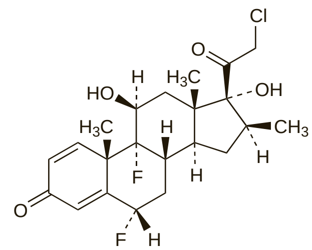
CAS — 98651-66-2 (ulobetasol); 66852-54-8 (ulobetasol propionate).

ATC — D07AC21.

ATC Vet — QD07AC21.



(ulobetasol)

Profile

Ulobetasol propionate is a corticosteroid that is used topically for its glucocorticoid activity (p.1490) in the treatment of various skin disorders. It is usually used as a cream or ointment containing 0.05%.

When applied topically, particularly to large areas, when the skin is broken, or under occlusive dressings, corticosteroids may be absorbed in sufficient amounts to cause systemic effects (p.1490). The effects of topical corticosteroids on the skin are described on p.1492. For recommendations concerning the correct use of corticosteroids on the skin, and a rough guide to the clinical potencies of topical corticosteroids, see p.1497.

Cough Suppressants Expectorants Mucolytics and Nasal Decongestants

This chapter describes drugs that are used mainly as cough suppressants, expectorants, or mucolytics, and also those sympathomimetics primarily used for the relief of nasal congestion. Other drugs used in cough include antihistamines (p.561), bronchodilators (p.1108), and local anaesthetics (p.1850). Compounds with a demulcent action such as glycerol (p.2314) and sucrose (p.1969) are also used, as are various hydrating inhalations.

Cough suppressants

Cough suppressants have either a central or a peripheral action on the cough reflex or a combination of both. Centrally acting cough suppressants increase the threshold of the cough centre in the brain to incoming stimuli whereas those acting peripherally decrease the sensitivity of the receptors in the respiratory tract. Some drugs have an indirect peripheral mechanism of action and may alter mucociliary factors, exert a local analgesic or anaesthetic action on the receptors, protect the receptors from irritant stimuli, or act as bronchodilators.

Those centrally acting cough suppressants structurally related to morphine that are included in this chapter, such as dextromethorphan, have little or no analgesic action. Those that also have an important analgesic action, such as codeine or diamorphine, are described in the chapter on Analgesics, p.1.

Described in this chapter are

Acetyldihydrocodeine, p.1550	Helicidine, p.1562
Alloclamide, p.1550	Isoaminile, p.1563

Expectorants

Expectorants are considered to increase the volume of secretions in the respiratory tract thereby facilitating their removal by ciliary action and coughing. Many traditional expectorants, including ipecacuanha, squill, ammonium salts, some volatile oils, and various iodide compounds, have been considered to achieve this by a reflex irritant effect on the gastric mucosa.

Described in this chapter are

Ammonium Salts, p.1551	Guaietolin, p.1561
Calcium Iodide, p.1553	Guaifenesin, p.1561
Cocillana, p.1554	Guaimesal, p.1562
Coltsfoot, p.1555	Iodinated Glycerol, p.1562
Creosote, p.1555	Ipecacuanha, p.1562
Elecampane, p.1558	Marrubium, p.1564
Eprazinone, p.1559	Senega Root, p.1572
Eprozinol, p.1560	Squill, p.1573
Eriodictyon, p.1560	Sulfogaiacol, p.1573
Fudosteine, p.1561	Terpin, p.1573
Guacetisal, p.1561	Tolu Balsam, p.1574
Guaiacol, p.1561	

Mucolytics

Mucolytics alter the structure of mucus to decrease its viscosity thereby facilitating its removal by ciliary action or expectoration.

Acetylcysteine, carbocisteine, and mecysteine all have thiol groups; if this group is free, as in acetylcysteine, it may be substituted for disulfide bonds in mucus and therefore break the mucus chains. However, drugs such as carbocisteine with 'protected' thiol groups cannot act by this mechanism and their exact mode of action is unclear. Thiol groups are also involved in the mechanism of action of some of these drugs when they are used in the treatment of poisoning.

Deoxyribonucleases such as dornase alfa act as mucolytics by hydrolysing the accumulated extracellular DNA from decaying neutrophils that contributes to the viscous respiratory secretions of cystic fibrosis.

Drugs with **mucoregulatory** actions, typically affecting mucin and chloride secretion by acting on ion channels in the respiratory tract, are also being developed; examples under investigation include denufosol and talniflumate.

Described in this chapter are

Acetylcysteine, p.1548	Erdosteine, p.1560
Ambroxol, p.1550	Ethyl Cysteine Hydrochloride, p.1560
Bromhexine, p.1552	Letosteine, p.1563
Brovanexine, p.1553	Mecysteine, p.1564
Carbocisteine, p.1553	Methyl Dacisteine, p.1564
Dembrexine, p.1555	Neltenexine, p.1566
Denufosol, p.1555	Sobrerol, p.1572
Dornase Alfa, p.1557	Talniflumate, p.1573
Eprazinone, p.1559	Telmesteine, p.1573
Eprozinol, p.1560	

Sympathomimetics

Sympathomimetics described in this chapter may be used systemically (such as phenylephrine) or locally (such as naphazoline), for their alpha agonist actions to produce vasoconstriction of the nasal mucosa, thus relieving congestion. Others such as ephedrine have both alpha and beta agonist actions. The beta agonist actions confer upon them bronchodilating properties, but they have been superseded as bronchodilators by the more selective beta$_2$ agonists such as salbutamol. The value of bronchodilators in non-asthmatic cough has not been confirmed.

Described in this chapter are

Amidefrine, p.1551	Naphazoline, p.1565
Clonazoline, p.1554	Oxymetazoline, p.1567
Ephedra, p.1558	Phenylephrine, p.1568
Ephedrine, p.1558	Phenylpropanolamine, p.1569
Etafedrine, p.1560	Pseudoephedrine, p.1571
Fenoxazoline, p.1560	Tetryzoline, p.1574
Indanazoline, p.1562	Tramazoline, p.1574
Levmetamfetamine, p.1564	Tuaminoheptane, p.1575
Methoxyphenamine, p.1564	Tymazoline, p.1575
Methylephedrine, p.1564	Xylometazoline, p.1575
Metizoline, p.1565	

Cough

Cough is an important physiological protective mechanism, but may also occur as a symptom of an underlying disorder such as asthma, gastro-oesophageal reflux disease, and postnasal drip. Treatment of the disorder often alleviates the cough, but there are times when symptomatic treatment is appropriate. The treatment chosen depends on whether the cough is productive or non-productive.[1-11]

A **non-productive cough** such as that often seen with the common cold serves no useful purpose for the patient, and cough suppressants may provide some relief, particularly if given at night.

- Of the commonly used *cough suppressants*, pholcodine and dextromethorphan are considered to have fewer adverse effects than codeine. However, there is little evidence that these drugs are effective in severe cough. Codeine or similar opioids are not generally recommended as cough suppressants in children, and should be avoided altogether in those under 1 year of age.
- Sedating *antihistamines* such as diphenhydramine are frequently used as cough suppressants in compound preparations. Suggested mechanisms of action have included reduction in cholinergic nerve transmission, or cough suppression as a result of their sedative effects. Antihistamines reduce nasal secretions and may be of value in treating cough caused by postnasal drip, particularly if associated with allergic rhinitis (see p.565). However, they should not be used to treat a productive cough because they may cause formation of viscid mucus plugs. Their sedative effects are a disadvantage for daytime use but may be a short-term advantage for night coughs.
- *Demulcents* probably act as indirect peripherally acting cough suppressants by providing a protective coating over sensory receptors in the pharynx. Demulcents include glycerol, honey, liquorice, and sucrose syrups.

A potent cough suppressant such as morphine is needed for the relief of **intractable cough** in terminal illness. The use of such a potent opioid is not otherwise considered appropriate for cough.

- *Local anaesthetics* such as lidocaine or bupivacaine have been inhaled in severe intractable cough, including cough caused by malignant neoplasms. Cough suppression is produced by an indirect peripheral action on sensory receptors, but as all protective pulmonary reflexes may be lost and bronchospasm may be induced, such treatment should be used with care. There may also be temporary loss of the swallowing reflex.

A **productive cough** is characterised by the presence of sputum and may be associated with conditions such as chronic bronchitis, bronchiectasis, or cystic fibrosis. Cough suppressants are inappropriate, since the cough serves the purpose of clearing the airways, but expectorants have been used on the grounds that increasing the volume of secretions in the respiratory tract facilitates removal by ciliary action and coughing. However, clinical evidence of efficacy is lacking, and many authorities consider expectorants to be of no value other than as a placebo.

- Commonly used *expectorants* include ammonium salts, guaifenesin, ipecacuanha, and sodium citrate. Iodides have also been used but there has been concern over their safety for prolonged use in respiratory disorders and because of their potential for thyroid suppression; in particular, it has been recommended that they should not be given to children, adolescents, pregnant women, or patients with goitre.
- *Mucolytics* have been shown to affect sputum viscosity and structure and patients have reported alleviation of their symptoms, but no consistent improvement in lung function has been found. Commonly used mucolytics include acetylcysteine, bromhexine, carbocisteine, and mecysteine. Dornase alfa is also available, in particular for patients with cystic fibrosis. In theory mucolytics may disrupt the gastric mucosal barrier and caution has been recommended in patients with a history of peptic ulcer disease.
- *Hydrating agents* liquefy mucus and also have a demulcent effect. Hydration may be achieved simply by inhaled warm moist air. The addition of substances such as menthol, benzoin, or volatile oils is unlikely to provide any additional benefit but may encourage the use of such inhalations. Inhaled aerosols of water, sodium bicarbonate, sodium chloride, surfactants such as tyloxapol, and proteolytic enzymes such as chymotrypsin and trypsin, have also been used for their reported hydrating or mucolytic effects on respiratory secretions.

Cough may sometimes be associated with **bronchospasm** in patients with asthma.

- *Bronchodilators* such as salbutamol (a beta$_2$ agonist) or ipratropium (an antimuscarinic) alleviate cough associated with bronchospasm. However, they are not generally considered of benefit in other forms of cough, and hence are not recommended other than in asthma or selected patients with chronic obstructive pulmonary disease.

Cough and cold preparations containing various combinations of cough suppressants and/or expectorants, with sympathomimetics, antihistamines, or analgesics are available. Some combinations, such as a cough suppressant and an expectorant, seem illogical and have little evidence to support their efficacy. As with many combinations, doses of individual drugs may be inadequate or inappropriate, and the large number of ingredients may expose the patient to unnecessary adverse effects. In particular, concern has been expressed about the safety in *children* of cough and cold preparations that contain antihistamines, cough suppressants, expectorants, and sympathomimetic decongestants, either alone or in combination. A systematic review[12] has found no good evidence for or against the effectiveness of over-the-counter preparations in acute cough. The British Thoracic Society considers that over-the-counter medications are as effective as placebo for acute cough with head colds in children.[13] In early 2008, the FDA[14] and MHRA[15] both advised that over-the-counter cough and cold preparations should not be given to children under 2 years of age. They warn of the potential for serious and potentially life-threatening adverse effects and that such preparations provide only symptomatic relief, at best. If these products are used in children older than 2 years of age, the recommended dose should be followed carefully and measured accurately, and only one preparation should be used to avoid overdosage of the same drug or similar drugs. A review by the FDA of the use of such preparations in older children (2 to 11 years of age) is ongoing.

To alleviate symptoms of coughs and colds in children aged under 2 years, the MHRA recommends using single-constituent paracetamol or ibuprofen, simple cough preparations (such as those containing glycerol or honey and lemon), vapour rubs and inhalant decongestants (that can be applied to clothing), and, particularly in infants, sodium chloride nasal drops.

Nasal congestion

Nasal congestion is frequently a symptom of conditions such as rhinitis (p.565), treatment of which can include the use of antihistamines, sympathomimetics, corticosteroids, antimuscarinics, and cromoglicate or nedocromil.

Sympathomimetics are also widely used as nasal decongestants to provide symptomatic relief of the common cold (p.850). They are used for the vasoconstriction produced by their alpha-adrenergic effects; redistribution of local blood flow reduces oedema of the nasal mucosa, thus improving ventilation, drainage, and nasal stuffiness. Sympathomimetics such as ephedrine, phenylephrine, naphazoline, oxymetazoline, and xylometazoline can be used topically as nasal drops or sprays. Those such as pseudoephedrine are given orally. Over-the-counter cough and cold preparations containing sympathomimetic decongestants should be used with caution in children and generally avoided in those under 2 years of age (see above). However, the *BNFC* suggests that, in certain circumstances, specialists may prescribe ephedrine or xylometazoline nasal drops for children under 2 years in the short-term treatment of severe nasal congestion that has not responded to sodium chloride nasal drops or inhalation of warm moist air (see below).

Topical use, particularly if prolonged, may lead to rebound congestion as vasodilatation becomes prominent and the effects of vasoconstriction subside. Use is therefore restricted to periods of not more than 7 consecutive days. Oral use is not associated with such rebound congestion, but is more likely to be associated with systemic adverse effects and a higher risk of drug interactions. A systematic review found no difference in efficacy between oral and topical decongestants from the limited evidence available.[1]

The benefits of *antihistamines* in nasal congestion other than that associated with allergic rhinitis are doubtful, particularly by topical application.

Inhalations of warm moist air are also useful in the treatment of nasal congestion associated with the common cold. As in the case of cough (see above) the addition of substances such as menthol, benzoin, or volatile oils may encourage the use of such inhalations. Sodium chloride nasal drops may also be effective, particularly in infants and young children.

Acetylcysteine *(BAN, USAN, rINN)*

5052; Acetilcisteína; Acetilcisteinas; Acetilcisztein; Acetylcystein; Acétylcystéine; Acetylcysteinum; Asetilsistein; Asetyylikysteiini; NSC-111180. *N*-Acetyl-L-cysteine.

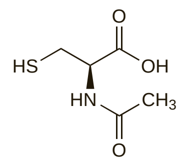
Ацетилцистеин

$C_5H_9NO_3S$ = 163.2.

CAS — 616-91-1.

ATC — R05CB01; S01XA08; V03AB23.

ATC Vet — QR05CB01; QS01XA08; QV03AB23.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Acetylcysteine). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water and in alcohol; practically insoluble in dichloromethane. A 1% solution in water has a pH of 2.0 to 2.8. Protect from light.

USP 31 (Acetylcysteine). A white crystalline powder having a slight acetic odour. Soluble 1 in 5 of water and 1 in 4 of alcohol; practically insoluble in chloroform and in ether. pH of a 1% solution in water is between 2.0 and 2.8. Store in airtight containers.

Incompatibility. Acetylcysteine is incompatible with some metals, including iron and copper, with rubber, and with oxygen and oxidising substances. Some antimicrobials including amphotericin B, ampicillin sodium, erythromycin lactobionate, and some tetracyclines are either physically incompatible with, or may be inactivated on mixture with, acetylcysteine.

Stability. A change in colour of solutions of acetylcysteine to light purple does not indicate significant impairment of safety or efficacy.

Acetylcysteine Sodium *(BANM, rINNM)*

Acetilcisteína sódica; Acétylcystéine Sodique; Natrii Acetylcysteinum.

Натрий Ацетилцистеин

$C_5H_8NNaO_3S$ = 185.2.

CAS — 19542-74-6.

ATC — R05CB01; S01XA08; V03AB23.

ATC Vet — QR05CB01; QS01XA08; QV03AB23.

Adverse Effects

Hypersensitivity reactions have been reported in patients receiving acetylcysteine, including bronchospasm, angioedema, rashes and pruritus; hypotension, or occasionally hypertension, may occur. Other adverse effects reported with acetylcysteine include flushing, nausea and vomiting, fever, syncope, sweating, arthralgia, blurred vision, disturbances of liver function, acidosis, convulsions, and cardiac or respiratory arrest. Haemoptysis, rhinorrhoea, and stomatitis have been associated with inhalation of acetylcysteine.

Hypersensitivity. The most common symptoms of patients experiencing **anaphylactoid** reactions after the intravenous use of acetylcysteine in the treatment of paracetamol poisoning are rash and pruritus; other features have included flushing, nausea or vomiting, angioedema, tachycardia, bronchospasm, hypotension, and hypertension;[1-3] ECG abnormalities associated with an anaphylactoid reaction have also been reported in a patient.[4] Anaphylactoid reactions to intravenous acetylcysteine appear to be dose-related.[5] One group estimated that when acetylcysteine was given correctly the **frequency** of the anaphylactoid response was between 0.3 and 3%, whereas 11 of 15 patients who had received an overdose had an anaphylactoid reaction.[6] Intradermal testing and study of plasma-acetylcysteine concentrations in patients who developed reactions to acetylcysteine suggests a 'pseudo-allergic' rather than an immunological reaction,[7,8] although symptoms consistent with a serum sickness-like illness developed after exposure to acetylcysteine in one patient.[9] It has been suggested that generalised reactions to acetylcysteine can be **treated** with intravenous injection of an antihistamine;[5,10] infusion of acetylcysteine should be temporarily stopped but can usually be restarted at a slower rate without further reaction.[3]

Symptoms after **overdosage** with acetylcysteine have been more severe. Hypotension appears to be especially prominent;[6] additional symptoms have included respiratory depression, haemolysis, disseminated intravascular coagulation, and renal failure, but some of these may have been due to paracetamol poisoning.[1] Death occurred in 3 patients who received an overdose of acetylcysteine while being treated for paracetamol poisoning,[1,11] but in 2 of them the role of acetylcysteine in this outcome was unclear.

Precautions

Acetylcysteine should be used with caution in asthmatic patients. It should also be used with caution in patients with a history of peptic ulcer disease, both because drug-induced nausea and vomiting may increase the risk of gastrointestinal haemorrhage in patients predisposed to the condition, and because of a theoretical risk that mucolytics may disrupt the gastric mucosal barrier.

Asthma. Bronchospasm precipitated in 2 asthmatic patients[1] and severe asthma and respiratory arrest in another[2] have been reported after intravenous treatment with acetylcysteine. There is also a report of a patient with brittle asthma who had a similar reaction and subsequently died after receiving intravenous treatment with acetylcysteine.[3] The increased risk does not justify delaying or witholding acetylcysteine in asthmatic patients with paracetamol poisoning, but consideration might be given to initial intravenous infusion over 30 to 60 minutes rather than the conventional 15 minutes.[4] However, a large multicentre study found no benefit from the more prolonged infusion—see Paracetamol under Poisoning and Toxicity, below.

4. Schmidt LE, Dalhoff K. Risk factors in the development of adverse reactions to N-acetylcysteine in patients with paracetamol poisoning. *Br J Clin Pharmacol* 2001; **51:** 87–91.

Hepatic impairment. The total clearance of acetylcysteine in patients with cirrhosis was found to be markedly impaired, and the elimination half-life almost twice that of healthy controls.[1] Since some of the more serious adverse effects of acetylcysteine occur when plasma concentrations are high, the authors considered that increased vigilance for untoward anaphylactoid reactions and other adverse effects was necessary in patients with cirrhosis receiving acetylcysteine, and further studies to determine the optimum dosage regimen in such patients were required.

1. Jones AL, *et al.* Pharmacokinetics of N-acetylcysteine are altered in patients with chronic liver disease. *Aliment Pharmacol Ther* 1997; **11:** 787–91.

Pharmacokinetics

◊ Acetylcysteine is rapidly absorbed from the gastrointestinal tract and peak plasma concentrations occur about 0.5 to 1 hour after oral doses of 200 to 600 mg.[1] Some studies indicate dose-dependent pharmacokinetics with peak concentrations, the time taken to reach peak concentrations, and bioavailability increasing with increasing doses.[2] Acetylcysteine may be present in plasma as the parent compound or as various oxidised metabolites such as *N*-acetylcystine, *N*,*N*-diacetylcystine, and cysteine either free or bound to plasma proteins by labile disulfide bonds or as a fraction incorporated into protein peptide chains.[3] In a study about 50% was in a covalently protein-bound form 4 hours after a dose.[4] Oral bioavailability is low and mean values have ranged from 4 to 10% depending on whether total acetylcysteine or just the reduced forms are measured.[4,5] It has been suggested that acetylcysteine's low oral bioavailability may be due to metabolism in the gut wall and first-pass metabolism in the liver.[4,5] Renal clearance may account for about 30% of total body clearance.[5] On intravenous dosage mean terminal half-lives have been calculated to be 1.95 and 5.58 hours for reduced and total acetylcysteine, respectively; the terminal half-life of total acetylcysteine was 6.25 hours after oral doses.[4]

For reference to altered pharmacokinetics in patients with hepatic impairment, see above.

Uses and Administration

Acetylcysteine is a mucolytic that reduces the viscosity of secretions probably by the splitting of disulfide bonds in mucoproteins. This action is greatest at a pH of 7 to 9 and the pH may have been adjusted in commercial preparations with sodium hydroxide. It is sometimes stated that acetylcysteine sodium is used, although the dose is expressed in terms of acetylcysteine.

Acetylcysteine is also able to promote the detoxification of an intermediate paracetamol metabolite, and has a key role in the management of paracetamol overdosage.

Acetylcysteine is used for its **mucolytic** activity in respiratory disorders associated with productive cough. It can be given by nebulisation of 3 to 5 mL of a 20% solution or 6 to 10 mL of a 10% solution through a face mask or mouthpiece 3 or 4 times daily. If necessary 1 to 10 mL of a 20% solution or 2 to 20 mL of a 10% solution may be given by nebulisation every 2 to 6 hours. It can also be given by direct endotracheal instillation of 1 to 2 mL of a 10 to 20% solution as often as every hour. Mechanical suction of the liquefied secretions may be necessary, and nebulisers containing iron, copper, or rubber components should not be used.

Acetylcysteine as a mucolytic is also given orally, as lozenges, or as granules or effervescent tablets dissolved in water, in a usual dose of 600 mg daily as a single dose or in 3 divided doses.

In the treatment of **dry eye** (p.2140) associated with abnormal mucus production, acetylcysteine, usually as a 5% solution with hypromellose, is given topically 3 or 4 times daily. Higher concentrations have been used in some centres.

Acetylcysteine is given by intravenous infusion or by mouth in the treatment of **paracetamol poisoning**.

- If given intravenously: 150 mg/kg of acetylcysteine in 200 mL of glucose 5% is given initially over 15 minutes, followed by infusion of 50 mg/kg in 500 mL of glucose 5% over the next 4 hours and then 100 mg/kg in one litre of glucose 5% over the next 16 hours. Sodium chloride 0.9% may be used where glucose 5% is unsuitable.
- If given orally: an initial dose of 140 mg/kg as a 5% solution is followed by 70 mg/kg every 4 hours for an additional 17 doses.

Acetylcysteine is reported to be most effective when given within 8 hours of paracetamol overdosage, with the protective effect diminishing after this time. However, starting treatment with acetylcysteine later (up to and beyond 24 hours) may still be of benefit (see also below).

Acetylcysteine is under investigation for the treatment of idiopathic pulmonary fibrosis (see Diffuse Parenchymal Lung Disease, below).

For administration in children, see below.

Administration in children. Acetylcysteine is used for its **mucolytic** activity in respiratory disorders associated with productive cough. Doses in children are similar to adults; 3 to 5 mL of a 20% solution, or 6 to 10 mL of a 10% solution, may be nebulised through a face mask or mouthpiece 3 or 4 times daily. If necessary 1 to 10 mL of a 20% solution, or 2 to 20 mL of a 10% solution, may be given by nebulisation every 2 to 6 hours. It can also be given by direct endotracheal instillation of 1 to 2 mL of a 10 to 20% solution as often as every hour.

Acetylcysteine has also been given orally in a variety of dosage forms. Licensed doses and age ranges vary somewhat from country to country and even from preparation to preparation. For example, in France, children may be given the following doses:

- 1 month to 2 years: 100 mg twice daily
- 2 to 7 years: 200 mg twice daily
- 7 years and over: 200 mg 3 times daily (adult dose)

In Germany and Switzerland, however, a more typical dose for children under 2 years of age is 50 mg two or three times daily.

Acetylcysteine has been used to treat meconium ileus in neonates and distal obstruction syndrome in children with **cystic fibrosis**, although the *BNFC* states that evidence of its efficacy is lacking. Such use is not licensed in the UK, but if it is to be used the *BNFC* suggests an oral dose of acetylcysteine 200 to 400 mg up to 3 times daily for meconium ileus in neonates. For the *treatment* of distal intestinal obstruction syndrome in children with cystic fibrosis, a single oral dose is recommended as follows:

- 1 month to 2 years: 400 mg to 3 g
- 2 to 7 years: 2 to 3 g
- 7 to 18 years: 4 to 6 g

For the *prevention* of distal intestinal obstruction syndrome, it is recommended to be given orally as follows:

- 1 month to 2 years: 100 to 200 mg 3 times daily
- 2 to 12 years: 200 mg 3 times daily
- 12 to 18 years: 200 to 400 mg 3 times daily

The injection may be used orally, diluted to a concentration of 50 mg/mL; orange or black currant juice or cola may be used as diluents to mask the bitter taste.

In the treatment of **dry eye** associated with impaired or abnormal mucus production, acetylcysteine 5% eye drops with hypromellose may be applied, as in adults, 3 or 4 times daily.

Acetylcysteine is given by intravenous infusion or by mouth in the treatment of **paracetamol poisoning**. Doses for children are similar to adults (see also above and on p.108), although the volume of intravenous fluid is modified. The *BNFC* suggests the following *intravenous* doses:

- neonates to 5 years (or body-weight under 20 kg): initially 150 mg/kg in 3 mL/kg glucose 5% given over 15 minutes, followed by 50 mg/kg in 7 mL/kg glucose 5% given over 4 hours, then 100 mg/kg in 14 mL/kg glucose 5% given over 16 hours
- 5 to 12 years (or body-weight over 20 kg): initially 150 mg/kg in 100 mL glucose 5% given over 15 minutes, followed by 50 mg/kg in 250 mL glucose 5% given over 4 hours, then 100 mg/kg in 500 mL glucose 5% given over 16 hours
- 12 to 18 years: adult dose

In the USA, the following *oral* dose has also been suggested for children: 140 mg/kg initially, followed by 70 mg/kg every 4 hours for an additional 17 doses.

Aspergillosis. Although it is not one of the standard therapies discussed on p.517, local instillation of acetylcysteine into the cavity containing the fungus ball has been used to treat aspergilloma.[1] There is some evidence *in vitro* that acetylcysteine has inhibitory properties against *Aspergillus* and *Fusarium* spp.[2]

Burns. Children with inhalation injury (see Burns, p.1578) who were treated with aerosolised heparin 5000 units alternating with 3 mL of 20% acetylcysteine solution, inhaled every 2 hours for the first 7 days after injury, appeared to have significantly reduced mortality and reintubation rates compared with historical controls.[1]

1. Desai MH, *et al.* Reduction in mortality in pediatric patients with inhalation injury with aerosolized heparin/N-acetylcystine [sic] therapy. *J Burn Care Rehabil* 1998; **19:** 210–12. Correction. *ibid.* 1999; **20:** 49.

Cystic fibrosis. Mucolytics such as acetylcysteine are generally not considered[1] to be effective in treating the pulmonary manifestations of cystic fibrosis (p.166).

Meconium ileus equivalent (bowel obstruction due to abnormally viscid contents of the terminal ileum and right colon[2]) in patients with cystic fibrosis has largely disappeared with the use of pancreatic enzymes but may occur when insufficient doses are given;[3] mild cases may be treated with acetylcysteine.[3] Doses of 10 mL of a 20% solution of acetylcysteine have been given orally 4 times daily with 100 mL of a 10% solution of acetylcysteine given as an enema up to 4 times daily depending on the degree of the obstruction.[2]

For suggested children's doses in meconium ileus and distal obstruction syndrome, see Administration in Children, above.

Diffuse parenchymal lung disease. Acetylcysteine is under investigation for the treatment of idiopathic pulmonary fibrosis (see Diffuse Parenchymal Lung Disease, p.1502). In a randomised controlled study, adjunctive treatment with acetylcysteine 600 mg three times daily by mouth slowed the loss of vital lung capacity compared with standard therapy with azathioprine and prednisone.[1]

1. Demedts M, *et al.* High-dose acetylcysteine in idiopathic pulmonary fibrosis. *N Engl J Med* 2005; **353:** 2229–42.

HIV infection and AIDS. The cysteine-containing peptide glutathione is involved in intracellular defence mechanisms, and it has been shown that low glutathione concentrations are associated with poorer survival in HIV-infected patients.[1] Since acetylcysteine can replenish glutathione, it has been suggested[2,3] that it may have a role in the treatment of AIDS (p.856). *In-vitro* studies indicate that acetylcysteine can suppress HIV expression,[4,5] and there has been a suggestion from observational data that acetylcysteine supplements can improve survival in HIV-infected individuals.[1] However, an attempt to use acetylcysteine supplementation to reduce the frequency of adverse reactions to co-trimoxazole in HIV-infected patients was not successful.[6] Nonetheless, reviews of preliminary studies[7,8] have concluded that acetylcysteine may be a beneficial supplementary therapy in HIV-infected patients.

Kidney disorders. Acetylcysteine has been reported to improve kidney function in patients with the hepatorenal syndrome and may offer a potential bridging therapy in such patients awaiting liver transplantation.[1] It has also been used in the prevention of contrast media-induced nephrotoxicity in patients with chronic renal impairment, but evidence of benefit is conflicting and its role remains to be established; see Effects on the Kidney under Adverse Effects of Amidotrizoic Acid (p.1476) for further details.

1. Holt S, *et al.* Improvement in renal function in hepatorenal syndrome with N-acetylcysteine. *Lancet* 1999; **353:** 294–5.

Liver disorders. Although benefit has been reported from studies of acetylcysteine in acute liver failure,[1] and some have suggested that it may be useful in preventing tissue hypoxia in patients with acute liver failure receiving vasopressors,[2] studies have mainly been small and clinical outcomes are not well studied.[1] It does not appear to be of benefit in patients undergoing orthotopic liver transplantation.[3,4]

For reference to use in the hepatorenal syndrome, see Kidney Disorders, above. For use in paracetamol-induced liver damage see Overdosage, under Paracetamol, p.108.

Meconium ileus. For the use of acetylcysteine in infants with meconium ileus see Cystic Fibrosis, above.

Myocardial infarction. Some studies suggest that addition of intravenous acetylcysteine to thrombolytic therapy in patients with acute myocardial infarction (p.1175) may be of benefit.[1,2] The value of acetylcysteine as an adjunct in patients with or at risk of myocardial infarction has been reviewed.[3,4]

Nitrate tolerance. Acetylcysteine appears to be able to potentiate the peripheral and coronary effects of glyceryl trinitrate.[1] While some studies[2-5] have suggested that acetylcysteine can reverse tolerance to nitrates in patients with coronary heart disease or heart failure, others have failed to find any benefit,[6] although there may be a specific subgroup of responders.[5] The various attempts at overcoming nitrate tolerance are discussed on p.1297.

Poisoning and toxicity. Acetylcysteine has been studied for the potential treatment of many forms of toxicity,[1] but only treatment of acute paracetamol poisoning is widely accepted.

1. Chyka PA, *et al.* Utility of acetylcysteine in treating poisonings and adverse drug reactions. *Drug Safety* 2000; **22:** 123–48.

CARBON TETRACHLORIDE. The treatment of carbon tetrachloride poisoning is discussed on p.2021. Reports suggest that prompt intravenous therapy with acetylcysteine may help to minimise hepatorenal damage in acute poisoning with carbon tetrachloride.[1,2] When added to supportive therapy the initial dosage regimen should be the same as that used for paracetamol poisoning but as carbon tetrachloride has a much longer half-life than paracetamol, the duration of treatment may need to be increased.[3]

PARACETAMOL. Acetylcysteine is usually the antidote of choice for paracetamol overdose (see p.108). The intravenous route is favoured in the UK, despite possible anaphylactic reaction, mainly because of concerns over the effects of vomiting and activated charcoal on oral absorption.[1] In the USA the oral route has conventionally been used, despite the unpleasant odour and taste of acetylcysteine solutions, with no evident reduction in effect by charcoal.[2] The intravenous route is now also licensed in the USA. Oral and intravenous formulations appear to be equally effective.[3] A disadvantage of the oral route is therapeutic failure in those patients who develop nausea and vomiting, which occurs in most patients with severe poisoning; delays in absorption may also be of concern especially when the end of the critical 8-hour interval is approaching. However, with oral doses, the whole absorbed dose passes through the liver, producing high local concentrations at the site of toxicity.[4] Some consider the intravenous route to be more reliable, and to require fewer doses and a shorter duration of treatment.[5] The major disadvantage of intravenous use is possible anaphylactic reaction. Although these reactions are considered uncommon in patients with paracetamol poisoning, rare fatalities have been reported, and patients with asthma appear to be at particular risk (see also above).[4] Some infuse the first dose of acetylcysteine over 60 minutes instead of the recommended 15 minutes[5] in order to reduce the incidence and severity of reactions. However, a multicentre, randomised study found no reduction in adverse outcomes with a 60-minute infusion compared to the standard infusion period of 15 minutes.[6] It has been suggested that intravenous acetylcysteine may be preferred in those patients with severe poisoning, who present late, who have nausea and vomiting, or who have problems with absorption. Oral use might be preferred in those who present early with uncomplicated mild to moderate poisoning, or who have asthma.[4,7] Whichever route is given, the interval is considered the single most important factor for the prevention of severe hepatic damage.[3,4]

Respiratory disorders. Acetylcysteine has been used as a mucolytic in a variety of respiratory disorders associated with productive cough (p.1547). Although there is controversy over the benefits of mucolytics in treating chronic bronchitis or chronic obstructive pulmonary disease (COPD), there is some evidence that they may reduce exacerbations (see p.1112). However, a double-blind multicentre study in patients with COPD failed to find evidence that acetylcysteine 600 mg daily by mouth reduced exacerbations;[1] like most other interventions in this condition, it could also not be shown to reduce the rate of decline in lung function.

For the use of aerosolised heparin and acetylcysteine to treat inhalation injury see Burns, above. It has been suggested that intravenous acetylcysteine might also be of use in acute respiratory distress syndrome (ARDS—p.1498),[2] possibly due to its action as a free radical scavenger,[2,3] but controlled studies in established ARDS failed to show benefit.[4,5]

Acetylcysteine has been investigated in idiopathic pulmonary fibrosis (see Diffuse Parenchymal Lung Disease, above). See also above for the use of acetylcysteine in the management of cystic fibrosis.

Scleroderma. Acetylcysteine has also been reported to be of benefit in Raynaud's syndrome resulting from scleroderma (see p.1817).

Preparations

BP 2008: Acetylcysteine Injection;

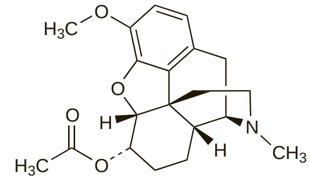
Acetyldihydrocodeine Hydrochloride

Acetildihidrocodeína, hidrocloruro de. 4,5-Epoxy-3-methoxy-9a-methylmorphinan-6-yl acetate hydrochloride.

Ацетилдигидрокодеина Гидрохлорид

$C_{20}H_{25}NO_4$,HCl = 379.9.
CAS — 3861-72-1 (acetyldihydrocodeine).
ATC — R05DA12.
ATC Vet — QR05DA12.



(acetyldihydrocodeine)

Profile

Acetyldihydrocodeine hydrochloride is an opioid derivative related to dihydrocodeine (p.48). It is used as a centrally acting cough suppressant for non-productive cough (p.1547) and has been given in a usual oral daily dose of 20 to 50 mg; no more than 20 mg should be taken as a single dose.

Preparations

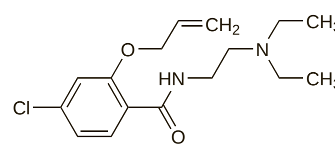
Proprietary Preparations (details are given in Part 3)
Belg.: Acetylcodone.

Alloclamide Hydrochloride *(rINNM)*

Alloclamide, Chlorhydrate d'; Alloclamidi Hydrochloridum; CE-264; Hidrocloruro de aloclamida. 2-Allyloxy-4-chloro-*N*-(2-diethylaminoethyl)benzamide hydrochloride.

Аллокламида Гидрохлорид

$C_{16}H_{23}ClN_2O_2$,HCl = 347.3.
CAS — 5486-77-1 (alloclamide); 5107-01-7 (alloclamide hydrochloride).



(alloclamide)

Profile

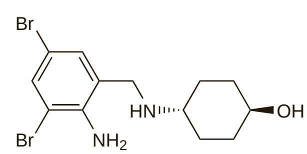
Alloclamide hydrochloride is a cough suppressant.

Ambroxol Hydrochloride *(BANM, rINNM)*

Ambroksolihydrokloridi; Ambroksolio hidrochloridas; Ambroxol, chlorhydrate d'; Ambroxol hydrochlorid; Ambroxol-hidroklorid; Ambroxolhydroklorid; Ambroxoli hydrochloridum; Hidrocloruro de ambroxol; NA-872 (ambroxol). *trans*-4-(2-Amino-3,5-dibromobenzylamino)cyclohexanol hydrochloride.

Амброксола Гидрохлорид

$C_{13}H_{18}Br_2N_2O$,HCl = 414.6.
CAS — 18683-91-5 (ambroxol); 15942-05-9 (ambroxol hydrochloride); 23828-92-4 (ambroxol hydrochloride).
ATC — R05CB06.
ATC Vet — QR05CB06.



(ambroxol)

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).
Ph. Eur. 6.2 (Ambroxol Hydrochloride). A white or yellowish crystalline powder. Sparingly soluble in water; practically insoluble in dichloromethane; soluble in methyl alcohol. A 1% solution in water has a pH of 4.5 to 6.0. Protect from light.

Profile

Ambroxol is a metabolite of bromhexine (p.1552) and is used similarly as a mucolytic. It is given in a usual oral daily dose of

60 to 120 mg of the hydrochloride in 2 divided doses. Ambroxol has also been given by inhalation, injection, or rectally.

Adverse effects. HYPERSENSITIVITY. A report[1] of contact allergy to ambroxol, but not bromhexine.

Respiratory disorders. Mixed results[1-3] were obtained when ambroxol was used in chronic bronchitis or chronic obstructive pulmonary disease (COPD—p.1112); in a randomised study, it was no better than placebo in preventing acute exacerbations of COPD; however, in a subset of patients with more severe disease, ambroxol therapy reduced the number of exacerbations.[4] It was ineffective[5] when given to mothers for the prophylaxis of neonatal respiratory distress syndrome (p.1508), although it may be of modest benefit in the early treatment of established disease in infants.[6,7]

Inhalation of ambroxol aerosol has also produced beneficial effects in a patient with alveolar proteinosis who refused alveolar lavage.[8]

For the use of mucolytics in productive cough see p.1547.

Uricosuric action. A study[1] was carried out in 48 young male healthy subjects to examine the uricosuric effect of ambroxol. The minimum effective dose for lowering plasma-uric acid concentrations was found to be between 250 and 500 mg daily given in 2 divided doses. Although these doses are much higher than those used to treat bronchopulmonary disease, doses as high as 1 g daily were well tolerated.

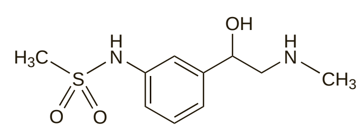
Amidefrine Mesilate *(BANM, rINN)* ⊗

5190; Amidéfrine, Mésilate d'; Amidefrini Mesilas; Amidephrine Mesylate *(USAN)*; Mesilato de amidefrina; MJ-5190. 3-(1-Hydroxy-2-methylaminoethyl)methanesulphonanilide methanesulphonate.

Амидефрина Мезилат

$C_{10}H_{16}N_2O_3S,CH_4O_3S = 340.4.$

CAS — 3354-67-4 (amidefrine); 1421-68-7 (amidefrine mesilate).



(amidefrine)

Profile

Amidefrine mesilate is a sympathomimetic with alpha-adrenergic activity similar to that of phenylephrine (p.1568). It is used for its vasoconstrictor properties in the local treatment of nasal congestion.

Preparations

Proprietary Preparations (details are given in Part 3)

Austria: Fentrinol.

Ammonium Acetate

Amonio, acetato de; Amonowy octan.

Ацетат Аммония; Уксуснокислый Аммоний

$CH_3CO_2NH_4 = 77.08.$

CAS — 631-61-8 (ammonium acetate); 8013-61-4 (ammonium acetate solution).

Pharmacopoeias. *Br.* includes Strong Ammonium Acetate Solution.

Ammonium Bicarbonate *(BAN)*

Ammonii hydrogenocarbonas; Ammonium, bicarbonate d'; Ammónium-hidrogén-karbonát; Ammoniumvätekarbonat; Ammoniumvetykarbonaatti; Amonio, bicarbonato de; Amonio-vandenilio karbonatas; E503; Hydrogenuhličitan amonný. Ammonium hydrogen carbonate.

Бикарбонат Аммония; Гидрокарбонат Аммония; Двууглекислый Аммоний

$NH_4HCO_3 = 79.06.$

CAS — 1066-33-7.

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Ammonium Hydrogen Carbonate; Ammonium Bicarbonate BP 2008). A fine, white or almost white, slightly hygroscopic, crystalline powder or white or almost white crystals. It volatilises rapidly at 60°; volatilisation takes place slowly at ambient temperatures if slightly moist. It is in a state of equilibrium with ammonium carbamate. Freely soluble in water; practically insoluble in alcohol. Store in airtight containers.

The BP 2008 directs that when Ammonium Carbonate is prescribed or demanded Ammonium Bicarbonate shall be dispensed or supplied.

Ammonium Carbonate

Amonio, carbonato de; Amonowy węglan; Carbonato de Amonio; E503.

Карбонат Аммония; Углекислый Аммоний

CAS — 8000-73-5.

Pharmacopoeias. In *Fr.* Also in *USNF.*

USNF 26 (Ammonium Carbonate). A white powder, or hard, white or translucent masses having a strong odour of ammonia, without empyreuma. It consists of ammonium bicarbonate and ammonium carbamate, in varying proportions. It yields 30 to 34% of NH_3. On exposure to air it loses ammonia and carbon dioxide, becoming opaque, and is finally converted into friable porous lumps or a white powder of ammonium bicarbonate. Soluble 1 in 4 of water. It is decomposed by hot water. Its solutions are alkaline to litmus. Store in airtight containers at a temperature not exceeding 30°. Protect from light.

NOTE. The **BP 2008** directs that Ammonium Bicarbonate shall be dispensed or supplied when Ammonium Carbonate is prescribed or demanded.

Ammonium Chloride

510; Ammonii chloridum; Ammonium Chloratum; Ammonium, chlorure d'; Ammoniumklorid; Ammónium-klorid; Ammoniumkloridi; Amonio chloridas; Amonio, cloruro de; Amonowy chlorek; Chlorid amonný; Cloruro de Amonio; Muriate of Ammonia; Sal Ammoniac.

Хлорид Аммония; Хлористый Аммоний

$NH_4Cl = 53.49.$

CAS — 12125-02-9.

ATC — B05XA04; G04BA01.

ATC Vet — QB05XA04; QG04BA01.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *US*, and *Viet.*

Ph. Eur. 6.2 (Ammonium Chloride). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water.

USP 31 (Ammonium Chloride). Colourless crystals or white, fine or course, crystalline powder. Is somewhat hygroscopic. Freely soluble in water and in glycerol, and even more so in boiling water; sparingly soluble in alcohol. pH of a 5% solution in water is between 4.6 and 6.0. Store in airtight containers.

Adverse Effects and Treatment

Ammonium salts are irritant to the gastric mucosa and may produce nausea and vomiting particularly in large doses. Large doses of ammonium chloride may cause a profound acidosis and hypokalaemia which should be treated symptomatically. Intravenous ammonium chloride can cause pain and irritation at the site of injection, which may be decreased by slowing the rate of infusion.

Excessive doses of ammonium salts, particularly if given by rapid intravenous injection, may give rise to hepatic encephalopathy due to the inability of the liver to convert the increased load of ammonium ions to urea.

Precautions

Ammonium salts are contra-indicated in patients with hepatic or renal impairment.

Pharmacokinetics

Ammonium chloride is absorbed from the gastrointestinal tract. The ammonium ion is converted into urea in the liver; the anion thus liberated into the blood and extracellular fluid causes a metabolic acidosis and decreases the pH of the urine; this is followed by transient diuresis.

Uses and Administration

Ammonium chloride is used as an expectorant in productive cough (p.1547). Other ammonium salts that have been used similarly include the acetate, bicarbonate, camphorate, carbonate, citrate (p.2256), and glycyrrhizate (p.2316).

Giving ammonium chloride produces a transient diuresis and acidosis. It may be used in the treatment of severe metabolic alkalosis (p.1667). Each g of ammonium chloride represents 18.69 mmol of chloride. It is usually given as a 1 to 2% solution by slow intravenous infusion, in a dosage depending on the severity of the alkalosis. A concentrated solution of ammonium chloride may be diluted by sodium chloride injection.

Ammonium chloride may also be used to maintain the urine at an acid pH in the treatment of some urinary-tract disorders. It is usually given orally, often as enteric-coated tablets, in a dose of 1 to 2 g every four to six hours. Higher doses were sometimes used in forced acid diuresis procedures to aid the excretion of basic drugs, such as amfetamines, in severe cases of overdosage (but see p.2153).

Ammonium chloride has been promoted for self administration as a diuretic, for example in premenstrual water retention; an oral dose of 650 mg three times daily for up to 6 days has been suggested, but such use is generally considered inappropriate.

Preparations

BP 2008: Ammonium Chloride Mixture; Aromatic Ammonia Solution; Aromatic Ammonia Spirit; Strong Ammonium Acetate Solution; White Liniment;
USP 31: Ammonium Chloride Delayed-release Tablets; Ammonium Chloride Injection; Aromatic Ammonia Spirit; Potassium Gluconate, Potassium Citrate, and Ammonium Chloride Oral Solution.

Proprietary Preparations (details are given in Part 3)
Austral.: Nyal Bronchitis; ***Fr.:*** Chlorammonic†; ***Ger.:*** Extin N; ***Switz.:*** Chloramon.

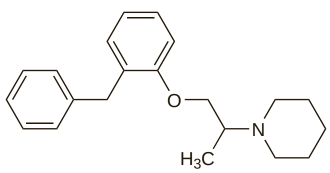
Multi-ingredient: numerous preparations are listed in Part 3.

Benproperine *(rINN)*

ASA-158/5 (benproperine phosphate); Benproperiini; Benproperin; Benproperina; Benpropérine; Benproperinum. 1-[2-(2-Benzylphenoxy)-1-methylethyl]piperidine.

Бенпроперин

$C_{21}H_{27}NO = 309.4$.
CAS — 2156-27-6.
ATC — R05DB02.
ATC Vet — QR05DB02.



Pharmacopoeias. *Chin.* includes the phosphate.

Profile

Benproperine is used as a cough suppressant in non-productive cough (p.1547). It is reported to have a peripheral and central action and has been given in usual oral doses of 25 to 50 mg two to four times daily as the phosphate. Benproperine embonate has been used similarly.

Preparations

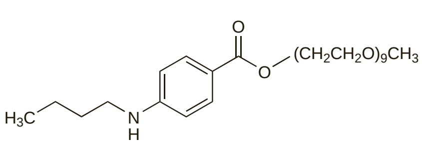
Proprietary Preparations (details are given in Part 3)
Ger.: Tussafug; ***Hong Kong:*** Cofrel; ***Jpn:*** Flaveric.

Benzonatate *(BAN, rINN)*

Bensonatat; Bentsonataatti; Benzonatato; Benzonatatum; Benzononatine; KM-65. 3,6,9,12,15,18,21,24,27-Nonaoxaoctacosyl 4-butylaminobenzoate.

Бензонатат

$C_{13}H_{18}NO_2(OCH_2CH_2)_nOCH_3$, where *n* has an average value of 8.
CAS — 104-31-4 (where n = 8).
ATC — R05DB01.
ATC Vet — QR05DB01.



Pharmacopoeias. In *US.*

USP 31 (Benzonatate). A clear, pale yellow, viscous liquid having a faint characteristic odour. Soluble 1 in less than 1 of water, of alcohol, of chloroform, and of ether; freely soluble in benzene. Store in airtight containers. Protect from light.

Adverse Effects

Headache, dizziness, gastrointestinal disturbances, nasal congestion, hypersensitivity, pruritus, and skin rash have been reported. There may be drowsiness. Benzonatate has local anaesthetic properties and can produce numbness of the mouth, tongue, and pharynx. CNS stimulation and convulsions, followed by CNS depression, may occur in overdosage.

Uses and Administration

Benzonatate is a cough suppressant used in non-productive cough (p.1547); it is stated to act peripherally. It is related to tetracaine (p.1871) and has a local anaesthetic action on mucosa. It is given to adults and children over the age of 10 years in an oral dose of 100 mg three times daily; up to 600 mg daily in divided doses may be given if necessary. Benzonatate is reported to act within about 20 minutes and its effects are reported to last for 3 to 8 hours.

Preparations

USP 31: Benzonatate Capsules.

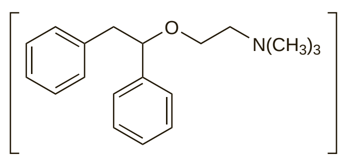
Proprietary Preparations (details are given in Part 3)
Mex.: Alzomed-F†; Beknol; Benzonal; Bronpax; Capsicof; D-Tato; Lemtosid; Nactol†; Novapsyl; Parven†; Pebegal; Pharben; Supracof; Tesalon; Tesopen; Texoven; Tusical; Tusitato; Tuzzil; Velpro; ***USA:*** Tessalon.

Bibenzonium Bromide *(BAN, rINN)*

Bibenzonii Bromidum; Bibenzonium, Bromure de; Bromuro de bibenzonio; Diphenetholine Bromide; ES-132. [2-(1,2-Diphenylethoxy)ethyl]trimethylammonium bromide.

Бибензония Бромид

$C_{19}H_{26}BrNO = 364.3$.
CAS — 59866-76-1 (bibenzonium); 15585-70-3 (bibenzonium bromide).
ATC — R05DB12.
ATC Vet — QR05DB12.



Profile

Bibenzonium bromide is a cough suppressant used in non-productive cough (p.1547) which is stated to have a central action. It has been given in a usual oral dose of 30 to 60 mg two or three times daily.

Preparations

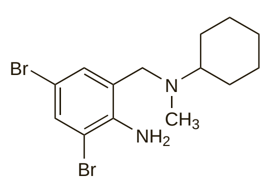
Proprietary Preparations (details are given in Part 3)
Austria: Lysbex.

Bromhexine *(BAN, rINN)*

Bromexina; Bromhexin; Bromhexina; Bromhexinum; Bromiheksiini; Butamirat. 2-Amino-3,5-dibromobenzyl(cyclohexyl)methylamine.

Бромгексин

$C_{14}H_{20}Br_2N_2 = 376.1$.
CAS — 3572-43-8.
ATC — R05CB02.
ATC Vet — QR05CB02.



Bromhexine Hydrochloride *(BANM, USAN, rINNM)*

Bromheksino hidrochloridas; Bromhexine, chlorhydrate de; Brómhexin-hidroklorid; Bromhexin-hydrochlorid; Bromhexinhydroklorid; Bromhexini hydrochloridum; Bromiheksiinihydrokloridi; Bromoheksyny chlorowodorek; Cloridrato de Bromexina; Hidrocloruro de bromhexina; NA-274.

Бромгексина Гидрохлорид

$C_{14}H_{20}Br_2N_2,HCl = 412.6$.
CAS — 611-75-6.
ATC — R05CB02.
ATC Vet — QR05CB02.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn.*

Ph. Eur. 6.2 (Bromhexine Hydrochloride). A white or almost white crystalline powder. It exhibits polymorphism. Very slightly soluble in water; slightly soluble in alcohol and in dichloromethane. Protect from light.

Adverse Effects

Gastrointestinal adverse effects may occur occasionally with bromhexine and a transient rise in serum aminotransferase values has been reported. Other reported adverse effects include headache, dizziness, sweating, and skin rashes. Inhalation of bromhexine has occasionally produced cough or bronchospasm in susceptible subjects.

Precautions

Since mucolytics may disrupt the gastric mucosal barrier bromhexine should be used with care in patients with a history of peptic ulcer disease. Care is also advisable in asthmatic patients. Clearance of bromhexine or its metabolites may be reduced in patients with severe hepatic or renal impairment.

Pharmacokinetics

Bromhexine hydrochloride is rapidly absorbed from the gastrointestinal tract; peak plasma concentrations occur after about 1 hour. Bromhexine undergoes extensive first-pass metabolism in the liver: its oral bioavailability is stated to be only about 20%. It is widely distributed to body tissues. About 85 to 90% of a dose is excreted in the urine mainly as metabolites. Ambroxol (p.1550) is a metabolite of bromhexine. Bromhexine is highly bound to plasma proteins. It has a terminal elimination half-life of 13 to 40 hours. Bromhexine crosses the blood-brain barrier and small amounts cross the placenta.

Uses and Administration

Bromhexine is a mucolytic used in the treatment of respiratory disorders associated with productive cough (p.1547). Bromhexine is usually given orally in a dose of 8 to 16 mg of the hydrochloride three times daily. It has also been given by deep intramuscular or slow intravenous injection or inhaled as an aerosol solution.

Bromhexine has also been used orally and topically in the treatment of dry eye syndromes associated with abnormal mucus production (see below).

Dry eye. Bromhexine has been used orally in the treatment of dry eye (p.2140) in Sjögren's syndrome but results have been conflicting; it appears to have no effect on tear secretion in healthy subjects.[1] It has also been tried topically.

1. Avisar R, *et al.* Oral bromhexine has no effect on tear secretion in healthy subjects. *Ann Pharmacother* 1996; **30:** 1498.

Respiratory-tract infection. *USE WITH AN ANTIBACTERIAL.* Bromhexine has been shown to enhance the penetration of erythromycin into bronchial secretions.[1] Although bromhexine is used as an adjuvant in the treatment of respiratory infections, few controlled studies appear to have been conducted to determine if any additional benefit is obtained. However, some studies have found improved responses with cefalexin[2] and amoxicillin.[3]

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Amiorel; Aseptobron Expectorante; Balsasulf; Bisolvon; Brometos; Bromexidryl; Broncocalmine; Brondilax; Bronquisedan Elixir; Bronquisedan Paediatrico; Catarrosine; Expectosan Extra Forte; Funciobron B; Jarabe Medex; Lisi-Tos; Lorbi; Lorbi-Bis; Namir; Nastizol Expectorante; No-Tos Mucolitico; Pectoral Pagliano†; Pulmonix; Pulmosan; Qura Plus; Sandival; Toscalmin; Tostop; ***Austral.:*** Bisolvon Chesty; Duro-Tuss Mucolytic Cough Liquid; ***Austria:*** Bisolvon; ***Belg.:*** Bisolvon; Bromex; Bronchi-Mereprine; ***Braz.:*** Bisolvon; Clarus†; ***Chile:*** Bisolvon; Flumed; ***Cz.:*** Bisolvon†; Flegamina†; Mucohex; Paxirasol; ***Denm.:*** Bisolvon; Viscolyt†; ***Fin.:*** Bisolvon; Medipekt; Mucovin; ***Fr.:*** Bisolvon; ***Ger.:*** Aparsonin N†; Bisolvon; Hustentabs†; Omniapharm†; ***Gr.:*** Bisolvon; Bolisegna†; Bromiramin†; Bronchotussine; ***Hong Kong:*** Asthmaxine; Bisolvon; Bromoson; Bromxine; Duro-Tuss Mucolytic; Exolit; Vasican; ***Hung.:*** Paxirasol; ***India:*** Bromex; ***Indon.:*** Bisolvon; Bromika; Dexolut; Ethisolvan; Exovon; Farmavon; Hexon; Lexavon; Mucobron; Mucohexin; Mucosolvan; Poncosolvon; Solvinex; Thephidron; Yavon; ***Irl.:*** Bisolvon; ***Israel:*** Movex; Solvex; ***Ital.:*** Bisolvon; Broncokin†; ***Jpn:*** Bisolvon; ***Malaysia:*** Beacolytic; Bislan; Bisolvon†; Bromxine; Disol; Ekxine†; Hexolvon†; Vasican; ***Mex.:*** Bisolvon; Bromicof; Dibroxin†; Dizolvin†; Meroxan; Nastizol Ex; Normoflex; Tesacof; Toridran-N; ***Neth.:*** Bisolvon; Darolan Slijmoplossende; Famel Broomhexine†; Kruidvat Hoestelixer; Kruidvat Hoesttabletten; Streptuss vastzittende hoest†; Trekpleister Hoesttabletten†; ***Norw.:*** Bisolvon; ***NZ:*** Bisolvon; Duro-Tuss Mucolytic†; ***Philipp.:*** Bisolvon; Dur-Elix; Easepex; Fleminate; Mucolyptus; Xinebrom; ***Pol.:*** Flegamina; ***Port.:*** Bisolvon; Bromocal; Lisomucin; Tosseque; ***Rus.:*** Flegamin (Флегамин); ***S.Afr.:*** Bisolvon; Bronkese; ***Singapore:*** Bislan; Bisolvon; Bromxine; Broxine†; Duro-Tuss Mucolytic; Mucosol†; Vasican; ***Spain:*** Bisolvon; ***Swed.:*** Bisolvon; ***Switz.:*** Bisolvon; Hustosol†; Solvolin; ***Thai.:*** Asovon; Axistal; Behexine†; Bisoltab; Bisolvon; Bomexin; Bromex†; Bromoson; Bromso; Bromxin†; Bromxine; Bronclear; Disol; Dutross†; Exolit†; Ida; Manovon; Mihexine; Mucine†; Mucola†; Mucoxin; Ohexine; Romulin; Tromadil; ***Turk.:*** Bromek; Bromeksin; Viscol; ***UAE:*** Mucolyte; ***Venez.:*** Bedena; Bexilon; Bisectron; Bisolvon; Bromedrina; Brometix†; Bromexol; Bromox; Bronacim†; Drometox†; Inquixol; Kecnitril; Lisomucin; Mucobrol; Reosil; Teraflem; Tolmix†.

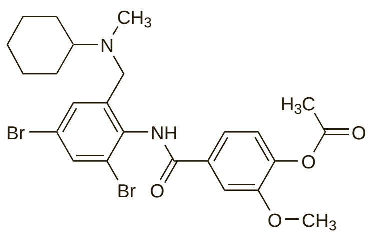
Multi-ingredient: numerous preparations are listed in Part 3.

Brovanexine Hydrochloride *(rINNM)*

Brovanexine, Chlorhydrate de; Brovanexini Hydrochloridum; Hidrocloruro de brovanexina. 4-(Acetyloxy)-*N*-[2,4-dibromo-6-[(cyclohexylmethylamino)methyl]phenyl]-3-methoxybenzamide monohydrochloride.

Брованексина Гидрохлорид

$C_{24}H_{29}Br_2ClN_2O_4$ = 604.8.
CAS — 54340-61-3 (brovanexine); 54340-60-2 (brovanexine hydrochloride).



(brovanexine)

Profile

Brovanexine is a derivative of bromhexine (above) and is given orally as the hydrochloride, usually as an adjunct to antibacterials in preparations for the treatment of respiratory-tract infections.

Preparations

Proprietary Preparations (details are given in Part 3)
Braz.: Bronquimucil; ***Port.:*** Bronquimucil†; Pulmo-San†; ***Spain:*** Broncimucil.

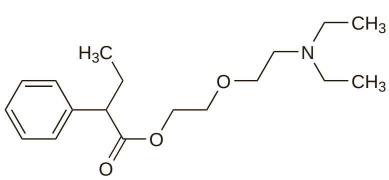
Multi-ingredient: ***Arg.:*** Trifamox Bronquial; ***Spain:*** Bronquimucil†; Eupen Bronquial.

Butamirate Citrate *(BANM, USAN, rINNM)*

Abbott-36581; Butamirát-citrát; Butamirate, Citrate de; Butamirati Citras; Butamyrate Citrate; Citrato de butamirato; HH-197. 2-(2-Diethylaminoethoxy)ethyl 2-phenylbutyrate dihydrogen citrate.

Бутамирата Цитрат

$C_{18}H_{29}NO_3,C_6H_8O_7$ = 499.6.
CAS — 18109-80-3 (butamirate); 18109-81-4 (butamirate citrate).
ATC — R05DB13.
ATC Vet — QR05DB13.



(butamirate)

Profile

Butamirate citrate is a cough suppressant used in non-productive cough (p.1547) and stated to have a central action. The usual oral dose is up to 30 mg daily in 3 or 4 divided doses; some countries permit up to 90 mg daily in divided doses. Modified-release tablets containing 50 mg have been given 2 or 3 times daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Dosodos; Talasa NF; Tossec; ***Belg.:*** Quintex†; Sinecod; ***Braz.:*** Besedan†; ***Cz.:*** Sinecod; Tussin; ***Gr.:*** Antis; Antitoss; Betavix; Boutavixal; Bronchofyl; Butacodin; Butagan; Butamir; Butrin; Buvastin; Chemisolv; Chributan; Codexine-R; Codimin; Cyne†; Devix; Doctamine; Drosten; Ellisek-S; Gertotus; Leogumil; Mebronol; Minatuss; Nontoss; Novamir; Oaxen; Pandigal; Pintal; Roctylan; Rondover; Safarol; Sinecod; Siroflex; Stilex; Velkacet; Verocod; Vilvom; Zeleven; Zestapron†; Zetapron; ***Hung.:*** NeoCitran Antitussive; Sinecod; ***Ital.:*** Butiran; Lenistar; Lexosedin; Sinecod Tosse Sedativo; ***Neth.:*** Sinecod; ***Philipp.:*** Sinecod; ***Pol.:*** Sinecod; Supremin; ***Port.:*** Sinecod; ***Rus.:*** Sinecod (Синекод); ***Switz.:*** DemoTussol; NeoCitran Antitussif; Sinecod; ***Thai.:*** Sinecod; ***Turk.:*** Kreval; Sinecod.

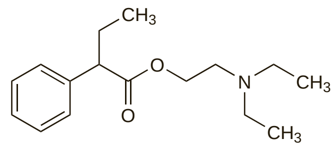
Multi-ingredient: ***Arg.:*** Muco Dosodos; ***Braz.:*** Novotussan†; ***Cz.:*** Stoptussin; ***Rus.:*** Stoptussin (Стоптуссин); ***Switz.:*** Hicoseen.

Butetamate Citrate *(BANM, rINNM)*

Butétamate, Citrate de; Butetamati Citras; Butethamate Citrate; Butethamate Dihydrogen Citrate; Citrato de butetamato. 2-Diethylaminoethyl 2-phenylbutyrate citrate.

Бутетамата Цитрат

$C_{16}H_{25}NO_2,C_6H_8O_7$ = 455.5.
CAS — 14007-64-8 (butetamate); 13900-12-4 (butetamate citrate).



(butetamate)

Profile

Butetamate citrate is reported to be an antispasmodic and bronchodilator and has been used alone or in combination preparations for the symptomatic treatment of coughs and other associated respiratory-tract disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Heliphenicol.

Multi-ingredient: ***Arg.:*** Febrigrip; Fugafebril; Kiper; Mejoral Grip; Muco Cortos†; Mucoprednibron; Piritos; Pulmocler; Refenax Jarabe; Tavinex Antigripal; ***Austria:*** Coldadolin; Influbene; ***Switz.:*** Bronchotussine.

Calcium Iodide

Calcii Iodidum; Calciumjodid; Ioduro de calcio; Kalcio jodidas; Kalsiumjodidi.

Йодид Кальция

CaI_2 = 293.9.
CAS — 10102-68-8.

Pharmacopoeias. *Eur.* (see p.vii) includes the tetrahydrate for homoeopathic preparations.

Ph. Eur. 6.2 (Calcium Iodide Tetrahydrate for Homoeopathic Preparations; Calcii Iodidi Tetrahydricum ad Praeparationes Homoeopathicas). A white or almost white, very hygroscopic, powder. Very soluble to freely soluble in water and in alcohol. Store in airtight containers.

Profile

Calcium iodide has been used orally in expectorant mixtures. The limitations of iodides as expectorants are discussed under Cough, p.1547. The actions of the iodides are discussed under Iodine (p.2169).

Homoeopathy. Calcium iodide has been used in homoeopathic medicines under the following names: Calcium iodatum; Calcium jodatum; Calcarea iodata; Cal. iod.

Preparations

Proprietary Preparations (details are given in Part 3)

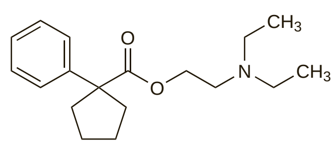
Multi-ingredient: ***Arg.:*** Zantril†; ***Gr.:*** Vitreolent; ***USA:*** Calcidrine; Norisodrine with Calcium Iodide.

Caramiphen Edisilate *(BANM, rINNM)*

Caramiphen Edisylate; Caramiphène, Edisilate de; Caramipheni Edisilas; Edisilato de caramifeno. 2-Diethylaminoethyl 1-phenylcyclopentane-1-carboxylate ethane-1,2-disulphonate.

Карамифена Эдизилат

$C_{38}H_{60}N_2O_{10}S_2$ = 769.0.
CAS — 77-22-5 (caramiphen); 125-86-0 (caramiphen edisilate); 125-85-9 (caramiphen hydrochloride).



(caramiphen)

Profile

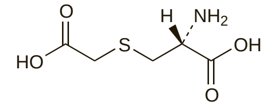
Caramiphen is a centrally acting cough suppressant that has been used as the edisilate in combination preparations for coughs (p.1547). Caramiphen hydrochloride was originally used similarly to trihexyphenidyl (p.820) for its antimuscarinic actions.

Carbocisteine *(BAN, rINN)*

AHR-3053; Carbocisteína; Carbocistéine; Carbocisteinum; Carbocysteine *(USAN)*; Karbocistein; Karbocisteinas; Karbociszteín; Karbocystein; Karbocysteina; Karbosisteiini; Karbosistein; LJ-206. *S*-Carboxymethyl-L-cysteine.

Карбоцистеин

$C_5H_9NO_4S$ = 179.2.
CAS — 2387-59-9; 638-23-3 (carbocisteine, L-form).
ATC — R05CB03.
ATC Vet — QR05CB03.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn.*

Ph. Eur. 6.2 (Carbocisteine). A white or almost white, crystalline powder. Practically insoluble in water and in alcohol; dissolves in dilute mineral acids and in dilute solutions of alkali hydroxides. A 1% suspension in water has a pH of 2.8 to 3.0. Protect from light.

Incompatibility. UK licensed product information states that mixing carbocisteine with pholcodine linctus causes precipitation of carbocisteine from solution but no information is given on whether this incompatibility is with the pholcodine or some component of the formulation used.

Carbocisteine Lysine *(BANM, rINNM)*

Carbocisteína lisina; Carbocistéine Lysine; Carbocisteinum Lysinum; Carbocysteine Lysine.

Карбоцистеина Лизин

CAS — 49673-81-6.
ATC — R05CB03.
ATC Vet — QR05CB03.

Carbocisteine Sodium *(BANM, rINNM)*

Carbocisteína sódica; Carbocistéine Sodique; Carbocysteine Sodium; Natrii Carbocisteinum.

Натрий Карбоцистеин

CAS — 49673-84-9 (carbocisteine sodium, L-form).
ATC — R05CB03.
ATC Vet — QR05CB03.

Adverse Effects and Precautions

Nausea and gastric discomfort, and gastrointestinal bleeding have occasionally occurred with carbocisteine. Skin rashes have also been reported.

Carbocisteine should be used with caution in patients with a history of peptic ulcer disease because of the risk that mucolytics may disrupt the gastric mucosal barrier.

Effects on endocrine function. Transient hypothyroidism associated with the use of carbocisteine developed in a patient with compromised thyroid function.[1]

1. Wiersinga WM. Antithyroid action of carbocisteine. *BMJ* 1986; **293:** 106.

Pharmacokinetics

Carbocisteine is rapidly and well absorbed from the gastrointestinal tract with peak plasma concentrations occurring about 2 hours after an oral dose. It appears to penetrate into lung tissue and respiratory mucus. Carbocisteine is excreted in the urine as unchanged drug and metabolites. Acetylation, decarboxylation, and sulfoxidation have been identified as the major metabolic pathways. Sulfoxidation may be governed by genetic polymorphism.

4. Jovanovic D, *et al.* A comparative bioavailability study of a generic capsule formulation containing carbocysteine. *Pharmazie* 2006; **61:** 446–9.

Uses and Administration

Carbocisteine is used for its mucolytic activity in respiratory disorders associated with productive cough (p.1547). It is given orally in a dose of 750 mg three times daily, reduced by one-third when a response is obtained. Carbocisteine is also given orally as the sodium or lysine salts.

For children's doses, see Administration in Children, below.

Administration in children. Children from 2 to 5 years may be given oral carbocisteine 62.5 to 125 mg four times daily and those aged 5 to 12 years 250 mg three times daily.

Chronic obstructive pulmonary disease. The value of mucolytic therapy in chronic obstructive pulmonary disease (COPD—p.1112) is controversial. Two studies have reported some improvements in lung function in patients with chronic bronchitis given carbocisteine for up to 6 months,[1,2] but it appeared to have no effect on the number of acute exacerbations.[1] However, later studies[3,4] have reported reductions in the number of acute exacerbations; the number of common colds was also lower in the carbocisteine group in one of the studies.[4] Carbocisteine may also produce some beneficial effects on sputum rheology.[2,5]

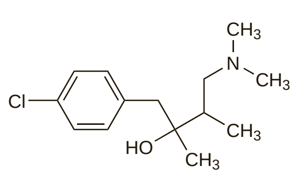
Clobutinol Hydrochloride *(rINNM)*

Clobutinol, Chlorhydrate de; Clobutinoli Hydrochloridum; Hidrocloruro de clobutinol; KAT-256. 2-(4-Chlorobenzyl)-3-(dimethylaminomethyl)butan-2-ol hydrochloride.

Клобутинола Гидрохлорид

$C_{14}H_{22}ClNO,HCl = 292.2.$
CAS — 14860-49-2 (clobutinol); 1215-83-4 (clobutinol hydrochloride).
ATC — R05DB03.
ATC Vet — QR05DB03.



(clobutinol)

Profile

Clobutinol hydrochloride is a centrally acting cough suppressant for non-productive cough (p.1547) that has been given orally in doses of 40 to 80 mg three times daily; it has also been given by subcutaneous, intramuscular, or intravenous injection. However, the EMEA has recommended for its withdrawal due to the risk of QT interval prolongation.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Proking; Silomat†; ***Austria:*** Silomat†; ***Belg.:*** Silomat†; ***Braz.:*** Silomat†; ***Chile:*** Broncodual; Calfetos; Clobatos†; Cloval; Pulbronc Simple; Silomat†; ***Cz.:*** Silomat†; ***Fin.:*** Mixtus; Silomat†; ***Fr.:*** Silomat†; ***Ger.:*** Hustenstiller†; Nullatuss†; Rofatuss†; Silomat†; stas-Hustenstiller N†; Tussed†; ***Gr.:*** Silomat†; ***Ital.:*** Silomat-Fher†; ***Malaysia:*** Silomat†; ***Port.:*** Silomat†; ***Singapore:*** Silomat†; ***Thai.:*** Silomat†; ***Venez.:*** Silomat†.

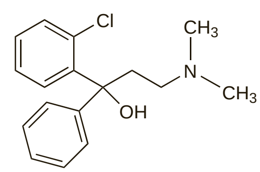
Clofedanol Hydrochloride *(BANM, rINNM)*

Chlophedianol Hydrochloride *(USAN)*; Clofédanol, Chlorhydrate de; Clofedanoli Hydrochloridum; Hidrocloruro de clofedanol; SL-501. 2-Chloro-α-(2-dimethylaminoethyl)benzyl alcohol hydrochloride.

Клофеданола Гидрохлорид

$C_{17}H_{20}ClNO,HCl = 326.3.$
CAS — 791-35-5 (clofedanol); 511-13-7 (clofedanol hydrochloride).
ATC — R05DB10.
ATC Vet — QR05DB10.



(clofedanol)

Pharmacopoeias. In *Jpn.*

Profile

Clofedanol hydrochloride is a centrally acting cough suppressant for non-productive cough (p.1547) that has been given in oral doses of 25 mg three or four times daily. For children's doses, see Administration in Children, below.

Administration in children. The following oral doses of clofedanol hydrochloride have been recommended for children:

- 2 to 6 years: 12.5 mg 3 or 4 times daily
- 6 to 12 years: 12.5 to 25 mg 3 or 4 times daily

Preparations

Proprietary Preparations (details are given in Part 3)
Canad.: Ulone; ***Hong Kong:*** Coldrin†; ***Singapore:*** Coldrin†; ***Spain:*** Gentos†.

Clopérastine, Chlorhydrate de; Cloperastini Hydrochloridum; Hidrocloruro de cloperastina.

Клоперастина Гидрохлорид

$C_{20}H_{24}ClNO,HCl = 366.3.$
CAS — 14984-68-0.
ATC — R05DB21.
ATC Vet — QR05DB21.

Pharmacopoeias. In *Jpn.*

Profile

Cloperastine is primarily a centrally acting cough suppressant used for non-productive cough (p.1547). It also has some antihistaminic action. The hydrochloride has been given orally as tablets in usual doses of 10 to 20 mg three times daily. Cloperastine fendizoate is used in oral liquid preparations in equivalent doses. Cloperastine fendizoate 17.7 mg is equivalent to about 10 mg of cloperastine hydrochloride. Levocloperastine fendizoate has been used similarly.

Coltsfoot

Coughwort; Fárfara; Huflattich; Tusílago; Tussilage.

Камчужная Трава

Pharmacopoeias. *Chin.* and *Fr.* include Coltsfoot Flower.

Profile

The leaves and flowers of coltsfoot (*Tussilago farfara*) have been used for their demulcent and supposed expectorant properties in the treatment of cough and other mild respiratory disorders. However, there has been some concern about potential hepatotoxicity and carcinogenicity due to the content of pyrrolizidine alkaloids.

◊ A review[1] of the actions and uses of coltsfoot pointed out that given the potential risks of its use long-term or in pregnancy, and the availability of other demulcent herbs, the use of coltsfoot preparations to treat throat irritations can no longer be considered appropriate.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Arceligasol; Negacne; ***Cz.:*** Perospir†; Species Pectorales Planta; ***Ital.:*** Lozione Same Urto; ***Pol.:*** Mucosit; Pyrosal; ***Spain:*** Llantusil†; ***UK:*** Antibron; Chesty Cough Relief.

Creosote

Creasote; Creosota; Creosotal (creosote carbonate); Wood Creosote.

Древесный Креозот

CAS — 8021-39-4 (creosote); 8001-59-0 (creosote carbonate).
ATC — R05CA08.
ATC Vet — QR05CA08.

Pharmacopoeias. In *Jpn.*

Profile

Creosote is a liquid consisting of a mixture of guaiacol, cresol, and other phenols obtained from wood tar. It possesses disinfectant properties and has been used as an expectorant. It has also been used as the carbonate and as lactocreosote.

Adverse effects are similar to those of Phenol, p.1656.

Commercial creosote used for timber preservation is obtained from coal tar.

Preparations

Proprietary Preparations (details are given in Part 3)

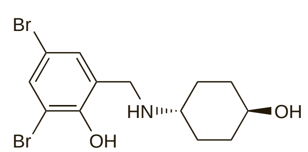
Multi-ingredient: ***Austral.:*** Compound Inhalation of Menthol; ***Austria:*** Famel cum Codein; Famel cum Ephedrin; ***Braz.:*** Rhum Creosotado; ***Hung.:*** Fagifor†; ***India:*** Pulmo-Cod (C & G); ***Ital.:*** Creosoto Composto; Famel†; ***Switz.:*** Famel; ***UK:*** Famel Original.

Dembrexine *(BAN, rINN)*

Dembreksiini; Dembrexin; Dembrexina; Dembrexinum; Dembroxol. *trans*-4-[(3,5-Dibromosalicyl)amino]cyclohexanol.

Дембрексин

$C_{13}H_{17}Br_2NO_2$ = 379.1.
CAS — 83200-09-3 (dembrexine); 52702-51-9 (dembrexine hydrochloride).



Pharmacopoeias. In *Eur.* (see p.vii) for veterinary use only.

Ph. Eur. 6.2 (Dembrexine Hydrochloride Monohydrate for Veterinary Use; Dembrexine Hydrochloride Monohydrate BP(Vet) 2008). A white or almost white, crystalline powder. Slightly soluble in water and in anhydrous ethanol; freely soluble in methyl alcohol.

Profile

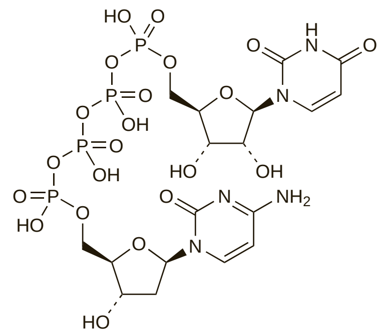
Dembrexine is a mucolytic used as the hydrochloride in veterinary medicine.

Denufosol Tetrasodium *(USAN, rINNM)*

Denufosol tetrasódico; Dénufosol tetrasodique; Denufosolum tetranatricum; INS-37217. 2′-Deoxycytidine(5′)tetraphospho(5′)uridine tetrasodium.

Денуфозол Тетранатрий

$C_{18}H_{23}N_5Na_4O_{21}P_4$ = 861.3.
CAS — 211448-85-0 (denufosol); 318250-11-2 (denufosol tetrasodium).



(denufosol)

Profile

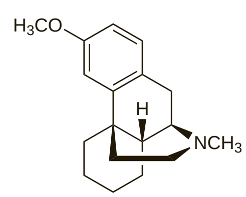
Denufosol tetrasodium is a selective $P2Y_2$-receptor agonist that stimulates chloride and water secretion from respiratory tract epithelial cells, and increases mucosal hydration and mucociliary clearance. An inhaled preparation is under investigation for the treatment of cystic fibrosis.

Dextromethorphan *(BAN, pINN)*

Dekstrometorfaani; Dextrométhorphane; Dextromethorphanum; Dextrometorfán; Dextrometorfano. (+)-3-Methoxy-9a-methylmorphinan; (9*S*,13*S*,14*S*)-6,18-Dideoxy-7,8-dihydro-3-*O*-methylmorphine.

Декстрометорфан

$C_{18}H_{25}NO$ = 271.4.
CAS — 125-71-3.
ATC — R05DA09.
ATC Vet — QR05DA09.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of dextromethorphan: Bromage; Brome; Candy; CCC; C-C-C; Dex; Dextro; DM; Drex; DXM; Red Devils; Robo; Rojo; Skittles; Triple C; Triple C's; Tussin; Velvet; Vitamin D.

Pharmacopoeias. In *US.*

USP 31 (Dextromethorphan). A practically white to slightly yellow, odourless, crystalline powder. Practically insoluble in water; freely soluble in chloroform. Store in airtight containers.

Dextromethorphan Hydrobromide *(BANM, pINNM)*

Dekstrometorfaanihydrobromidi; Dekstrometorfan Hidrobromür; Dekstrometorfano hidrobromidas; Dekstrometorfanu bromowodorek; Dextromethorfan-hydrobromid monohydrát; Dextrométhorphane, bromhydrate de; Dextromethorphani hydrobromidum; Dextromethorphani Hydrobromidum Monohydricum; Dextrometorfán-hidrobromid; Dextrometorfanhydrobromid; Hidrobromuro de dextrometorfano. Dextromethorphan hydrobromide monohydrate.

Декстрометорфана Гидробромид

$C_{18}H_{25}NO,HBr,H_2O$ = 370.3.
CAS — 125-69-9 (anhydrous dextromethorphan hydrobromide); 6700-34-1 (dextromethorphan hydrobromide monohydrate).
ATC — R05DA09.
ATC Vet — QR05DA09.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *Jpn*, *US*, and *Viet.*

Ph. Eur. 6.2 (Dextromethorphan Hydrobromide). An almost white, crystalline powder. Sparingly soluble in water; freely soluble in alcohol. Protect from light.

USP 31 (Dextromethorphan Hydrobromide). Practically white crystals or crystalline powder having a faint odour. Soluble 1 in 65 of water; freely soluble in alcohol and in chloroform; insoluble in ether. pH of a 1% solution in water is between 5.2 and 6.5. Store in airtight containers.

Adverse Effects and Treatment

Adverse effects with dextromethorphan appear to be rare and may include dizziness and gastrointestinal disturbances. Excitation, confusion, and respiratory depression may occur after overdosage. Dextromethorphan has been subject to abuse, but there is little evidence of dependence of the morphine type.

◊ General references.

Hypersensitivity. A fixed-drug reaction developed in a patient after ingestion of dextromethorphan 30 mg.[1] Oral provocation with dextromethorphan produced a positive reaction but the results of topical application tests were negative. Urticaria, angioedema, and shortness of breath were reported in another patient;[2] symptoms recurred on oral challenge, but no skin test was performed. Similar symptoms were reported in a third patient;[3] skin testing provoked a positive reaction. On oral rechallenge, the patient developed urticaria initially, followed by generalised erythema and pruritus and decreased blood pressure after a second dose.

Overdosage. There have been reports[1-7] of overdosage or accidental poisoning (usually in children) due to dextromethorphan, including rare fatalities. Naloxone may be effective in reversing toxicity. Extrapyramidal reactions were seen in a child who ingested dextromethorphan.[6] Overdosage has also been associated with abuse (see below).

Precautions

Dextromethorphan should not be given to patients at risk of developing respiratory failure. Caution is needed in patients with a history of asthma and it should not be given during an acute attack. Care is also advisable in patients with bronchitis, emphysema, or in other conditions where chronic or persistent cough occurs.

Abuse. Dextromethorphan has been abused,[1-12] alone or with other drugs in over-the-counter preparations or as a powder sold under the name DXM. There have been a few reports of dependence,[1,2,11] but evidence of classical opioid dependence is generally considered to be lacking.

Children. For doubts about the use of dextromethorphan as an antitussive in children see Cough, under Uses and Administration, below.

Interactions

Severe and sometimes fatal reactions have been reported after use of dextromethorphan in patients receiving

MAOIs. Dextromethorphan is primarily metabolised by the cytochrome P450 isoenzyme CYP2D6; the possibility of interactions with inhibitors of this enzyme, including amiodarone, haloperidol, propafenone, quinidine, SSRIs, and thioridazine, should be borne in mind.

Antiarrhythmics. *Quinidine* can increase serum concentrations of dextromethorphan markedly, and some patients have experienced symptoms of dextromethorphan toxicity when the two drugs have been used together.[1,2] Based on this interaction, the combination has been studied for its therapeutic effect in amyotrophic lateral sclerosis (see Neurological Disorders, below). *Amiodarone* also appears to be able to increase serum concentrations of dextromethorphan.[3]

3. Funck-Brentano C, *et al.* Influence of amiodarone on genetically determined drug metabolism in humans. *Clin Pharmacol Ther* 1991; **50:** 259–66.

Antibacterials. Serotonin syndrome-like symptoms have occurred when dextromethorphan has been taken with *linezolid*.

Antidepressants. A patient receiving *fluoxetine* experienced visual hallucinations after she began taking dextromethorphan.[1] The hallucinations were similar to those she had had 12 years earlier with lysergide. She had previously taken dextromethorphan alone without any adverse reactions. A serotonin syndrome (p.416) has been reported in a patient who took a cold-remedy containing dextromethorphan while receiving *paroxetine*.[2]

2. Skop BP, *et al.* The serotonin syndrome associated with paroxetine, an over-the-counter cold remedy, and vascular disease. *Am J Emerg Med* 1994; **12:** 642–4.

Pharmacokinetics

Dextromethorphan is rapidly absorbed from the gastrointestinal tract. It is metabolised in the liver and excreted in the urine as unchanged dextromethorphan and demethylated metabolites including dextrorphan (p.2293), which has some cough suppressant activity.

Genetic polymorphism. The *O*-demethylation of dextromethorphan and the hydroxylation of debrisoquine are under common polymorphic control, involving the cytochrome P450 isoenzyme CYP2D6, and dextromethorphan has been used as an alternative to debrisoquine (p.1256) for the phenotyping of oxidative metabolism.[1,2] Non-invasive determinations can be made using samples of urine or saliva.[3,4] Dextromethorphan has also been suggested as a tool to investigate *N*-demethylation, an alternate metabolic pathway for this drug.[5]

Uses and Administration

Dextromethorphan hydrobromide is a cough suppressant used for the relief of non-productive cough; it has a central action on the cough centre in the medulla. It is also an antagonist of *N*-methyl-D-aspartate (NMDA) receptors. Although structurally related to morphine, dextromethorphan has no classical analgesic properties (but see Pain below) and little sedative activity.

Dextromethorphan hydrobromide is reported to act within half an hour of an oral dose and to exert an effect for up to 6 hours. It is given orally in doses of 10 to 20 mg every 4 hours, or 30 mg every 6 to 8 hours, to a usual maximum of 120 mg in 24 hours.

Dextromethorphan polistirex (a dextromethorphan and sulfonated diethenylbenzene-ethenylbenzene copolymer complex) is used in modified-release oral preparations. The dosage of dextromethorphan polistirex, expressed as dextromethorphan hydrobromide, is the equivalent of 60 mg every 12 hours.

Dextrorphan (p.2293), the *O*-demethylated metabolite of dextromethorphan, also has cough suppressant properties.

For dosage of dextromethorphan in children, see Administration in Children, below.

Administration in children. Although dextromethorphan hydrobromide is licensed for use in children, over-the-counter cough and cold preparations containing cough suppressants (including dextromethorphan) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547 and also Cough, below).

In the USA, the following oral doses have been used:

- 2 to 6 years: 2.5 to 5 mg every 4 hours, or 7.5 mg every 6 to 8 hours, to a maximum of 30 mg in 24 hours
- 6 to 12 years: 5 to 10 mg every 4 hours or 15 mg every 6 to 8 hours to a maximum of 60 mg in 24 hours

Dextromethorphan polistirex is used in modified-release oral preparations. The following dosage of dextromethorphan polistirex, expressed as dextromethorphan hydrobromide, has been given to children:

- 2 to 6 years: 15 mg every 12 hours
- 6 to 12 years: 30 mg every 12 hours

Cough. Equal doses of dextromethorphan hydrobromide and codeine phosphate were of similar efficacy in reducing the frequency of chronic cough (p.1547) in a double-blind crossover study in adults, but dextromethorphan had a greater effect than codeine on cough intensity.[1] However, these drugs were little more effective than placebo in suppressing night-time cough in children.[2-4] The American Academy of Pediatrics has commented[5] that there is no good evidence for the antitussive efficacy of dextromethorphan in children, that dosage guidelines are derived from (possibly inappropriate) extrapolation from effects in adults, and that adverse effects have been reported. Furthermore, in 2008, the FDA and the MHRA advised that over-the-counter cough and cold preparations containing cough suppressants (including dextromethorphan) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547).

There is also some evidence that genetic polymorphism in the cytochrome P450 isoenzyme CYP2D6, and hence variations in metabolism, may have a significant influence on the antitussive efficacy of dextromethorphan.[6]

Neurological disorders. Dextromethorphan appears to have anticonvulsant activity and may have neuroprotective effects in cerebral ischaemia.[1] These effects may be related to its activity as an antagonist of *N*-methyl-D-aspartate (NMDA) receptors or to interaction with σ-receptors. It has been studied in Parkinson's disease for treatment[2] or for management of levodopa-induced dyskinesias,[3] and for its potential protective action in stroke and acute brain injury. Dextromethorphan has also been studied for the management of amyotrophic lateral sclerosis (see Motor Neurone Disease, p.2380) but has not been found to be of benefit.[4-6] A study[7] in which quinidine was given to inhibit the metabolism of dextromethorphan did find the combination to be more effective in controlling pseudobulbar affect (emotional lability) than either drug alone, but also associated with more adverse effects. In the treatment of pseudobulbar affect in multiple sclerosis patients the dextromethorphan and quinidine combination was found to be well tolerated and more effective than placebo.[8] The NMDA-antagonist properties of dextromethorphan have also been investigated for the treatment[9,10] of nonketotic hyperglycinaemia (p.2393).

Pain. Dextromethorphan has a potential role in the blockade of pain. It has been investigated[1-3] in the management of neuropathic pain with promising results in diabetic neuropathy (p.6), although pain was not reduced in postherpetic neuralgia (p.9). High doses of dextromethorphan may be needed for an effect, or combination with quinidine, which inhibits dextromethorphan metabolism.[4] However, the use of dextromethorphan in diabetic neuropathy remains investigational, and further well-controlled trials are needed.[5]

A systematic review[6] of 28 studies of dextromethorphan as an adjunct for postoperative pain found that despite a tendency for patients to report less pain than with placebo, and to use less opioid analgesia postoperatively, the differences tended to be inconsistent and of questionable clinical significance. There was some suggestion that parenteral dextromethorphan was more effective than oral.

Dornase Alfa *(BAN, USAN, rINN)*

Deoxyribonuclease; Desoxyribonuclease; DNase I; Dornasa alfa; Dornasum Alfa; Dornaz Alfa; rhDNase. Deoxyribonuclease I (human recombinant).

Дорназа Альфа

$C_{1321}H_{1995}N_{339}O_{396}S_9$ = 29249.6.
CAS — 143831-71-4; 132053-08-8.
ATC — B06AA10; R05CB13.
ATC Vet — QB06AA10; QR05CB13.

Description. Dornase alfa is a recombinant enzyme having the same amino acid sequence and glycosylation pattern as human deoxyribonuclease I.

Adverse Effects

Common adverse effects with dornase alfa aerosol include pharyngitis, hoarseness of the voice, and chest pain. Occasionally laryngitis, conjunctivitis, and skin rashes and urticaria have been reported. There may be a transient decline in pulmonary function on beginning therapy with dornase alfa.

Uses and Administration

Dornase alfa acts as a mucolytic by hydrolysing DNA that has accumulated in sputum from decaying neutrophils. It is used as a nebulised solution in patients with cystic fibrosis; in the UK its indication is limited to patients with a forced vital capacity (FVC) greater than 40% of predicted value and to patients over 5 years of age, but in the USA it may also be given for advanced disease (FVC less than 40%) and to younger children. The usual dose is 2500 units (2.5 mg) of dornase alfa given once daily via a jet nebuliser. This dose may be given twice daily to patients over 21 years of age.

Bovine deoxyribonuclease has been used similarly. It has also been used topically, often with fibrinolysin, as a debriding agent for inflammatory and infected lesions. Bovine deoxyribonuclease has also been given by injection.

Administration in children. Although in some countries dornase alfa is not recommended for use in children under 5 years of age, a study[1] to assess the delivery of dornase alfa to the lungs of children with cystic fibrosis aged between 3 months and 5 years, showed that the amounts present in the lower airways were comparable to those in older children. It also appeared to be safe in these younger patients during the 2-week study period.

1. Wagener JS, *et al.* Aerosol delivery and safety of recombinant human deoxyribonuclease in young children with cystic fibrosis: a bronchoscopic study. *J Pediatr* 1998; **133:** 486–91.

Asthma. There are reports of the use of dornase alfa to liquefy mucus plugs and relieve an attack of acute severe asthma (p.1108) in children.[1-3] However, a randomised controlled study[4] found that adding a single dose of nebulised dornase alfa to standard emergency treatment has no benefits in children with moderate to severe acute asthma.

4. Boogaard R, *et al.* Recombinant human deoxyribonuclease for the treatment of acute asthma in children. *Thorax* 2008; **63:** 141–6.

Chronic obstructive pulmonary disease. A large phase III study in patients hospitalised for acute exacerbations of chronic bronchitis (p.1112) was halted prematurely because of a non-significant trend to increased mortality in patients given dornase alfa.[1]

1. Hudson TJ. Dornase in treatment of chronic bronchitis. *Ann Pharmacother* 1996; **30:** 674–5.

Cystic fibrosis. There is good evidence that inhalation therapy with dornase alfa can produce modest but useful improvement in lung function in some patients with cystic fibrosis (p.166). Most studies have concentrated on patients with mild or moderate disease (forced vital capacity at least 40% of the predicted value) in whom FEV_1 and forced vital capacity have shown improvements generally of the order of 5 to 10%,[1-3] and in whom more prolonged therapy (24 weeks) has been shown to reduce the risk of exacerbations of respiratory infections, and hence the need for intravenous antibacterial therapy.[3] There is also evidence that benefit may occur in patients with more severe disease.[4] A systematic review[5] of studies concluded that there is evidence to show that dornase alfa therapy over a 1-month period is associated with improved lung function. Furthermore, a randomised, multicentre, placebo-controlled study[6] in children showed that dornase alfa maintained lung function and reduced the risk of exacerbations over a period of 96 weeks. However, only a minority of patients, perhaps about one-third,[7] benefit from the drug, and at present there is no way of identifying those who will respond other than by a therapeutic trial.[8,9]

Given the high cost of therapy, which is not entirely recouped by savings in acute care, there has been some controversy about the appropriate use of dornase alfa:[10-13] it seems to be generally felt that it should be reserved for specialist use in cystic fibrosis clinics, but that patients should not be denied a trial where appropriate. Most responders with mild to moderate impairment of lung function will show improvements within 2 weeks, although in more severely affected patients a 6-week trial is advocated.[8] A review of the use of dornase alfa in cystic fibrosis concluded that dosing on alternate days would be as effective as daily dosing, and would reduce costs and treatment time.[14]

$C_{13}H_{20}N_2O_2$ = 236.3.
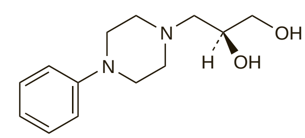
CAS — 99291-25-5.
ATC — R05DB27.
ATC Vet — QR05DB27.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Levodropropizine). A white or almost white powder. Slightly soluble in water and in alcohol; freely soluble in dilute acetic acid and in methyl alcohol. A 2.5% solution in water has a pH of 9.2 to 10.2. Protect from light.

Profile

Dropropizine is a cough suppressant reported to have a peripheral action in non-productive cough (p.1547). It is given orally usually in a dose of 30 mg three or four times daily. Levodropropizine, the (−)-(*S*)-isomer of dropropizine, is claimed to produce fewer CNS effects and is used similarly in an oral dose of 60 mg up to three times daily.

Elecampane

Ala; Alant; Aunée; Énula; Énula campana; Helenio; Ínula; Inula.

Девясил Высокий

CAS — 97676-35-2 (elecampane oil).

Pharmacopoeias. In *Chin.* (which also includes various other species of *Inula*) and *Fr.*

Profile

Elecampane is the root of *Inula helenium* (Compositae). It has been used in herbal preparations for the treatment of cough for its supposed expectorant and cough suppressant properties. It is also used as a flavouring in foods and alcoholic beverages.

Elecampane contains sesquiterpene lactones including alantolactone (alant camphor; elecampane camphor; inula camphor; helenin), which was formerly used in the treatment of worm infections, and has also been an ingredient of some cough preparations.

Elecampane oil has been used in aromatherapy.

Ephedra ⊗

Efedra; Ma-huang.

Хвойник; Эфедра хвощевая (*Ephedra equisetina*)

Pharmacopoeias. In *Chin., Ger.,* and *Jpn.*

Chin. also includes the roots of *Ephedra sinica* or *E. intermedia*.

Profile

Ephedra consists of the dried young branches of *Ephedra sinica*, *E. equisetina*, and *E. gerardiana* (including *E. nebrodensis*) (Ephedraceae), containing not less than 1.25% of alkaloids, calculated as ephedrine.

The action of ephedra is due to the presence of ephedrine (below) and pseudoephedrine (p.1571). It has been used chiefly as a source of these alkaloids. The FDA states that ephedra-containing dietary supplements are unsafe and the sale of these products is banned in the USA. Other countries have also banned the sale of ephedra-containing dietary supplements.

◊ For reference to the adverse effects of herbal products containing ephedra see Abuse under Ephedrine, below.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Canad.:*** Herbal Cold Relief†; ***Ger.:*** Cardibisana†; Cefadrin.

Ephedrine *(BAN)* ⊗

Efedriini; Efedrin; Efedrina; Efedrinas; Ephedrina; Éphédrine; (−)-Ephedrine; Ephedrinum. (1*R*,2*S*)-2-Methylamino-1-phenylpropan-1-ol.

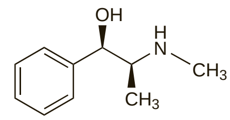
Эфедрин

$C_{10}H_{15}NO$ = 165.2.

CAS — 299-42-3 (anhydrous ephedrine); 50906-05-3 (ephedrine hemihydrate).

ATC — R01AA03; R01AB05; R03CA02; S01FB02.

ATC Vet — QG04BX90; QR01AA03; QR01AB05; QR03CA02; QS01FB02.



Description. Ephedrine is an alkaloid obtained from species of *Ephedra*, or prepared synthetically. It may exist in a hemihydrate form or as the anhydrous substance.

The following terms have been used as 'street names' (see p.vi) or slang names for various forms of ephedrine:

Trucker's Speed.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *US*, which have specifications, in either the same monograph or in separate monographs, for the anhydrous form and for the hemihydrate.

Ph. Eur. 6.2 (Ephedrine, Anhydrous). A white or almost white, crystalline powder or colourless crystals. Soluble in water; very soluble in alcohol. It melts at about 36°. Protect from light.

Ph. Eur. 6.2 (Ephedrine Hemihydrate; Ephedrine BP 2008). A white or almost white, crystalline powder or colourless crystals. Soluble in water; very soluble in alcohol. It melts at about 42°, determined without previous drying. Protect from light.

USP 31 (Ephedrine). It is anhydrous or contains not more than one-half molecule of water of hydration. It is an unctuous, practically colourless solid or white crystals or granules. It gradually decomposes on exposure to light. M.p. between 33° and 40°, the variability being the result of differences in the moisture content, anhydrous ephedrine having a lower melting-point than the hemihydrate. Soluble 1 in 20 of water and 1 in 0.2 of alcohol; soluble in chloroform and in ether; moderately and slowly soluble in liquid paraffin, the solution becoming turbid if the ephedrine contains more than about 1% of water. Its solutions are alkaline to litmus. Store in airtight containers at a temperature not exceeding 8°. Protect from light.

Ephedrine Hydrochloride *(BANM)* ⊗

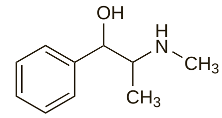
CAS — 90-81-3 (racephedrine); 134-71-4 (racephedrine hydrochloride).



(racephedrine)

Pharmacopoeias. In *Eur.*

Ph. Eur. 6.2 (Ephedrine Hydrochloride, Racemic; Racephedrine Hydrochloride BP 2008). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; soluble in alcohol; practically insoluble in ether. It melts at about 188°. Protect from light.

Adverse Effects

As for Sympathomimetics, p.1407. Ephedrine has both alpha- and beta-agonist effects and its commonest adverse effects are tachycardia, anxiety, restlessness, and insomnia. Tremor, dry mouth, impaired circulation to the extremities, hypertension, and cardiac arrhythmias may also occur.

Ephedrine may be used in labour to maintain blood pressure during spinal anaesthesia but can cause fetal tachycardia.

Paranoid psychosis, delusions, and hallucinations may also follow ephedrine overdosage. Prolonged use has no cumulative effect, but tolerance with dependence has been reported.

◊ For a discussion of the toxicity reported from the self-administration of ephedrine-containing dietary supplements or herbal stimulants, see Abuse, below.

Precautions

As for Sympathomimetics, p.1407. Ephedrine should be given with care to patients with hyperthyroidism, diabetes mellitus, ischaemic heart disease, hypertension, renal impairment, or angle-closure glaucoma. In patients with prostatic enlargement, ephedrine may increase difficulty with micturition.

Irritability and disturbed sleep have been reported in breast-fed infants.

Abuse. Although illicit use of ephedrine is primarily in the manufacture of street stimulants such as metamfetamine (p.2158), there is increasing evidence of the abuse of ephedrine preparations in some countries,[1] and the public health and social problems associated with its abuse appear to be significant, particularly in certain African countries. Ephedrine is also sold as a street substitute for 'Ecstasy' (Methylenedioxymethamfetamine, p.2159).

Adverse effects reported with illicit ephedrine use include cardiovascular toxicity[2,3] and chest pain.[4]

There is controversy over the abuse liability of over-the-counter (OTC) stimulants such as ephedrine:[5] some studies have indicated that ephedrine is, overall, a relatively weak reinforcer whereas others have suggested that the abuse potential may be high. Examination of the characteristics of 5 patients who had been taking ephedrine-containing OTC preparations in high doses for periods ranging from 8 months to 2 years, emphasised the reinforcing and, therefore, addictive potential of ephedrine; similar observations were made for 2 patients who had ingested phenylpropanolamine long term, combined with pseudoephedrine in one of these cases. The authors suggested that, for most people, OTC preparations containing weaker sympathomimetics will not be reinforcing at the recommended doses. However, these cases strengthen the research findings that high-dose use of an OTC stimulant increases its potency, and thus its effects become more like amfetamine (p.2150).

Toxicity has also been reported[6-8] from the self-administration of ephedrine-containing dietary supplements or herbal stimulants, usually based on ephedra (ma-huang) and marketed for a variety of purposes including weight loss and as an alternative to illegal drugs of abuse. Not all cases of ephedrine toxicity have arisen as a result of overt abuse but rather because of inadequate labelling of content and dosage instructions on some unlicensed products. A small study found that combinations of herbal caffeine and ephedra alkaloids taken in recommended amounts resulted in plasma ephedrine concentrations that exceeded the usual therapeutic range. Significant increases occurred in blood pressure and heart rate, and unfavourable effects on glucose and potassium homoeostasis were noted.[9] The use of ephedra-containing dietary supplements is now banned in the USA and some other countries.

Adverse effects from ingestion of ephedrine-containing OTC preparations, including herbal products (usually in high doses and/or long term) have included coronary artery thrombosis,[10] myocardial infarction, seizures,[11] psychotic reactions,[12] nephrolithiasis,[13-15] and myocarditis;[16] a number of fatalities have been reported. Frank dependence has been reported in female weight-lifters following long-term use of high doses.[17]

For a report of urinary calculi developing in a patient who had ingested a preparation containing guaifenesin and ephedrine, see Abuse, under Guaifenesin, p.1561.

Interactions

As for Sympathomimetics, p.1407. Ephedrine has direct and indirect actions and may cause a hypertensive crisis in patients receiving an MAOI (including a RIMA); the possibility of such an interaction after intranasal use of ephedrine should also be borne in mind. See also under Phenelzine (p.418) and Moclobemide (p.411). Since ephedrine has both alpha- and beta-agonist properties it should be avoided or used with care in patients undergoing anaesthesia with cyclopropane, halothane, or other volatile anaesthetics. An increased risk of arrhythmias may occur if given to patients receiving cardiac glycosides, quinidine, or tricyclic antidepressants, and there is an increased risk of vasoconstrictor or pressor effects in patients receiving ergot alkaloids or oxytocin. The rate of metabolism of some other drugs is increased by ephedrine. For mention of the potential additive stimulant effects seen with caffeine and ephedrine, see Sympathomimetics, under Caffeine, p.1118.

Pharmacokinetics

Ephedrine is readily and completely absorbed from the gastrointestinal tract. It is excreted largely unchanged in the urine, with small amounts of metabolites produced by hepatic metabolism. Ephedrine has been variously reported to have a plasma half-life ranging from 3 to 6 hours depending on urinary pH; elimination is enhanced and half-life accordingly shorter in acid urine.

Uses and Administration

Ephedrine is a sympathomimetic (p.1408) with direct and indirect effects on adrenergic receptors. It has alpha- and beta-adrenergic activity and has pronounced stimulating effects on the CNS. It has a more prolonged though less potent action than adrenaline. In therapeutic doses it raises the blood pressure by increasing cardiac output and also by inducing peripheral vasoconstriction. Tachycardia may occur but is less frequent than with adrenaline. Ephedrine also causes bronchodilatation, reduces intestinal tone and motility, relaxes the bladder wall while contracting the sphincter muscle but relaxes the detrusor muscle of the bladder and usually reduces the activity of the uterus. It has a stimulant action on the respiratory centre. It dilates the pupil but does not affect the light reflexes. After ephedrine has been used for a short while, tachyphylaxis may develop.

Ephedrine salts are used, either alone or in combination preparations, in the symptomatic relief of nasal congestion (p.1548). They may be given orally, or topically as nasal drops or sprays. Ephedrine salts have sometimes been used in motion sickness in combination preparations with hyoscine or an antihistamine and have been tried for postoperative nausea and vomiting (p.1700).

Ephedrine salts have been given parenterally to combat a fall in blood pressure during spinal or epidural anaesthesia. Ephedrine is of little value in hypotensive crises due to shock, circulatory collapse, or haemorrhage. It is no longer generally advocated for orthostatic hypotension.

Ephedrine salts have been used as bronchodilators, but the more $beta_2$-selective sympathomimetics, such as salbutamol, are now preferred.

Other uses of ephedrine salts include diabetic neuropathic oedema, in which they may provide marked relief. They have also been used in micturition disorders.

Nasal drops or sprays usually containing ephedrine 0.5 or 1% are used in the treatment of **nasal congestion**. Ephedrine salts have also been given by oral inhalation.

To reverse **hypotension** induced by spinal or epidural anaesthesia, a solution containing ephedrine hydrochloride 3 mg/mL is given by slow intravenous injection in doses of 3 to 6 mg (or at most 9 mg) repeated every 3 to 4 minutes as required; the maximum total dose is 30 mg. Ephedrine salts have also been given by intramuscular or subcutaneous injection.

The *BNF* suggests an oral dose of 30 to 60 mg of ephedrine hydrochloride three times daily in the treatment of **diabetic neuropathic oedema**.

Several other salts of ephedrine have been given including the camsilate, the levulinate, and the tannate. Racephedrine hydrochloride has also been used.

For children's doses, see Administration in Children, below.

Administration in children. Over-the-counter cough and cold preparations containing sympathomimetic decongestants (including ephedrine) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547). However, the *BNFC* suggests that, in certain circumstances, specialists may prescribe ephedrine nasal drops for children under 2 years in the short-term treatment of severe **nasal congestion** that has not responded to sodium chloride nasal drops or inhalation of warm moist air. Nasal drops or sprays containing ephedrine hydrochloride 0.5% are licensed to treat nasal congestion in young children over 3 months of age. Although not licensed for such use, the *BNFC* recommends a strength of 0.25% for use in children aged 1 to 3 months.

Ephedrine is rarely needed in children for reversal of **hypotension** induced by spinal or epidural anaesthesia, but if it is used the *BNFC* suggests the following doses of a solution containing ephedrine hydrochloride 3 mg/mL, given by slow intravenous injection via a central line:

- 1 to 12 years: 500 to 750 micrograms/kg or 17 to 25 mg/m^2 every 3 to 4 minutes according to response up to a maximum total dose of 30 mg
- 12 to 18 years: 3 to 7.5 mg (maximum 9 mg) repeated every 3 to 4 minutes according to response up to a maximum total dose of 30 mg

Micturition disorders. Ephedrine salts have been used in nocturnal enuresis, although other treatments are usually preferred, and have been tried in patients with stress incontinence but the value of such treatment is not clear.

Spinal anaesthesia. Parenteral sympathomimetics such as ephedrine and phenylephrine have been advocated for the correction of hypotension associated with local anaesthesia. The risk of hypotension with spinal or epidural block is greater than many other forms of nerve block (see Adverse Effects of Central Block, p.1850). Ephedrine has been used[1,2] although not always successfully[3] for the correction of such hypotension. It has also been used prophylactically,[4,5] although prophylactic use during labour has been associated with fetal tachycardia,[5] and adequate hydration of the patient beforehand is more important in minimising hypotension.

Eprazinone Hydrochloride *(rINNM)*

CE-746; Éprazinone, Chlorhydrate d'; Eprazinoni Hydrochloridum; Hidrocloruro de eprazinona. 3-[4-(β-Ethoxyphenethyl)piperazin-1-yl]-2-methylpropiophenone dihydrochloride.

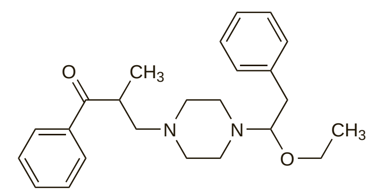
Эпразинона Гидрохлорид

$C_{24}H_{32}N_2O_2,2HCl = 453.4.$

CAS — 10402-90-1 (eprazinone); 10402-53-6 (eprazinone hydrochloride).

ATC — R05CB04.

ATC Vet — QR05CB04.



(eprazinone)

Profile

Eprazinone hydrochloride has been variously described as having mucolytic or expectorant properties (p.1547) as well as a direct relaxant action on bronchial smooth muscle. It is given in oral doses of 50 to 100 mg three times daily. It has also been given rectally.

Effects on the skin. Skin eruptions have been associated with the oral use of eprazinone.[1,2]

Eprozinol Hydrochloride *(rINNM)*

Éprozinol, Chlorhydrate d'; Eprozinoli Hydrochloridum; Hidrocloruro de eprozinol. 3-[4-(β-Methoxyphenethyl)piperazin-1-yl]-1-phenylpropan-1-ol dihydrochloride.

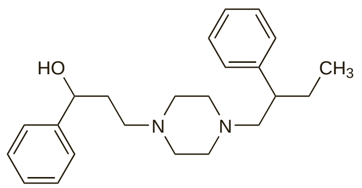
Эпрозинола Гидрохлорид

$C_{22}H_{30}N_2O_2,2HCl$ = 427.4.

CAS — 32665-36-4 (eprozinol).

ATC — R03DX02.

ATC Vet — QR03DX02.



(eprozinol)

Profile

Eprozinol hydrochloride has been given orally for its mucolytic or expectorant properties.

Adverse effects. Convulsions and coma were reported in a 19-year-old patient after taking eprozinol.[1]

1. Merigot P, *et al.* Les convulsions avec trois antitussifs dérivés substitués de la pipérazine: (zipéprol, éprazinone, éprozinol). *Ann Pediatr (Paris)* 1985; **32:** 504–11.

Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Eupneron†.

Erdosteine *(rINN)*

Erdosteiini; Erdostein; Erdosteína; Erdostéine; Erdosteinum. (±)-({[(Tetrahydro-2-oxo-3-thienyl)carbamoyl]methyl}thio)acetic acid.

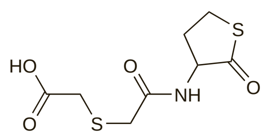
Эрдостеин

$C_8H_{11}NO_4S_2$ = 249.3.

CAS — 84611-23-4.

ATC — R05CB15.

ATC Vet — QR05CB15.



Adverse Effects and Precautions

Gastrointestinal disturbances may occur with erdosteine. Headache, dyspnoea, taste alterations, urticaria, erythema, and dermatitis have been reported rarely. Licensed product information for erdosteine suggests that it should not be used in patients with active peptic ulcer disease.

Pharmacokinetics

Erdosteine is rapidly absorbed after oral use; absorption is unaffected by food. Peak plasma concentrations are reached after about an hour. Erdosteine undergoes first-pass metabolism to an active metabolite, *N*-thiodiglycolyl-homocysteine. Plasma protein binding is about 64.5%. The elimination half-life is about 1.46 hours for erdosteine, and about 1.62 hours for the metabolite. Excretion is mainly via the urine, as metabolites; faecal elimination is negligible.

Uses and Administration

Erdosteine is a mucolytic that is used in the treatment of disorders of the respiratory tract characterised by productive cough (p.1547). It is given in usual oral doses of 300 mg twice daily for a maximum of 10 days.

Administration in hepatic and renal impairment. Exposure to erdosteine is increased in patients with hepatic impairment. UK licensed product information states that no increase in adverse effects has been observed in patients with mild liver failure, but restricts the dose in these patients to a maximum of 300 mg daily by mouth. Erdosteine is contra-indicated in severe hepatic impairment.

Although no difference in absorption or elimination has been seen in patients with moderate renal impairment, the risk of accumulation of metabolites cannot be excluded. For this reason, use of erdosteine is contra-indicated in patients with a creatinine clearance of less than 25 mL/minute.

Chronic obstructive pulmonary disease. Erdosteine has been used[1-3] in the management of chronic obstructive pulmonary disease (p.1112) but the value of mucolytics in this disorder is controversial.

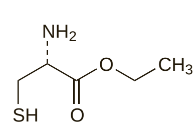
Ethyl Cysteine Hydrochloride

Etilcisteína, hidrocloruro de. Ethyl L-2-amino-3-mercaptopropionate hydrochloride.

Этиловый Эфир Цистеина Гидрохлорида

$C_5H_{11}NO_2S,HCl$ = 185.7.

CAS — 3411-58-3 (ethyl cysteine); 868-59-7 (ethyl cysteine hydrochloride).



(ethyl cysteine)

Pharmacopoeias. In *Jpn.*

Profile

Ethyl cysteine hydrochloride is a mucolytic that has been used in the treatment of disorders of the respiratory tract associated with productive cough.

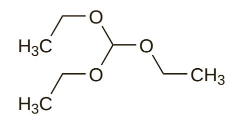
Ethyl Orthoformate

Ether de Kay; Triethoxymethane; Trietoximetano. Triethyl orthoformate.

Этиловый Эфир Ортомуравьиной Кислоты

$C_7H_{16}O_3$ = 148.2.

CAS — 122-51-0.



Pharmacopoeias. In *Fr.*

Profile

Ethyl orthoformate is a cough suppressant (see p.1547). It is reported to be a respiratory antispasmodic and has been given by mouth or rectally.

Fedrilate *(rINN)*

Fédrilate; Fedrilato; Fedrilatum; UCB-3928. 1-Methyl-3-morpholinopropyl perhydro-4-phenylpyran-4-carboxylate.

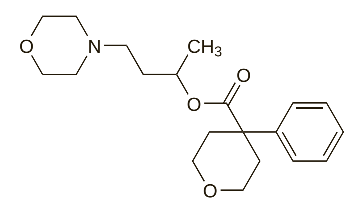
Федрилат

$C_{20}H_{29}NO_4$ = 347.4.

CAS — 23271-74-1.

ATC — R05DB14.

ATC Vet — QR05DB14.



Profile

Fedrilate is a cough suppressant used orally for non-productive cough.

Preparations

Proprietary Preparations (details are given in Part 3)
Braz.: Gotas Binelli.

Fenoxazoline Hydrochloride *(rINNM)* ⊗

Fénoxazoline, Chlorhydrate de; Fenoxazolini Hydrochloridum; Hidrocloruro de fenoxazolina. 2-(2-Isopropylphenoxymethyl)-2-imidazoline hydrochloride.

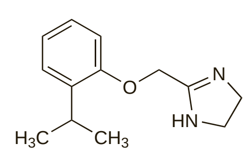
Феноксазолина Гидрохлорид

$C_{13}H_{18}N_2O,HCl$ = 254.8.

CAS — 4846-91-7 (fenoxazoline); 21370-21-8 (fenoxazoline hydrochloride).

ATC — R01AA12.

ATC Vet — QR01AA12.



(fenoxazoline)

Profile

Fenoxazoline hydrochloride is a sympathomimetic with effects similar to those of naphazoline (p.1565) that has been used topically for its vasoconstrictor properties in the symptomatic treatment of nasal congestion.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Nebulicina; ***Braz.:*** Aturgyl†; Nasofelin.

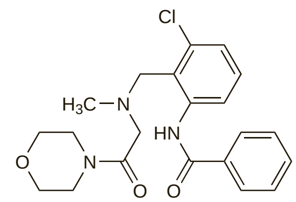
Fominoben Hydrochloride *(rINNM)*

Fominobène, Chlorhydrate de; Fominobeni Hydrochloridum; Hidrocloruro de fominobén; PB-89. 3′-Chloro-2′-[*N*-methyl-*N*-(morpholinocarbonylmethyl)aminomethyl]benzanilide hydrochloride.

Фоминобена Гидрохлорид

$C_{21}H_{24}ClN_3O_3,HCl$ = 438.3.

CAS — 18053-31-1 (fominoben); 24600-36-0 (fominoben hydrochloride).



(fominoben)

Profile

Fominoben hydrochloride is a centrally acting cough suppressant (see p.1547) that is also reported to have respiratory stimulant properties. It is given in oral doses of 160 mg up to three times daily; it has also been given by slow intravenous injection.

Preparations

Proprietary Preparations (details are given in Part 3)
Jpn: Noleptan; ***Mex.:*** Noleptan; ***Spain:*** Tosifar.

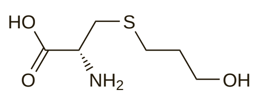
Fudosteine *(rINN)*

Fudosteína; Fudostéine; Fudosteinum; SS-320A. (−)-3-[(3-Hydroxypropyl)thio]-L-alanine.

Фудостеин

$C_6H_{13}NO_3S$ = 179.2.

CAS — 13189-98-5.



Profile

Fudosteine is an expectorant given orally in a dose of 400 mg three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Jpn: Cleanal.

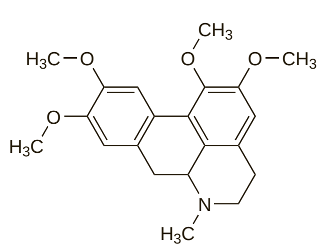
Glaucine

Boldine Dimethyl Ether; DL-832 (*dl*-glaucine phosphate); Glaucina; *dl*-Glaucine; MDL-832 (*dl*-glaucine phosphate). DL-1,2,9,10-Tetramethoxyaporphine.

Глауцин

$C_{21}H_{25}NO_4$ = 355.4.

CAS — 5630-11-5 (dl-glaucine); 73239-87-9 (dl-glaucine phosphate); 475-81-0 (d-glaucine); 5996-06-5 (d-glaucine hydrobromide).



(dl-glaucine)

Profile

Glaucine is a centrally acting cough suppressant used in non-productive cough (p.1547); it has been given as the phosphate.

d-Glaucine has also been used, as the hydrobromide and the hydrochloride. It has been obtained from *Glaucium flavum* (Papaveraceae).

Preparations

Proprietary Preparations (details are given in Part 3)
Rus.: Glauvent (Глаувент)†.

Multi-ingredient: ***Rus.:*** Bronchitussin (Бронхитусен); Bronchocin (Бронхоцин); Broncholytin (Бронхолитин).

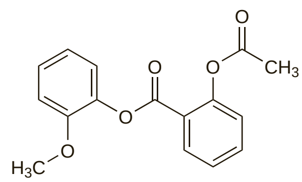
Guacetisal *(rINN)*

Acetylsalicylic Acid Guaiacol Ester; Guacétisal; Guacetisalum. *o*-Methoxyphenyl salicylate acetate.

Гуацетисал

$C_{16}H_{14}O_5$ = 286.3.

CAS — 55482-89-8.
ATC — N02BA14.
ATC Vet — QN02BA14.



Profile

Guacetisal has been used in respiratory disorders as an expectorant (see p.1547). It has also been used as an antipyretic to reduce fever (p.10). It has been given by mouth and rectally.

Preparations

Proprietary Preparations (details are given in Part 3)
Ital.: Prontomucil.

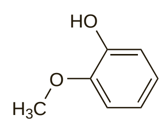
Guaiacol

Gaïacol; Guaiacolum; Guajacol; Guayacol; Gwajakol; Methyl Catechol. 2-Methoxyphenol.

Гваякол

$C_7H_8O_2$ = 124.1.

CAS — 90-05-1 (guaiacol); 553-17-3 (guaiacol carbonate); 60296-02-8 (calcium guaiacolglycolate); 4112-89-4 (guaiacol phenylacetate).



Pharmacopoeias. In *Eur.* (see p.vii). *Fr.* also includes guaiacol carbonate.

Ph. Eur. 6.2 (Guaiacol). A crystalline mass or colourless or yellowish hygroscopic liquid. Sparingly soluble in water; freely soluble in alcohol; very soluble in dichloromethane. Store in airtight containers. Protect from light.

Profile

Guaiacol has disinfectant properties and has been used in dentistry and as an expectorant for productive cough (p.1547).

In high concentrations, adverse effects are similar to, but less severe than, those of phenol (p.1656).

A wide range of salts and derivatives of guaiacol have been used similarly including the carbonate, cinnamate, ethylglycolate, calcium and sodium glycolates, phenylacetate, and phenylbutyrate. See also Guaifenesin, p.1561 and Sulfogaiacol, p.1573.

Preparations

Proprietary Preparations (details are given in Part 3)
Mex.: Eucaliptine.

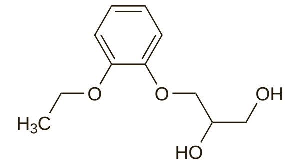
Guaietolin *(rINN)*

Glycerylguethol; Glyguetol; Guaietolina; Guaïétoline; Guaietolinum; Guayetolina. 3-(2-Ethoxyphenoxy)propane-1,2-diol.

Гвайэтолин

$C_{11}H_{16}O_4$ = 212.2.

CAS — 63834-83-3.



Profile

Guaietolin is an analogue of guaifenesin which is used as an expectorant (see p.1547). It has been given in oral doses of 300 to 600 mg two or three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Guethural.

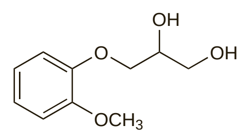
Guaifenesin *(BAN, USAN, rINN)*

Glyceryl Guaiacolate; Glycerylguayacolum; Guaiacol Glycerol Ether; Guaiacyl Glyceryl Ether; Guaifenesiini; Guaifenesina; Guaïfénésine; Guaifénésine; Guaifenesinum; Guaiphenesin; Guajacolum Glycerolatum; Gvajfenezin; Gvajfenezinas. (*RS*)-3-(2-Methoxyphenoxy)propane-1,2-diol.

Гвайфенезин

$C_{10}H_{14}O_4$ = 198.2.

CAS — 93-14-1.
ATC — R05CA03.
ATC Vet — QM03BX90; QR05CA03.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Guaifenesin). A white or almost white, crystalline powder. Sparingly soluble in water; soluble in alcohol.

USP 31 (Guaifenesin). A white to slightly grey crystalline powder. May have a slight characteristic odour. Soluble 1 in 60 to 70 of water; soluble in alcohol, in chloroform, and in propylene glycol; sparingly soluble in glycerol. Store in airtight containers.

Adverse Effects and Precautions

Gastrointestinal discomfort, nausea, and vomiting have occasionally been reported with guaifenesin, particularly in very large doses.

Abuse. Urinary calculi have been reported in patients consuming large quantities of over-the-counter preparations containing guaifenesin.[1,2] Spectroscopic analysis[1] revealed that the stones were composed of a calcium salt of beta-(2-methoxyphenoxy)-lactic acid, which is a metabolite of guaifenesin. Small quantities of ephedrine were also present in the stones of one of several patients who had ingested preparations containing a combination of guaifenesin and ephedrine.[2]

1. Pickens CL, *et al.* Abuse of guaifenesin-containing medications generates an excess of a carboxylate salt of beta-(2-methoxyphenoxy)-lactic acid, a guaifenesin metabolite, and results in urolithiasis. *Urology* 1999; **54:** 23–7.
2. Assimos DG, *et al.* Guaifenesin- and ephedrine-induced stones. *J Endourol* 1999; **13:** 665–7.

Porphyria. Guaifenesin is considered to be unsafe in patients with porphyria because it has been shown to be porphyrinogenic in *animals*.

Pharmacokinetics

Guaifenesin is well absorbed from the gastrointestinal tract. It is metabolised and then excreted in the urine.

Uses and Administration

Guaifenesin is reported to increase the volume and reduce the viscosity of tenacious sputum and is used as an expectorant for productive cough. It is given in oral doses of 200 to 400 mg every 4 hours. Modified-release preparations, given every 12 hours, are also available. For doses in children see Administration in Children, below.

Guaifenesin has been used similarly as the calcium salt.

Guaifenesin is used as an adjunct to anaesthesia in veterinary medicine.

Administration in children. Guaifenesin is licensed for use as an expectorant in children; however, over-the-counter cough and cold preparations containing expectorants (including guaifenesin) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547). Typical licensed oral doses, given every 4 hours, are:

- 6 months to 2 years, 25 to 50 mg
- 2 to 6 years, 50 to 100 mg
- 6 to 12 years, 100 to 200 mg

UK preparations suggest that these doses be given up to a maximum of 4 times daily, although in other countries higher total doses may be given.

Respiratory disorders. An FDA review of preparations available over-the-counter concluded that guaifenesin was an effective expectorant.[1] The use of expectorants for productive cough is discussed on p.1547. A small study[2] found that guaifenesin also appeared to reduce cough reflex sensitivity in patients with upper respiratory-tract infections, which produce a transient increase in sensitivity, although it had no effect on cough reflex in healthy subjects. The mechanism for this effect was unclear.

Guaifenesin has been given to patients with altered nasal mucociliary clearance associated with HIV infection.[3]

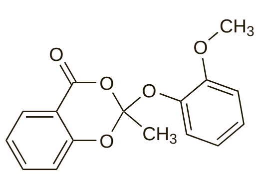
Multi-ingredient: Numerous preparations are listed in Part 3.

Guaimesal *(rINN)*

Guaïmésal; Guaimesalum. (±)-2-(*o*-Methoxyphenoxy)-2-methyl-1,3-benzodioxan-4-one.

Гваймесал

$C_{16}H_{14}O_5$ = 286.3.
CAS — 81674-79-5.



Profile

Guaimesal is reported to have expectorant and antipyretic properties and has been given orally as an adjunct in the treatment of respiratory-tract disorders. It has also been given rectally in suppositories.

Helicidine

Helicidina; Helixinum.

Гелицидин

Profile

Helicidine is a mucoglycoprotein from the snail *Helix pomatia* that has been used as a cough suppressant.

◊ References.

Preparations

Proprietary Preparations (details are given in Part 3)

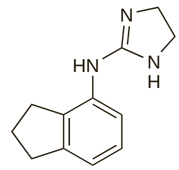
Multi-ingredient: ***Ger.:*** Original Schneckensirup†.

Indanazoline Hydrochloride *(rINNM)* ⊗

Hidrocloruro de indanazolina; Indanazolin Hidroklorür; Indanazoline, Chlorhydrate d'; Indanazolini Hydrochloridum.

Инданазолина Гидрохлорид

$C_{12}H_{15}N_3,HCl$ = 237.7.
CAS — 56601-85-5.



(indanazoline)

Profile

Indanazoline is a sympathomimetic with effects similar to those of naphazoline (p.1565). It has been used as the hydrochloride for its vasoconstrictor effect in the management of nasal congestion (p.1548). It has been given as nasal drops, a nasal gel, or a nasal spray in a concentration equivalent to indanazoline 0.1%.

Preparations

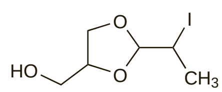
Proprietary Preparations (details are given in Part 3)
Ger.: Farial; ***Turk.:*** Farial.

Iodinated Glycerol *(BAN, USAN)*

Glicerol yodado; Iodopropylidene Glycerol.

Глицерин Йодированный

$C_6H_{11}IO_3$ = 258.1.
CAS — 5634-39-9.



Profile

Iodinated glycerol, a methyl derivative of domiodol, is an isomeric mixture of iodinated dimers of glycerol. It has been used as an expectorant. The limitations of iodides as expectorants are discussed in Cough on p.1547. The actions of iodides and iodine compounds are discussed under Iodine p.2169. Prolonged use of iodinated glycerol has been associated with thyroid dysfunction (see Effects on the Thyroid Gland, below) and severe skin eruptions; gastrointestinal disturbances and hypersensitivity reactions have also occurred. Malignant neoplasms have developed in *animals* given iodinated glycerol.

Chronic obstructive pulmonary disease. Studies[1-3] of the use of iodinated glycerol in patients with chronic bronchitis have produced conflicting results. The use of mucolytics or expectorants in chronic obstructive pulmonary disease (p.1112) is controversial.

1. Petty TL. The National Mucolytic Study: results of a randomized, double-blind, placebo-controlled study of iodinated glycerol in chronic obstructive bronchitis. *Chest* 1990; **97:** 75–83.
2. Repsher LH. Treatment of stable chronic bronchitis with iodinated glycerol: a double-blind, placebo-controlled trial. *J Clin Pharmacol* 1993; **33:** 856–60.
3. Rubin BK, *et al.* Iodinated glycerol has no effect on pulmonary function, symptom score, or sputum properties in patients with stable chronic bronchitis. *Chest* 1996; **109:** 348–52.

Effects on the thyroid gland. Thyroid dysfunction (both hyperthyroidism and hypothyroidism) has developed after giving iodinated glycerol to previously euthyroid patients. It was recommended that baseline thyroid function tests should be carried out before starting treatment with iodinated glycerol;[1] it should be withdrawn if abnormal results are obtained during use.

Preparations

Proprietary Preparations (details are given in Part 3)
USA: Iophen; Par Glycerol; R-Gen.

Ipecacuanha

Hlavěnkový kořen; Ipecac; Ipecacuana; Ipécacuanha, racine d'; Ipecacuanha Root; Ipecacuanhae radix; Ipekakuána-gyökér; Ipekakuananjuuri (ipecacuanha root); Ipekakuanarot (ipecacuanha root); Ipekakuanų šaknys; Korzeń ipekakuany; Raíz de ipecacuana.

Ипекакуана

CAS — 8012-96-2.
ATC — R05CA04; V03AB01.
ATC Vet — QR05CA04; QV03AB01.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*
Eur., *Jpn*, and *US* also include a monograph for Prepared Ipecacuanha or a similar standardised form.

Ph. Eur. 6.2 (Ipecacuanha Root; Ipecacuanha BP 2008). It consists of the fragmented and dried underground organs of *Cephaelis ipecacuanha* known as Matto Grosso ipecacuanha, or of *C. acuminata* known as Costa Rica ipecacuanha, or a mixture of both species. It contains not less than 2.0% of total alkaloids, calculated as emetine. It has a slight odour. Store in airtight containers. Protect from light.

The BP 2008 directs that when Ipecacuanha, Ipecacuanha Root, or Powdered Ipecacuanha is prescribed or demanded, Prepared Ipecacuanha shall be dispensed or supplied.

Ph. Eur. 6.2 (Ipecacuanha, Prepared; Ipecacuanhae Pulvis Normatus). It is ipecacuanha root powder adjusted to an alkaloidal content of 1.9 to 2.1% of total alkaloids, calculated as emetine. Store in airtight containers. Protect from light.

USP 31 (Ipecac). The dried rhizome and roots of *Cephaelis acuminata* or of *C. ipecacuanha* (Rubiaceae). It yields not less than 2% of ether-soluble alkaloids of which not less than 90% is emetine and cephaeline; the content of cephaeline varies from an amount equal to, to an amount not more than 2.5 times, that of emetine.

USP 31 (Powdered Ipecac). It contains 1.9 to 2.1% of ether-soluble alkaloids, with emetine and cephaeline content as for Ipecacuanha. It is pale brown, weak yellow, or light olive-grey powder that should be stored in airtight containers.

Adverse Effects

Large doses of ipecacuanha have an irritant effect on the gastrointestinal tract, and persistent bloody vomiting or bloody diarrhoea may occur. Mucosal erosions of the entire gastrointestinal tract have been reported. The absorption of emetine, which is most likely if vomiting does not occur after emetic doses of ipecacuanha, may give rise to adverse effects on the heart, such as conduction abnormalities or myocardial infarction. These, combined with dehydration due to vomiting may cause vasomotor collapse followed by death.

There have been several reports of chronic abuse of ipecacuanha to induce vomiting in eating disorders; cardiotoxicity and myopathy have occurred and may be a result of accumulation of emetine.

There have also been several reports of ipecacuanha poisoning due to the unwitting substitution of Ipecac Fluidextract (a former USP preparation) for Ipecac Syrup (USP); the fluidextract was about 14 times the strength of the syrup.

◊ References.

Hypersensitivity. Allergy, characterised by rhinitis, conjunctivitis, and chest tightness, has occurred due to inhalation of ipecacuanha dust in packers of ipecacuanha tablets.[1]

1. Luczynska CM, *et al.* Occupational allergy due to inhalation of ipecacuanha dust. *Clin Allergy* 1984; **14:** 169–75.

Vomiting. Prolonged vomiting has been reported in 17% of patients given ipecacuanha in the treatment of poisoning and may lead to gastric rupture, Mallory-Weiss tears of the oesophagogastric junction, cerebrovascular events, and pneumomediastinum and pneumoperitoneum.[1]

1. Bateman DN. Adverse reactions to antidotes. *Adverse Drug React Bull* 1988; **133:** (Dec.): 496–9.

Treatment of Adverse Effects

After acute overdose of ipecacuanha, activated charcoal is given to delay absorption followed if necessary by gastric lavage. Prolonged vomiting may be controlled by the injection of antiemetics. Fluid and electrolyte imbalance should be corrected and facilities should be available to correct any cardiac effects and subsequent shock.

When ipecacuanha is withdrawn after chronic abuse, recovery may be prolonged due to the slow elimination of emetine.

Precautions

The use of emetics is now rarely favoured; in particular, ipecacuanha should not be used as an emetic in patients who are unconscious or whose condition otherwise increases the risk of aspiration, nor in patients who have taken substances, such as corrosive compounds or petroleum products, that might be especially dangerous if aspirated. Ipecacuanha should not be given to patients in shock or to those at risk from seizures either as a result of their condition or from compounds, such as strychnine, that have been ingested. Patients with cardiovascular disorders are at risk if ipecacuanha is absorbed.

Abuse. Ipecac syrup has been abused by patients with eating disorders to induce vomiting.[1] Adverse effects of repeated vomiting, such as metabolic complications, aspiration pneumonitis, parotid enlargement, dental abnormalities, and oesophagitis or haematemesis due to mucosal lacerations (the Mallory-Weiss syndrome) may be observed. Cardiotoxicity may occur and fatalities have been reported including one patient who had ingested 90 to 120 mL of ipecac syrup daily for 3 months.[2] It has been suggested that cardiac effects and myopathy following the prolonged abuse of ipecac syrup may be due to the long-term accumulation of emetine[3,4] but some have expressed doubts.[5]

Cardiomyopathy has also been reported in children given ipecacuanha to produce factitious illness (Munchausen's syndrome by proxy);[6-8] fatalities have occurred.

Interactions

The action of ipecacuanha may be delayed or diminished if it is given with or after charcoal; antiemetics may also reduce its effect.

Food. Milk had been believed to impair the emetic efficacy of ipecacuanha but there was no significant difference in the time to onset of vomiting, the duration of vomiting, or the number of episodes in 250 children who were given ipecac syrup with milk compared with 250 given ipecac syrup with clear fluids.[1]

1. Klein-Schwartz W, *et al.* The effect of milk on ipecac-induced emesis. *J Toxicol Clin Toxicol* 1991; **29:** 505–11.

Uses and Administration

Ipecacuanha has been used as an **expectorant** in productive cough (p.1547) in doses of up to about 1.4 mg of total alkaloids.

Ipecacuanha may also be used in larger doses as an **emetic** but is of very limited value (see Emesis Induction in Acute Poisoning, below). Vomiting usually occurs within 30 minutes of an oral emetic dose, due to an irritant effect on the gastrointestinal tract and a central action on the chemoreceptor trigger zone. Doses are usually followed by a copious drink of water or fruit juice. Adults have been given doses of about 21 to 42 mg of total alkaloids; each 5 mL of Ipecac Syrup (USP 31) supplies about 7 mg of total alkaloids. Doses may be repeated once only after 20 to 30 minutes if emesis has not occurred. For children's doses, see Administration in Children, below.

Homoeopathy. Ipecacuanha has been used in homoeopathic medicines under the following names: Ipeca; Cephaelis ipecacuanha; Ipecac.

Administration in children. Over-the-counter cough and cold preparations containing expectorants (including ipecacuanha) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547).

In the UK, induction of emesis with ipecacuanha is not recommended because there is no evidence that it affects absorption and it may increase the risk of aspiration (see also Emesis Induction in Acute Poisoning, below).

In the USA, children aged 6 months to 1 year have been given about 7 to 14 mg of total alkaloids and older children about 21 mg. Each 5 mL of Ipecac Syrup (USP 31) supplies about 7 mg of total alkaloids. Doses are usually followed by a copious drink of water or fruit juice; in young children this may be given before the dose. Doses may be repeated once only after 20 to 30 minutes if emesis has not occurred.

Emesis induction in acute poisoning. Standard practice in the management of acute poisoning (p.1435) has varied widely, with different procedures favoured at different times and in different countries. However, measures to reduce absorption of the toxic substance, such as stomach emptying, have often been advocated.

Two techniques of stomach emptying have been very widely used: gastric lavage; and emesis induction, with ipecacuanha as the emetic of choice. Neither technique is without hazard and the dangers of attempting to empty the stomach have to be balanced against the toxicity of the ingested poison. If the patient presents late or the risk of toxicity is small, then gastric emptying is unnecessary.

- **Gastric lavage** is not recommended in the routine management of poisoned patients[1] because there is little evidence from experimental studies that it improves the clinical outcome and it may cause significant morbidity. *It should only be considered if a potentially life-threatening amount of toxic substance has been ingested within the preceding hour.* There is significant danger of aspiration of stomach contents associated with the procedure and it should only be attempted in fully conscious patients with good airway protective reflexes, unless other means are undertaken to protect the airway. Gastric lavage is also contra-indicated if corrosive or petroleum products have been ingested. Another risk that has been suggested with gastric lavage is that the procedure may propel stomach contents beyond the pylorus and thus enhance absorption,[2] but this conclusion has been challenged[3] and the evidence appears to be limited.
- Induction of **emesis** with ipecacuanha has often been advocated for use in children, in whom gastric lavage may be particularly traumatic; it has also been used in adults. However, like gastric lavage, its routine use is not recommended in the management of poisoned patients[4] because there is no clear evidence from clinical studies that it improves the outcome; clinically significant absorption may not be prevented even if it is given within 1 hour of the ingested poison. It may also delay the use or reduce the effectiveness of activated charcoal or oral antidotes. Ipecacuanha should not be given to patients with compromised airway reflexes, nor following ingestion of corrosive or petroleum products. In addition it should be avoided in debilitated or elderly patients, or those with medical conditions that may be compromised by induction of emesis. *It may be considered in alert, conscious patients, if a potentially life-threatening amount of toxic substance has been ingested within the preceding hour, and if gastric lavage or activated charcoal are deemed inappropriate.*

Because of the limitations of both methods of gastric emptying, a number of studies have addressed the question of whether either is appropriate. Such studies have indicated that the use of activated charcoal alone to prevent absorption, without gastric emptying, is as effective as a combination of both methods.[5-7]

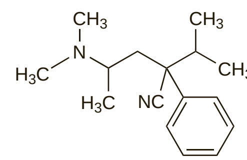
Isoaminile *(BAN, rINN)*

Isoaminiili; Isoaminil; Isoaminilo; Isoaminilum. 4-Dimethylamino-2-isopropyl-2-phenylpentanonitrile.

Изоаминил

$C_{16}H_{24}N_2$ = 244.4.
CAS — 77-51-0.
ATC — R05DB04.
ATC Vet — QR05DB04.



Isoaminile Citrate *(BANM, rINNM)*

Citrato de isoaminilo; Isoaminile, Citrate d'; Isoaminili Citras. 4-Dimethylamino-2-isopropyl-2-phenylvaleronitrile dihydrogen citrate.

Изоаминила Цитрат

$C_{16}H_{24}N_2,C_6H_8O_7$ = 436.5.
CAS — 126-10-3; 28416-66-2.
ATC — R05DB04.
ATC Vet — QR05DB04.

Isoaminile Cyclamate *(rINNM)*

Ciclamato de isoaminilo; Isoaminile, Cyclamate d'; Isoaminili Cyclamas. 4-Dimethylamino-2-isopropyl-2-phenylvaleronitrile cyclohexanesulfamate.

Изоаминила Цикламат

$C_{16}H_{24}N_2,C_6H_{13}NO_3S$ = 423.6.
CAS — 10075-36-2.
ATC — R05DB04.
ATC Vet — QR05DB04.

Profile

Isoaminile is a centrally acting cough suppressant. Isoaminile cyclamate has been given orally in doses of 40 to 80 mg up to 5 times daily. For children's doses, see Administration in Children, below. The citrate has also been used.

Administration in children. Isoaminile cyclamate has been given orally in the following doses:
- 1 to 6 years: 20 mg 2 or 3 times daily
- over 6 years: 40 mg 2 or 3 times daily

Preparations

Proprietary Preparations (details are given in Part 3)
Gr.: Peracon†; ***Indon.:*** Peracon; ***S.Afr.:*** Peracon†.

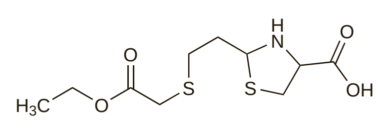
Multi-ingredient: ***S.Afr.:*** Peracon Expectorant†.

Letosteine *(pINN)*

Letosteína; Létostéine; Letosteinum. 2-[2-(Ethoxycarbonylmethylthio)ethyl]thiazolidine-4-carboxylic acid.

Летостеин

$C_{10}H_{17}NO_4S_2$ = 279.4.
CAS — 53943-88-7.
ATC — R05CB09.
ATC Vet — QR05CB09.



Profile

Letosteine is a mucolytic that has been used in the treatment of respiratory disorders associated with productive cough (p.1547).

Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Viscotiol†; ***Spain:*** Broluidan†.

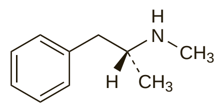
Levmetamfetamine (USAN, rINN) ⊗

l-Deoxyephedrine; L-Desoxiefedrina; L-Desoxyephedrine; Lesoxyephedrine; Levmétamfétamine; Levmetamfetaminum; Levmetanfetamina; Levometanfetamina; *l*-Methamphetamine; *l*-Methylamphetamine. (*R*)-*N*,α-Dimethylbenzeneethanamine; (−)-(*R*)-*N*,α-Dimethylphenethylamine.

Левметамфетамин

$C_{10}H_{15}N$ = 149.2.

CAS — 33817-09-3.



Pharmacopoeias. In *US.*

USP 31 (Levmetamfetamine). A clear, practically colourless, liquid. Store in airtight containers. Protect from light.

Profile

Levmetamfetamine is the *laevo* isomer of metamfetamine (p.2158) and is used topically in the treatment of nasal congestion (p.1548).

Abuse. Levmetamfetamine is a less potent central stimulant than metamfetamine, but it has been subject to occasional abuse.[1,2] In addition, as a stimulant its use is prohibited in sport during competition. However, it is classed by the World Anti-Doping Agency as one of the specified substances particularly susceptible to unintentional anti-doping rule violations because of general availability in medicinal products or which are less likely to be successfully abused as doping agents.[3]

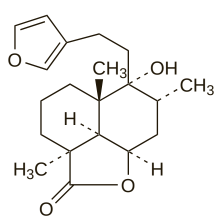
Preparations

Proprietary Preparations (details are given in Part 3)
USA: Vicks Vapor Inhaler.

Marrubium

Andornkraut; Herba Marrubii; Hurtanminttu; Jablečníková nať; Juanrubio; Kransborre; Malva de sapo; Malvarrubia; Marrube blanc, parties aériennes fleuries de; Marrubii herba; Marrubio; Šantrų žolė; White Horehound.

Шандра Обыкновенная



(marrubiin)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (White Horehound). The whole or fragmented dried flowering aerial parts of *Marrubium vulgare*. It contains a minimum 0.7% of marrubiin ($C_{20}H_{28}O_4$ = 332.4), calculated as the dried drug.

Profile

Marrubium is the flower or leaf of *Marrubium vulgare* (Labiatae). It has been used for its supposed expectorant properties in herbal preparations for the treatment of cough. It has also been used as a flavouring.

Preparations

Proprietary Preparations (details are given in Part 3)
Ger.: Angocin Bronchialtropfen.

Multi-ingredient: ***Austral.:*** Broncafect; Verbascum Complex†; ***Austria:*** Asthmatee EF-EM-ES; Gallen- und Lebertee St Severin; ***Canad.:*** Herbal Throat†; Original Herb Cough Drops; Swiss Herb Cough Drops; ***Chile:*** Fucus Compuesto†; ***Cz.:*** Original Schwedenbitter; Species Cholagogae Planta; The Salvat; Zlucnikova Cajova Smes; ***Ital.:*** Altuss; Broncosedina; ***Pol.:*** Amarosal; ***S.Afr.:*** Cough Elixir; ***Spain:*** Natusor Asmaten†; Natusor Broncopul†; ***Switz.:*** Hederix; ***UK:*** Allens Chesty Cough; Asthma & Catarrh Relief; Catarrh-eeze; Chest Mixture; Cough-eeze; Herb and Honey Cough Elixir; Honey & Molasses; Horehound and Aniseed Cough Mixture; Modern Herbals Cough Mixture; Vegetable Cough Remover.

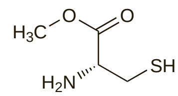
Mecysteine Hydrochloride (BANM, rINNM)

Hidrocloruro de mecisteína; Mécystéine, Chlorhydrate de; Mecysteini Hydrochloridum; Methyl Cysteine Hydrochloride; Methylcysteine Hydrochloride. Methyl L-2-amino-3-mercaptopropionate hydrochloride.

Мецистеина Гидрохлорид

$C_4H_9NO_2S,HCl$ = 171.6.

CAS — 2485-62-3 (mecysteine); 18598-63-5 (mecysteine hydrochloride); 5714-80-7 (mecysteine hydrochloride).



(mecysteine)

Adverse Effects and Precautions

Nausea and heartburn have occasionally been reported. Since mucolytics may disrupt the gastric mucosal barrier mecysteine hydrochloride should be used with caution in patients with a history of peptic ulcer disease.

Uses and Administration

Mecysteine hydrochloride is used as a mucolytic in respiratory disorders associated with productive cough (p.1547). It is given orally in a usual dose of 200 mg three times daily before meals reduced to 200 mg twice daily after 6 weeks. A rapid clinical effect can be achieved by giving 200 mg four times daily for the first 2 days. For children's doses, see Administration in Children, below. Mecysteine has also been given by inhalation.

Administration in children. The recommended oral dose of mecysteine hydrochloride in children aged 5 to 12 years is 100 mg 3 times daily.

Respiratory disorders. Mecysteine hydrochloride given orally has reduced symptoms of cough in patients with chronic bronchitis or other respiratory disorders, but its effect on sputum production and pulmonary function has been variable.[1,2] The use of mucolytics in chronic obstructive pulmonary disease (p.1112) is controversial.

1. Aylward M, *et al.* Clinical therapeutic evaluation of methylcysteine hydrochloride in patients with chronic obstructive bronchitis: a balanced double-blind trial with placebo control. *Curr Med Res Opin* 1978; **5:** 461–71.

Preparations

Proprietary Preparations (details are given in Part 3)
Irl.: Visclair; ***UK:*** Visclair.

Multi-ingredient: ***Ital.:*** Donatiol.

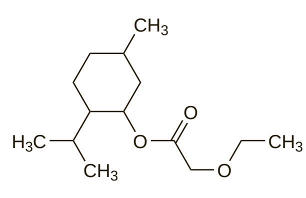
Menglytate (rINN)

Menglitato; Menglytatum; Menthol Ethylglycolate. *p*-Menth-3-yl ethoxyacetate.

Менглитат

$C_{14}H_{26}O_3$ = 242.4.

CAS — 579-94-2.



Profile

Menglytate is an ingredient of a number of preparations promoted for the treatment of cough.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ital.:*** Coryfin C; Neo Borocillina Balsamica.

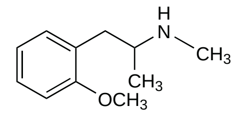
Methoxyphenamine Hydrochloride (BANM, rINNM) ⊗

Hidrocloruro de metoxifenamina; Methoxiphenadrin Hydrochloride; Méthoxyphénamine, Chlorhydrate de; Methoxyphenamini Hydrochloridum; Mexyphamine Hydrochloride. 2-Methoxy-*N*α-dimethylphenethylamine hydrochloride.

Метоксифенамина Гидрохлорид

$C_{11}H_{17}NO,HCl$ = 215.7.

CAS — 93-30-1 (methoxyphenamine); 5588-10-3 (methoxyphenamine hydrochloride).
ATC — R03CB02.
ATC Vet — QR03CB02.



(methoxyphenamine)

Profile

Methoxyphenamine is a sympathomimetic with effects similar to those of ephedrine (p.1558), given orally as the hydrochloride. It has been used as a bronchodilator mainly in combination preparations for the relief of cough and nasal congestion.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Chile:*** Cheracol; ***Hong Kong:*** Asmeton; ***Irl.:*** Casacol; ***Thai.:*** Asmeton†; ***Venez.:*** Metoxifilin.

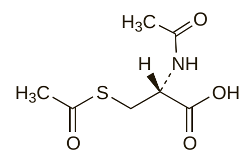
Methyl Dacisteine (rINNM)

Dacisteína de metilo; Dacistéine Méthyle; Dacisteinum Methylis; EL-1035 (dacisteine); Methyl Diacetylcysteinate. Methyl *N*,*S*-diacetyl-L-cysteinate.

Дацистеин Метил

$C_8H_{13}NO_4S$ = 219.3.

CAS — 18725-37-6 (dacisteine); 19547-88-7 (methyl dacisteine).



(dacisteine)

Profile

Like acetylcysteine (p.1548), methyl dacisteine has been used as a mucolytic in respiratory disorders associated with productive cough (p.1547). It has been given orally in a usual dose of 600 mg daily, divided into 3 or 4 doses.

Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Mucothiol; ***Hung.:*** Mucothiol†; ***Ital.:*** Mucothiol.

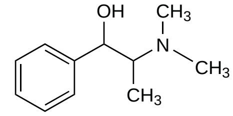
Methylephedrine Hydrochloride (BANM) ⊗

dl-Methylephedrine Hydrochloride; *dl*-*N*-Methylephedrine Hydrochloride; Metilefedrina, hidrocloruro de. (1*RS*,2*RS*)-2-Dimethylamino-1-phenylpropan-1-ol hydrochloride.

Метилэфедрина Гидрохлорид

$C_{11}H_{17}NO,HCl$ = 215.7.

CAS — 552-79-4 ((−)-methylephedrine); 1201-56-5 ((±)-methylephedrine); 38455-90-2 ((−)-methylephedrine hydrochloride); 942-46-1 ((±)-methylephedrine hydrochloride); 18760-80-0 ((±)-methylephedrine hydrochloride).



(methylephedrine)

Pharmacopoeias. In *Jpn.*

Profile

Methylephedrine hydrochloride is a sympathomimetic with effects similar to those of ephedrine (p.1558). It has been used as a bronchodilator and is given orally in combination preparations for the relief of cough and nasal congestion.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austria:*** Tussoretardin; ***Hong Kong:*** Codaewon; ***Jpn:*** Colgen Kowa IB Toumei; Sin Colgen Kowa Kaze; ***S.Afr.:*** Ilvico; ***Switz.:*** Tossamine plus; ***Thai.:*** Coughmin†; Hustazol-C†; Methorcon; ***Venez.:*** Ilvico.

Metizoline Hydrochloride *(BANM, USAN, rINNM)* ⊗

EX-10-781; Hidrocloruro de metizolina; Métizoline, Chlorhydrate de; Metizolini Hydrochloridum; Metyzoline Hydrochloride; RMI-10482A. 2-(2-Methylbenzo[*b*]thienylmethyl)-2-imidazoline hydrochloride.

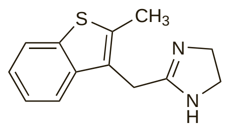
Метизолина Гидрохлорид

$C_{13}H_{14}N_2S,HCl = 266.8.$

CAS — 17692-22-7 (metizoline); 5090-37-9 (metizoline hydrochloride).

ATC — R01AA10.

ATC Vet — QR01AA10.



(metizoline)

NOTE. The name benazoline has been used as a synonym for metizoline. Care should be taken to distinguish it from benazolin (4-chloro-2,3-dihydro-2-oxo-1,3-benzothiazol-3-ylacetic acid, $C_9H_6ClNO_3S = 243.7$), which is a herbicide. Also do not confuse with benzazoline (see Tolazoline, p.1415), which is a vasodilator.

Profile

Metizoline hydrochloride is a sympathomimetic with effects similar to those of naphazoline (p.1565) that has been used for its vasoconstrictor activity in the treatment of nasal congestion.

Morclofone *(rINN)*

Dimeclofenone; Morclofona; Morclofonum; Morclophon. 4′-Chloro-3,5-dimethoxy-4-(2-morpholinoethoxy)benzophenone.

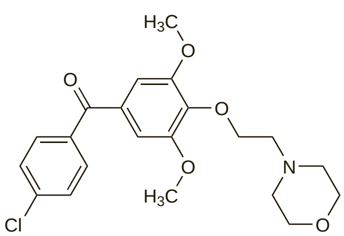
Морклофон

$C_{21}H_{24}ClNO_5 = 405.9.$

CAS — 31848-01-8 (morclofone); 31848-02-9 (morclofone hydrochloride).

ATC — R05DB25.

ATC Vet — QR05DB25.



Profile

Morclofone is a centrally acting cough suppressant used for non-productive cough (p.1547); it is given orally in usual doses of 150 mg four or five times daily. It has also been given as the hydrochloride.

Preparations

Proprietary Preparations (details are given in Part 3)
Ital.: Plausitin; ***Switz.:*** Nitux.

Naphazoline *(BAN, rINN)* ⊗

Nafatsoliini; Nafazolin; Nafazolina; Naphazolinum. 2-(1-Naphthylmethyl)-2-imidazoline.

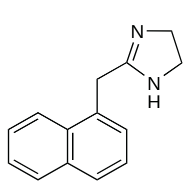
Нафазолин

$C_{14}H_{14}N_2 = 210.3.$

CAS — 835-31-4.

ATC — R01AA08; R01AB02; S01GA01.

ATC Vet — QR01AA08; QR01AB02; QS01GA01.



Naphazoline Hydrochloride *(BANM, rINNM)* ⊗

Hidrocloruro de nafazolina; Nafatsoliinihydrokloridi; Nafazolin Hidroklorür; Nafazolin-hidroklorid; Nafazolin-hydrochlorid; Nafazolinhydroklorid; Nafazolino hidrochloridas; Naphazoline, chlorhydrate de; Naphazolini hydrochloridum.

Нафазолина Гидрохлорид

$C_{14}H_{14}N_2,HCl = 246.7.$

CAS — 550-99-2.

ATC — R01AA08; R01AB02; S01GA01.

ATC Vet — QR01AA08; QR01AB02; QS01GA01.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Naphazoline Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water; soluble in alcohol. Protect from light.

USP 31 (Naphazoline Hydrochloride). A white, odourless, crystalline powder. Freely soluble in water and in alcohol; very slightly soluble in chloroform; practically insoluble in ether. pH of a 1% solution in water is between 5.0 and 6.6. Store in airtight containers. Protect from light.

Naphazoline Nitrate *(BANM, rINNM)* ⊗

Nafatsoliininitraatti; Nafazolin Nitrat; Nafazolinnitrat; Nafazolin-nitrát; Nafazolino nitratas; Nafazoliny azotan; Naphazoline, nitrate de; Naphazolini nitras; Naphazolinium Nitricum; Naphthizinum; Nitrato de nafazolina.

Нафазолина Нитрат

$C_{14}H_{14}N_2,HNO_3 = 273.3.$

CAS — 5144-52-5.

ATC — R01AA08; R01AB02; S01GA01.

ATC Vet — QR01AA08; QR01AB02; QS01GA01.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *Viet.*

Ph. Eur. 6.2 (Naphazoline Nitrate). A white or almost white, crystalline powder. Sparingly soluble in water; soluble in alcohol. A 1% solution in water has a pH of 5.0 to 6.5. Protect from light.

Adverse Effects, Treatment, and Precautions

As for Sympathomimetics, p.1407; naphazoline has mainly alpha-agonist effects. After local use, transient irritation may occur. Rebound congestion may occur after frequent or prolonged use. Systemic effects, including nausea, headache, and dizziness have occurred after topical use. Overdosage or accidental dosage by mouth may cause CNS depression with marked reduction of body temperature and bradycardia, sweating, drowsiness, and coma, particularly in children; it should be used with great caution, if at all, in infants and young children. Use of naphazoline in the eye may liberate pigment granules from the iris, especially when given in high doses to elderly patients. Hypertension may be followed by rebound hypotension. Treatment of adverse effects is symptomatic.

Effects on the eyes. For mention of conjunctivitis induced by ophthalmic decongestant preparations containing naphazoline, see under Phenylephrine, p.1568.

Intraoperative use. A report[1] of 2 cases of toxicity associated with intraoperative use of a naphazoline-soaked sponge to control excessive bleeding after adenoidectomy. Both patients experienced hypertension and reflex bradycardia, which evolved in one case into marked hypotension. There was evidence of CNS depression with a reduced respiration rate and prolonged recovery from anaesthesia.

1. Wenzel S, *et al.* Course and therapy of intoxication with imidazoline derivate naphazoline. *Int J Pediatr Otorhinolaryngol* 2004; **68:** 979–83.

Interactions

Since naphazoline is absorbed through the nasal mucosa interactions may follow topical application. The *BNF* considers that all sympathomimetic nasal decongestants may cause a hypertensive crisis if used during treatment with an MAOI. For the interactions of sympathomimetics in general, see p.1407.

Pharmacokinetics

Systemic absorption has been reported after topical use of solutions of naphazoline. It is not given systemically, but it is readily absorbed from the gastrointestinal tract. Naphazoline instilled into the eye causes conjunctival vasoconstriction within 10 minutes and effects can last for up to 6 hours.

Uses and Administration

Naphazoline is a sympathomimetic (p.1408) with marked alpha-adrenergic activity. It is a vasoconstrictor with a rapid and prolonged action in reducing swelling and congestion when applied to mucous membranes.

Naphazoline and its salts are used for the symptomatic relief of nasal congestion (p.1548). Solutions containing 0.05 to 0.1% of the hydrochloride or the nitrate may be applied topically as nasal drops or a spray usually up to once every 6 hours. Children aged 7 years and over have used a preparation containing 0.05%.

Solutions containing up to 0.1% of naphazoline hydrochloride have been instilled into the eye as a conjunctival decongestant (see Conjunctivitis, p.564).

Naphazoline has been used as a vasoconstrictor with local anaesthetics.

Naphazoline acetate has also been used in nasal preparations.

Preparations

USP 31: Naphazoline Hydrochloride and Pheniramine Maleate Ophthalmic Solution; Naphazoline Hydrochloride Nasal Solution; Naphazoline Hydrochloride Ophthalmic Solution.

Proprietary Preparations (details are given in Part 3)

Arg.: Actifedrin Nasal; Bactio Rhin; Bano Ocular Agrand; Dazolin; Disel; Gotabiotic D; Gotinal; Let-Nasal; Mirasan; Mirus-S; Nafazolex; Nasalex; Privina; Rhinal; ***Austral.:*** Albalon; Clear Eyes†; Naphcon; Optazine†; ***Austria:*** Aconex; Coldan; Isoftal; Mertan; Privin; Rhinon; Rhinoperd; ***Belg.:*** Albalon†; Deltarhinol-Mono; Naphcon; Neusinol; Priciasol; Vasocedine; ***Braz.:*** Clarivit†; Claroft; Multisoro; Narial†; Narix; Nazicol; Neosoro; Privina; Rino Resfenol†; Rinos-A; ***Canad.:*** Ak-Con; Albalon; Allergy Drops; Clear Eyes; Diopticon; Naphcon Forte; Red Away†; Vasocon†; ***Chile:*** Albasol†; Clarimir; Red Off; Vi-Claro†; ***Cz.:*** Proculin†; Sanorin; ***Ger.:*** Idril N sine†; Piniol Nasenspray†; Privin; Proculin; Rhinex mit Naphazolin; Telestulln; ***Gr.:*** Coldan; Naphcon; ***Hong Kong:*** Albalon; All Clear; ***Hung.:*** Naphcon†; Proculin†; ***India:*** Clearine; Ocustress; ***Indon.:*** Optrine; ***Israel:*** Naphasal; Naphcon Forte; ***Ital.:*** Collirio Alfa; Desamin Same; Imidazyl; Iridina Due; Naftazolina; Pupilla; Rinazina; Rino Naftazolina; Video-Mill; Virginiana Gocce Verdi†; ***Malaysia:*** Albalon; ***Mex.:*** Afazol; Alphadinal; Celunaf; Fazolin; Gotinal; Nazil; ***Neth.:*** Albalon; ***NZ:*** Albalon†; Clear Eyes; Naphcon; ***Philipp.:*** Cosooth; ***Pol.:*** Rhinazin; ***Rus.:*** Naphthyzin (Нафтизина)†; Sanorin (Санорин); ***S.Afr.:*** Murine Clear Eyes†; Safyr Bleu; ***Spain:*** Alfa; Euboral; Miraclar; Vasoconstrictor Pensa; ***Swed.:*** Rimidol†; ***Switz.:*** Albalon; Minha†; ***Thai.:*** Albalon; Naphcon; ***Turk.:*** Deltarhinol; Enflucide; ***UK:*** Murine; ***USA:*** Ak-Con; Albalon; All Clear; Allerest†; Allergy Drops†; Clear Eyes; Clear Eyes Plus Redness Relief; Comfort Eye Drops†; Degest†; Nafazair†; Napha Forte; Naphcon; Privine; Vasocon†; ***Venez.:*** Clarasol; Clearize; Fanasal†; Fazolan; Fazonil†; Gotinal; Nafin†; Naphcon; Nas; Niazol; Ninazo.

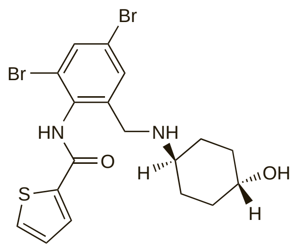
Neltenexine *(rINN)*

Neltenexina; Nelténexine; Neltenexinum. 4′,6′-Dibromo-α-[(*trans*-4-hydroxycyclohexyl)amino]-2-thiophene-carboxy-*o*-toluidide.

Нелтенексин

$C_{18}H_{20}Br_2N_2O_2S$ = 488.2.
CAS — 99453-84-6.
ATC — R05CB14.
ATC Vet — QR05CB14.



Profile

Neltenexine is a mucolytic that has been used in respiratory disorders associated with productive cough (p.1547). It has been given orally as the monohydrate, in usual doses of 37.4 mg three times daily. Neltenexine has also been given rectally as the hydrochloride.

Preparations

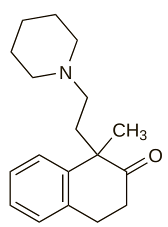
Proprietary Preparations (details are given in Part 3)
Ital.: Alveoten; Muco4; Tenoxol.

Nepinalone *(rINN)*

Nepinalona; Népinalone; Nepinalonum. (±)-3,4-Dihydro-1-methyl-1-(2-piperidinoethyl)-2(1*H*)-napthalenone.

Непиналон

$C_{18}H_{25}NO$ = 271.4.
CAS — 22443-11-4.
ATC — R05DB26.
ATC Vet — QR05DB26.



Profile

Nepinalone has been used as the hydrochloride as a cough suppressant in non-productive cough (p.1547). Oral doses of nepinalone hydrochloride 10 mg have been given three times daily.

Preparations

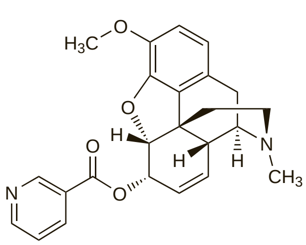
Proprietary Preparations (details are given in Part 3)
Ital.: Nepituss; Placatus; Tussolvina.

Nicocodine *(BAN, rINN)*

Nicocodina; Nicocodinum. 6-Nicotinoylcodeine; 3-*O*-Methyl-6-*O*-nicotinoylmorphine.

Никокодин

$C_{24}H_{24}N_2O_4$ = 404.5.
CAS — 3688-66-2.



Profile

Nicocodine is an opioid related to codeine (p.37). It has been used as the hydrochloride for its central cough suppressant effects in non-productive cough (p.1547). Nicocodine hydrochloride is given orally in doses of 5 to 7.5 mg up to three times daily.

Preparations

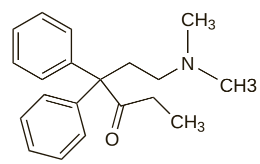
Proprietary Preparations (details are given in Part 3)
Austria: Tusscodin.

Normethadone Hydrochloride *(BANM, rINNM)*

Desmethylmethadone Hydrochloride; Hidrocloruro de normetadona; Hoechst-10582 (normethadone); Norméthadone, Chlorhydrate de; Normethadoni Hydrochloridum; Phenyldimazone Hydrochloride. 6-Dimethylamino-4,4-diphenylhexan-3-one hydrochloride.

Норметадона Гидрохлорид

$C_{20}H_{25}NO,HCl$ = 331.9.
CAS — 467-85-6 (normethadone); 847-84-7 (normethadone hydrochloride).
ATC — R05DA06.
ATC Vet — QR05DA06.



(normethadone)

Profile

Normethadone is closely related to methadone (p.82). The hydrochloride is given orally as a cough suppressant in preparations for non-productive cough.

Preparations

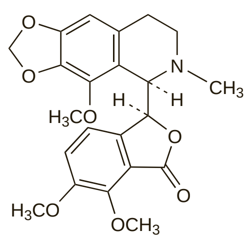
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Canad.:*** Cophylac.

Noscapine *(BAN, rINN)*

Narcotine; L-α-Narcotine; Noscapina; Noscapinum; Noskapiini; Noskapin; Noskapinas; Noszkapin; NSC-5366. (3*S*)-6,7-Dimethoxy-3-[(5*R*)-5,6,7,8-tetrahydro-4-methoxy-6-methyl-1,3-dioxolo[4,5-*g*]isoquinolin-5-yl]phthalide.

Носкапин

$C_{22}H_{23}NO_7$ = 413.4.
CAS — 128-62-1.
ATC — R05DA07.
ATC Vet — QR05DA07.



Description. Noscapine is an alkaloid obtained from opium.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Noscapine). A white or almost white, crystalline powder or colourless crystals. Practically insoluble in water at 20°, very slightly soluble at 100°; slightly soluble in alcohol; soluble in acetone; dissolves in strong acids although the base may be precipitated on dilution with water. Protect from light.

USP 31 (Noscapine). A fine, white or practically white, crystalline powder. Practically insoluble in water; slightly soluble in alcohol and in ether; soluble in acetone; freely soluble in chloroform.

Noscapine Camsilate *(BANM, rINNM)*

Camphoscapine; Camsilato de noscapina; Noscapine, Camsilate de; Noscapine Camsylate; Noscapini Camsilas. Noscapine camphor-10-sulphonate.

Носкапина Камзилат

$C_{22}H_{23}NO_7, C_{10}H_{16}O_4S$ = 645.7.
CAS — 25333-79-3.
ATC — R05DA07.
ATC Vet — QR05DA07.

Noscapine Hydrochloride *(BANM, rINNM)*

Hidrocloruro de noscapina; Narcotine Hydrochloride; Noscapine, chlorhydrate de; Noscapini hydrochloridum; Noscapini Hydrochloridum Monohydricum; Noscapinium Chloride; Noskapiinihydrokloridi; Noskapin hydrochlorid monohydrát; Noskapinhydroklorid; Noskapino hidrochloridas; Noskapiny chlorowodorek; Noszkapin-hidroklorid.

Носкапина Гидрохлорид

$C_{22}H_{23}NO_7,HCl,H_2O$ = 467.9.
CAS — 912-60-7 (anhydrous noscapine hydrochloride).
ATC — R05DA07.
ATC Vet — QR05DA07.

Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* (both with H_2O); in *Jpn* (with xH_2O).

Ph. Eur. 6.2 (Noscapine Hydrochloride). A white or almost white, hygroscopic, crystalline powder or colourless crystals. Freely soluble in water and in alcohol. Aqueous solutions are faintly acid; the base may be precipitated when the solutions are allowed to stand. A 2% solution in water has a pH of not less than 3.0. Protect from light.

Adverse Effects and Precautions

As for Dextromethorphan, p.1555. Hypersensitivity reactions have been reported.

Breast feeding. Maximum concentrations of noscapine in the breast milk of 8 women given 100 or 150 mg of noscapine ranged[1] from 11 to 83 nanograms/mL. It was estimated that breast-fed infants of mothers receiving noscapine 50 mg three times daily would ingest at most 300 nanograms/kg of noscapine, an amount considered unlikely to be a hazard. No adverse effects have been seen in breast-fed infants whose mothers were given noscapine, and the American Academy of Pediatrics[2] considers that it is therefore usually compatible with breast feeding.

Pregnancy. The UK CSM stood by their recommendation[1] that products containing noscapine should be contra-indicated in women of child-bearing potential (because of potential mutagenic effects[2]), after criticism that the decision was based solely on the results of *in-vitro* work.[3]

1. Asscher AW, Fowler LK. Papaveretum in women of childbearing potential. *BMJ* 1991; **303:** 648.
2. Committee on Safety of Medicines. Genotoxicity of papaveretum and noscapine. *Current Problems 31* 1991. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2024449&RevisionSelectionMethod=LatestReleased (accessed 21/03/07)
3. Allen S, *et al.* Papaveretum in women of child bearing potential. *BMJ* 1991; **303:** 647.

Interactions

Noscapine should not be given with alcohol or other CNS depressants.

Anticoagulants. For mention of a possible interaction between noscapine and *warfarin,* see Cough Suppressants, p.1430.

Pharmacokinetics

◊ References.

1. Karlsson MO, *et al.* Pharmacokinetics of oral noscapine. *Eur J Clin Pharmacol* 1990; **39:** 275–9.

Uses and Administration

Noscapine is a centrally acting cough suppressant that has actions and uses similar to those of dextromethorphan (p.1556). It is given in an oral dose of up to 50 mg three times daily. It is also used rectally. Noscapine has also been given as the ascorbate, camsilate, embonate, and the hydrochloride.

Preparations

Proprietary Preparations (details are given in Part 3)
Belg.: Nosca-Mereprine; Noscaflex; Noscafex†; ***Chile:*** Factoss†; ***Ger.:*** Capval; ***Hong Kong:*** Recoma; ***Indon.:*** Longatin; Mercotin; ***Neth.:*** Roter Noscapect; Streptuss kriebelhoest†; ***S.Afr.:*** Nitepax; ***Spain:*** Tuscalman; ***Swed.:*** Nipaxon; ***Switz.:*** Tussanil N.

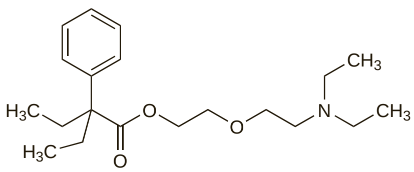
Oxeladin Citrate *(BANM, rINNM)*

Citrato de oxeladina; Okseladiinivetysitraatti; Okseladino-vandenilio citratas; Oxeladin-citrát; Oxéladine, Citrate d'; Oxéladine, hydrogénocitrate d'; Oxeladini Citras; Oxeladini hydrogenocitras; Oxeladinvätecitrat. 2-(2-Diethylaminoethoxy)ethyl 2-ethyl-2-phenylbutyrate dihydrogen citrate.

Окселадина Цитрат

$C_{20}H_{33}NO_3,C_6H_8O_7$ = 527.6.
CAS — 468-61-1 (oxeladin); 52432-72-1 (oxeladin citrate).
ATC — R05DB09.
ATC Vet — QR05DB09.



(oxeladin)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Oxeladin Hydrogen Citrate). A white or almost white, crystalline powder. It exhibits polymorphism. Freely soluble in water; slightly to very slightly soluble in ethyl acetate.

Profile

Oxeladin citrate has been given orally as a centrally acting cough suppressant for non-productive cough (p.1547). Up to 50 mg daily in divided doses has been given orally. Higher doses of up to 120 mg daily have been given as a modified-release preparation.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Elitos; Frenotos; Nadetos; Plardox; ***Fr.:*** Paxeladine.

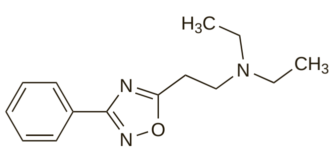
Multi-ingredient: ***Arg.:*** Aseptobron Bromexina; Aseptobron C; Frenotos Muc; Pectoral Lafedar; ***Braz.:*** Novotussan†; Tossivitan†; Tripulmin†; ***Mex.:*** Fluxedan; TheraFlu Tenalif.

Oxolamine *(rINN)*

683-M; Oksolamiini; Oksolamin; Oxolamin; Oxolamina; Oxolaminum. 5-[2-(Diethylamino)ethyl]-3-phenyl-1,2,4-oxadiazole.

Оксоламин

$C_{14}H_{19}N_3O$ = 245.3.
CAS — 959-14-8.
ATC — R05DB07.
ATC Vet — QR05DB07.



Oxolamine Citrate *(rINNM)*

AF-438; Citrato de oxolamina; Oxolamine, Citrate d'; Oxolamini Citras; SKF-9976.

Оксоламина Цитрат

$C_{14}H_{19}N_3O,C_6H_8O_7$ = 437.4.
CAS — 1949-20-8.
ATC — R05DB07.
ATC Vet — QR05DB07.

Oxolamine Phosphate *(rINNM)*

Fosfato de oxolamina; Oxolamine, Phosphate d'; Oxolamini Phosphas.

Оксоламина Фосфат

CAS — 1949-19-5.
ATC — R05DB07.
ATC Vet — QR05DB07.

Profile

Oxolamine is a cough suppressant with a mainly peripheral action that has been used for non-productive cough (p.1547). It has been given as the citrate in usual oral doses of 100 to 200 mg three times daily. The phosphate has been used similarly. It has also been given as the tannate.

Hallucinations in children have been reported after oxolamine use.

◊ References.

1. McEwen J, *et al.* Hallucinations in children caused by oxolamine citrate. *Med J Aust* 1989; **150:** 449–52.

Interactions. *ANTICOAGULANTS.* For mention of a possible interaction between oxolamine and *warfarin*, see Cough Suppressants, p.1430.

Preparations

Proprietary Preparations (details are given in Part 3)
Chile: Numosol; Perebron; Respibron; Tulox; ***Israel:*** Symphocal; ***Ital.:*** Gantrimex†; Perebron; Tussibron; ***Mex.:*** Aledron; Bredon; Contuxin; Eumol; Expecmin; Fartoxol†; Kentosanil†; Oxathos; Oxobron; Oxomar; Oxomifer; Oxotus; Oxotusin; Toxal†; Tukson†; ***Turk.:*** Kalamin; Oksabron; Perbrons; Perebron; Sekodin; Subitol; ***Venez.:*** Broxol; Cafox; Calcimonio; Citralamina; Exeton†; Lexo; Opilina; Oxalcor; Oxolam†; Oxotil; Perebron; Toxolen†.

Multi-ingredient: ***Ital.:*** Uniplus; ***Mex.:*** Caltusine; Caobe; ***Turk.:*** Forza; Katarin; Katarin Forte; Oledro; ***Venez.:*** Broxamel†; Opilina Compuesta; Oxolavin Compuesto; Perebron con Miel†.

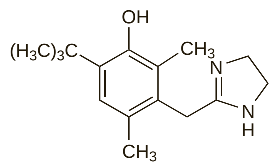
Oxymetazoline Hydrochloride

(BANM, USAN, rINNM) ⊗

H-990; Hidrocloruro de oximetazolina; Oksimetatsoliinihydrokloridi; Oksimetazolin Hidroklorür; Oksimetazolino hidrochloridas; Oximetazolin-hidroklorid; Oximetazolinhydroklorid; Oxymetazolin hydrochlorid; Oxymétazoline, chlorhydrate d'; Oxymetazolini hydrochloridum; Sch-9384.

Оксиметазолина Гидрохлорид

$C_{16}H_{24}N_2O,HCl$ = 296.8.
CAS — 2315-02-8.
ATC — R01AA05; R01AB07; S01GA04.
ATC Vet — QR01AA05; QR01AB07; QS01GA04.



(oxymetazoline)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Oxymetazoline Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water and in alcohol.

USP 31 (Oxymetazoline Hydrochloride). A white to practically white, fine, hygroscopic, crystalline powder. Soluble 1 in 6.7 of water, 1 in 3.6 of alcohol, and 1 in 862 of chloroform; practically insoluble in ether and in benzene. pH of a 5% solution in water is between 4.0 and 6.5. Store in airtight containers.

Adverse Effects and Precautions

As for Naphazoline, p.1565.

Porphyria. Oxymetazoline has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Interactions

Since oxymetazoline is absorbed through the mucosa interactions may follow topical application. The *BNF* considers that all sympathomimetic nasal decongestants may cause a hypertensive crisis if used during treatment with an MAOI. For the interactions of sympathomimetics in general, see p.1407.

Uses and Administration

Oxymetazoline is a direct-acting sympathomimetic (p.1408) with marked alpha-adrenergic activity. It is a vasoconstrictor and reduces swelling and congestion when applied to mucous membranes. It acts within a few minutes and the effect lasts for up to 12 hours. It is used as the hydrochloride for the symptomatic relief of nasal congestion (p.1548). In adults and children over 6 years, a 0.05% solution of oxymetazoline hydrochloride is applied topically as nasal drops or a spray, usually 2 or 3 times daily to each nostril as required. Over-the-counter cough and cold preparations containing sympathomimetic decongestants (including oxymetazoline) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547).

A 0.025% solution of oxymetazoline hydrochloride may be instilled into the eye every 6 hours when necessary as a conjunctival decongestant in adults and children over 6 years (see Conjunctivitis, p.564).

Preparations

USP 31: Oxymetazoline Hydrochloride Nasal Solution; Oxymetazoline Hydrochloride Ophthalmic Solution.

Proprietary Preparations (details are given in Part 3)

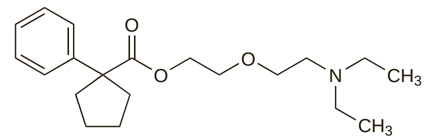
Pentoxyverine *(BAN, rINN)*

Carbetapentane; Pentoksiveriini; Pentoxiverin; Pentoxiverina; Pentoxyvérine; Pentoxyverinum. 2-[2-(Diethylamino)ethoxy]ethyl 1-phenylcyclopentanecarboxylate.

Пентоксиверин

$C_{20}H_{31}NO_3$ = 333.5.
CAS — 77-23-6.
ATC — R05DB05.
ATC Vet — QR05DB05.



Pentoxyverine Citrate *(BANM, rINNM)*

Carbetapentane Citrate; Citrato de pentoxiverina; Pentoksiveriinivetysitraatti; Pentoksiverino-vandenilio citratas; Pentoxiverin-hidrogén-citrát; Pentoxiverinvätecitrat; Pentoxyverin-citrát; Pentoxyvérine, Citrate de; Pentoxyverine Hydrogen Citrate; Pentoxyvérine, hydrogénocitrate de; Pentoxyverini Citras; Pentoxyverini hydrogenocitras; UCB-2543.

Пентоксиверина Цитрат

$C_{20}H_{31}NO_3,C_6H_8O_7$ = 525.6.
CAS — 23142-01-0.
ATC — R05DB05.
ATC Vet — QR05DB05.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn.*

Ph. Eur. 6.2 (Pentoxyverine Hydrogen Citrate; Pentoxyverine Citrate BP 2008). A white or almost white crystalline powder. M.p. about 93°. Freely soluble in water and in methyl alcohol; soluble in alcohol and in dichloromethane; very soluble in glacial acetic acid. A 10% solution in water has a pH of 3.3 to 3.7. Protect from light.

Pentoxyverine Hydrochloride *(BANM)*

Pentoksiverin Hidroklorür; Pentoxiverina, hidrocloruro de.

Пентоксиверина Гидрохлорид

$C_{20}H_{31}NO_3,HCl$ = 369.9.
CAS — 1045-21-2.
ATC — R05DB05.
ATC Vet — QR05DB05.

Profile

Pentoxyverine is a centrally acting cough suppressant used for non-productive cough (p.1547). Usual doses of up to 180 mg daily of the citrate or hydrochloride have been given orally in divided doses. The tannate is also given orally and the base has been given rectally.

Preparations

Proprietary Preparations (details are given in Part 3)

Phenylephrine *(BAN, rINN)*

Fenilefrin; Fenilefrina; Fenilefrinas; Fenylefrin; Fenyyliefriini; Phényléphrine; Phenylephrinum; *m*-Synephrine. (1*R*)-1-(3-Hydroxyphenyl)-2-methylaminoethanol.

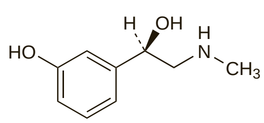
Фенилэфрин

$C_9H_{13}NO_2$ = 167.2.

CAS — 59-42-7.

ATC — C01CA06; R01AA04; R01AB01; R01BA03; S01FB01; S01GA05.

ATC Vet — QC01CA06; QR01AA04; QR01AB01; QR01BA03; QS01FB01; QS01GA05.



NOTE. Synephrine has been used as a synonym for oxedrine (p.1364). Care should be taken to avoid confusion with phenylephrine (*m*-synephrine).

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Phenylephrine). A white or almost white crystalline powder. Slightly soluble in water and in alcohol; sparingly soluble in methyl alcohol. It dissolves in dilute mineral acids and in solutions of alkali hydroxides. Store in airtight containers. Protect from light.

Phenylephrine Acid Tartrate

Phenylephrine Bitartrate *(rINNM)*; Bitartrato de fenilefrina; Phényléphrine, Bitartrate de; Phenylephrine Tartrate *(BANM)*; Phenylephrini Bitartras; Tartrato ácido de fenilefrina.

Фенилэфрина Битартрат

$C_9H_{13}NO_2,C_4H_6O_6$ = 317.3.

CAS — 13998-27-1.

ATC — C01CA06; R01AA04; R01AB01; R01BA03; S01FB01; S01GA05.

ATC Vet — QC01CA06; QR01AA04; QR01AB01; QR01BA03; QS01FB01; QS01GA05.

Pharmacopoeias. In *US.*

USP 31 (Phenylephrine Bitartrate). A white or almost white powder or colourless crystals. Freely soluble in water. pH of a 10% solution in water is between 3.0 and 4.0. Store in airtight containers. Protect from light.

Phenylephrine Hydrochloride *(BANM, rINNM)*

Fenilefrin Hidroklorür; Fenilefrin-hidroklorid; Fenilefrino hidrochloridas; Fenylefrin hydrochlorid; Fenylefrinhydroklorid; Fenylefryny chlorowodorek; Fenyyliefriinihydrokloridi; Hidrocloruro de fenilefrina; Mesatonum; Metaoxedrini Chloridum; Phényléphrine, chlorhydrate de; Phenylephrini hydrochloridum.

Фенилэфрина Гидрохлорид

$C_9H_{13}NO_2,HCl$ = 203.7.

CAS — 61-76-7.

ATC — C01CA06; R01AA04; R01AB01; R01BA03; S01FB01; S01GA05.

ATC Vet — QC01CA06; QR01AA04; QR01AB01; QR01BA03; QS01FB01; QS01GA05.

NOTE. PHNL is a code approved by the BP 2008 for use on single unit doses of eye drops containing phenylephrine hydrochloride where the individual container may be too small to bear all the appropriate labelling information. PHNCYC is a similar code approved for eye drops containing phenylephrine hydrochloride and cyclopentolate hydrochloride.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Phenylephrine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water and in alcohol.

USP 31 (Phenylephrine Hydrochloride). White or practically white, odourless, crystals. Freely soluble in water and in alcohol. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°. Protect from light.

Incompatibility. Phenylephrine is stated to be incompatible with the local anaesthetic butacaine.

Adverse Effects and Precautions

As for Sympathomimetics, p.1407; phenylephrine has mainly alpha-agonist effects. It has a longer duration of action than noradrenaline and an excessive vasopressor response may cause a prolonged rise in blood pressure. It induces tachycardia or reflex bradycardia and should therefore be avoided in severe hyperthyroidism and used with caution in severe ischaemic heart disease. Patients with diabetes mellitus or prostatic hyperplasia should also avoid phenylephrine.

Since phenylephrine is absorbed through the mucosa systemic effects may follow application to the eyes or the nasal mucosa. In particular, phenylephrine 10% eye drops can have powerful systemic effects. They should be avoided or only used with extreme caution in infants, the elderly, and in patients with cardiac disease, significant hypertension, or advanced arteriosclerosis. Fatalities have been reported in patients with pre-existing cardiovascular disease.

Use of phenylephrine in the eye may liberate pigment granules from the iris, especially when given in high doses to elderly patients. Ophthalmic solutions of phenylephrine are contra-indicated in patients with angle-closure glaucoma. Corneal clouding may occur if corneal epithelium has been denuded or damaged.

Excessive or prolonged use of phenylephrine nasal drops can lead to rebound congestion.

Phenylephrine hydrochloride is irritant and may cause local discomfort at the site of application; extravasation of the injection may even cause local tissue necrosis.

Effects on the cardiovascular system. Systemic adverse effects have occurred after the use of phenylephrine as eye drops (particularly at a strength of 10%), or nasal drops.

Hypertension[1] and hypertension with pulmonary oedema[2] have been described in infants and children after the use of phenylephrine 10% eye drops. Hypertension with arrhythmias has also been reported in an 8-year-old child[3] and in an adult[4] after phenylephrine 10% eye drops had been used. Details have also been published on a series of 32 patients who had systemic cardiovascular reactions, including fatal myocardial infarctions, after the use of phenylephrine 10% solutions in the eye.[5] Severe cardiovascular adverse reactions have also been reported to the use of phenylephrine as topical 10% ocular[6] or 0.25% nasal[7] pledgets. Although the incidence of such reactions seems low,[8] the use of lower concentrations[1,5] and caution in susceptible patients such as those with cardiovascular disorders or the elderly,[5] have been advocated. A reduction in the eye-drop volume has been found to produce adequate mydriasis and may reduce systemic absorption and the risk of adverse cardiovascular effects.[9,10]

10. Wheatcroft S, *et al.* Reduction in mydriatic drop size in premature infants. *Br J Ophthalmol* 1993; **77:** 364–5.

Effects on the eyes. Acute and chronic conjunctivitis has been reported[1] after use of over-the-counter ophthalmic decongestant preparations of phenylephrine, naphazoline, or tetryzoline. The conjunctival inflammation took several weeks to resolve in some cases. Dermatoconjunctivitis[2] has also been reported after use of phenylephrine eye drops.

1. Soparkar CN, *et al.* Acute and chronic conjunctivitis due to over-the-counter ophthalmic decongestants. *Arch Ophthalmol* 1997; **115:** 34–8.
2. Moreno-Ancillo A, *et al.* Allergic contact reactions due to phenylephrine hydrochloride in eyedrops. *Ann Allergy Asthma Immunol* 1997; **78:** 569–72.

Effects on mental function. Hallucinations and paranoid delusions have been reported[1] in a patient after excessive use of a nasal spray containing phenylephrine 0.5%. Mania has also followed the use of large oral doses.[2]

2. Waters BGH, Lapierre YD. Secondary mania associated with sympathomimetic drug use. *Am J Psychiatry* 1981; **138:** 837–40.

Hypersensitivity. Cross-sensitivity to phenylephrine has been reported in a patient hypersensitive to pseudoephedrine.[1] See also Effects on the Eyes, above.

1. Buzo-Sanchez G, *et al.* Stereoisomeric cutaneous hypersensitivity. *Ann Pharmacother* 1997; **31:** 1091.

Interactions

As for Sympathomimetics, p.1407. Phenylephrine has mainly direct alpha-agonist properties and is less liable than adrenaline or noradrenaline to induce ventricular fibrillation if used as a pressor agent during anaesthesia with inhalational anaesthetics such as cyclopropane and halothane; nevertheless, caution is necessary. Since phenylephrine is absorbed through the mucosa, interactions may also follow topical application, particularly in patients receiving an MAOI (including a RIMA). See also under Phenelzine (p.418) and Moclobemide (p.411).

Cardiovascular drugs. Hypertensive reactions have been reported in a patient stabilised on *debrisoquine* when given phenylephrine orally,[1] in patients receiving *reserpine* or *guanethidine* when given phenylephrine eye drops,[2] and a fatal reaction occurred in a patient receiving *propranolol* and *hydrochlorothiazide* also after the instillation of phenylephrine eye drops.[3]

1. Aminu J, *et al.* Interaction between debrisoquine and phenylephrine. *Lancet* 1970; **ii:** 935–6.
2. Kim JM, *et al.* Hypertensive reactions to phenylephrine eyedrops in patients with sympathetic denervation. *Am J Ophthalmol* 1978; **85:** 862–8.
3. Cass E, *et al.* Hazards of phenylephrine topical medication in persons taking propranolol. *Can Med Assoc J* 1979; **120:** 1261–2.

Pharmacokinetics

Phenylephrine has low oral bioavailability owing to irregular absorption and first-pass metabolism by monoamine oxidase in the gut and liver. When injected subcutaneously or intramuscularly it takes 10 to 15 minutes to act; subcutaneous and intramuscular injections are effective for up to about 1 hour and up to about 2 hours, respectively. Intravenous injections are effective for about 20 minutes.

Systemic absorption follows topical application.

Uses and Administration

Phenylephrine hydrochloride is a sympathomimetic (p.1408) with mainly direct effects on adrenergic receptors. It has mainly alpha-adrenergic activity and is without significant stimulating effects on the CNS at usual doses. Its pressor activity is weaker than that of noradrenaline (p.1360) but of longer duration. After injection it produces peripheral vasoconstriction and increased arterial pressure; it also causes reflex bradycardia. It reduces blood flow to the skin and to the kidneys.

Phenylephrine and its salts are most commonly used, either topically or by mouth, for the symptomatic relief of **nasal congestion** (p.1548). They are frequently included in preparations intended for the relief of cough and cold symptoms. For nasal congestion, a 0.25 to 1% solution may be instilled as nasal drops or a spray into each nostril every 4 hours as required, or phenylephrine hydrochloride may be given in usual oral doses of 10 mg every four hours (up to a maximum of 60 mg daily) or 12 mg up to four times daily.

In ophthalmology, phenylephrine hydrochloride is used as a **mydriatic** (p.1874) in concentrations of up to 10%; generally solutions containing 2.5 or 10% are used but systemic absorption can occur (see Effects on the Cardiovascular System, above) and the 10% strength, in particular, should be used with caution. The mydriatic effect can last several hours. Solutions containing 2.5% or more may cause intense irritation and a local anaesthetic other than butacaine (which is incompatible) should be instilled into the eye a few minutes beforehand.

Ocular solutions containing lower concentrations (usually 0.12% phenylephrine hydrochloride) are used as a **conjunctival decongestant** (see Conjunctivitis, p.564).

Phenylephrine has been used parenterally in the treatment of hypotensive states, such as those encountered during circulatory failure or spinal anaesthesia. Phenylephrine has also been used in orthostatic hypotension (see under Fludrocortisone, p.1530). For **hypotension**, an initial dose of phenylephrine hydrochloride 2 to 5 mg may be given as a 1% solution subcutaneously or intramuscularly with further doses of 1 to 10 mg if necessary, according to response. A dose of 100 to 500 micrograms by slow intravenous injection as a 0.1% solution, repeated as necessary after at least 15 minutes, has also been used. In severe hypotensive states, 10 mg in 500 mL of glucose 5% or sodium chloride 0.9% has been infused intravenously, initially at a rate of up to 180 micrograms/minute, reduced, according to the response, to 30 to 60 micrograms/minute.

For children's doses, see Administration in Children, below.

Phenylephrine hydrochloride has been given by intravenous injection to stop **paroxysmal supraventricular tachycardia** but other drugs are preferred (see Cardiac Arrhythmias, p.1160). The initial dose is usually not greater than 500 micrograms given as a 0.1% solution with subsequent doses gradually increased in increments of 100 to 200 micrograms up to 1 mg if necessary.

Phenylephrine hydrochloride has been used for its vasoconstrictor action as an **adjunct** to local anaesthetics.

Phenylephrine has also been used as the acid tartrate to prolong the bronchodilator effects of isoprenaline when given by inhalation. However, isoprenaline is now little used by this route.

Phenylephrine tannate has also been used.

Administration in children. Phenylephrine hydrochloride is used for the symptomatic relief of **nasal congestion**; however, over-the-counter cough and cold preparations containing sympathomimetic decongestants (including phenylephrine) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547). In the USA, the following doses have been used in children:

- 2 to 6 years: 2 or 3 drops of a 0.125% or 0.16% solution into each nostril every four hours as needed
- 6 to 12 years: 2 or 3 drops, or 1 or 2 sprays, of a 0.25% solution may be instilled into each nostril every four hours as needed.

In the UK, oral preparations for nasal congestion associated with colds and hay fever are not licensed in children under 12 years of age.

Phenylephrine is used for **mydriasis** in diagnostic or therapeutic procedures. Solutions containing 2.5% are used in children as the 10% strength is contra-indicated owing to the risk of systemic effects.

For acute **hypotension**, the *BNFC* states that phenylephrine hydrochloride may be given subcutaneously or intramuscularly in the following doses:

- 1 to 12 years: 100 micrograms/kg every 1 to 2 hours as needed (to a maximum dose of 5 mg)
- 12 to 18 years: 2 to 5 mg, followed if necessary by further doses of 1 to 10 mg (maximum initial dose 5 mg)

Although the intravenous route is not licensed in the UK for such use in children, intravenous injection is preferred to the other parenteral routes; the *BNFC* recommends the following doses given as a 0.1% solution:

- 1 to 12 years: 5 to 20 micrograms/kg (maximum 500 micrograms), repeated as needed after at least 15 minutes.
- 12 to 18 years: 100 to 500 micrograms, repeated as needed after at least 15 minutes

For intravenous infusion, the solution is diluted with glucose 5% or sodium chloride 0.9% to a concentration of 20 micrograms/mL and given as a continuous infusion via a central venous catheter. The *BNFC* gives the following doses:

- 1 to 16 years: 100 to 500 nanograms/kg per minute, adjusted according to response
- 16 to 18 years: initially up to 180 micrograms/minute, reduced to 30 to 60 micrograms/minute according to response

Faecal incontinence. Topical application of phenylephrine gel has been shown to increase resting anal tone[1] and has been investigated in patients with faecal incontinence.[2] Although application of a 10% gel did not appear to be of clinical benefit in a double-blind crossover study in 36 patients with faecal incontinence caused by internal sphincter dysfunction,[3] continence was improved in another small study in patients with ileoanal pouches.[4]

3. Carapeti EA, *et al.* Randomized controlled trial of topical phenylephrine in the treatment of faecal incontinence. *Br J Surg* 2000; **87:** 38–42.
4. Carapeti EA, *et al.* Randomized, controlled trial of topical phenylephrine for fecal incontinence in patients after ileoanal pouch construction. *Dis Colon Rectum* 2000; **43:** 1059–63.

Nasal congestion. A meta-analysis concluded that there was insufficient evidence that phenylephrine 10 mg was an effective oral decongestant.[1]

1. Hatton RC, *et al* Efficacy and safety of oral phenylephrine: systematic review and meta-analysis. *Ann Pharmacother* 2007; **41:** 381–90.

Priapism. Alpha agonists, including phenylephrine, may be used in the management of priapism (see under Metaraminol, p.1333). For reference to phenylephrine in low dosage and dilute solution being given by intracavernosal injection to reverse priapism, see under Alprostadil, p.2184.

Preparations

BP 2008: Phenylephrine Eye Drops; Phenylephrine Injection;
USP 31: Antipyrine, Benzocaine, and Phenylephrine Hydrochloride Otic Solution; Isoproterenol Hydrochloride and Phenylephrine Bitartrate Inhalation Aerosol; Phenylephrine Hydrochloride Injection; Phenylephrine Hydrochloride Nasal Jelly; Phenylephrine Hydrochloride Nasal Solution; Phenylephrine Hydrochloride Ophthalmic Solution.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: numerous preparations are listed in Part 3.

Used as an adjunct in: ***Braz.:*** Anestesico.

Phenylpropanolamine *(BAN, rINN)*

Fenilpropanolamina; Fennylpropanolamin; Fenyylipropanoliamiini; (±)-Norephedrine; Phénylpropanolamine; Phenylpropanolaminum. (1*RS*,2*SR*)-2-Amino-1-phenylpropan-1-ol.

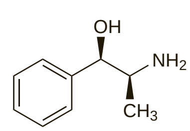
Фенилпропаноламин

$C_9H_{13}NO$ = 151.2.

CAS — 14838-15-4.

ATC — R01BA01.

ATC Vet — QG04BX91; QR01BA01.



(+)-Form

NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of phenylpropanolamine: Pseudocaine.

Phenylpropanolamine Hydrochloride

(BANM, rINNM)

Fenilpropanolamin-hidroklorid; Fenilpropanolamino hidrochloridas; Fenylpropanolamin hydrochlorid; Fenylpropanolaminhydroklorid; Fenyylipropanoliamiinihydrokloridi; Hidrocloruro de fenilpropanolamina; Mydriatin; Phénylpropanolamine, chlorhydrate de; Phenylpropanolamini Hydrochloridum; Phenylpropanolamini hydrochloridum.

Фенилпропаноламина Гидрохлорид

$C_9H_{13}NO,HCl$ = 187.7.

CAS — 154-41-6.

ATC — R01BA01.

ATC Vet — QG04BX91; QR01BA01.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

US also includes phenylpropanolamine bitartrate.

Ph. Eur. 6.2 (Phenylpropanolamine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water and in alcohol; practically insoluble in dichloromethane.

USP 31 (Phenylpropanolamine Hydrochloride). A white crystalline powder, having a slight aromatic odour. Soluble 1 in 1.1 of water, 1 in 7.4 of alcohol, and 1 in 4100 of chloroform; insoluble in ether. pH of a 3% solution in water is between 4.2 and 5.5. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

As for Ephedrine, p.1558.

Severe hypertensive episodes have followed phenylpropanolamine ingestion (see below). As with other indirect-acting sympathomimetics, tolerance to the therapeutic effects of phenylpropanolamine has been reported with prolonged use.

◊ An extensive and detailed review[1] of adverse effects attributed to phenylpropanolamine noted in 1990 that many of the adverse drug reactions reported in Europe described an alteration of mental status whereas those in North America were more often compatible with hypertension. The author suggested that this might be due to a difference in the isomers present in phenylpropanolamine preparations, based on earlier reports that *d*-norpseudoephedrine, the most potent of several isomeric forms as a stimulant of the CNS, was present in European preparations of phenylpropanolamine. However, later investigation suggests that currently the racemic mixture (±)-norephedrine (*d*,*l*-norephedrine) is the isomeric form present in commercial preparations in both Europe and the USA.[2]

The original review[1] concentrated on North American cases. The majority of products available were decongestants or cough or cold remedies; a small number were promoted as diet aids.

The data suggested that over-the-counter (OTC) products were more likely to be associated with an adverse reaction than a prescription medication; this may be because such OTC products were more likely to be overused and to be considered innocuous by the patient. It was also likely that drug interactions (below) rather than 'true overdosages' were involved in many of the adverse events, particularly as many OTC preparations contain other ingredients. (See also Abuse under Ephedrine, p.1558, for further discussion about the consequences of use of OTC preparations containing sympathomimetics, including phenylpropanolamine.)

The adverse reactions varied widely ranging from headache and elevated blood pressure to cardiopulmonary arrest, intracranial haemorrhage, and death. Mild reactions included blurred vision, dizziness, anxiety, agitation, tremor, confusion, and hypersensitivity reaction. Severe reactions included hypertensive crisis with hypertensive encephalopathy, seizures, arrhythmias, psychosis, and acute tubular necrosis. One unifying theme of many of the severe cases was that high blood pressure or symptoms suggestive of this were the presenting feature; an acute, persistent, severe headache was also noted in many cases.

It was pointed out that overall phenylpropanolamine was relatively safe. Although billions of doses were consumed annually, few cases of adverse drug reactions had been reported.

It was believed that certain groups may be at particular risk of adverse reactions to phenylpropanolamine: persons with elevated blood pressure, overweight persons (who are likely to be both hypertensive and to use diet aids), patients with eating disorders (who tend to abuse substances including diet aids), and the elderly (who may be multiple drug takers and likely to be hypertensive and at risk already of a stroke).

Subsequently, after a large case-control study in the USA which found an increased risk of haemorrhagic stroke associated with the use of preparations containing phenylpropanolamine (and in particular in women who used phenylpropanolamine as an appetite suppressant),[3] the FDA took steps to remove phenylpropanolamine from all drug products in the USA and requested that it no longer be marketed. Products containing phenylpropanolamine have also been withdrawn in some other countries. However, this study and the FDA decision have been criticised[4-6] notably on the basis that there was no evidence of an increased risk with the amount of phenylpropanolamine normally present in decongestant preparations and the study may have been subject to confounding. The UK CSM[7] considered that the evidence of a link between UK products containing phenylpropanolamine and haemorrhagic stroke was weak (phenylpropanolamine is not licensed as an appetite suppressant in the UK and the maximum recommended dose of 100 mg daily was lower than the 150 mg daily recommended in the USA). It was therefore suggested by UK commentators that use of licensed doses, with appropriate precautions, posed no additional risk.[2] However, subsequently, UK preparations containing phenylpropanolamine have either been reformulated (mainly with pseudoephedrine) or withdrawn by the manufacturers.

Interactions

As for Sympathomimetics, p.1407. For a comment that drug interactions were likely to have been involved in many adverse events associated with phenylpropanolamine see under Adverse Effects and Precautions, above. Due to its indirect action, hypertensive crisis is a particular risk in patients receiving MAOIs.

Amantadine. Severe psychosis has been reported[1] in a woman taking amantadine with phenylpropanolamine. In another report,[2] a 39-year-old man had intense and recurrent *déjà vu* experiences after taking amantadine with phenylpropanolamine for viral influenza. The effect ceased when he stopped both drugs. The authors suggested that his symptoms were due to increased dopamine activity caused by the combination.

1. Stroe AE, *et al.* Psychotic episode related to phenylpropanolamine and amantadine in a healthy female. *Gen Hosp Psychiatry* 1995; **17:** 457–8.
2. Taiminen T, Jääskeläinen SK. Intense and recurrent déjà vu experiences related to amantadine and phenylpropanolamine in a healthy male. *J Clin Neurosci* 2001; **8:** 460–2.

Antipsychotics. A 27-year-old woman with schizophrenia and T-wave abnormality of the heart, who had responded to *thioridazine* 100 mg daily with procyclidine 2.5 mg twice daily, died from ventricular fibrillation within 2 hours of taking a single dose of a preparation reported to contain chlorphenamine maleate 4 mg with phenylpropanolamine hydrochloride 50 mg (*Contac C*), concurrently with thioridazine.[1]

1. Chouinard G, *et al.* Death attributed to ventricular arrhythmia induced by thioridazine in combination with a single Contac C capsule. *Can Med Assoc J* 1978; **119:** 729–31.

Antivirals. A patient taking an over-the-counter nasal decongestant preparation containing phenylpropanolamine and clemastine as well as a triple-drug HIV prophylactic regimen, had a hypertensive crisis 3 days after *stavudine* was substituted for *zidovudine*;[1] the other antivirals in the regimen were *indinavir* and *lamivudine*.

1. Khurana V, *et al.* Hypertensive crisis secondary to phenylpropanolamine interacting with triple-drug therapy for HIV prophylaxis. *Am J Med* 1999; **106:** 118–19.

Bromocriptine. For a report of hypertension and life-threatening complications after use of phenylpropanolamine with bromocriptine, see Sympathomimetics, p.800.

NSAIDs. A 27-year-old woman who had been taking D-phenylpropanolamine [sic] 85 mg daily for some months, experienced severe hypertension when she also took *indometacin* 25 mg. It was considered that the inhibition of prostaglandin synthesis by indometacin might have caused enhancement of the sympathomimetic effect of phenylpropanolamine.[1]

1. Lee KY, *et al.* Severe hypertension after ingestion of an appetite suppressant (phenylpropanolamine) with indomethacin. *Lancet* 1979; **i:** 1110–11.

Pharmacokinetics

Phenylpropanolamine is readily and completely absorbed from the gastrointestinal tract, peak plasma concentrations being achieved about 1 or 2 hours after oral doses. It undergoes some metabolism in the liver, to an active hydroxylated metabolite, but up to 80 to 90% of a dose is excreted unchanged in the urine within 24 hours. The half-life has been reported to be about 3 to 5 hours.

Uses and Administration

Phenylpropanolamine is a mainly indirect-acting sympathomimetic (p.1408) with an action similar to that of ephedrine (p.1559) but less active as a CNS stimulant.

Phenylpropanolamine has been given orally as the hydrochloride for the symptomatic treatment of **nasal congestion** (p.1548). It has frequently been used in combination preparations for the relief of cough and cold symptoms.

In the management of nasal congestion, phenylpropanolamine hydrochloride has been given in oral doses of up to 50 mg twice daily as modified-release preparations.

Other uses of phenylpropanolamine have included the control of urinary incontinence in some patients (see p.2180). It has also been given in the management of some forms of priapism (see under Metaraminol, p.1333). Phenylpropanolamine has been used to suppress appetite in the management of obesity (p.2149) but the use of stimulants is no longer recommended.

Phenylpropanolamine polistirex (a phenylpropanolamine and sulfonated diethenylbenzene-ethenylbenzene copolymer complex) has also been used, as have phenylpropanolamine bitartrate, phenylpropanolamine maleate, and phenylpropanolamine sulfate.

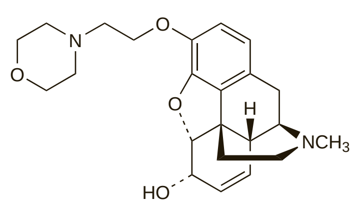
Pholcodine *(BAN, rINN)*

Folcodina; Folkodiini; Folkodin; Folkodin monohydrát; Folkodinas; Pholcodinum; Pholcodinum Monohydricum. 3-*O*-(2-Morpholinoethyl)morphine monohydrate.

Фолкодин

$C_{23}H_{30}N_2O_4,H_2O = 416.5.$
CAS — 509-67-1 (anhydrous pholcodine).
ATC — R05DA08.
ATC Vet — QR05DA08.



Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).
Ph. Eur. 6.2 (Pholcodine). A white or almost white crystalline powder or colourless crystals. Sparingly soluble in water; freely soluble in alcohol and in acetone; dissolves in dilute mineral acids.

Adverse Effects and Precautions

As for Dextromethorphan, p.1555. Constipation, drowsiness, and skin rashes have been reported occasionally.

Interactions

Use of pholcodine with alcohol or other CNS depressants may increase the effects on the CNS.

Uses and Administration

Pholcodine is a centrally acting cough suppressant that has actions and uses similar to those of dextromethorphan (p.1556). It is given orally in a usual dose of 5 to 10 mg three or four times daily. For children's doses, see Administration in Children, below. The citrate has also been used. Pholcodine polistirex (a pholcodine and sulfonated diethenylbenzene-ethenylbenzene copolymer complex) has been used in modified-release preparations.

Administration in children. Although pholcodine is licensed for use in children, over-the-counter cough and cold preparations containing cough suppressants (including pholcodine) should be used with caution and generally avoided in those under 2 years of age (see p.1547). The following oral doses of pholcodine are given in the *BNFC* for use in children:

- 2 to 5 years: 2 mg three times daily
- 5 to 12 years: 2 to 5 mg three or four times daily

$C_{10}H_{15}NO,HCl = 201.7.$

CAS — 345-78-8.

ATC — R01BA02.

ATC Vet — QR01BA02.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Pseudoephedrine Hydrochloride). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water and in alcohol; sparingly soluble in dichloromethane. Protect from light.

USP 31 (Pseudoephedrine Hydrochloride). A fine, white to off-white crystalline powder, having a faint characteristic odour. Soluble 1 in 0.5 of water, 1 in 3.6 of alcohol, 1 in 91 of chloroform, and 1 in 7000 of ether. pH of a 5% solution in water is between 4.6 and 6.0. Store in airtight containers. Protect from light.

Pseudoephedrine Sulfate *(USAN, rINNM)*
Pseudoéphédrine, Sulfate de; Pseudoephedrine Sulphate *(BANM)*; Pseudoephedrini Sulfas; Sch-4855; Sulfato de pseudoefedrina.

Псевдоэфедрина Сульфат

$(C_{10}H_{15}NO)_2,H_2SO_4 = 428.5.$

CAS — 7460-12-0.

ATC — R01BA02.

ATC Vet — QR01BA02.

Pharmacopoeias. In *US.*

USP 31 (Pseudoephedrine Sulfate). Odourless, white crystals or crystalline powder. Freely soluble in alcohol. pH of a 5% solution in water is between 5.0 and 6.5. Store in airtight containers. Protect from light.

Adverse Effects and Precautions
As for Ephedrine, p.1558. The commonest adverse effects of pseudoephedrine include tachycardia, anxiety, restlessness, and insomnia; skin rashes and urinary retention have occasionally occurred. Hallucinations have been reported rarely, particularly in children.

◊ In response to reports in the USA of overdosages associated with cough and cold medications, the CDC and the National Association of Medical Examiners investigated deaths in infants aged under 12 months associated with such use; 3 cases were identified. All 3 infants had high concentrations of pseudoephedrine in postmortem blood samples, 2 had detectable blood concentrations of dextromethorphan and paracetamol, and 1 was also found to have detectable concentrations of doxylamine. None of the deaths were determined to be intentional. Two infants had evidence of respiratory infection upon autopsy; no cardiac abnormalities were found in any of the infants.[1]

1. CDC. Infant deaths associated with cough and cold medications—two States, 2005. *MMWR* 2007; **56:** 1–4. Also available at: http://www.cdc.gov/mmwr/preview/mmwrhtml/mm5601a1.htm (accessed 19/04/07)

Abuse. Acute psychosis and visual and tactile hallucinations have been reported[1] in an 18-year-old male after intravenous misuse of pseudoephedrine hydrochloride. Pseudoephedrine has also been used for the illicit manufacture of street stimulants such as metamfetamine (p.2158).

For reference to toxic effects after long-term use of over-the-counter preparations containing sympathomimetics, such as pseudoephedrine, see under Ephedrine, p.1558.

1. Sullivan G. Acute psychosis following intravenous abuse of pseudoephedrine: a case report. *J Psychopharmacol* 1996; **10:** 324–5.

Breast feeding. The American Academy of Pediatrics[1] states that, although usually compatible with breast feeding, preparations used by breast-feeding mothers that contain pseudoephedrine with dexbrompheniramine maleate have resulted in crying, irritability, and poor sleep patterns in the infant.

The concentrations of pseudoephedrine and triprolidine in plasma and breast milk of 3 mothers for up to 48 hours after ingestion of a preparation containing pseudoephedrine hydrochloride 60 mg with triprolidine hydrochloride 2.5 mg have been studied.[2] Concentrations of pseudoephedrine in milk were consistently higher than in plasma; the half-life in both fluids was between 4.2 and 7.0 hours. Assuming a generous milk secretion of 500 mL over 12 hours it was calculated that the excreted dose was the equivalent of 250 to 330 micrograms of pseudoephedrine base, or 0.5 to 0.7% of the dose ingested by the mothers. Triprolidine did not appear to be concentrated in breast milk. The amounts of pseudoephedrine and triprolidine distributed into breast milk were probably not high enough to warrant cessation of breast feeding.

A small, randomised, crossover study concluded that a single dose of 60 mg pseudoephedrine hydrochloride decreased 24-hour milk production by 24%. The authors of the study suggested that pseudoephedrine might be of benefit for suppressing excess milk production.[3]

3. Aljazaf K, *et al.* Pseudoephedrine: effects on milk production in women and estimation of infant exposure via breastmilk. *Br J Clin Pharmacol* 2003; **56:** 18–24.

Convulsions. A child who suffered a generalised seizure after ingesting a large quantity of pseudoephedrine hydrochloride tablets was believed to be the first report of convulsions associated with overdose of a preparation containing the drug as a single ingredient.[1]

1. Clark RF, Curry SC. Pseudoephedrine dangers. *Pediatrics* 1990; **85:** 389–90.

Effects on the gastrointestinal tract. Ischaemic colitis has been reported[1-3] after acute or chronic use of pseudoephedrine in combination cold and allergy preparations. In one case[3] the authors suggested that use with tramadol may have contributed to adrenergic vasoconstriction by inhibition of noradrenaline reuptake.

1. Dowd J, *et al.* Ischemic colitis associated with pseudoephedrine: four cases. *Am J Gastroenterol* 1999; **94:** 2430–4.

3. Stokes MA. Visual hallucinations in children receiving decongestants. *BMJ* 1984; **288:** 1540.

4. Roberge RJ, *et al.* Dextromethorphan and pseudoephedrine-induced agitated psychosis and ataxia: case report. *J Emerg Med* 1999; **17:** 285–8.
5. Soutullo CA, *et al.* Psychosis associated with pseudoephedrine and dextromethorphan. *J Am Acad Child Adolesc Psychiatry* 1999; **38:** 1471–2.

Effects on the skin. Recurrent pseudo-scarlatina has been described in a female patient and attributed, on some occasions at least, to ingestion of pseudoephedrine.[1] Further fixed drug eruptions associated with pseudoephedrine have been reported.[2-4] In another woman, an erythematous macular rash developed 5⁄ hours after an oral challenge with pseudoephedrine 60 mg; other symptoms, which mimicked the effects of toxic shock syndrome, included nausea and vomiting, fever, orthostatic hypotension, light-headedness, fatigue, and desquamation of the skin on her palms and soles.[3] However, considering the frequent use of pseudoephedrine in over-the-counter medications, associated drug eruptions generally appear to be rare.[2]

1. Taylor BJ, Duffill MB. *Br J Dermatol* 1988; **118:** 827–9.
2. Camisa C. Fixed drug reactions to pseudoephedrine hydrochloride. *Br J Dermatol* 1989; **120:** 857–8.
3. Cavanah DK, Ballas ZK. Pseudoephedrine reaction presenting as recurrent toxic shock syndrome. *Ann Intern Med* 1993; **119:** 302–3.
4. Hauken M. Fixed drug eruption and pseudoephedrine. *Ann Intern Med* 1994; **120:** 442.

Pregnancy. During pregnancy taking pseudoephedrine with paracetamol has been suggested to increase the risk of gastroschisis (defective closure of the abdominal wall) in newborns.[1] Although the evidence for this is weak, it is advisable that pseudoephedrine should be avoided during pregnancy because of the severity of the abnormality and the availability of alternatives to pseudoephedrine.

1. Werler MM, *et al.* Maternal medication use and risks of gastroschisis and small intestinal atresia.*Am J Epidemiol* 2002; **155:** 26–31.

Tolerance. In 34 healthy males given pseudoephedrine 120 or 150 mg twice daily for 7 days, as a modified-release preparation, mean plasma concentrations were about 450 or 510 nanograms/mL, respectively. Adverse effects (dry mouth, anorexia, insomnia, anxiety, tension, restlessness, tachycardia, palpitations) were common; there was some evidence of tachyphylaxis.[1]

1. Dickerson J, *et al*. Dose tolerance and pharmacokinetic studies of L(+) pseudoephedrine capsules in man. *Eur J Clin Pharmacol* 1978; **14:** 253–9.

Interactions

As for Ephedrine, p.1559. Pseudoephedrine may cause a hypertensive crisis in patients receiving a MAOI (including a RIMA). For additional warnings see under phenelzine (p.418) and moclobemide (p.411). For mention of a possible interaction between pseudoephedrine and tramadol, see Effects on the Gastrointestinal Tract, above.

Antacids. The absorption rate of pseudoephedrine hydrochloride was increased by *aluminium hydroxide* mixture but was decreased by *kaolin*; in the latter case adsorption may have competed with absorption.[1]

1. Lucarotti RL, *et al.* Enhanced pseudoephedrine absorption by concurrent administration of aluminium hydroxide gel in humans. *J Pharm Sci* 1972; **61:** 903–5.

Vaccines. A 21-year-old mildly obese man taking pseudoephedrine in an over-the-counter formulation for weight loss collapsed and died with a core temperature of 42.2° while exercising, shortly after inoculation with *Japanese encephalitis vaccine* and *typhoid vaccine*.[1] The combined effects of the pseudoephedrine, activity, and the pyrogenic action of the vaccines appeared to have contributed to failure of the thermoregulatory system.

1. Franklin QJ. Sudden death after typhoid and Japanese encephalitis vaccination in a young male taking pseudoephedrine. *Mil Med* 1999; **164:** 157–9.

Pharmacokinetics

Pseudoephedrine is readily absorbed from the gastrointestinal tract. It is excreted largely unchanged in the urine with small amounts of its hepatic metabolite. It has a half-life of about 5 to 8 hours; elimination is enhanced and half-life accordingly shorter in acid urine. Small amounts are distributed into breast milk.

◊ References.

Uses and Administration

Pseudoephedrine is a direct- and indirect-acting sympathomimetic (p.1408). It is a stereoisomer of ephedrine (p.1558) and has a similar action, but has been stated to have less pressor activity and fewer CNS effects.

Pseudoephedrine and its salts are given orally for the symptomatic relief of nasal congestion (p.1548). They are commonly combined with other ingredients in preparations intended for the relief of cough and cold symptoms.

Pseudoephedrine hydrochloride or sulfate are generally given orally in doses of 60 mg every 4 to 6 hours up to a maximum of 4 doses in 24 hours. For children's doses, see Administration in Children, below. Modified-release preparations are also available; a usual adult dose is 120 mg every 12 hours or 240 mg every 24 hours.

Other uses of pseudoephedrine include the control of urinary incontinence (p.2180) in some patients. It has also been given in the management of some forms of priapism (see under Metaraminol, p.1333).

Pseudoephedrine polistirex (a pseudoephedrine and sulfonated diethenylbenzene-ethenylbenzene copolymer complex) has also been used, as has pseudoephedrine tannate.

Administration in children. The *BNFC* states there is little evidence to support the use of systemic decongestants in children. However, the following oral doses of pseudoephedrine hydrochloride are suggested for children in the management of mucosal congestion of the upper respiratory tract:

- 2 to 6 years: 15 mg 3 or 4 times daily
- 6 to 12 years: 30 mg 3 or 4 times daily

Over-the-counter cough and cold preparations containing sympathomimetic decongestants (including pseudoephedrine) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547).

Barotrauma. Results from a controlled study[1] suggest that pseudoephedrine given to adults at least 30 minutes before flying appears to decrease the incidence of ear pain associated with pressure changes.[1] However, a similar decrease in risk was not noted in children.[2]

1. Jones JS, *et al.* A double-blind comparison between oral pseudoephedrine and topical oxymetazoline in the prevention of barotrauma during air travel. *Am J Emerg Med* 1998; **16:** 262–4.

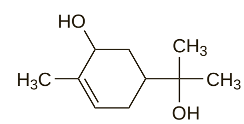
$C_{10}H_{18}O_2$ = 170.2.
CAS — 498-71-5.
ATC — R05CB07.
ATC Vet — QR05CB07.



Pharmacopoeias. In *It.*

Profile

Sobrerol is a mucolytic that has been used in respiratory disorders characterised by productive cough (p.1547). Oral doses of up to 800 mg have been given daily in divided doses. Sobrerol has also been given by injection, inhalation, or rectally.

Pharmacokinetics. The pharmacokinetics of sobrerol after oral or intravenous doses has been studied in patients with acute exacerbations of chronic bronchitis.[1] Sobrerol was rapidly absorbed from the gastrointestinal tract and rapidly distributed. After intravenous and oral dosage, 13 and 23% of the dose respectively was excreted in the urine as unchanged drug, glucuronidated sobrerol, and hydrated carvone. Sobrerol was shown to accumulate in bronchial mucus.

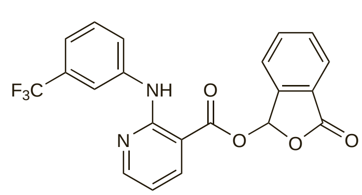
Talniflumate *(USAN, rINN)*

BA-7602-06; Talniflumato; Talniflumatum. Phthalidyl 2-(α,α,α-trifluoro-*m*-toluidino)nicotinate.

Тальнифлумат

$C_{21}H_{13}F_3N_2O_4$ = 414.3.

CAS — 66898-62-2.



Profile

Talniflumate inhibits the human calcium-activated chloride channel protein hCLCA1, which is overexpressed in the lungs of patients with certain pulmonary diseases associated with excessive or abnormal mucus production. Talniflumate is under investigation for the management of cystic fibrosis, chronic obstructive pulmonary disease, and asthma. Talniflumate has also been used to treat inflammation.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Somalgen.

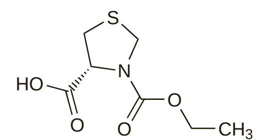
Telmesteine *(rINN)*

Telmesteína; Telmestéine; Telmesteinum. (−)-3-Ethyl hydrogen (*R*)-3,4-thiazolidinedicarboxylate.

Тельместеин

$C_7H_{11}NO_4S$ = 205.2.

CAS — 122946-43-4.



Profile

Telmesteine has been used as a mucolytic (p.1547) in the treatment of respiratory-tract disorders in oral doses of 300 mg two or three times daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Ital.: Muconorm†; Reolase.

Multi-ingredient: *UK:* Atopiclair; Xclair; ***USA:*** Atopiclair.

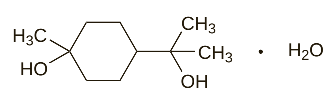
Terpin Hydrate *(BANM)*

Terpene Hydrate; Terpiinihydraatti; Terpina, hidrato de; Terpinhydrat; Terpini Hydras; Terpinol. *p*-Menthane-1,8-diol monohydrate; 4-Hydroxy-α,α,4-trimethylcyclohexanemethanol monohydrate.

Терпингидрат

$C_{10}H_{20}O_2,H_2O$ = 190.3.

CAS — 80-53-5 (anhydrous terpin); 2451-01-6 (terpin monohydrate).



Pharmacopoeias. In *Fr.*, *Swiss*, *US*, and *Viet.*

USP 31 (Terpin Hydrate). Colourless lustrous crystals or white powder with a slight odour. It effloresces in dry air. Soluble 1 in 200 of water, 1 in 35 of boiling water, 1 in 13 of alcohol, 1 in 3 of boiling alcohol, and 1 in 140 of chloroform and of ether. A hot 1% solution is neutral to litmus. Store in airtight containers.

Stability. If crystals form in terpin hydrate elixir, they may be redissolved by warming the closed container of solution in warm water and then gently shaking it.

Profile

Terpin hydrate has been stated to increase bronchial secretion directly and has been given orally as an expectorant in productive cough (p.1547).

Nausea, vomiting, or abdominal pain may follow the ingestion of terpin hydrate on an empty stomach.

Terpin hydrochloride has also been used.

Preparations

USP 31: Terpin Hydrate and Codeine Elixir; Terpin Hydrate Elixir.

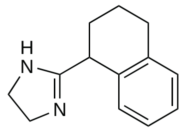
Тетризолина Гидрохлорид

$C_{13}H_{16}N_2$,HCl = 236.7.

CAS — 84-22-0 (tetryzoline); 522-48-5 (tetryzoline hydrochloride).

ATC — R01AA06; R01AB03; S01GA02.

ATC Vet — QR01AA06; QR01AB03; QS01GA02.



(tetryzoline)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Tetryzoline Hydrochloride). A white or almost white crystalline powder. Freely soluble in water, in alcohol, and in dehydrated alcohol; practically insoluble in acetone.

USP 31 (Tetrahydrozoline Hydrochloride). A white odourless solid. Soluble 1 in 3.5 of water and 1 in 7.5 of alcohol; very slightly soluble in chloroform; practically insoluble in ether. Store in airtight containers.

Profile

Tetryzoline is a sympathomimetic with effects similar to those of naphazoline (p.1565). It is used as the hydrochloride for its vasoconstrictor effect in the symptomatic relief of nasal congestion (p.1548). A 0.1% solution is instilled into each nostril as nasal drops or a spray as necessary, although not more often than every 3 hours. Children aged 2 to 6 years of age may be given 2 or 3 drops of a 0.05% solution in each nostril as necessary, although again not more often than every 3 hours.

Solutions of tetryzoline hydrochloride containing 0.05% are used as a conjunctival decongestant (see Conjunctivitis, p.564).

Other salts of tetryzoline including the nitrate, phosphate, and sulfate have been used similarly.

Effects on the eyes. For mention of conjunctivitis induced by ophthalmic decongestant preparations containing tetryzoline, see under Phenylephrine, p.1568.

Preparations

USP 31: Tetrahydrozoline Hydrochloride Nasal Solution; Tetrahydrozoline Hydrochloride Ophthalmic Solution.

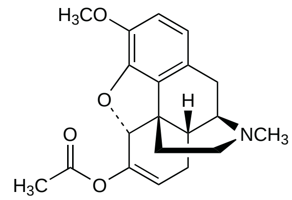
Тебакона Гидрохлорид

$C_{20}H_{23}NO_4$,HCl = 377.9.

CAS — 466-90-0 (thebacon); 20236-82-2 (thebacon hydrochloride).

ATC — R05DA10.

ATC Vet — QR05DA10.



(thebacon)

Profile

Thebacon hydrochloride is a centrally acting cough suppressant used for non-productive cough (p.1547). It has actions similar to those of codeine (p.37) but is stated to be about 4 times more potent. It is given orally in a usual daily dose of 10 mg in divided doses; the maximum daily dose should not exceed 20 mg.

Preparations

Proprietary Preparations (details are given in Part 3)

Belg.: Acedicon.

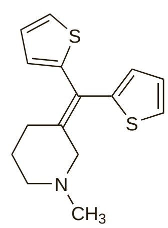
Типепидина Гибензат

$C_{15}H_{17}NS_2$,$C_{14}H_{10}O_4$ = 517.7.

CAS — 5169-78-8 (tipepidine); 31139-87-4 (tipepidine hibenzate).

ATC — R05DB24.

ATC Vet — QR05DB24.



(tipepidine)

Pharmacopoeias. In *Jpn.*

Profile

Tipepidine hibenzate is a cough suppressant used for non-productive cough (p.1547) which is claimed also to have an expectorant action. It is given orally as the hibenzate but doses are expressed as the citrate; tipepidine hibenzate 22.2 mg is equivalent to about 20 mg of tipepidine citrate. A usual dose is the equivalent of 20 to 40 mg of the citrate 3 times daily.

Epileptogenic effect. Generalised convulsions associated with therapeutic oral doses of tipepidine hibenzate have occurred in some patients.[1]

Tolu Balsam

Bálsamo de tolú; Balsamum tolutanum; Baume de tolu; Tolu balzamas; Toluánský balzám; Tolubalsam; Tolubalzsam; Tolupalsami.

Толуанский Бальзам

CAS — 9000-64-0; 8017-09-2.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Tolu Balsam). Oleoresin obtained from the trunk of *Myroxylon balsamum* var. *balsamum*. It contains 25 to 50% of free or combined acids, expressed as cinnamic acid, calculated with reference to the dried drug. It occurs as a hard, friable, brownish to reddish-brown mass; thin fragments are brownish-yellow when examined against the light. It has an odour reminiscent of vanillin. Practically insoluble in water and in petroleum spirit; very soluble or freely soluble in alcohol. Do not store in powdered form.

USP 31 (Tolu Balsam). A balsam obtained from *Myroxylon balsamum* (Leguminosae). It is a brown or yellowish-brown plastic solid transparent in thin layers and brittle when old, dried, or exposed to cold temperatures. It has a pleasant aromatic odour, resembling that of vanilla. Practically insoluble in water and in petroleum spirit; soluble in alcohol, in chloroform, and in ether, sometimes with slight residue or turbidity. Store at a temperature not exceeding 40° in airtight containers.

Profile

Tolu balsam is considered to have very mild antiseptic properties and some expectorant action but is mainly used in the form of a syrup to flavour cough mixtures. However, Tolu Syrup (BP 2008) no longer contains tolu balsam but is based on cinnamic acid (p.1640).

Preparations

BPC 1954: Compound Iodoform Paint;
USNF 26: Tolu Balsam Syrup; Tolu Balsam Tincture;
USP 31: Compound Benzoin Tincture.

Tramazoline Hydrochloride *(BANM, USAN, rINNM)* ⊗

Hidrocloruro de tramazolina; Tramazoline, chlorhydrate de; Tramazolin-hidroklorid; Tramazolin-hydrochlorid; Tramazolini hydrochloridum; Tramazolino hidrochloridas; Tramazoliny chlorowodorek. 2-(5,6,7,8-Tetrahydro-1-naphthylamino)-2-imidazoline hydrochloride monohydrate.

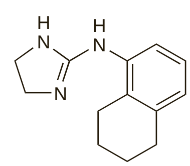
Трамазолина Гидрохлорид

$C_{13}H_{17}N_3$,HCl,H_2O = 269.8.

CAS — 1082-57-1 (tramazoline); 3715-90-0 (tramazoline hydrochloride).

ATC — R01AA09.

ATC Vet — QR01AA09.



(tramazoline)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Tramazoline Hydrochloride Monohydrate). A white or almost white crystalline powder. Soluble in water and in alcohol. A 5% solution in water has a pH of 4.9 to 6.3.

Profile

Tramazoline hydrochloride is a sympathomimetic with effects similar to those of naphazoline (p.1565). It is used to provide symptomatic relief of nasal congestion (p.1548). Tramazoline hydrochloride is given as a solution containing about 0.12%, instilled into each nostril as nasal drops or a spray three or four times daily.

Solutions of tramazoline hydrochloride containing about 0.06% have also been used in eye drops as a conjunctival decongestant (see Conjunctivitis, p.564).

Xylometazoline Hydrochloride

(BANM, rINNM) ⊗

Hidrocloruro de xilometazolina; Ksilometazolin Hidroklorür; Ksilometazolino hidrochloridas; Ksylometatsoliinihydrokloridi; Ksylometazoliny chlorowodorek; Xilometazolinhidroklorid; Xylométazoline, chlorhydrate de; Xylometazolinhydro; Xylometazolin-hydrochlorid; Xylometazolini hydrochloridum. 2-(4-*tert*-Butyl-2,6-dimethylbenzyl)-2-imidazoline hydrochloride.

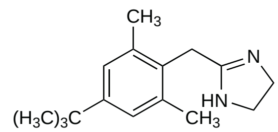
Ксилометазолина Гидрохлорид

$C_{16}H_{24}N_2,HCl$ = 280.8.

CAS — 526-36-3 (xylometazoline); 1218-35-5 (xylometazoline hydrochloride).

ATC — R01AA07; R01AB06; S01GA03.

ATC Vet — QR01AA07; QR01AB06; QS01GA03.



(xylometazoline)

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Xylometazoline Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water, in alcohol, and in methyl alcohol. Protect from light.

USP 31 (Xylometazoline Hydrochloride). A white to off-white, odourless, crystalline powder. Soluble 1 in 35 of water; freely soluble in alcohol; sparingly soluble in chloroform; practically insoluble in ether and in benzene. pH of a 5% solution in water is between 5.0 and 6.6. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

As for Naphazoline, p.1565.

Interactions

Since xylometazoline is absorbed through the mucosa interactions may follow topical application. The *BNF* considers that all sympathomimetic nasal decongestants may cause a hypertensive crisis if used during treatment with an MAOI. For the interactions of sympathomimetics in general, see p.1407.

Uses and Administration

Xylometazoline is a direct-acting sympathomimetic (p.1408) with marked alpha-adrenergic activity. It is a vasoconstrictor which reduces swelling and congestion when applied to mucous membranes. The effect begins within 5 to 10 minutes of application and lasts for up to 10 hours.

Xylometazoline is used as the hydrochloride for the short-term symptomatic relief of nasal congestion (p.1548). A 0.1% solution of xylometazoline hydrochloride is applied topically as nasal drops or a spray into each nostril two or three times daily. For children's doses, see Administration in Children, below.

Xylometazoline hydrochloride solution is instilled into the eye as a conjunctival decongestant (see Conjunctivitis, p.564). Preparations containing 0.05% xylometazoline hydrochloride with 0.5% antazoline sulfate are typical; 0.1% xylometazoline hydrochloride has also been used.

Administration in children. Over-the-counter cough and cold preparations containing sympathomimetic decongestants (including xylometazoline) should be used with caution in children and generally avoided in those under 2 years of age (see p.1547). However, the *BNFC* suggests that, in certain circumstances, specialists may prescribe xylometazoline nasal drops for children under 2 years in the short-term treatment of severe nasal congestion which has not responded to sodium chloride nasal drops or inhalation of warm moist air. A 0.05% solution of xylometazoline hydrochloride is licensed for use in children aged from 2 to 12 years; 1 or 2 drops are instilled into each nostril once or twice daily, for a maximum of 7 days. The *BNFC* suggests that younger children aged 3 months and over may be given similar doses.

Preparations

BP 2008: Xylometazoline Nasal Drops;
USP 31: Xylometazoline Hydrochloride Nasal Solution.

(zipeprol)

Profile

Zipeprol is a centrally acting cough suppressant that is stated to have a peripheral action on bronchial spasm. It has been given as the hydrochloride, typically in an oral dose of 150 to 300 mg daily in divided doses. There have been reports of abuse and overdosage producing neurological symptoms.

Abuse and overdosage. Severe neurological symptoms have been reported in young adults after habitual abuse of zipeprol for euphoria. Patients have presented with generalised seizures, followed by coma.[1] One patient who ingested 750 mg of zipeprol [over twice the maximum daily dose] had several opisthotonic crises and developed cerebral oedema.[2] Symptoms of overdosage in children have included restlessness, somnolence, ataxia, choreic movements, forced deviation of the head and eyes, generalised seizures, respiratory depression, and coma.[1,3] Fatalities have been reported.

Dependence and withdrawal symptoms similar to those produced by opioids have been reported.[4] WHO has assessed zipeprol to have a moderate potential for dependence and liability for abuse.[5] Although zipeprol is a weak opioid agonist at high doses its toxicity and hallucinogenic and other psychotropic effects constitute a significant element in its abuse, and the public health and social problems associated with such abuse were considered substantial.

The skin is subject to a very wide range of lesions. Some may be characteristic of specific systemic diseases and fade as the disease regresses. Some are caused by specific local infections and are best treated by the appropriate antimicrobial (see Skin Infections in the chapters Antibacterials, p.194, and Antifungals, p.521). The skin is also subject to damage from environmental hazards. Excessive or prolonged exposure to solar radiation is associated with degenerative changes in the skin (premature ageing of the skin or photoageing, p.1581), actinic (solar) keratoses (which are risk factors or precursors of skin cancers), and malignant neoplasms of the skin (p.672). Some skin disorders are adverse effects of therapeutic and other agents, ranging from mild hypersensitivity to the life-threatening Stevens-Johnson syndrome or toxic epidermal necrolysis (see Drug-induced Skin Reactions, p.1578, and Drug-induced Photosensitivity, p.1581). There also remain skin disorders whose aetiology is poorly understood.

The distribution and morphological description of the skin lesion (its shape, colour, and surface characteristics) are important in the diagnosis of skin disorders. There are many terms used to describe skin lesions:

- abscess–a collection of pus in a cavity
- bulla (or blister)–a fluid-filled circumscribed lesion larger than 0.5 cm in diameter
- comedo–a plug of keratin and sebum in a pilosebaceous follicle
- ecchymosis (bruise)–an extravasation of blood into the skin
- erythema–red coloration due to vascular dilatation
- fissure–a slit through the whole thickness of the skin
- horn–a thickening of the skin that is taller than it is broad
- keratosis–a horny thickening of the skin
- lichenification–hard, thickened skin with increased markings
- macule–an area of altered colour or texture with no elevation above the surface of the surrounding skin
- nodule–a dome-shaped or spherical-shaped, solid lesion, usually more than 0.5 cm in diameter and depth
- papilloma–a nipple-like mass
- papule–a raised solid lesion, usually less than 0.5 cm in diameter
- petechia–a pinhead-sized macule of blood in the skin
- plaque–a raised, flat-topped, circumscribed lesion, usually larger than 2 cm in diameter but with no substantial depth
- purpura–a macule of blood in the skin, larger than a petechia
- pustule–an accumulation of pus in the skin
- scale–a flat plate or flake of stratum corneum
- stria–a streak-like, linear, atrophic lesion, pink, purple, or white in colour
- telangiectasia–a visible permanent dilatation of small cutaneous blood vessels
- ulcer–a loss of the whole thickness of dermis and epidermis produced by sloughing of necrotic tissue; healing results in a scar
- vesicle–a fluid-filled circumscribed lesion less than 0.5 cm in diameter
- wheal–an elevated, white, compressible area of oedema often surrounded by a red flare

Dermatological Drug Groups

Treatment of skin disorders may include topical and/or systemic drug therapy, although the pharmacology of many of the drugs used in dermatology is poorly understood. Physical methods such as cryotherapy, UV radiation, radiotherapy, and surgery also have a role. Some of the main drug groups used in dermatology are described below.

Antidandruff Drugs

Antidandruff drugs have antibacterial and antifungal properties and are used particularly in shampoos to manage dandruff and seborrhoeic dermatitis of the scalp.

Described in this chapter are
Dipyrithione, p.1595
Piroctone Olamine, p.1610
Pyrithione Zinc, p.1611
Selenium Sulfide, p.1613

Corticosteroids

Corticosteroids are widely used for their anti-inflammatory (glucocorticoid) and immunosuppressant properties in the management of various skin conditions. Topical preparations are commonly used, but systemic treatment may be required for severe conditions or to control acute exacerbations. The actions and uses of the corticosteroids are discussed in much greater detail in the section beginning on p.1490. See also below for other immunosuppressants used in dermatology.

Immune System Modifiers

Some immunosuppressants are used specifically in psoriasis or eczema, and are included in this chapter. Other immunosuppressants and antineoplastics with immunosuppressant properties that are used in dermatology and covered in other chapters include azathioprine (p.1818), ciclosporin (p.1822), methotrexate (p.745), and tacrolimus (p.1843). Corticosteroids are also widely used for their anti-inflammatory and immunosuppressant effects (see above). Adalimumab (p.15), etanercept (p.50), and infliximab (p.69) are immunomodulators also used in the management of psoriasis.

Described in this chapter are
Alefacept, p.1587
Efalizumab, p.1596
Pimecrolimus, p.1609

Keratolytics

Keratolytics help to soften and ease exfoliation of the horny layer of the epidermis, and are used in conditions such as acne, seborrhoeic dermatitis and dandruff, and hyperkeratotic disorders.

Described in this chapter are
Alcloxa, p.1587
Aldioxa, p.1587
Allantoin, p.1588
Benzoyl Peroxide, p.1590
Glycolic Acid, p.1598
Keluamid, p.1603
Resorcinol, p.1612
Salicylic Acid, p.1612
Salnacedin, p.1613
Sulfur, p.1614
Urea, p.1620

Photosensitisers

Psoralen photosensitisers markedly increase the skin's sensitivity to UVA light, and are used in photochemotherapy (PUVA) for the management of disorders such as psoriasis, vitiligo, cutaneous T-cell lymphoma, and polymorphic light eruption. For a discussion of photodynamic therapy, a form of light-activated treatment used in the management of malignant neoplasms, see under Porfimer Sodium, p.764.

Described in this chapter are
5-Methoxypsoralen, p.1607
Methoxsalen, p.1605
Trioxysalen, p.1620

Pigment Modifiers

Drugs such as hydroquinone that reduce pigmentation are used to lighten skin in hyperpigmentation conditions such as chloasma. Dihydroxyacetone is used to darken skin in vitiligo, and monobenzone is used to permanently depigment normal skin in extensive vitiligo. Erythrulose is used to darken skin, either alone or with dihydroxyacetone, in artificial suntan preparations. Photosensitisers (above) are also used in vitiligo.

Described in this chapter are
Arbutin, p.1589
Dihydroxyacetone, p.1594
Erythrulose, p.1597
Hydroquinone, p.1598
Mequinol, p.1604
Monobenzone, p.1607

Retinoids

Retinoids, and the retinoid analogue adapalene, are vitamin A analogues used in the management of various skin conditions including acne, psoriasis, and keratinisation disorders.

Described in this chapter are
Acitretin, p.1586
Adapalene, p.1587
Etretinate, p.1597
Isotretinoin, p.1599
Motretinide, p.1608
Retinaldehyde, p.1612
Tazarotene, p.1617
Tretinoin, p.1618

Sunscreens

Sunscreens are used to protect the skin against sunlight. There are 2 types: *physical* (reflective or inorganic) agents that are opaque and reflect both UVA and UVB radiation and *chemical* (absorbent or organic) agents that because of their chromophore groups absorb a particular range of wavelengths within the UV spectrum (for definitions, see Light-induced Skin Reactions, p.1580). Physical sunscreens include titanium dioxide and zinc oxide. A classification of the chemical sunscreens included in this chapter is given in Table 1, below. Many products combine sunscreens from different groups in order to widen the protection afforded.

Table 1. Chemical sunscreens.

UVA absorbers	UVB absorbers
Anthranilates	**Aminobenzoates**
Meradimate	Aminobenzoic acid
Camphorsulfonic acid derivatives	Lisadimate
Ecamsule	Padimate
Dibenzoylmethanes	Padimate O
Avobenzone	**Camphor derivatives**
Dibenzoylmethane	Enzacamene
Isopropyldibenzoylmethane	**Cinnamates**
UVA and UVB absorbers	Amiloxate
Benzophenones	Cinoxate
Dioxybenzone	Diolamine methoxycinnamate
Mexenone	Octinoxate
Oxybenzone	Octocrilene
Sulisobenzone	**Salicylates**
	Homosalate
	Octisalate

Trolamine salicylate (p.132) and salol (p.122) are salicylic acid derivatives that have analgesic properties, but have also been used as sunscreens.

Described in this chapter are
Amiloxate, p.1589
Aminobenzoic Acid, p.1589
Avobenzone, p.1589
Bemotrizinol, p.1590
Bisoctrizole, p.1591
Cinoxate, p.1593
Dibenzoylmethane, p.1594
Diolamine Methoxycinnamate, p.1594
Dioxybenzone, p.1594
Drometrizole, p.1596
Ecamsule, p.1596
Ensulizole, p.1597
Enzacamene, p.1597
Homosalate, p.1598
Iscotrizinol, p.1599
Isopropyldibenzoylmethane, p.1599
Lisadimate, p.1604
Melanin, p.1604
Meradimate, p.1604
Methyl Anthranilate, p.1607
Mexenone, p.1607
Octil Triazone, p.1608
Octinoxate, p.1608
Octisalate, p.1608
Octocrilene, p.1608
Oxybenzone, p.1608
Padimate, p.1609
Padimate O, p.1609
Sulisobenzone, p.1614
Titanium Dioxide, p.1617
Zinc Oxide, p.1621

Vitamin D Derivatives

Some vitamin D derivatives are used in the treatment of psoriasis because they appear to induce differentiation and suppress proliferation of keratinocytes. Mention of other vitamin D derivatives that have been studied in psoriasis can be found under Vitamin D Substances, p.1986.

Described in this chapter are

Calcipotriol, p.1591	Tacalcitol, p.1615

Wound Management Agents

Many compounds and dressings are used in the management of wounds and ulcers. Although some are included in this chapter, others can be found throughout *Martindale*, including white and yellow soft paraffins (p.2031), alginates such as calcium alginate (p.1058), proteolytic enzymes such as collagenase (p.2286) and fibrinolysin (p.1287), and fibrin glue (p.1069).

Described in this chapter are

Becaplermin, p.1590	Polyphloroglucinol Phosphate, p.1611
Centella, p.1592	Polyurethane Foam, p.1611
Cerous Nitrate, p.1593	Prezatide Copper Acetate, p.1611
Crilanomer, p.1593	Skin Substitutes, p.1613
Dextranomer, p.1593	
Maggots, p.1604	

Topical Drug Administration

For drugs that are applied topically, the vehicle and formulation may be as important as the active drug. Indeed, some cream and ointment bases are used alone for their protective or emollient properties, while adverse effects of topical preparations are sometimes attributed to constituents of the vehicle such as stabilisers and preservatives. The choice of formulation depends on the skin condition being treated and the area affected. Lotions and gels are useful for hairy areas. Creams (oil-in-water emulsions) have cooling and emollient effects, are readily absorbed by the skin, and are used for acute and exudative conditions. Ointments (water-in-oil emulsions) are more occlusive than creams and are particularly suitable for dry lesions. Pastes (powder incorporated in an ointment basis) are also occlusive and are useful for their protective properties and for their use on circumscribed lesions. Less frequently used formulations include applications, collodions, and dusting powders. Typical quantities of preparations required per week for twice daily application to specific areas of an adult are given in Table 2, below.

Table 2. Typical quantities of preparations required per week for twice daily application to an adult.

	Creams and Ointments	Lotions
Face	15 to 30 g	100 mL
Both hands	25 to 50 g	200 mL
Scalp	50 to 100 g	200 mL
Both arms or both legs	100 to 200 g	200 mL
Trunk	400 g	500 mL
Groins and genitalia	15 to 25 g	100 mL

NOTE. These quantities do *not* apply to corticosteroid preparations.

Management of Dermatological Disorders

The management of some of the commoner skin conditions is discussed below.

Acne

Acne is a disorder of the pilosebaceous follicle; common features include increased sebum production, follicular keratinisation, colonisation by *Propionibacterium acnes*, and localised inflammation. Mild acne is characterised by open or closed comedones (blackheads and whiteheads), some of the latter developing into inflamed lesions such as papules and pustules. In moderate acne, the papules and pustules are more widespread, and there may be mild scarring. Severe acne is characterised by the presence of nodular abscesses or cysts in addition to widespread pustules and papules, and may lead to extensive scarring.

The most common form of acne is acne vulgaris. It is common in teenagers and while by their mid-20s the majority of cases have resolved, a few people still require treatment in their 30s and 40s. Skin areas typically affected are the face, shoulders, upper chest, and back. Acne may also occur in late middle age and in the elderly (late onset acne) and in infants (infantile acne). Certain drugs, including androgens, corticosteroids, corticotropin, hormonal contraceptives containing androgenic progestogens such as levonorgestrel, isoniazid, lithium, methoxsalen, and some antiepileptics may produce an acneform rash, as may substances such as tars, oils, and oily cosmetics.

Treatment aims to reduce the bacterial population of the pilosebaceous follicles, reduce the rate of sebum production, reduce inflammation, and remove the keratinised layer blocking the follicles. Drugs used include keratolytics, retinoids, and antibacterials. If topical preparations are not effective, oral preparations may be required. Response to therapy is commonly slow and long-term treatment is usually necessary.

Mild acne is treated topically, in particular with benzoyl peroxide, retinoids, and antibacterials. Abrasives have been used but their effectiveness is doubtful, and preparations based on sulfur or salicylic acid are considered by some to be obsolete; irritating astringents, harsh cleansers, and antibacterial soaps should be avoided. Topical corticosteroids, despite their presence in some compound preparations, should not be used.

Benzoyl peroxide has an antimicrobial action and mild keratolytic properties, and both comedones and inflammation generally respond well. It is probably the most widely used drug in mild acne because of its ready availability. Azelaic acid is an alternative to benzoyl peroxide that may cause less local irritation, but be less effective. Topical retinoids are effective in both comedonal and inflammatory acne; tretinoin is widely used but isotretinoin and tazarotene are considered to be equally effective. Adapalene, a naphthoic acid derivative with retinoid activity, also has similar efficacy, but may be better tolerated. Topical antibacterials can be used particularly for inflammatory acne. Tetracycline, clindamycin, and erythromycin are generally used, and appear to be roughly equivalent in efficacy. However, development of resistance by the skin flora is an increasing problem. Nicotinamide has also been used topically in mild to moderate inflammatory acne.

Generally, benzoyl peroxide is used alone as a first-line therapy for mild inflammatory acne, and topical retinoids can be used when comedones predominate.[1,2] Topical antibacterials may be used in inflammatory acne but should not be used alone; the addition of a topical retinoid or benzoyl peroxide improves efficacy and reduces the risk of developing resistance. However, many patients have both comedonal and inflammatory acne to some degree, and a retinoid with benzoyl peroxide, or a retinoid with benzoyl peroxide and a topical antibacterial, can be used.[3] Once there is clinical improvement and inflammatory lesions are under control, which may take 8 to 12 weeks,[4] the antibacterial can be stopped and the retinoid continued as maintenance therapy.[3] If there is no improvement within 6 to 8 weeks with antibacterial therapy, treatment should be stopped.[5] Further courses of topical antibacterial may be needed for flare-ups.[3]

Moderate acne is best treated with oral rather than topical antibacterials, of which tetracyclines appear to be the drugs of first choice. Tetracycline, doxycycline, lymecycline, or oxytetracycline may be used. Minocycline has also been reported to be effective; however, it can cause skin pigmentation and may be associated rarely with immunologically mediated reactions. Alternatives to the tetracyclines include erythromycin, co-trimoxazole, and trimethoprim. Resistance is an important problem, especially with erythromycin, and benzoyl peroxide is therefore also used.[3,6] To further limit the development of resistance, antibacterials should be used for no longer than necessary, the same antibacterial should be used for subsequent courses if the patient relapses,[3,6] and oral and topical antibacterials should not be used together.[6] Oral antibacterials have to be used for at least 3 months.[3,6] A total course of up to 6 months may be needed; longer treatment should generally be avoided but may be warranted in some cases.[6] If there is no response after 6 to 8 weeks, the antibacterial should be changed.[3] A topical retinoid may also be used for additional comedolytic activity. After the course of antibacterial has finished, a topical retinoid alone or with benzoyl peroxide is continued as maintenance therapy.[3,6] Women with moderate acne who also require oral contraception may be treated additionally with a combined oral contraceptive containing a non-androgenic progestogen.[2,4]

Severe acne is usually treated with oral isotretinoin;[3] there are also reports of oral isotretinoin being used outside this licensed indication for less severe acne that is resistant to treatment or that is causing physical scarring or psychological distress.[1] Where it cannot be used, high doses of oral antibacterials with a topical retinoid and benzoyl peroxide may be considered.[6] In women with signs of hyperandrogenism,[2-4] adjunctive use of the combination of anti-androgenic cyproterone with ethinylestradiol may be considered (this is available as a combination preparation that also provides contraception). A combined (non-androgenic) contraceptive is an alternative. Spironolactone has been used for its anti-androgenic properties in women when oestrogens are contra-indicated.

There is evidence to suggest that photodynamic therapy with a photosensitiser, such as 5-aminolevulinic acid, may be beneficial in acne.

Alopecia

Alopecia (hair loss) has many causes but androgenetic alopecia is the most common form. Alopecia may also be congenital, be associated with systemic disorders, severe emotional and physical stress, or skin disorders, or be due to nutritional deficiencies. Some drugs may cause alopecia; examples include antineoplastics (see p.639), beta blockers, diazoxide, heparin, verapamil, and warfarin. In cicatricial alopecia there is destruction of the hair follicles (scarring) resulting in permanent hair loss. Drug treatment may be tried in alopecia areata and androgenetic alopecia but it is often unsuccessful or has only a modest effect. Treatment of any other associated underlying condition causing alopecia, or removal of a suspected drug, may produce hair regrowth. Some treatments have also been tried in cicatricial alopecia in an attempt to stop the scarring process and permanent hair loss. Non-drug options include the use of wigs and hairpieces, cosmetic hair products, or hair transplantation surgery.

Alopecia areata is an auto-immune disorder in which there is a loss of hair in sharply defined areas of skin that normally bear hair. The affected area can vary in size from about 1 cm^2 to the whole scalp (alopecia totalis) or all body hair (alopecia universalis).

Small or isolated patches of alopecia areata may not need treatment and in many patients hair regrows within a few months. If loss of hair becomes a problem cosmetically, treatment may be offered but is often not totally satisfactory. Several treatment options have been tried.[1-3] Intralesional corticosteroids stimulate hair regrowth at the site of injection and may be of benefit for limited patchy hair loss. Oral pulsed or continuous corticosteroids may be used in severe progressive cases. Potent topical corticosteroids, topical dithranol, and minoxidil lotion may also be used, although their efficacy is debatable. Contact immunotherapy with diphencyprone has shown benefit in patients with extensive patchy hair loss, alopecia totalis and universalis. Photochemotherapy with ultraviolet A radiation (PUVA) with either systemic or topical psoralens such as methoxsalen has been tried, but potentially serious adverse effects and limited efficacy restrict its use.

Androgenetic alopecia is hereditary thinning of the hair induced by androgens in genetically susceptible men and women.[1] Over time, the growth phase of the hair cycle becomes shorter and hair follicles become smaller, producing shorter, finer hairs that cover the scalp poorly. *Male-pattern alopecia* (male-pattern baldness)[1,3,4] involves recession of the hairline in the frontal region of the scalp or loss of hair at the vertex. It is usually associated with increasing age in men. Topical minoxidil is more effective in male-pattern alopecia than it is in the areata forms of alopecia, but is still, at best, only modestly effective. Because of the role of androgens in this condition anti-androgens and 5α-reductase inhibitors may also be tried. The 5α-reductase inhibitor finasteride has been shown to be of benefit in men with male-pattern alopecia, but is restricted to use in males. Alfatradiol, another 5α-reductase inhibitor, is available in some countries for topical use. To maintain effectiveness, minoxidil or finasteride must be used continuously as any benefit will be lost within months of stopping treatment. Androgenetic alopecia also occurs in women (*female-pattern alopecia*);[5] there is a similar pattern of hair loss although the thinning may be more diffuse and milder in women than men. Most women with androgenetic alopecia do not have elevated androgen concentrations and are treated with topical minoxidil. However, an anti-androgen such as cyproterone acetate or spironolactone might be considered for women with accompanying signs of hyperandrogenism such as hirsutism (p.2089).

Cicatricial alopecia involves inflammation and replacement of the hair follicles by fibrous tissue and the aim of treatment is to stop this process before hair loss is permanent. As well as hair loss, there can be pustules, crusting, scaling, and itching. There are a number of different types of cicatricial alopecia and many treatments have been tried, but there is no standard therapy.[6,7] In those where the scalp biopsy shows mainly lymphocytic infiltration, topical and/or intralesional corticosteroids can be used alone for limited disease or added to systemic therapy. Systemic corticosteroids may be used and other oral treatments that have been tried for more extensive or progressive disease include hydroxychloroquine, isotretinoin, mycophenolate mofetil, and ciclosporin. There are also reports of benefit from other topical therapies such as pimecrolimus, tacrolimus, and tazarotene. In neutrophilic cicatricial alopecia, oral antibacterials are used to control follicular infection and suppuration. Oral isotretinoin has been used in patients with neutrophilic dissecting cellulitis.

Burns

Burns may be caused by chemicals or heat. Initial treatment of burns is irrigation with cold or tepid water for at least 20 minutes; hypothermia should be avoided. This limits the skin damage in burns caused by heat and removes the causative agent in chemical burns. Sodium bicarbonate solution is then used on acid burns and acetic acid solution on alkaline burns. The extent of a burn injury is described by area and depth. The affected body-surface can be calculated, and the depth of the burn may be classified as superficial (first-degree); partial thickness (second-degree), which may be further classified as superficial or deep partial thickness; or full thickness (third-degree). The major problems associated with burns are hypovolaemic shock, inhalation injury, metabolic abnormalities, and infection. For burns affecting the eye, see p.1674.

- After a burn, fluid accumulates rapidly in the wound area due to increased permeability of the microcirculation and this loss of fluid from the circulation may produce hypovolaemic shock (p.1183) if burns involve at least 15 to 20% of the body-surface.
- Inhalation injury producing airway oedema is mainly a result of exposure to toxic gases. Endotracheal intubation is required until the oedema subsides. Oxygen therapy is used, and nebulised beta$_2$ agonists may be given to treat bronchospasm. Inhalation of heparin and acetylcysteine may be of benefit in reducing pulmonary failure.
- Hypermetabolism and marked catabolism can result from major burn injury. Protein breakdown and loss causes muscle wasting and weakness, impaired wound healing and skin breakdown, and impaired immunity. Other effects of metabolic disturbances include an increase in liver fat and hepatomegaly, osteopenia, tachycardia and increased myocardial oxygen consumption. Enteral feeding (p.1923) to match nutrient requirements is essential for metabolic management. Other treatments that have been tried to reduce net catabolism include the amino acids arginine and glutamine, drugs with anabolic effects including insulin, oxandrolone, and somatropin (for concerns about the latter use see p.1802), and catecholamine antagonism using beta blockers such as propranolol.
- Prevention of infection is an important part of burn wound management. Micro-organisms proliferate rapidly in burn wounds, especially those severe enough to impair immune function, and sepsis remains the major fatal complication of burns. Burn wounds should be cleansed with normal saline (see Wounds and Ulcers, below). This may be all that is required for very minor burn wounds; a non-adherent dressing, such as paraffin tulle, may be used if necessary. Topical antibacterials, such as chlorhexidine, sulfadiazine silver, silver nitrate, and mafenide acetate, may be applied as required. Sodium hypochlorite (Dakin's solution) may also be of value, although opinions differ as to its usefulness. Removal of devitalised tissue is also an essential element of management. Infections require aggressive systemic treatment (see under Skin Infections, p.194).

Full thickness burn wounds require skin grafting. This is performed as soon as possible after stabilisation of the patient. Skin grafting may also be considered for deep partial thickness wounds. If the area to be grafted is very extensive, the grafting procedure may have to be in stages (at intervals of about a week) as sufficient autologous skin becomes available. Alternatively, temporary skin substitutes may be used to supplement autologous skin and allow wound closure in one stage.

Darier's disease

Darier's disease (keratosis follicularis) is an uncommon inherited keratinisation disorder (see below) and is characterised by groups of horny papules over the body. These may become irritated and/or infected, exudative, and crusted. Involvement of the nails is characteristic. Severity varies greatly; emollients, use of soap substitutes, and wearing cool clothing are important in controlling irritation in all patients, and may be sufficient in the mildest cases. More severe cases are treated by topical application of keratolytics such as salicylic acid or topical retinoids such as isotretinoin, tretinoin, or tazarotene. Topical corticosteroids are helpful in some patients to alleviate retinoid-induced irritation. Treatment with oral retinoids (acitretin, etretinate, or isotretinoin) is needed in more extensive disease, and has been combined with topical retinoids. Ciclosporin and topical fluorouracil have also been tried; some patients have been reported to respond to dietary supplementation with essential fatty acids. There is only anecdotal evidence to support the use of surgery or laser therapy, although these may be tried in refractory cases.

Dermatitis herpetiformis

Dermatitis herpetiformis is a rare blistering disorder of the subepidermal tissue in which the vesicles and papules are intensely irritant and pruritic. The knees, elbows, buttocks, shoulders, and scalp are areas typically affected. The disease presents usually during early to middle adult life and is a chronic condition, although there may be periods of remission that last several months. In most patients there is also a mild gastrointestinal absorptive defect characterised by gluten hypersensitivity (gluten enteropathy or coeliac disease, see p.1922). Skin lesions can be suppressed by dapsone; the sulfonamides sulfamethoxypyridazine or sulfapyridine have been used as alternatives to dapsone.[1-5] A gluten-free diet may improve both gastrointestinal symptoms and the skin disorder.[2,4-6]

Drug-induced skin reactions

Drugs are a frequent cause of adverse skin reactions. The skin reaction may mimic a spontaneously occurring skin disorder and is therefore included in the differential diagnosis of most skin diseases. Alternatively, the drug may produce quite specific changes. The reaction can develop after the first dose or after a period of sensitisation. Pigmentation changes or effects on hair may take some months to become apparent. Drug-induced nail changes have also been reported.

Reactions range from mild rashes to severe life-threatening reactions including angioedema with urticaria, Stevens-Johnson syndrome, and toxic epidermal necrolysis. Other serious skin reactions include hypersensitivity syndromes, serum sickness, and vasculitis.

Stevens-Johnson syndrome (see also Erythema Multiforme, below) is a severe, blistering skin reaction also affecting the mucous membranes of the oropharynx, eyes, and genitalia and accompanied sometimes by fever, pain, and malaise. **Toxic epidermal necrolysis** (Lyell's syndrome or scalded skin syndrome) as described on p.1584, is a more severe form of the reaction where considerable amounts of the epidermis may be shed. Sulfonamides, carbamazepine, and allopurinol are among the many drugs that have been associated with both these reactions.

Hypersensitivity syndrome is a severe, idiosyncratic reaction which includes rash and fever, and often hepatitis, arthralgias, lymphadenopathy, and haematological abnormalities. It tends to have a relatively late and slow onset. Some antiepileptics and sulfonamides cause this syndrome, as well as allopurinol, dapsone, and gold salts. **Serum sickness** is manifest as rash, fever, arthralgia and arthritis and typically develops 8 to 14 days after doses of serum preparations and vaccines. **Vasculitic reactions** may occur 7 to 21 days after beginning therapy with drugs such as allopurinol, penicillins, and sulfonamides (see Hypersensitivity Vasculitis, p.1505). The vasculitis usually affects small vessels of the lower extremities producing purpura, although it can also affect vessels in the kidney, liver, and gastrointestinal tract, in which case it may be life-threatening.

Maculopapular exanthematic eruptions are probably the most frequent drug-induced skin reaction. Drugs commonly causing these rashes include carbamazepine, chlorpromazine, nitrofurantoin, penicillins, and sulfonamides. **Urticaria** (p.1584) is also frequently drug-induced. **Photosensitivity** rashes where the skin reaction is confined to light-exposed areas may be phototoxic or photoallergic in nature (see Drug-induced Photosensitivity, p.1581). Amiodarone produces a phototoxic reaction in many patients. Some drugs cause **pigmentary changes** (see Pigmentation Disorders, p.1582). Chlorpromazine can cause both photosensitivity and pigmentary changes. **Acneform eruptions** may be produced by a number of drugs (see Acne, above). Some drugs produce skin reactions resembling **pemphigus** and **pemphigoid** (see p.1582). Most of the drugs implicated contain a thiol group or metabolism of the drug generates a thiol group. Examples include captopril, penicillamine, penicillins, piroxicam, and rifampicin. **Fixed-drug eruptions** are inflammatory patches that appear at the same sites each time the drug is taken, and may occur with many drugs including dapsone, sulfonamides, and tetracycline.

Drug-induced **nail changes** include onychomadesis, nail fragility, onycholysis, paronychia, pigmentation, and vascular changes. The effect is usually transient and disappears with drug withdrawal. Drugs reported to cause nail changes include antineoplastics, psoralens, retinoids, tetracyclines, and zidovudine.

The majority of drug-induced adverse skin reactions are mild. However, in severe reactions rapid withdrawal of the suspected drug is needed. In some cases, this may mean stopping several drugs. In most cases the skin reaction will be resolved by symptomatic treatment. Another dose of the offending drug may establish whether the skin eruption is drug-induced, although reactions may be more severe and therefore rechallenge should not be performed after a serious reaction.

Eczema

Eczema (often used synonymously with the term dermatitis) refers to a variety of skin conditions characterised by epidermal inflammation and itching. The areas of skin affected vary in the different types of eczema, but the skin lesions share certain common features. In acute eczema the skin is typically red and inflamed with papules, vesicles, and blisters. In chronic eczema the skin may show the same features but be more dry, scaly, pigmented, and thickened. Eczema may be categorised as exogenous (including allergic, irritant, and photosensitivity eczema) or endogenous (such as atopic, discoid/nummular, gravitational, and seborrhoeic eczema), but there may be multiple causes of eczema, both endogenous and exogenous, in an individual patient. Two of the most common forms of eczema are atopic eczema (see below) and seborrhoeic dermatitis (p.1584).

Atopic eczema mainly affects infants and children although adults may also suffer. The skin is itchy and there is a chronic or relapsing dermatitis in which the face and neck and flexures of the elbows and knees are involved most often and are excoriated and lichenified.

General principles for the management of **atopic eczema** may also be applied to other eczematous skin disorders. Cure of atopic eczema is said to be unrealistic, but good control can be achieved with proper management. The objective of treatment should be to reduce signs and symptoms, to prevent or reduce recurrences, and to provide long-term management by preventing exacerbation. Guidelines have been issued by, among others, the Primary Care Dermatology Society with the British Association of Dermatologists,[1] the American Academy of Dermatology,[2] and the International Consensus Conference on Atopic Dermatitis (ICCAD II).[3] The management of eczema is also frequently reviewed.[4-6]

First-line treatment.

- Regular bathing using soap substitutes is important to *cleanse and hydrate* the skin; soaps and detergents should be avoided as these remove the natural lipid from the skin. Suitable bath oils should be used to maintain skin hydration. Emollients should be applied liberally to the whole body at least twice daily, especially after bathing, and more frequently throughout the day to hands and face.
- Patients should be educated on the *avoidance of trigger factors*. These may include irritants, microbes, and psychological or allergic factors.

Acute control of pruritus and inflammation.

- Intermittent topical *corticosteroids* are the mainstay of treatment and are used for up to a week to manage acute flares of atopic eczema. Treatment for up to 6 weeks may be needed for initial control of chronic eczema. To minimise potential adverse effects the minimum strength preparation to control the disease should be used, and the age of patient, site of eczema, and extent of disease should be considered when selecting the appropriate preparation. Very potent preparations should be used in children only under specialist supervision.
- Topical *calcineurin inhibitors* (pimecrolimus or tacrolimus) may be used as alternative therapy when corticosteroids are contra-indicated, or as second-line therapy in patients who have not responded adequately to topical corticosteroids. Pimecrolimus is indicated for mild to moderate disease and tacrolimus for moderate to severe eczema. The main adverse effect is burning at the site of application. Once the condition settles the patient should revert to treatment with emollients.

Maintenance therapy.

- Topical corticosteroids may be used intermittently for acute exacerbations. Once the patient is back in remission emollients should be continued.
- For persistent disease or frequent flares, topical calcineurin inhibitors are effective and may be used at the earliest sign of recurrence. While these drugs prevent disease progression they do not have the adverse effects of corticosteroids and consequently may be used on all body areas (including sensitive areas like the face, eyelids, and neck) for extended periods. Studies so far suggest that these new drugs are safe in the short term. However, they do suppress T lymphocytes and although systemic absorption is minimal there may be a possibility of immunosuppression, skin cancers, or bacterial infection. There has been considerable debate about the possible risk of cancer associated with topical calcineurin inhibitors (see Carcinogenicity, under Tacrolimus, p.1843). These concerns in particular prompted licensing authorities in Europe and the USA in 2006 to remind prescribers that these drugs should only be used intermittently as second-line treatments, and should not be used in children less than 2 years of age.[7-9]
- *Coal tar* preparations may be used occasionally for chronic atopic eczema, and *ichthammol* may be used as an ointment or paste bandages for chronic lichenified eczema.

Adjunctive therapy.

- Overt bacterial, fungal, or viral infections should be treated with an appropriate systemic drug (see Skin Infections under Antibacterials, p.194, and under Antifungals, p.521). Topical preparations are generally not used as they should be restricted to limited areas and patients with eczema often have widespread infections.
- A sedating *antihistamine* may be used short term for severe pruritus associated with relapse or at night-time if scratching disturbs sleep or occurs while asleep. Non-sedating antihistamines are generally ineffective in eczema but may be of benefit in atopic dermatitis and concomitant urticaria. Topical *doxepin* may provide short-term relief from pruritus, but drowsiness and contact dermatitis can occur.

Patients whose eczema fails to respond to these first-line treatments, even under specialist supervision, require further measures.

Severe refractory disease.

- *Phototherapy* with ultraviolet A or B, or in combination, may be useful, and photochemotherapy using a psoralen (generally methoxsalen) with ultraviolet A (PUVA) may be used in severe, widespread disease. However, potential long term effects such as premature ageing of the skin and skin malignancy need to be considered.
- Therapy with *more potent topical and oral corticosteroids* may be considered for short periods of time. In general, only mild corticosteroids (such as 1% hydrocortisone) should be used on the face and in flexures as absorption is increased in these areas.
- *Wet-wrap dressings* are sometimes used intermittently, particularly in children, for hydration and anti-inflammatory effects.[10,11] Different techniques have been described: wet bandages or dressings may be applied to skin already covered with an emollient or diluted corticosteroid cream, alternatively the dressing may be soaked in warm diluted cream before use; a dry outer dressing may be added. Dressings may be used only on affected parts of the body, or a whole-body suit may be used for extensive eczema, and left in place for up to 24 hours. Treatment can continue for several weeks, but should probably be limited to 1 week when corticosteroids are used because of the risk of adverse effects from systemic absorption.[10] Wet-wrapping may not be appropriate in patients whose eczema has become infected.
- Various *other drugs* have been tried in resistant eczema. Azathioprine, ciclosporin, or methotrexate may be tried in selected patients.

Evening primrose oil and borage oil have also been tried although evidence in favour of a useful therapeutic effect is poor. Other drugs at an experimental stage include interferons, mycophenolate mofetil, and thymopentin. There has been much interest in the use of complementary and alternative therapies and herbal medicines, but serious adverse effects have occasionally occurred and although encouraging results have been reported the degree of benefit is still uncertain.[12,13]

Epidermolysis bullosa

Epidermolysis bullosa consists of a group of similar congenital disorders characterised by severe blistering of the skin.[1,2] Sometimes the mucosae, especially of the mouth and oesophagus, are also affected. The blistering may be caused by various structural and metabolic defects and occurs at different levels in the skin in the different forms (simple, junctional, and dystrophic). Blistering can follow even minor trauma or can arise spontaneously. In some patients blistering and scarring can cause marked tissue loss of the affected areas and the most severe forms are fatal in early infancy because of infection of the blisters. Milder forms may be managed by avoiding trauma and keeping blisters clean and dry, but there is no truly effective treatment for the severe forms. High-dose oral corticosteroids may be needed. Phenytoin has been tried, but was unsuccessful in a controlled study. Thalidomide has also been tried, and oral tetracycline has reduced the number of lesions in a few cases.

There is also an acquired form of the disease, epidermolysis bullosa acquisita, and it too is difficult to treat;[3] corticosteroids and other immunosuppressants may be tried. Individual patients have responded to high-dose intravenous immunoglobulins or extracorporeal photochemotherapy (oral methoxsalen followed by removal of blood and UV irradiation of leucocytes outside the body before reinfusion).[4,5] There are individual case reports of successful treatment with monoclonal antibodies such as basiliximab (an interleukin-2 receptor antibody)[6] and rituximab (an anti-CD20 antibody).[7]

Erythema multiforme

Erythema multiforme is an inflammatory reaction of the skin characterised by maculopapular lesions that may become annular and blister. Areas typically affected are the hands, forearms, elbows, knees, and feet. It is usually associated with a precipitating trigger such as infection (notably herpes simplex infection); it may also be associated with drug use, neoplastic disease, or collagen or inflammatory diseases. In severe forms there is also blistering of the mucous membranes (usually of the mouth). There is some overlap in the descriptions of erythema multiforme, Stevens-Johnson syndrome, and toxic epidermal necrolysis, and attempts have been made to classify them into distinct categories.[1-3] Erythema multiforme occurs mainly after infections, whereas the Stevens-Johnson syndrome is mainly a drug-induced reaction and seems to be part of a spectrum of skin reactions, with life-threatening toxic epidermal necrolysis being the more severe form (see Drug-induced Skin Reactions, above).

As erythema multiforme is usually an acute reaction of relatively short duration, symptomatic treatment as for burns (see above) may be all that is required. If severe reactions occur systemic corticosteroids may be considered, although there has been controversy about their value. Erythema multiforme may become a recurrent disorder in some patients and various drugs have been tried for treatment and prophylaxis.[4] Aciclovir, given in short courses or continuously, has been used particularly when herpes simplex infection appeared to be a trigger factor. Other drugs that have been tried for recurrent erythema multiforme include dapsone, hydroxychloroquine, mepacrine, azathioprine, mycophenolate, and thalidomide.

Hyperhidrosis

Hyperhidrosis (excessive sweating) can be generalised or focal, affecting the palms of the hands, soles of the feet, axillae, or less commonly the craniofacial region. No cause can usually be established although it may be secondary to an underlying endocrinological, neurological, or neoplastic disorder;[1,2] in some cases, it may be drug-induced.[3]

Drug therapy should be tried initially but is often ineffective in severe cases. Aluminium salts, such as aluminium chloride or aluminium chlorohydrate in alcoholic solvents applied topically, may be successful in milder forms of focal hyperhidrosis.[1,2,4] Topical antimuscarinics such as diphemanil metilsulfate, glycopyrronium bromide, or hyoscine hydrobromide may also provide some relief, particularly in craniofacial sweating.[2] Adverse effects of oral antimuscarinics generally preclude such use, although oral propantheline bromide has been used successfully to control excessive sweating in a few patients with spinal cord injuries. An intravenous infusion of phentolamine mesilate may be effective in some patients with generalised hyperhidrosis.[5] Tap water iontophoresis is an alternative first-line option for palmar or plantar hyperhidrosis.[1,2,4] Intradermal injection of botulinum A toxin is used for focal hyperhidrosis when topical therapies are insufficient, although injections are painful and local or regional anaesthesia may be needed, especially for treatment of the hands and feet.[1,2,4] Formaldehyde and glutaral solutions have been used topically for hyperhidrosis affecting the feet but are not very effective and are not usually recommended.

When drug therapy fails to provide adequate relief surgery may be attempted.[1,2,4] Subcutaneous curettage or excision of skin bearing the eccrine glands has been used but minimally invasive techniques, notably endoscopic thoracic sympathectomy, are now available; the latter offers a simple and effective management for severe localised upper limb hyperhidrosis.

Ichthyosis

Ichthyosis is a term used for generalised noninflammatory dry scaling or keratinisation disorders (see below). There are several different forms of ichthyosis and severity and incidence varies. They are generally inherited disorders. Emollients, including urea, are used to provide relief to the dry skin by coating the skin surface with an oily film thus preventing evaporation of water. If scaling is more severe topical keratolytics such as salicylic acid or urea are used. Topical retinoids such as tazarotene may be tried. In the severest forms of ichthyosis oral retinoids may be necessary. Acitretin, etretinate, and isotretinoin have all been used. A few patients have responded to topical calcipotriol or tacrolimus, but systemic absorption may be a problem. Liarozole, an oral inhibitor of retinoic acid catabolism, is under investigation.

Keratinisation disorders

Keratinisation is the process whereby basal epidermal cells are transformed into dead cells of the stratum corneum from where they are shed. The process takes about 14 days and shedding normally balances production so that the thickness of the stratum corneum does not alter. Keratinisation disorders (keratoses) are characterised by reduced shedding and the formation of scale at the skin surface. A scale is an aggregate of horn cells that have failed to separate horizontally and hyperkeratosis is an exaggeration of this failure in which there is also a vertical build up of the horn cells. Keratinisation disorders include Darier's disease and ichthyosis (see above). Certain inflammatory skin disorders, such as psoriasis (see p.1583), also show enhanced epidermal proliferation.

Lichen planus

Lichen planus is an inflammatory skin disorder with itchy papular lesions arising usually on the extremities. The nails and oral or buccal mucosa, and rarely the genital mucosa, may also be affected. Its cause is uncertain although sufferers have a higher incidence of auto-immune disease than normal. Some drugs can produce lichenoid reactions; examples include mepacrine, methyldopa, penicillamine, and sodium aurothiomalate.

Evidence for the efficacy of the various treatments that have been tried is mostly scanty.[1,2] In most patients lichen planus remits spontaneously and, if mild and localised, little or no treatment is needed. Potent topical corticosteroids are often used for localised cutaneous disease when treatment is needed, and occlusive dressings may be used to enhance efficacy.[1,3] However, less potent corticosteroids should generally be used on the face, axillae, groin, or genitals. Intralesional corticosteroids, such as triamcinolone acetonide, can be used for hyperkeratotic or resistant localised plaques. Symptomatic mucosal disease is also treated with topical corticosteroids;[1,3,4] various dosage forms have been used including ointments, adhesive bases, pastes, lozenges, and mouthwashes. Other drugs that have been used topically, with variable results, include ciclosporin and the retinoids isotretinoin and tretinoin. Intralesional corticosteroids have also been used for resistant or erosive mucosal lesions.[1,4]

Systemic corticosteroids may be used in generalised cutaneous lichen planus and acute exacerbations of mucosal disease.[1,3,4] If the condition becomes resistant to corticosteroid therapy, an oral retinoid such as acitretin, etretinate, or isotretinoin, may be tried. Other oral treatments for which there are reports of benefit in small numbers of patients include ciclosporin, griseofulvin, chloroquine and hydroxychloroquine, and photochemotherapy using a psoralen with UVA (PUVA).[1,4] Topical tacrolimus and pimecrolimus have also been tried.

Lichen sclerosus

Lichen sclerosus is a chronic inflammatory skin condition that most commonly occurs in women, but is also seen in men and children.[1-5] It affects the anogenital area, causing itching, soreness, and urinary and sexual problems. Extragenital lesions may occur, but do not usually itch, and some patients may show no symptoms at all.[1,2,5] Lichen sclerosus runs a relapsing and remitting course and complications include secondary infection, most commonly with *Candida*, physical scarring, and vulvodynia. The most common complication seen in male patients is phimosis. Although the exact cause of the disease is unknown, there appears to be a strong association with auto-immune disorders and genetic factors have also been implicated. There is also an association between lichen sclerosus and squamous cell and verrucous carcinoma.[2,3,5]

Management of lichen sclerosus includes the control of symptoms, prevention and treatment of complications, and the early detection of malignancies.[3,5] Topical potent corticosteroids such as clobetasol propionate or betamethasone dipropionate 0.05% have been shown to be safe and effective for both genital and extragenital disease. Intralesional triamcinolone was found to be effective in a small trial. The benefit and safety of other topical treatments, such as pimecrolimus, tacrolimus, retinoids, testosterone, and progesterone are not clear. Systemic retinoids may be useful in complicated disease that is not responding to topical corticosteroids. There have been reports of benefit for treatment with stanozolol, photochemotherapy using a psoralen with UVA (PUVA), photodynamic therapy using topical 5-aminolevulinic acid, and laser therapy. Surgical intervention is only indicated for complications of scarring or the development of malignancy.[2,3,5]

Light-induced skin reactions

Light, although essential for many biological functions, may cause a variety of disorders, particularly due to the ultraviolet portion of the solar spectrum.

Ultraviolet (UV) light has different properties according to its wavelength.

- **UVA** (wavelengths 320 to 400 nm) produces immediate direct tanning of the skin with little erythema although it does contribute to the long-term harmful effects of photoageing and cancers. UVA has also been subdivided into UVA-I (340 to 400 nm) and UVA-II (320 to 340 nm); the effects of UVA-II are more like those of UVB.
- **UVB** (wavelengths 290 to 320 nm) is about 1000 times stronger than UVA in producing erythema and is that part of the sun's spectrum that is responsible for producing sunburn and it too contributes to long-term effects. UVB also produces tanning by indirect pigmentation.
- **UVC** (wavelengths 200 to 290 nm) produces erythema without tanning. The earth's surface is usually screened by the ozone layer from UVC radiation although UVC may be emitted by artificial sources such as bactericidal lamps and industrial welding arcs.

In normal healthy individuals **exposure to sunlight** (including reflected light from snow, white sand, or water) causes an increase in pigmentation (tanning). This is an adaptive mechanism to protect the skin from UV radiation. Immediate tanning results from the oxidation of melanin precursors in the uppermost layers of the skin. There may also be a delayed and indirect pigmentation due to the formation of new melanin. The ability of an individual to form a tan is genetically predetermined. Melanin provides some protection against further exposure, but the main protection is provided by thickening of the corneous layer. However, excessive exposure to strong sunlight causes erythema and sunburn, which is an inflammatory response to the damage caused by UV radiation.

Excessive and prolonged exposure to intense sunlight may lead to degenerative changes in the skin (premature ageing of the skin or photoageing, below), actinic (solar) keratoses (which are risk factors or precursors of skin cancers), immunosuppression, and some skin cancers such as basal cell or squamous cell carcinomas and malignant melanomas (see Malignant Neoplasms of the Skin, p.672). Some patient groups are also at higher risk of adverse effects from sunlight exposure. Even brief exposure to sunlight can trigger a reaction in those with photosensitivity disorders (below), patients with hypopigmentation disorders such as vitiligo and albinism (see Pigmentation Disorders, p.1582) are more susceptible to sunburn, and transplant patients receiving systemic immunosuppressants are at increased risk of skin cancers (see under Organ and Tissue Transplantation, p.1810). Many drugs can cause a phototoxic or photoallergic reaction (see Drug-induced Photosensitivity, below).

Protection against sunlight is therefore beneficial, both in healthy people to prevent skin damage, and in patients at increased risk of adverse effects from sunlight exposure. Medical and scientific personnel exposed to ultraviolet lamps may need protection against the whole of the UV spectrum. This may be achieved by appropriate dress and through the use of **sunscreens** applied to the skin. Sunscreens may be of chemical or physical types (see p.1576) and many products combine sunscreens of different types to maximise protection. A broad-spectrum sunscreen should be effective against both UVA and UVB, but UVA coverage can be variable. It may be difficult to formulate physical sunscreens in cosmetically acceptable ways.

The efficacy of a particular sunscreen preparation is often expressed as its **sun protection factor (SPF)**. This is a ratio of the time required for irradiation to produce minimal perceptible erythema (minimal erythemal dose; MED) with the skin protected with the sunscreen compared with the MED without protection, for a standard 2 mg/cm^2 dose of sunscreen. Thus the SPF is mainly an indication of efficacy against UVB light. Various systems have been suggested for classifying the relative efficacies of sunscreens against UVA light but none appears, as yet, to be universally accepted. The efficacy of a sunscreen is also highly dependent upon its correct application and studies have found that, in general, sunscreen preparations are applied haphazardly and in insufficient quantities to provide optimal protection.

Governmental authorities and dermatologists in many countries issue guidance to the public on sun protection, including sunscreen use. General measures include avoiding sunlight exposure when UV radiation is strongest (usually between 10 a.m. and 3 p.m.), seeking shade when outdoors in strong sunlight, using wrap-around sunglasses that conform to appropriate standards, and wearing a broad-brimmed hat and clothing that protect against sunlight. Sunscreens should be applied liberally and evenly to all exposed areas of skin at least 15 to 30 minutes before sunlight exposure, and re-applied at least every 2 hours and after swimming or perspiring. Broad-spectrum products are recommended; dermatologists in some countries such as the UK and USA advocate the use of preparations with at least SPF 15 (SPF 15+), while in Australia SPF 30+ is recommended.

Many treatments have been tried in the management of acute *sunburn*, but studies have been small and results often conflicting. There is a lack of strong evidence to show that any specific treatment reduces epidermal damage or the time to healing once the signs and symptoms of sunburn have developed. Emollients, cool compresses, paracetamol, and NSAIDs, are often used for symptomatic relief of erythema, pain, and pruritus; oral antihistamines, topical hydrocortisone, and topical anaesthetics might also be considered.

Drug-induced photosensitivity. Photosensitivity can be produced by drugs either given systemically or applied topically, and the reaction can be phototoxic or photoallergic in nature.[1] In *phototoxicity,* a direct toxic effect on tissues occurs when the drug is energised by absorbing radiation. The reaction has a rapid onset (usually within 24 hours) and occurs on exposed skin areas. Resembling an exaggerated sunburn, the reaction can include erythema, oedema, hyperpigmentation causing a darker red than sunburn, pruritus, and urticaria. The response is dependent on the dose of the photosensitiser and the intensity of sunlight exposure. In *photoallergy,* the hypersensitivity reaction has an immunological basis requiring previous exposure to the photosensitising drug. The onset may be delayed until several days after exposure to sunlight and present as a papulovesicular eruption, pruritus, and eczematous dermatitis. Photoallergic reactions are less common than phototoxicity.

Systemic drug groups that have been reported to cause photosensitivity include:

- antibacterials (fluoroquinolones, sulfonamides, and tetracyclines)
- antidepressants (tricyclic antidepressants and St John's wort)
- antiepileptics (carbamazepine, lamotrigine, phenobarbital, and phenytoin)
- antihistamines (including cyproheptadine, diphenhydramine, and loratadine)
- antimalarials (chloroquine, quinine, pyrimethamine, and mefloquine)
- antineoplastics (including fluorouracil, methotrexate, and vinblastine)
- cardiovascular drugs (including ACE inhibitors, amiodarone, quinidine, thiazide diuretics, and simvastatin)
- corticosteroids
- NSAIDs
- phenothiazine antipsychotics
- sex hormones (oestrogens and progestogens)
- sulfonylurea antidiabetic drugs
- retinoids (isotretinoin)

Photocontact dermatitis occurs from the interaction between sunlight and topically applied substances, and can be either a phototoxic or photoallergic reaction. Implicated drugs have included antiseptics, antifungals, coal tar, corticosteroids, local anaesthetics, and retinoids.[1] Photosensitivity reactions have also occurred to the topical sunscreens intended to prevent them.[1,2] Photoallergic reactions have been reported for chemical sunscreens, particularly aminobenzoic acid and benzophenones (dioxybenzone, mexenone, oxybenzone, and sulisobenzone). Reactions to cinnamates seem to be less frequent.

Photosensitivity reactions are managed symptomatically as for sunburn (see Light-induced Skin Reactions, above); antihistamines and corticosteroids may be needed to treat photoallergic reactions. If the offending drug cannot be withdrawn or substituted, sun exposure should be minimised with appropriate clothing and sunscreens.[1]

Photoageing. Exposure to sunlight induces changes in the skin in addition to the normal ageing process. This photoageing, or photodamage, can manifest as wrinkles, skin roughness and dryness, irregular pigmentation, telangiectasia, sallowness, and lentigines (sun or liver spots). Photoageing is also associated with increased risks of actinic keratoses and skin cancers (see Malignant Neoplasms of the Skin, p.672).

Cosmetic treatments and procedures for the effects of photoageing have been extensively and widely promoted, but few have undergone rigorous scientific evaluation and there is a lack of data in general.[1] Measures to limit sunlight exposure, including the use of sunscreens, reduce the progression of photoageing.[2,3] Topical retinoids, such as isotretinoin, tazarotene, and tretinoin, can improve fine wrinkles, irregular pigmentation, roughness, and lentigines. However, the effect is dose-related and these drugs can cause irritation and photosensitivity.[1-4] Hydroxyacid keratolytics such as glycolic acid are also widely promoted for the reduction of photoageing effects. Low concentrations are used in nonprescription cosmetic preparations, and higher concentrations may be used as chemical peels. Overall, however, their effects are limited.[1,2] Local injection of botulinum A toxin to cause muscle paralysis is used for the cosmetic reduction of lines and wrinkles.[2,3] Injectable skin fillers such as bovine collagen and hyaluronic acid are also available to reduce lines and deep wrinkles.[2] Other procedures in use include dermabrasion to reduce wrinkles, and cryosurgery or electrosurgery for discrete pigmented lesions; lasers or other light therapies are also used for wrinkles, pigmented lesions, and benign vascular proliferations such as telangiectasia and angiomas.[2] Oral and topical antioxidants have also been promoted for the treatment and prevention of photoageing, but there is a lack of data to support such claims.[2,3]

Photosensitivity disorders. In some persons even brief exposure to sunlight can result in light-induced disorders of the skin.

Polymorphic light eruption is a common hypersensitivity reaction characterised by pruritic erythematous papulovesicular lesions that develop several hours after exposure to sunlight. The condition usually begins in adulthood and affects more women than men. For many patients the susceptibility to eruption starts in early spring and resolves by late summer as the skin becomes more tolerant to sunlight, but patients with severe forms may also be symptomatic in the winter. Mild forms can settle without scarring within days, by sun avoidance and use of a broad-spectrum sunscreen. Potent topical corticosteroids or a short course of oral prednisolone may be useful to control the acute rash. A gradual increase in exposure to sunlight may be sufficient for desensitisation in mild cases, but patients with more severe disease may need to undergo artificial hardening of the skin by UVB phototherapy or photochemotherapy using a psoralen with UVA (PUVA). However, this effect is temporary and usually needs to be repeated each spring.[1-3] Azathioprine may be considered in patients who are very sensitive to sunlight, for whom sunscreens are ineffective, and who cannot tolerate phototherapy.[2]

Chronic actinic dermatitis is manifested by a persistent, often lichenified, eczematous eruption that usually only affects the exposed areas although in a small number of patients larger areas can be affected. It mainly affects older men, and many patients may be unaware of the role that sunlight plays in the condition. These patients may also show clinically relevant allergy to many naturally occurring substances, as well as drugs and sunscreens.[3-5] Management is based on sunlight and allergen avoidance and the use of sunscreens, emollients, and topical or oral corticosteroids. Phototherapy or photochemotherapy may also be useful. Systemic immunosuppressants including azathioprine, ciclosporin, and mycophenolate mofetil have been used in resistant disease.[1,4,5] Interferon alfa and topical tacrolimus have also been used successfully in a few cases.[1]

Actinic prurigo is similar to polymorphic light eruption but less common, and is characterised by persistent pruritic papules on areas exposed to sunlight, often with extension to covered areas. Other features include scarring, cheilitis, and eye involvement. It is managed similarly with sunscreens, topical or oral corticosteroids, and phototherapy or photochemotherapy. Thalidomide has been used, but relapse frequently occurs when treatment is stopped.[1]

Solar urticaria is an uncommon condition that can often be managed with sunscreens alone, but non-sedating antihistamines such as loratadine may also be helpful. Phototherapy and photochemotherapy have also been used.[1]

Xeroderma pigmentosum is a rare autosomal recessive condition in which a defective DNA-repair system fails to repair UV-induced DNA damage.[6] The skin is hypersensitive to sunlight, resulting in serious sunburn after minimal exposure. From a very early age patients start to develop lentigines (sun or liver spots), spotty hypopigmentation, telangiectasias, calloused thickening, atrophy, scabbing, and scarring. Numerous actinic keratoses, precancerous lesions, and malignant neoplasms of the skin (p.672) develop in childhood and many patients die before reaching adulthood. Other effects of the disease include motor impairment, mental retardation, ocular damage, leukaemia, and dental caries. Management involves strict avoidance of sunlight and use of broad-spectrum sunscreens. There is some evidence that systemic retinoids, such as acitretin and isotretinoin, may be useful in preventing the development of skin cancers, although adverse effects from long-term use may be of concern. Topical fluorouracil may be used on actinic keratoses and malignant skin cancers. A topical preparation containing recombinant T4 endonuclease V, a DNA-repair enzyme, is under investigation to reduce the incidence of actinic keratoses and skin cancers.

Other conditions that can be exacerbated by sunlight include the cutaneous porphyrias (p.1448), lupus erythematosus (p.1513), and sometimes herpes labialis (p.854).

Pemphigus and pemphigoid

Pemphigus and pemphigoid are rare, disabling, and severe or potentially fatal blistering skin diseases. They are distinct disorders although both have an auto-immune basis. Some drugs might also trigger pemphigus or pemphigoid; implicated drugs have included penicillamine and ACE inhibitors.

- There are several types of pemphigus. In pemphigus vulgaris, the most common type, the blistering is intra-epidermal and can occur anywhere on the skin surface or present as ulceration of the mucous membranes. It is a chronic, progressive disorder requiring prolonged treatment.
- Pemphigoid is also known as bullous pemphigoid and occurs mainly in elderly persons. The blistering is sub-epidermal and affects the skin; mucous membranes can be affected in up to a half of all patients but it may be mild and not noticed by the patient. Pemphigoid is usually a self-limiting disorder and treatment can often be stopped after a couple of years.
- Mucous membrane pemphigoid (cicatricial pemphigoid) is a rare form that affects mainly the oral mucosa and conjunctiva, and may affect other mucosae, causing scarring.

The treatment of the blistering in both pemphigus and pemphigoid follows a similar pattern. Wet dressings and general treatment as for burns (see p.1578) are commonly used. Corticosteroids are used initially to induce remission. Maintenance treatment often includes adjunctive therapies aimed at keeping control of the disease while tapering the corticosteroid dose, with the ultimate aim of complete treatment withdrawal.

High doses of systemic corticosteroids may be required to control the blistering, which may take weeks.[1-3] The optimum dose has not been established and suggestions have varied enormously (for more detail see Pemphigus and Pemphigoid, under Corticosteroids, p.1509); very high doses of oral prednisolone have been used in the past.[2] Pulsed intravenous corticosteroids such as methylprednisolone may be considered for severe or refractory disease, particularly if there has been no response to high oral doses.[2,3] A very potent topical corticosteroid such as clobetasol propionate can be sufficient to control localised or mild to moderate disease in some patients, particularly in bullous pemphigoid.[1,3-5] Blistering and ulceration of the oral mucous membranes may be treated with topical corticosteroid preparations.[2,3,6] Intralesional injections have also been used for isolated lesions of the skin[3] and oral mucosa.[3,6] Topical corticosteroids may need to be added to initial systemic therapy to control acute ocular inflammation.[7]

Various therapies have been used as adjuncts or occasionally as alternatives to treatment with corticosteroids. However, given the rarity of the diseases, few controlled studies have been performed. Immunosuppressive therapy, usually with azathioprine, may be added to improve disease control and permit a reduction in corticosteroid dosage.[1,2,4,6] Cyclophosphamide and methotrexate have been used similarly although there is less information published about their use.[1,2,4] Oral or intravenous cyclophosphamide with a corticosteroid may be useful in severe or rapidly progressing mucous membrane pemphigoid.[6] Chlorambucil might be considered if other immunosuppressants cannot be used, but there is very limited evidence to support this.[1,2] Mycophenolate mofetil and ciclosporin have also been used in small numbers of patients with some reports of success.[1,2,4,6] Some patients with bullous pemphigoid respond to dapsone,[1,4] and it may be adequate for first-line treatment in mild to moderate inflammation in mucous membrane pemphigoid.[6,7] There have also been a number of reports suggesting that a tetracycline alone or with nicotinamide, may be useful in controlling the lesions of various types of pemphigus and pemphigoid. They may be tried in patients with mild to moderate disease.[1,2,4] Intramuscular gold therapy has also been used for pemphigus vulgaris, and might be considered when other adjunctive drugs cannot be used.[2] High-dose intravenous immunoglobulin has been given to permit reduction of corticosteroid therapy in pemphigus and pemphigoid, and in some patients has produced prolonged remission.[8] It is usually reserved for severe disease that has not responded to other therapies.[2,4] There have been a few reports of rituximab inducing remission in previously unresponsive pemphigus.[3] Plasmapheresis (plasma exchange) may be tried in severe, unresponsive disease,[1,2] but there is little evidence of benefit and its use can be limited by cost and adverse effects.[4]

Pigmentation disorders

The pigment melanin is produced in melanocytes in the basal layer of the epidermis. It is a complex polymer synthesised from the amino acid, dihydroxyphenylalanine. Melanin production is under pituitary control but is also influenced by other endocrine secretions.

Decreased pigmentation (hypopigmentation) and excessive pigmentation (hyperpigmentation) can occur and may be either generalised or localised.

Albinism is a rare inherited disorder that can cause generalised **hypopigmentation**. Affected individuals are extremely sensitive to solar irradiation and must use sunscreens regularly.

A common form of localised hypopigmentation is **vitiligo**. Sharply defined areas of depigmentation are seen and may remain localised or spread so that total depigmentation eventually occurs. Depigmented areas are more susceptible to sunburn and all exposed areas, both normal and depigmented, should be protected from sunlight with clothing or sunscreens. Cosmetic camouflage of the depigmented area is commonly used, and may be sufficient for patients when only small affected areas are visible.[1] Dihydroxyacetone produces a brown staining of the skin that may be cosmetically acceptable. There is no totally effective repigmentation treatment, although some therapies may offer a degree of benefit.[2] Oral or topical photochemotherapy with psoralens (PUVA) is currently considered to be the best treatment.[1,3] Topical corticosteroids are sometimes effective at inducing repigmentation.[4,5] Experimental drug therapy for re-inducing pigment has included UVA light therapy with either khellin or phenylalanine; oral levamisole, alone or with topical corticosteroids, has also been reported to be of benefit. UVB phototherapy has also been tried and some consider it to be superior to the use of UVA,[4,5] and the initial treatment of choice in moderate to severe disease.[6] There are a few small studies and case reports of benefit with the use of topical tacrolimus or pimecrolimus[6,7] and combinations of topical calcipotriol with either UV light therapy or a corticosteroid.[6] Transplantation of autologous cultured melanocytes, ultrathin epidermal sheets, or basal cell layer suspension may be beneficial in some forms of vitiligo. Transplantation is not suitable for progressive, widespread vitiligo vulgaris.[5,8] If the vitiligo affects a large proportion of the body (more than 50%), and if PUVA is ineffective at inducing repigmentation, an option is to consider inducing depigmentation in the remaining normal skin in order to match the lighter vitiligous areas. Permanent depigmentation may be induced by monobenzone, but patients must subsequently use topical sunscreens in order to avoid damage caused by solar exposure.[1]

Hyperpigmentation can be caused by increased amounts of melanin, or by other substances such as iron in the skin. Generalised hyperpigmentation may be seen in Addison's disease, acanthosis nigricans, and primary haemochromatosis; other causes may include cirrhosis, chronic renal failure, and glycogen storage disease. Darkening of the skin can also occur in patients taking certain drugs due to a deposition of the drug-melanin complex in the skin. Notable examples include amiodarone, minocycline, and phenothiazines. Localised hyperpigmentation is seen in chloasma (melasma) in which there is facial involvement and is encountered most commonly in pregnancy; it may also be associated with hormonal contraceptive use. A number of compounds have been used basically as bleaching agents in hyperpigmentary disorders, and of these hydroquinone has been used most often;[9,10] monobenzone is not recommended. A beneficial response to topical tretinoin and azelaic acid in patients with chloasma has been described. Combination preparations containing hydroquinone, tretinoin, and a corticosteroid are available in some countries. Laser therapy, or the use of chemical peels, has also been tried.[9,10]

Pruritus

Pruritus (itching) is a common and distressing symptom of many skin disorders but may also have a systemic cause such as obstructive jaundice, chronic renal disease, endocrine disease, certain malignancies, or a drug hypersensitivity reaction. The exact pathophysiology of itching is unclear, and different inflammatory mediators may be associated with itching in different disorders; the CNS is also thought to play a role in the perception of itch.

Pruritus should be considered as symptomatic of the underlying disorder and treatment should focus on the removal of the offending trigger. However, symptomatic treatment of pruritus may also be necessary.

Emollients may be useful where dry skin is a contributory factor, and may be applied for **topical** management of pruritus. Calamine and crotamiton are often used topically, despite some uncertainty about their value, as are preparations containing phenol or agents such as menthol that cause capillary dilatation with a subsequent sensation of cold and analgesia. Topical capsaicin has also been used and topical corticosteroids may be used to relieve pruritus when there is associated inflammation. Local anaesthetics or antihistamines are only marginally effective for topical use and can very occasionally cause sensitisation. However, lauromacrogol 400 has proved of benefit. Doxepin, a tricyclic antidepressant with very potent antihistaminic activity, has been used topically for the relief of pruritus associated with dermatitis, but adverse effects from systemic absorption can limit its use.

Sedating antihistamines given **by mouth** are commonly used to relieve more generalised pruritus and are used to control the severe itching associated with dermatoses such as atopic eczema (see p.1579). Mirtazapine, a noradrenergic and serotonergic antidepressant with a potent antihistamine effect, has been tried in various types of pruritus with reports of success. Bile-acid binding resins, such as colestyramine, are used to relieve pruritus associated with the deposition in dermal tissue of excess bile acids in patients with partial biliary obstruction, primary biliary cirrhosis, or intrahepatic cholestasis of pregnancy. There are reports of cholestatic pruritus also responding to ondansetron although results from controlled trials have been mixed. Pruritus caused by obstetric cholestasis has been treated with ursodeoxycholic acid, which also corrects the associated biochemical abnormalities. Central opioid receptors modulate itch and opioid antagonists such as nalmefene and naltrexone have been reported to relieve pruritus. Many other drugs, including cimetidine and propofol, have been of benefit in some patients. Paroxetine has been useful in some patients with cancer-related pruritus, but the effect tended to wear off after several weeks. PUVA (see under Methoxsalen, p.1606) may be helpful in some pruritic skin conditions including aquagenic pruritus.

Psoriasis

Psoriasis is a chronic inflammatory skin disorder characterised by enhanced epidermal proliferation leading to erythema, scaling, and thickening of the skin. It appears to be a T-cell mediated auto-immune disease. There are several types of psoriasis including guttate, flexural, pustular, and erythrodermic, but chronic plaque psoriasis (psoriasis vulgaris) is the most common form. In chronic plaque psoriasis the areas most commonly affected are the extensor sides of the knees, elbows, and hands, and the scalp and sacrum. There is no cure and treatment is designed to induce a remission or suppress disease to a tolerable level.

The treatment of psoriasis has been the subject of a number of reviews.[1-9]

Topical drugs are the treatment of first choice for chronic plaque psoriasis. Mild conditions may be managed with the use of emollients alone but dithranol, coal tar, calcipotriol, or tazarotene are the usual active treatments for mild to moderate forms. Patients unresponsive to one topical drug may respond to another and alternatives should be tried before considering more aggressive management. Topical drugs are often used in combination.

- Although effective, dithranol stains the skin and clothes and as it is irritant careful adjustment of the strength and duration of application needs to be made. It has traditionally been applied overnight in the form of ointments or pastes but newer short-contact regimens and creams are more suitable for home therapy.
- Coal tar is used either as crude extracts or refined products and although the refined products may be more aesthetically acceptable they may also be less effective.
- Salicylic acid enhances the rate of loss of surface scale and is included in many combination preparations with dithranol or coal tar.
- Calcipotriol and tacalcitol are vitamin D analogues, that have the advantage of being odourless and nonstaining. Maxacalcitol is another vitamin D analogue under investigation.
- Tazarotene, a retinoid, is also effective in psoriasis but significant irritation can limit its use and it should be avoided in pruritic psoriasis.
- Topical corticosteroids are also effective but they may lead to dermal atrophy, tachyphylaxis, systemic toxicity, and may precipitate unstable and pustular psoriasis. They are reported to be the most widely used treatment in the USA.[2]

Guttate psoriasis is strongly associated with streptococcal infection and patients may require antimicrobial treatment but firm evidence of a beneficial effect on the skin lesions[10] (or indeed of any intervention for guttate psoriasis[11]) is lacking.

Phototherapy with UVB light (290 to 320 nm) is effective when used alone for chronic plaque or guttate psoriasis but also enhances the effectiveness of calcipotriol, coal tar, or dithranol. Studies have indicated that the therapeutic wavelengths are in the region of 311 to 313 nm. Consequently, narrowband UVB lamps (TL-01) have been developed to emit a spectrum that peaks at 311 nm.[12]

Photochemotherapy (PUVA) involves the use of oral or topical psoralens such as methoxsalen with UVA light and is generally considered to be the treatment of first choice for psoriasis that is resistant to topical therapies. Guidelines for PUVA have been published.[13,14] Psoralens have also been used with UVB light. Commercially available sunbeds, which emit UVA light, are not recommended as they are rarely effective and induce skin ageing and fragility.

Psoriasis refractory to topical therapy and PUVA may respond to **systemic drugs**. Systemic treatment may also be indicated for extensive chronic plaque psoriasis in elderly or infirm patients, for generalised pustular or erythrodermic psoriasis, or for severe psoriatic arthritis (see Spondyloarthropathies, p.13).

- Immunosuppressants such as methotrexate are useful for severe refractory psoriasis, the aim of treatment being to bring psoriasis under control, enabling a return to other modes of treatment rather than to induce remission. Ciclosporin is also used in severe refractory psoriasis and may be used either to induce a remission or in low-dose maintenance therapy to prevent relapse. Tacrolimus, sirolimus, and mycophenolate are under investigation for both oral and topical use, and azathioprine has been tried.
- With the recognition that psoriasis is an auto-immune disease, immunomodulating drugs have been developed with an aim to provide selective immunotherapy, by either targeting T-cells or by cytokine modulation. Alefacept and efalizumab inhibit T-cell activation and show similar efficacy in the treatment of psoriasis. Cytokine modulating therapy includes blocking the action of tumour necrosis factor with adalimumab, etanercept, or infliximab, which have been found to be effective for psoriasis skin lesions and psoriatic arthritis.

  The British Association of Dermatologists recommends[15] that in chronic plaque psoriasis the biological therapies (efalizumab, etanercept, and infliximab) should be reserved for patients with severe disease that is unresponsive or refractory to standard therapies such as acitretin, ciclosporin, methotrexate, UVB, and PUVA, or when such therapies cannot be used. Etanercept is considered to be the first choice in stable disease, infliximab may be useful when rapid disease control is needed such as in unstable erythrodermic or pustular psoriasis, and efalizumab should be used in patients with a high risk of latent tuberculosis or evidence of demyelinating disease, as the other 2 drugs are contra-indicated in these patients.
- Systemic retinoids such as acitretin are also effective, and use with PUVA may allow a reduction in doses and associated toxicity for each therapy. Generalised pustular and palmoplantar pustular psoriasis are particularly responsive to acitretin. UVB therapy may also be used with acitretin.
- Hydroxycarbamide, fumarates, tioguanine, and sulfasalazine have also been tried. Many anecdotal reports note improvement of psoriasis when patients are given drug therapy for co-existing disease. The value of such drugs can be particularly difficult to establish because of the chronic relapsing and recurring nature of psoriasis.

The chronic nature of psoriasis has resulted in a number of different strategies being tried in order to maximise treatment efficacy and minimise toxicity.[5,6] Combinations of established drugs at lower doses can include methotrexate with either ciclosporin or acitretin, or acitretin with UV therapy. Sequential therapy uses a rapidly acting, potentially more toxic, drug to bring the condition under control initially, followed by a less toxic drug for maintenance; examples include using methotrexate or ciclosporin followed by acitretin. Rotational therapy may be used to minimise long-term toxicity by using each treatment for 1 to 2 years; methotrexate, acitretin, and UV therapy have been used in this way.[6] However, ciclosporin should not follow PUVA therapy in this way because of an increased risk of cutaneous squamous cell carcinoma.[5] There is limited experience with the use of newer immunomodulating drugs in these regimens.[6]

Pyoderma gangrenosum

Pyoderma gangrenosum is a rare serious ulcerative skin disorder often associated with systemic diseases such as inflammatory bowel disease, rheumatoid arthritis, or myeloproliferative disorders. Initially an acutely inflamed nodule is present which progresses very rapidly to large painful ulcers. Any area of the body may be involved, but the face, legs, and buttocks are frequent sites.

Treatment essentially consists of cleansing and dressings for the ulcers and appropriate therapy for any underlying disease. When necessary high doses of systemic corticosteroids or treatment with ciclosporin may be given. There have also been reports in small numbers of patients of benefit with sulfasalazine, dapsone, azathioprine, tacrolimus, thalidomide, infliximab, colchicine, and nicotine chewing gum.

A related but less severe form of the disease, superficial granulomatous pyoderma, has responded to intralesional or oral corticosteroids.

Rosacea

Rosacea is a chronic condition affecting the face; rarely, the trunk and limbs may be affected. Phases of this disorder include flushing episodes, persistent erythema and telangiectasia, an inflammatory papulopustular phase, and in advanced cases rhinophyma (nasal hypertrophy and deformity). Ocular involvement is also common and can cause conjunctivitis, keratitis, styes, and chalazia.[1-4] The precise cause of rosacea remains unclear. It has been suggested that *Helicobacter pylori* in the gastrointestinal tract may cause flushing by inducing the production of endogenous vasodilators, and that *Demodex folliculorum*, a mite found in human follicles, may have a role in papulopustular rosacea.[3]

The inflammatory episodes of rosacea (papules, swelling, and pustules) are responsive to treatment, but the underlying erythema and telangiectasia usually persist.

- Episodes of flushing may be limited by avoiding trigger factors such as alcoholic and hot drinks, and spicy foods.[1,4,5] Patients should use soap-free cleansers and high factor sunscreens.[1,3] In severe cases clonidine or a beta blocker such as atenolol, has been used.[3]
- Persistent erythema may be improved by *H. pylori* eradication (see Peptic Ulcer Disease, p.1702) but the effectiveness of such therapy has not been established.[3]

- Papulopustular rosacea is usually controlled effectively by oral antibacterials.[1,3-6] Tetracyclines (doxycycline, minocycline, oxytetracycline, tetracycline) have been widely used, but clarithromycin, erythromycin, and metronidazole are suitable alternatives. Improvement occurs over several weeks, and long-term treatment may be necessary. Systemic isotretinoin is also effective, but it is generally reserved for severe or resistant cases of rosacea.

  Topical therapies, particularly metronidazole and azelaic acid,[3-5,7,8] provide effective alternatives to oral drugs. Other topical therapies that may be useful include tetracyclines, clindamycin, erythromycin, retinoids, or a combination of sulfacetamide sodium with sulfur. Where infestations of *D. folliculorum* are suspected of aggravating the condition, topical treatments such as benzyl benzoate, crotamiton, or permethrin may be tried. There are also anecdotal reports of the successful treatment of demodicidosis with oral ivermectin. Topical corticosteroids should not be used because they exacerbate rosacea.
- Ocular rosacea symptoms are managed with eyelid hygiene and artificial tears. Metronidazole gel can be applied to the eyelids but systemic antibacterials may be needed for more severe disease.[4,5]
- Rhinophyma requires conventional or laser surgery;[1,3-5] isotretinoin may be used for a few months pre-operatively to shrink the bulbous portions.[1]

Non-drug therapies that have been advocated include facial massage;[1] however, as for many of the drug therapies[7] controlled studies are lacking. Laser therapy has been used to obliterate telangiectasia.[1,3,5]

Seborrhoeic dermatitis

Seborrhoeic dermatitis is a common eczematous skin disorder (see Eczema p.1579) in which erythematous pruritic patches of skin may become either scaly or exudative and crusted. Scaling lesions are the type most commonly observed. In some cases, known as seborrhoeic folliculitis, there may also be follicular papules or pustules. Seborrhoeic dermatitis occurs in regions of the body where sebaceous glands are plentiful, such as the scalp, face, and chest, although the condition is not associated with increased sebum production. The cause of seborrhoeic dermatitis is unknown, although it might be related to overgrowth with *Malassezia ovalis* (*Pityrosporum ovale*), a normal commensal yeast.

Treatment is suppressive rather than curative. Topical preparations containing antifungals such as ciclopirox olamine, terbinafine, or an imidazole (bifonazole, ketoconazole, miconazole), usually with hydrocortisone, are the main drugs used. If unsuccessful, keratolytics such as salicylic acid or tars may be used. Topical macrolactam immunosuppressants such as pimecrolimus and tacrolimus are being investigated as alternate therapy. Shampoos containing ketoconazole, pyrithione zinc, or selenium sulfide are commonly used for scalp involvement. Topical lithium succinate has been tried.

Dandruff due to normal shedding of scalp skin (pityriasis capitis) is treated similarly to seborrhoeic dermatitis of the scalp.

Toxic epidermal necrolysis

Toxic epidermal necrolysis (Lyell's syndrome or scalded skin syndrome) is usually a drug-induced skin reaction. It has been described as a severe form of Stevens-Johnson syndrome, or as the most severe form of erythema multiforme (p.1580), although such classifications have been debated. It generally begins with lesions of the mucous membranes of the oropharynx, eyes, and genitalia, and fever and pain. Subsequently, a macular rash, blisters, or diffuse erythema develop, and affected skin may detach irregularly, sometimes in large sheets. Toxic epidermal necrolysis is managed similarly to burns (p.1578), but specific treatments have not been established. The use of systemic corticosteroids is controversial because of a higher risk of infection. Other treatments that have been tried with some reports of benefit include plasmapheresis, intravenous immunoglobulin, cyclophosphamide, ciclosporin, and infliximab.

Urticaria and angioedema

Urticaria and angioedema are conditions caused by the release of inflammatory mediators from mast cells and basophils. **Urticaria** (also known as nettlerash or hives) is characterised by circumscribed, elevated, erythematous, and usually pruritic areas of oedema (wheals) involving the superficial portion of the dermis. Individual lesions arise suddenly, often within a few minutes, and may last up to 24 hours. In severe, acute urticaria, wheals may cover most of the skin surface. In chronic urticaria (continuous or recurrent lesions over at least 6 weeks) only a few wheals may develop each day. When subcutaneous or submucosal tissues are involved, causing swelling of the eyelids, lips, tongue, larynx, or genitalia, the condition is called **angioedema**. For hereditary angioedema, caused by complement C1 esterase inhibitor deficiency, see p.1081.

Although urticaria may be caused by an allergy, it often has a non-allergic mechanism. Urticaria occurs as an adverse effect of many drugs, for example aspirin and many antibacterials. Other types of urticaria include dermographism (linear wheal formation on scratching or stroking) and cholinergic urticaria (evoked by such triggers as exercise, heat, and emotion and characterised by small papulous wheals surrounded by an erythematous flare). In **idiopathic anaphylaxis**, patients experience attacks of urticaria or angioedema, sometimes with bronchospasm, hypotension, or syncope.

The **management** of urticaria and angioedema has been reviewed.[1-5] Avoidance of unnecessary exposure to known allergens or triggers is of prime importance in the management of urticaria, although in many chronic cases no trigger factor can be found. Severe, acute urticaria or angioedema requires urgent treatment as for anaphylaxis (p.1205).

- Topical treatment of urticaria is rarely effective except for mild cases. Calamine, menthol, and crotamiton have cooling or antipruritic effects. Topical corticosteroids are of no value; topical antihistamines are not very effective and carry a slight risk of sensitisation.
- Most patients with urticaria derive some benefit from oral antihistamines (H_1-antagonists), especially in the relief of pruritus. A non-sedating antihistamine is the first line of treatment. Sedating antihistamines are useful at bedtime. If such antihistamines are only partly successful, combination with an H_2-antagonist, such as cimetidine or ranitidine, may be tried. The tricyclic antidepressant doxepin has H_1- and H_2-antagonist properties and has sometimes been effective in patients with urticaria.
- Leukotriene antagonists such as montelukast and zafirlukast and the leukotriene inhibitor zileuton have been tried alone and with antihistamines in the management of urticaria. Montelukast may add benefit to an antihistamine in chronic urticaria associated with hypersensitivity to aspirin or food additives, and in patients with evidence of histamine-releasing autoantibodies, but not in chronic idiopathic urticaria. There is some anecdotal evidence that antileukotrienes might be useful in primary cold urticaria, delayed pressure urticaria, and dermographism.[6]
- Addition of a sympathomimetic such as terbutaline or a calcium-channel blocker such as nifedipine has also been suggested for patients unresponsive to treatment with an H_1-antagonist alone, but results have varied.
- A short course of an oral corticosteroid may be indicated for control of acute urticaria in patients refractory to other measures.

It has been suggested that chronic urticaria may be associated with thyroid auto-immunity and that levothyroxine therapy may be of benefit in patients with antithyroid antibodies. A number of other drugs including danazol, stanozolol, dapsone, sulfasalazine, ciclosporin, and intravenous immunoglobulin have reportedly produced benefit in limited numbers of patients, but such therapies are largely used empirically.

Patients with frequent attacks of idiopathic anaphylaxis have benefited from prophylaxis with a corticosteroid and antihistamine; once the condition is controlled the corticosteroid, and then the antihistamine, may be tapered and gradually withdrawn. Adjuvant ketotifen, cromoglicate, salbutamol, or montelukast may be helpful in permitting corticosteroid tapering in dependent patients. Adrenaline should be available for acute attacks.[7]

Warts

Warts are caused by human papillomaviruses. The lesions present in several different forms and can affect any skin site although the hands, feet, and anogenital areas are most frequently affected. Plantar warts on the soles of the feet are sometimes called verrucas. Anogenital warts are known as condylomata acuminata. Warts do disappear spontaneously but as they may not do so for months or years patients often seek treatment.

There is no specific antiviral therapy against the human papillomavirus,[1-6] although cidofovir has been tried (see below). Treatment usually relies on some form of local tissue destruction.

- Non-pharmacological techniques include surgical excision, electrocauterisation, or laser therapy. Photodynamic therapy using 5-aminolevulinic acid has also been investigated. Cryotherapy (tissue freezing) may be performed with liquid nitrogen or solid carbon dioxide.
- Chemical destruction with acids (acetic acid, lactic acid, nitric acid, salicylic acid, or trichloroacetic acid), silver nitrate, formaldehyde or glutaral, or podophyllum resin or its derivatives (podophyllotoxin) is another option. Podophyllum resin and podophyllotoxin are often used for anogenital warts.
- Intralesional injection of cytotoxics such as bleomycin or fluorouracil also destroys the wart and may be used in severe or resistant cases. Fluorouracil may also be applied topically.

Other treatments based on less destructive mechanisms have also been used.

- Tretinoin has been tried topically for its effect on epidermal growth.
- Imiquimod is an immune response modifier that is used topically to treat anogenital warts. There is also some evidence to suggest that it is effective for other cutaneous warts. Other drugs with immunomodulatory effects, such as cimetidine, have been tried in a few patients. There are also small studies of treatment with diphencyprone, a contact sensitiser.

- Interferons have antiviral, antiproliferative, and immunomodulatory actions and have thus been investigated in the management of warts; some studies, especially those involving intralesional administration, have showed benefit. Other routes of administration are under investigation; topical interferon alfa for anogenital warts, and an oral formulation for warts in the oral cavity of patients with HIV infection.
- Cidofovir is an antiviral that has activity against human papillomavirus. Investigational intravenous or topical use has been successful in a small number of patients with cutaneous or anogenital warts.
- Sinecatechins is a mixture of complex polyphenols extracted from green tea leaves. Although its mechanism of action is unclear, it is used in the treatment of external genital and perianal warts.

A quadrivalent recombinant human papillomavirus vaccine has recently been developed and is used to prevent anogenital warts, cervical cancer, and other pre-cancerous lesions caused by human papillomavirus types 6, 11, 16, and 18.

Wounds and ulcers

Wounds (physical injuries of the skin and underlying structures) may be the result of mechanical trauma, burns, or chemical injury. Ulcers are often the result of various underlying disorders. Among the commonest types, *decubitus ulcers* (bedsores, pressure sores) occur in patients with extended immobility when prolonged pressure on the skin over a bony prominence produces localised ischaemia. *Leg ulcers* may result from venous incompetence (venous ulcers) or be ischaemic in origin (arterial ulcers), while patients with peripheral neuropathy, such as diabetics or those with leprosy, may develop *neuropathic ulcers* due to repetitive inadvertent injury. Wounds or ulcers may be described as superficial, partial thickness, or full thickness. Superficial wounds are limited to epithelial tissue and heal rapidly by regeneration of epithelial cells. Partial thickness wounds involve the dermis and include some blood vessel damage, and therefore wound repair is a longer process. Full thickness wounds extend at least to subcutaneous fat, and healing requires synthesis of new connective tissue.

Healing mechanisms are essentially the same regardless of the cause of the damage:

- immediate haemostatic processes involve formation of a platelet plug and fibrin clot, as described under Haemostasis and Fibrinolysis, p.1045
- the early granulation and re-epithelialisation phase takes place up to about 21 days after injury depending on wound size and site. Platelet-derived growth factors stimulate fibroblasts to produce granulation tissue, comprising a collagen matrix well-supplied with capillary vessels, and growth of epidermal cells leading to re-epithelialisation of the wound surface
- during the final dermal repair and remodelling phase the collagen matrix undergoes strengthening and there is a reduction in vascularity. This phase can continue for up to 2 years after injury.

Several factors are important for efficient wound healing. Adequate supplies of nutrients, especially vitamin C and zinc (which are often given as supplements) and oxygen are needed. A good blood supply is thus essential. Clinical infection, either systemic or local, due to contamination by environmental microbes, causes tissue damage and delays healing. The process of wound repair requires many cellular and acellular factors, such as platelets and growth factors, and deficiencies in these may also be responsible for delayed healing. Thus, the patient's age, systemic conditions, concomitant drugs, nutritional status, and congenital deficiencies all influence the rate of healing.

Local **wound management** includes cleansing, removal of exudate, and prevention of microbial contamination. Choice of wound treatment preparation will depend on the size, location, type, and cause of the wound, on the presence of infection, and on the particular stage of healing.

Wound **cleansing** is required to remove any dirt or foreign bodies and to **remove exudate** and slough (pus and necrotic tissue). This helps to prevent infection and aids healing. Commonly used cleansing solutions are sodium chloride 0.9%, hypochlorite, hydrogen peroxide, povidone-iodine, and chlorhexidine. However, some antiseptics and hypochlorites might be associated with delayed wound healing, especially with prolonged use, as they delay collagen production and cause inflammation. Also, many antiseptics are inactivated by organic material. Sodium chloride solution may be all that is required for routine cleansing of non-infected wounds.

Many of the cleansing solutions also help to remove slough. Other wound management preparations more specifically directed at removing slough include dextranomer, hydrogels, hydrocolloids, and enzyme preparations such as a mixture of streptokinase and streptodornase. Dextranomer, hydrogels, and hydrocolloids cause debridement by their occlusive, rehydrating properties. Surgical debridement is a fast and efficient way of removing necrotic tissue. Larval therapy (the use of live sterile maggots of *Lucilia sericata*, the common greenbottle fly) has also been effective for debridement of infected or necrotic wounds, including diabetic foot ulceration.

Wounds may produce large volumes of exudate as a result of inflammatory reactions, especially during the first few days. Hydrocolloid and alginate preparations and foam dressings are effective moisture absorbers.

All wounds are colonised by bacteria to some extent and there is no evidence that this superficial **infection** affects healing. However, infection with *Pseudomonas aeruginosa* may delay healing and sulfadiazine silver is used especially in burns. Acetic acid has also been used. Infections are treated systemically if there are indications of clinical infection such as sudden pain, cellulitis, and increased discharge; systemic management of bacterial skin infections is described on p.194.

Wound **dressings** and packing preparations help to protect the wound and provide the correct environment for wound healing. Some also help by absorbing exudate. Superficial wounds usually only require a low-adherent dressing. Alginates may be used for exuding wounds. Traditional dry dressings such as cotton wool, gauze, and lint are not used for partial or full thickness cavity wounds since they shed fibres, adhere to the wound, and cause wound dehydration. Hydrogels, hydrocolloids, polysaccharides, cadexomer-iodine, alginates, and foam dressings are all effective cavity wound preparations. Hyaluronic acid is incorporated into some dressings to promote wound healing.

Activated charcoal is very effective at reducing offensive odours from **malodorous wounds**, as are sugar (sucrose) pastes. Sucrose may exert its antibacterial effect by competing for water present in the cells of bacteria. Metronidazole is active against anaerobic bacteria that are associated with the pungent smell and is used topically for deodorising malodorous tumours. Metronidazole is not generally used on wounds because of the risk of inducing resistance but it is sometimes used to deodorise malodorous venous leg ulcers or decubitus ulcers.

In addition to the use of wound preparations, there may be other measures that aid healing of specific wounds or ulcers. Some wounds may require skin grafting. Skin substitutes, and growth factors, such as becaplermin, molgramostim, trafermin, and urogastrone, are being used or developed for non-healing ulcers and wounds. Topical phenytoin has produced some encouraging results in promoting the healing of various types of ulcers. Measures that aid the return of fluid from the leg, such as flexing the ankles, elevation, and use of compression bandages are beneficial in **venous ulcers**. There is insufficient evidence to recommend one type of dressing in preference to another, including the use of hydrocolloid dressings instead of simple low adherent dressings. The bioflavonoids, given orally, may improve venous insufficiency and therefore also aid healing. Systemic drugs that improve the supply of oxygen to tissues, for example pentoxifylline, may be useful in ischaemic and venous ulcers. Topical and systemic ketanserin has been investigated in a few patients and may be beneficial in wounds and ulcers where there is impaired blood flow. Hyperbaric oxygen therapy has been tried in a range of chronic wounds; it might be useful in reducing amputation in patients with chronic diabetic foot ulcers. Vascular surgery may be necessary in the management of some ulcers caused by ischaemia or chronic venous insufficiency. In **decubitus ulcers**, relief of pressure is the most important measure in management. The management of **burns** and **chemical burns** is described on p.1578.

USP 31 (Pumice). Pumice is a substance of volcanic origin consisting chiefly of complex silicates of aluminium, potassium, and sodium. Odourless, very light, hard, rough, porous greyish masses or gritty, greyish powder. It is stable in air. Practically insoluble in water and not attacked by acids. Three grades of powdered pumice are recognised:

- superfine (=pumice flour)—not less than 97% passes through a No. 200 [US] sieve
- fine—not less than 95% passes through a No. 150 sieve and not more than 75% through a No. 200 sieve
- coarse—not less than 95% passes through a No. 60 sieve and not more than 5% through a No. 200 sieve

Profile

Abrasive agents such as fused synthetic aluminium oxide or powdered pumice have been used either as adjuncts in the treatment of acne (despite doubts about their value—see p.1577) or for the removal of hard skin. Pumice has also been used as a dental abrasive and as a filtering medium. Other agents used as abrasives for acne include polyethylene granules.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Acitretin). A yellow or greenish-yellow, crystalline powder. Practically insoluble in water; slightly soluble in alcohol and in acetone; very slightly soluble in cyclohexane; sparingly soluble in tetrahydrofuran. It is sensitive to air, heat, and light, especially in solution. Store at 2° to 8° in airtight containers. Protect from light. It is recommended that the contents of an opened container be used as soon as possible and any unused part be protected by an atmosphere of inert gas.

USP 31 (Acitretin). A yellow or greenish, crystalline powder. Practically insoluble in water; slightly soluble in acetone and in alcohol; very slightly soluble in cyclohexane; sparingly soluble in tetrahydrofuran. Store in airtight containers at 20° to 25°, excursions permitted between 15° and 30°. Protect from light.

Adverse Effects and Precautions

As for Isotretinoin, p.1599.

Acitretin has a relatively short half-life, but etretinate, which has a very prolonged half-life, has been detected in the plasma of some patients receiving acitretin. Recommendations vary slightly in different countries but pregnancy should be avoided for at least 2 to 3 years after treatment has been withdrawn (see also Pregnancy, below) and patients should not donate blood for at least 1 to 3 years after stopping therapy. Female patients should avoid alcohol during treatment with acitretin and for 2 months after stopping treatment (see under Interactions, below).

Breast feeding. Acitretin was distributed into the breast milk of a woman treated with oral acitretin for psoriasis. Although the estimated amount of acitretin that would be consumed by a breast-fed infant was only 1.5% of the maternal dose, the authors considered that the toxic potential of acitretin to the infant justified its avoidance. In this case, the infant was not breast-fed during acitretin therapy.[1] Licensed product information also recommends that breast-feeding women should not be given acitretin. The American Academy of Pediatrics, however, has found no mention of clinical effect on the infant, and considers the maternal use of acitretin to be usually compatible with breast feeding.[2]

Capillary leak syndrome. There are rare reports of capillary leak syndrome associated with acitretin. In one case, generalised oedema and weight gain, haemorrhagic lesions, and evidence of rhabdomyolysis were seen.[1] In another, there was oedema and weight gain, dyspnoea, pulmonary infiltrates, pleural effusion, hypotension, and oliguria.[2] These reactions may be related to the retinoic acid syndrome that can occur with tretinoin (see p.1618). Generalised oedema has also been reported with etretinate (p.1597).

Effects on the blood. For reports of adverse effects on the blood by oral retinoids, including agranulocytosis associated with acitretin, see under Isotretinoin, p.1599.

Effects on the eyes. For reference to maculopathy occurring during therapy with acitretin, and the ocular effects of benign intracranial hypertension caused by retinoids, see under Isotretinoin, p.1600.

Effects on the musculoskeletal system. For reference to myopathy occurring during therapy with acitretin, and a discussion of hyperostosis and calcinosis that can occur with oral retinoid therapy, see under Isotretinoin, p.1600.

Effects on the skin. For mention of the exacerbation of erythroderma by acitretin, see under Isotretinoin, p.1601.

Pregnancy. The risks of spontaneous abortion and malformations similar to those associated with isotretinoin (p.1601) are high when acitretin or etretinate are given during pregnancy, particularly the first trimester.[1,2] Although the risks might be lower after stopping treatment, malformations have still been reported in infants and aborted fetuses conceived within 2 years of stopping acitretin[1,3] and up to 45 months after stopping etretinate.[1] In the UK licensed product information for acitretin recommends that pregnancy should be avoided for at least 2 years (3 years is recommended in the USA) after withdrawal of therapy because etretinate, which has a much longer half-life than acitretin, has been detected in the plasma of some patients given acitretin. It has been pointed out that plasma-etretinate concentrations are a poor indication of total body stores; a study[4] has indicated that there may be substantial concentrations of etretinate in the fatty tissues of women who have received acitretin.

For information on contraceptive choice in women taking oral retinoids, see under Isotretinoin, p.1601.

4. Sturkenboom MCJM, *et al.* Inability to detect plasma etretinate and acitretin is a poor predictor of the absence of these teratogens in tissue after stopping acitretin treatment. *Br J Clin Pharmacol* 1994; **38:** 229–35.

Interactions

As for Isotretinoin, p.1602.

Etretinate has been detected in the plasma of some patients receiving acitretin and acitretin is also a metabolite of etretinate; therefore interactions associated with etretinate (see p.1597) may also apply to acitretin. Taking acitretin with alcohol has been associated with etretinate formation.

For discussion of the potential interactions of retinoids with hormonal contraceptives, and the effect this might have on contraceptive choice during retinoid treatment, see p.2068.

Alcohol. The consumption of alcohol has been associated with the formation of etretinate in patients taking acitretin.[1,2] One study[2] found a trend suggesting that a higher alcohol intake was associated with a higher risk of etretinate formation and higher etretinate concentrations. However, the presence of alcohol is not essential for this transformation to take place and etretinate has also been detected in a patient taking acitretin who did not drink alcohol.[3] Consequently, licensed product information warns that alcohol must not be consumed by female patients during acitretin therapy and for 2 months after stopping, to avoid the formation of etretinate and associated prolonged risks of teratogenicity (see Pregnancy, above).

2. Larsen FG, *et al.* Acitretin is converted to etretinate only during concomitant alcohol intake. *Br J Dermatol* 2000; **143:** 1164–9.
3. Maier H, Hönigsmann H. Concentration of etretinate in plasma and subcutaneous fat after long-term acitretin. *Lancet* 1996; **348:** 1107.

Pharmacokinetics

Acitretin is absorbed from the gastrointestinal tract and peak plasma concentrations have been obtained 1 to 5 hours after oral doses. Bioavailability after a single dose is about 60 to 70%, but this can vary considerably; bioavailability may be increased by dosage with food. Acitretin is highly bound to plasma proteins. It is metabolised to 13-*cis*-acitretin. Etretinate (p.1597) has also been detected in the plasma of some patients after doses of acitretin. The elimination half-life of acitretin is about 2 days but account should always be taken of the fact that the half-life of etretinate is much longer, being about 120 days. Acitretin is excreted as metabolites in bile and urine, and is distributed into breast milk.

Renal impairment. The pharmacokinetics of acitretin are reported to be altered in patients with chronic renal failure but neither acitretin nor its 13-*cis* metabolite are removed by haemodialysis.[1]

1. Stuck AE, *et al.* Pharmacokinetics of acitretin and its 13-cis metabolite in patients on haemodialysis. *Br J Clin Pharmacol* 1989; **27:** 301–4.

Uses and Administration

Acitretin is a retinoid and is a metabolite of etretinate (p.1597). It is used orally in the treatment of severe psoriasis resistant to other forms of therapy, palmoplantar pustular psoriasis, severe congenital ichthyosis and Darier's disease (keratosis follicularis), and in severe lichen planus.

In the UK, acitretin is given in an initial daily dose of 25 or 30 mg with food for 2 to 4 weeks; in the USA (where it is licensed only for use in psoriasis) initial doses up to 50 mg daily are permitted. The daily dosage is adjusted thereafter according to clinical response and adverse effects; optimal results are usually obtained with 25 to 50 mg given daily for a further 6 to 8 weeks but some patients may require up to 75 mg daily. For the treatment of Darier's disease a starting dose of 10 mg may be appropriate, adjusted thereafter according to response. In Darier's disease and congenital ichthyosis treatment may be required for more than 3 months but a daily dosage of 50 mg should not be exceeded. In the UK, licensed product information recommends that continuous treatment should not last longer than 6 months for any indication because of limited clinical data. For lichen planus, doses are similar to those used in the UK (see above).

For doses in children, see below.

Administration in children. Acitretin is not generally considered suitable for use in children. However, a review of its use in 29 children with severe inherited disorders of keratinisation[1] reported that acitretin was an effective and safe treatment provided that the minimal effective dose was used and that adverse effects were carefully monitored. UK licensed product information contra-indicates acitretin use in children unless the benefits significantly outweigh the risks, particularly premature epiphyseal closure and other skeletal effects associated with retinoids. However, if deemed necessary an oral dose of 500 micrograms/kg once daily (occasionally up to 1 mg/kg daily for limited periods) has been suggested, but the maximum daily dose should not exceed 35 mg. The *BNFC* suggests that these doses may be used under expert supervision for children aged 1 month to 12 years for the treatment of severe extensive psoriasis resistant to other forms of therapy, palmo-plantar pustular psoriasis, severe congenital ichthyosis, and Darier's disease. The adult dose (see above) is considered suitable for children from 12 years of age. The *BNFC* also includes a dose of 500 micrograms/kg daily (occasionally up to 1 mg/kg daily) for the management of harlequin ichthyosis in neonates.

1. Lacour M, *et al.* An appraisal of acitretin therapy in children with inherited disorders of keratinization. *Br J Dermatol* 1996; **134:** 1023–9.

Eye disorders. A case report indicated that acitretin, given for psoriasis at an initial dose of 30 mg daily for one month and then reduced to 20 mg daily, improved corneal opacities in a patient with chronic tuberculosis-related interstitial keratitis.[1]

1. Labetoulle M, *et al.* Rapid improvement of chronic interstitial keratitis with acitretin. *Br J Ophthalmol* 2002; **86:** 1445–6.

Malignant neoplasms. Acitretin may be useful in preventing the development of skin neoplasms in high-risk individuals, such as solid organ transplant recipients.[1,2] However, long-term therapy is needed to maintain the effect and adverse effects can limit its use[2] (see also Malignant Neoplasms under Isotretinoin, p.1603). Gradual dose escalation may help to minimise mucocutaneous effects, and one proposed schedule for oral acitretin starts with 10 mg on alternate days for 2 weeks, 10 mg daily for the next 2 weeks, then 20 mg daily for a month; the dose is then adjusted as tolerated. Maintenance regimens of 25 mg daily, or alternating daily doses of 10 mg and 20 mg, have been used.[3]

3. Otley CC, *et al.* Chemoprevention of nonmelanoma skin cancer with systemic retinoids: practical dosing and management of adverse effects. *Dermatol Surg* 2006; **32:** 562–8.

Skin disorders. Acitretin is used alone or with PUVA (a psoralen with UVA irradiation) or UVB in psoriasis[1-4] (p.1583). Studies have shown that use with PUVA or UVB light may increase efficacy and allow a reduction in the exposure to radiation required. It is also used in keratinisation disorders such as severe forms of ichthyosis[1,5-7] (p.1580) and Darier's disease (keratosis follicularis)[1,8] (p.1578). Benefit has been reported in various other skin disorders including lichen planus (p.1580), lichen sclerosus (p.1580), and cutaneous lupus erythematosus (p.1513).[1]

Preparations

USP 31: Acitretin Capsules.

Proprietary Preparations (details are given in Part 3)
Arg.: Neotigason; ***Austral.:*** Neotigason; ***Austria:*** Neotigason; ***Belg.:*** Neotigason; ***Braz.:*** Neotigason; ***Canad.:*** Soriatane; ***Chile:*** Neotigason; ***Cz.:*** Neotigason; ***Denm.:*** Neotigason; ***Fin.:*** Neotigason; ***Fr.:*** Soriatane; ***Ger.:*** Neotigason; ***Gr.:*** Neotigason; ***Hong Kong:*** Neotigason†; ***Hung.:*** Neotigason; ***Irl.:*** Neotigason; ***Israel:*** Neotigason; ***Ital.:*** Neotigason; ***Malaysia:*** Neotigason; ***Mex.:*** Neotigason; ***Neth.:*** Neotigason; ***Norw.:*** Neotigason; ***NZ:*** Neotigason; ***Philipp.:*** Neotigason; ***Pol.:*** Neotigason; ***Port.:*** Neotigason; ***S.Afr.:*** Neotigason; ***Singapore:*** Neotigason†; ***Spain:*** Neotigason; ***Swed.:*** Neotigason; ***Switz.:*** Neotigason; ***Thai.:*** Neotigason; ***Turk.:*** Neotigason; ***UK:*** Neotigason; ***USA:*** Soriatane; ***Venez.:*** Neotigason.

Adapalene *(BAN, USAN, rINN)*

Adapaleeni; Adapalen; Adapalène; Adapaleno; Adapalenum; CD-271. 6-[3-(1-Adamantyl)-4-methoxyphenyl]-2-naphthoic acid.

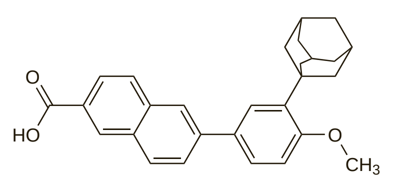
Адапален

$C_{28}H_{28}O_3$ = 412.5.

CAS — 106685-40-9.

ATC — D10AD03.

ATC Vet — QD10AD03.



Adverse Effects and Precautions

As for Tretinoin, p.1618.

Pregnancy. Anophthalmia and agenesis of the optic chiasma were found in a fetus after termination of pregnancy in a woman who had applied adapalene 0.1% topically from the month before pregnancy until 13 weeks of gestation.[1]

1. Autret E, *et al.* Anophthalmia and agenesis of optic chiasma associated with adapalene gel in early pregnancy. *Lancet* 1997; **350:** 339.

Uses and Administration

Adapalene is a naphthoic acid derivative and retinoid analogue with actions similar to those of tretinoin (p.1619). Adapalene is used in topical treatment of mild to moderate acne (p.1577) where comedones, papules, and pustules predominate.

Adapalene is usually applied once daily at night as a 0.1% solution, cream, or gel to skin that has been cleansed and dried; a 0.3% gel is also available. Some patients may require less frequent applications. Other topical preparations that may cause irritation should not be used concurrently. If treatment with topical antibacterials or benzoyl peroxide is required, these should be applied in the morning and adapalene applied at night.

There may be apparent exacerbations of the acne during early treatment and a consistent therapeutic response may not be evident for at least 8 weeks. However, if there is no response after 12 weeks, therapy should be reassessed.

For use in young children, see below.

Aldioxa is an astringent and keratolytic related to allantoin (below). It is present in multi-ingredient preparations intended for various skin and gastrointestinal disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** ZeaSorb; ***Austral.:*** ZeaSorb; ***Canad.:*** ZeaSorb; ***Chile:*** ZeaSorb†; ***Fr.:*** ZeaSorb; ***Indon.:*** ZeaSorb; ***Irl.:*** ZeaSorb; ***Israel:*** Aronal Forte; ***Ital.:*** Rikospray; ***Malaysia:*** ZeaSorb†; ***Mex.:*** Dentsiblen; ***Philipp.:*** ZeaSorb; ***S.Afr.:*** ZeaSorb; ***Singapore:*** ZeaSorb; ***Thai.:*** ZeaSorb; ***UK:*** Cetanorm; ZeaSorb.

Alefacept *(BAN, USAN, rINN)*

Aléfacept; Alefaceptum; BG-9273; BG-9712; LFA3TIP; Recombinant Human LFA-3/IgG$_1$ Fusion Protein. A dimer of 1-92 antigen LFA-3 (human) fusion protein with human immunoglobulin G1 (hinge-C$_H$2-C$_H$3 γ1-chain).

Алефацепт

CAS — 222535-22-0.

ATC — L04AA15.

ATC Vet — QL04AA15.

Adverse Effects and Precautions

Chills are common on intravenous dosage of alefacept. Other adverse effects are cough, dizziness, headache, injection site pain and inflammation, myalgia, nausea, pharyngitis, and pruritus. More serious adverse reactions are cardiovascular events (including coronary artery disorder and myocardial infarction), hypersensitivity reactions, lymphopenia, and serious infections requiring hospitalisation. Cases of hepatotoxicity including asymptomatic transaminase elevation, fatty infiltration of the liver, hepatitis, and acute liver failure have occurred. Like other drugs with immunosuppressant actions, alefacept may increase the risk of malignancies, particularly basal or squamous cell cancers of the skin. It should not be given to patients with a history of malignancy.

Alefacept should also not be given to patients with pre-existing serious infections, and should be stopped if these develop. Its use should be considered carefully in patients with chronic infections or a history of recurrent infection.

Alefacept induces a dose-dependent reduction in circulating CD4+ and CD8+ T-lymphocyte counts. It is therefore also contra-indicated in patients with HIV infection as the reduction in CD4+ T-lymphocytes could accelerate disease progression or increase complications of HIV infection. CD4+ T-lymphocyte counts should be monitored before starting alefacept therapy and then every 2 weeks during the 12-week treatment period. Treatment should not be started in patients with a CD4+ T-lymphocyte count below normal. Doses should be withheld and weekly monitoring started if the counts fall below 250 cells/microlitre, and treatment stopped if the counts remain below this level for one month.

Therapy should be stopped immediately, and appropriate treatment given, in patients who experience anaphylaxis or serious hypersensitivity; it should not be restarted.

1. Goffe B, *et al.* An integrated analysis of thirteen trials summarizing the long-term safety of alefacept in psoriasis patients who have received up to nine courses of therapy. *Clin Ther* 2005; **27:** 1912–21.

Pharmacokinetics

Alefacept has a bioavailability of about 63% after intramuscular injection. After an intravenous dose it has an elimination half-life of about 11 to 12 days.

◊ References.

1. Vaishnaw AK, TenHoor CN. Pharmacokinetics, biologic activity, and tolerability of alefacept by intravenous and intramuscular administration. *J Pharmacokinet Pharmacodyn* 2002; **29:** 415–26.

Uses and Administration

Alefacept is a recombinant human fusion protein that binds to CD2 on memory T-lymphocytes, preventing their activation and reducing their number. It is used in the management of moderate to severe chronic plaque psoriasis (p.1583) and is given in a dose of 7.5 mg once weekly by intravenous injection, or 15 mg once weekly by intramuscular injection, for 12 weeks. A second 12-week course may be given if necessary, starting not less than 12 weeks after the completion of the first.

Aloe Vera

Aloe.

Алоэ Вера; Алоэ Древовидное

Profile

Aloe vera gel is a mucilaginous preparation obtained from the leaves of *Aloe vera* (*A. barbadensis*). It does not include the sap of *Aloe vera*, which contains anthraquinones, and should not be confused with aloes (p.1705).

◊ Aloe vera is widely used in cosmetics and toiletries for a reported moisturising and revitalising action. There are also claims for the beneficial and even curative properties of aloe vera gel in the treatment of conditions such as acne, psoriasis, burns, wounds, arthritis, diabetes, hyperlipidaemia, peptic ulcer, and genital herpes.[1,2] Evidence to support these claims is lacking. There is also no strong evidence to support the use of aloe vera gel in the prevention or treatment of radiation-induced skin reactions in cancer patients.[3]

Aluminium Chloride

Aliuminio chloridas heksahidratas; Alumiinikloridiheksahydraatti; Aluminii chloridum hexahydricum; Aluminio, cloruro de; Aluminium Chloratum; Aluminium (chlorure d') hexahydraté; Alumínium-klorid-hexahidrát; Aluminiumkloridhexahydrat; Aluminum Chloride; Chlorid hlinitý hexahydrát; Cloreto de Alumínio; Cloruro de Aluminio; Glinu chlorek. Aluminium chloride hexahydrate.

Алюминия Хлорид

$AlCl_3,6H_2O$ = 241.4.
CAS — 7446-70-0 (anhydrous aluminium chloride); 7784-13-6 (aluminium chloride hexahydrate).
ATC — D10AX01.
ATC Vet — QD10AX01.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Aluminium Chloride Hexahydrate). A deliquescent, white or slightly yellow, crystalline powder or colourless crystals. Very soluble in water; freely soluble in alcohol; soluble in glycerol. Store in airtight containers.
USP 31 (Aluminium Chloride). Deliquescent, white or yellowish-white, practically odourless, crystalline powder. Its solutions are acid to litmus. Soluble 1 in 0.9 of water and 1 in 4 alcohol; soluble in glycerol. Store in airtight containers.

Adverse Effects

Aluminium chloride may cause irritation especially if applied to damp skin; this is attributed to the formation of hydrochloric acid.

Uses and Administration

Aluminium chloride has astringent properties and is used in a 20% alcoholic solution as an antiperspirant in the treatment of hyperhidrosis (p.1580). It is applied to dry skin, usually at bedtime, and is washed off in the morning before the sweat glands are fully active. Initially, it may be applied each night until sweating improves, then less frequently, as required, to maintain efficacy.

Aluminium Chlorohydrate

Aluminio, clorohidróxido de; Aluminium Chlorhydrate; Aluminium Chloride Hydroxide Hydrate; Aluminum Chlorhydroxide; Aluminum Chloride Hydroxide Hydrate; Aluminum Chlorohydrate *(USAN)*; Aluminum Hydroxychloride; Alüminyum Hidroksiklorür; Basic Aluminium Chloride.

Алюминия Хлорогидрат

$Al_2(OH)_5Cl,xH_2O$.
CAS — 1327-41-9 (anhydrous aluminium chlorohydrate).
ATC — D09AA08; M05BX02.
ATC Vet — QD09AA08; QM05BX02.

Pharmacopoeias. In *US.*
US also includes a range of compounds based on aluminium chlorohydrate. These are:

- aluminium dichlorohydrate and sesquichlorohydrate
- the polyethylene glycol (macrogol) complexes and propylene glycol complexes of aluminium chlorohydrex, aluminium dichlorohydrex, and aluminium sesquichlorohydrex
- the tri-, tetra-, penta-, and octachlorohydrates of aluminium zirconium and their respective glycine derivatives.

USP 31 (Aluminum Chlorohydrate). A 15% w/w solution in water has a pH of 3.0 to 5.0

Profile

Aluminium chlorohydrate is used similarly to aluminium chloride in hyperhidrosis (p.1580). Single-ingredient products for hyperhidrosis generally have a concentration in the range of 10 to 25%.

Aluminium chlorohydrate is also included in a variety of dermatological preparations for its astringent and antiperspirant properties.

Aluminium toxicity. Bone pain, extreme fatigue, and raised aluminium concentrations in a woman with normal renal function were attributed to the use of an antiperspirant cream containing aluminium chlorohydrate 20%. She had been applying about 1 g of cream to each underarm daily for 4 years. Within 8 months of stopping the antiperspirant, plasma-aluminium concentrations had returned to normal and symptoms had resolved.[1]

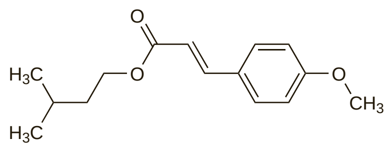
Amiloxato; Amiloxatum; E-1000; Isoamyl *p*-Methoxycinnamate. Isopentyl *p*-methoxycinnamate; 3-(4-Methoxyphenyl)-2-propenoic acid 3-methylbutyl ester.

Амилоксат

$C_{15}H_{20}O_3$ = 248.3.
CAS — 71617-10-2.



NOTE. Neo-Heliopan E 1000 is a trade name that has been used for amiloxate.

Pharmacopoeias. In *US.*

USP 31 (Amiloxate). Store in airtight containers.

Profile

Amiloxate, a substituted cinnamate, is a sunscreen (p.1576) with actions similar to those of octinoxate (p.1608). It is effective against UVB light (for definitions, see p.1580).

Preparations

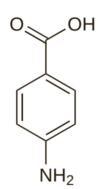
Proprietary Preparations some preparations are listed in Part 3.

Aminobenzoic Acid

Acide 4-Aminobenzoïque; Acidum 4-aminobenzoicum; Amben; 4-Aminobensoesyra; 4-Aminobentsoehappo; 4-aminobenzoesav; Aminobenzoico, ácido; 4-Aminobenzoinė rūgštis; Kwas 4-aminobenzoesowy; Kyselina 4-aminobenzoová; PAB; PABA; Pabacidum; Para-aminobenzoic Acid; Vitamin Bx; Vitamin H′. 4-Aminobenzoic acid.

Аминобензойная Кислота

$C_7H_7NO_2$ = 137.1.
CAS — 150-13-0.
ATC — D02BA01.
ATC Vet — QD02BA01.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (4-Aminobenzoic Acid; Aminobenzoic Acid BP 2008). White or slightly yellow crystalline powder. Slightly soluble in water; freely soluble in alcohol; it dissolves in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Aminobenzoic Acid). White or slightly yellow, odourless crystals or crystalline powder. It discolours on exposure to air or light. Slightly soluble in water and in chloroform; freely soluble in alcohol and in solutions of alkali hydroxides or carbonates; sparingly soluble in ether. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Adverse skin reactions such as local irritation and contact dermatitis have been reported after the topical use of aminobenzoate sunscreens. Aminobenzoate sunscreens should not be used by those with a history of photosensitivity or hypersensitivity reactions to structurally related drugs such as sulfonamides, thiazide diuretics, and ester-type local anaesthetics.

Aminobenzoic acid may stain clothing.

◊ Allergic and photoallergic contact dermatitis have been reported after topical use of aminobenzoic acid or its esters.[1] Early reports of such reactions led to the removal of these compounds from sunscreen preparations (many are now described as 'PABA-free'), although padimate O still appears to be widely used.[2] Patients allergic to aminobenzoic acid may also react to structurally related allergens such as para-aminobenzoic acid ester anaesthetics, sulfonamides, and paraphenylenediamine in hair dyes.[1,2]

Skin reactions (vitiligo) have also been reported with oral aminobenzoic acid[3] and the adverse effects associated with the former use of high oral doses for various conditions have been highlighted.[4]

1. Scheuer E, Warshaw E. Sunscreen allergy: A review of epidemiology, clinical characteristics, and responsible allergens. *Dermatitis* 2006; **17:** 3–11. Correction. *ibid.*; 162.
2. Mackie BS, Mackie LE. The PABA story. *Australas J Dermatol* 1999; **40:** 51–3.
3. Hughes CG. Oral PABA and vitiligo. *J Am Acad Dermatol* 1983; **9:** 770.
4. Worobec S, LaChine A. Dangers of orally administered para-aminobenzoic acid. *JAMA* 1984; **251:** 2348.

Pharmacokinetics

If given orally, aminobenzoic acid is absorbed from the gastrointestinal tract. It is metabolised in the liver and excreted in the urine as unchanged drug and metabolites.

Uses and Administration

Aminobenzoic acid is applied topically as a sunscreen (p.1576). Aminobenzoic acid and its derivatives effectively absorb light throughout the UVB range but absorb little or no UVA light (for definitions, see p.1580). Aminobenzoate sunscreens may therefore be used to prevent sunburn, but are unlikely to prevent drug-related or other photosensitivity reactions associated with UVA light; combination with a benzophenone may give some added protection against such photosensitivity.

Aminobenzoic acid has sometimes been included as a member of the vitamin-B group, but deficiency of aminobenzoic acid in man or *animals* has not been found.

Aminobenzoic acid has been used with bentiromide (p.2264) in the PABA or BTPABA test of pancreatic function.

Preparations

USP 31: Aminobenzoic Acid Gel; Aminobenzoic Acid Topical Solution.

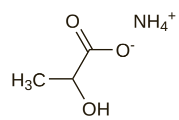
Proprietary Preparations some preparations are listed in Part 3.

Ammonium Lactate *(USAN)*

Amonio, lactato de; BMS-186091.

Аммония Лактат

$C_3H_9NO_3$ = 107.1.
CAS — 52003-58-4.
ATC Vet — QA16QA04.



Profile

Ammonium lactate is a humectant applied as a cream or lotion containing 12% lactic acid neutralised with ammonium hydroxide. It is used in the treatment of dry scaly conditions of the skin including ichthyosis. Adverse effects of topical ammonium lactate preparations include transient erythema, burning, and stinging. Treated areas may be more sensitive to sunlight and exposure should be minimised.

Preparations

Proprietary Preparations (details are given in Part 3)

Arg.: Lacto-Cev; Lactrex; ***Braz.:*** Lac-Hydrin; ***Canad.:*** Lac-Hydrin; ***Chile:*** Kerapil†; Topilact 12†; ***Fr.:*** Kerapil†; ***Malaysia:*** Lanate; ***Mex.:*** Lac-Hydrin; ***NZ:*** Lac-Hydrin; Lanate; ***Singapore:*** Lac-Hydrin; Lanate; ***USA:*** Amlactin; Geri-Hydrolac; Kerasal AL; Lac-Hydrin; LAC-Lotion.

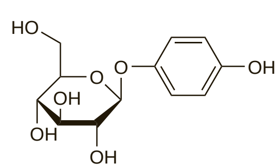
Arbutin

Arbutoside; Arbutyna; Beta-arbutin; Ursin. 4-Hydroxyphenyl-β-D-glucopyranoside.

Арбутин

$C_{12}H_{16}O_7$ = 272.3.
CAS — 497-76-7 (beta-arbutin); 84380-01-8 (alpha-arbutin).



Profile

Arbutin is a glycosylated derivative of hydroquinone (p.1598) extracted from bearberry (p.2263) and similar plants. It is used topically in concentrations of 1 to 5% as a depigmenting agent for the skin in hyperpigmentation disorders. The higher concentrations may lead to a paradoxical hyperpigmentation.

Alpha-arbutin has been used similarly.

Preparations

Proprietary Preparations (details are given in Part 3)

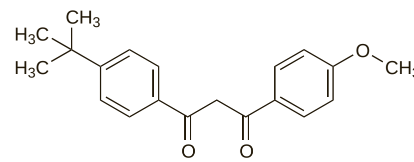
Multi-ingredient: ***Arg.:*** Cellskinlab Phyto Spot; Melasoft†; ***Chile:*** Phyto Corrective Gel; Phyto Spot; ***Port.:*** Despigmentante.

Avobenzone *(USAN, rINN)*

Avobenzona; Avobenzonum; Butylmethoxydibenzoylmethane; 4-*tert*-Butyl-4′-methoxydibenzoylmethane. 1-(*p*-*tert*-Butylphenyl)-3-(*p*-methoxyphenyl)-1,3-propanedione; 1-[4-(1,1-dimethylethyl)phenyl]-3-(4-methoxyphenyl)-1,3-propanedione.

Авобензон

$C_{20}H_{22}O_3$ = 310.4.
CAS — 70356-09-1.



NOTE. Escalol 517, Eusolex 9020, Neo-Heliopan 357, and Parsol 1789 are trade names that have been used for avobenzone.

Pharmacopoeias. In *US.*

USP 31 (Avobenzone). M.p. 81° to 86°. Store in airtight containers. Protect from light.

Profile

Avobenzone is a substituted dibenzoylmethane used by topical application as a sunscreen (p.1576). Dibenzoylmethanes absorb light in the UVA range (for definitions, see p.1580) and may therefore be used with other sunscreens that absorb UVB light to prevent sunburn; they will also provide some protection against drug-related or other photosensitivity reactions associated with UVA light.

Contact and photocontact allergic dermatitis has occasionally been reported with the topical use of dibenzoylmethane sunscreens.

Preparations

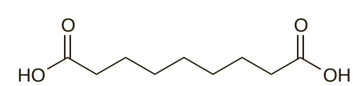
Proprietary Preparations numerous preparations are listed in Part 3.

Azelaic Acid *(USAN, rINN)*

Acide azélaïque; Ácido azelaico; Acidum azelaicum; Anchoic acid; Atselaiinihappo; Azelaik Asit; Azelainsyra; Lepargylic acid; ZK-62498. Nonanedioic acid; Heptane-1,7-dicarboxylic acid.

Азелаиновая Кислота

$C_9H_{16}O_4$ = 188.2.
CAS — 123-99-9.
ATC — D10AX03.
ATC Vet — QD10AX03.



Adverse Effects and Precautions

Topical application of azelaic acid may produce a transient skin irritation such as burning, stinging, pruritus, dryness, and scaling. It is usually mild and disappears on continued treatment, but in a few patients the irritation may persist, requiring reduced frequency of application or temporary suspension of treatment. There have been rare reports of hypopigmentation, rash, and photosensitivity. Azelaic acid should not be applied to the eyes, mouth, or other mucous membranes.

Uses and Administration

Azelaic acid inhibits the growth of *Propionibacterium* spp. and reduces keratinisation. It is used in the topical treatment of mild to moderate inflammatory acne (p.1577) and for the inflammatory papules and pustules of mild to moderate rosacea (p.1583). It has also been tried in hyperpigmentary skin disorders such as melasma, and in malignant melanoma.

In the treatment of **acne** azelaic acid is applied twice daily for up to 6 months as a 20% cream or 15% gel. Improvement usually occurs within four weeks.

For the treatment of mild to moderate **rosacea**, a 15% gel should be applied to the affected area twice daily for a period of up to 12 weeks. Improvement usually occurs in 4 to 8 weeks.

Becaplermin *(BAN, USAN, rINN)*

Becaplermina; Bécaplermine; Becaplerminum; Bekaplermiini; Bekaplermin; RWJ-60235. Recombinant human platelet-derived growth factor B.

Бекаплермин

CAS — 165101-51-9.
ATC — D03AX06.
ATC Vet — QD03AX06.

Profile

Becaplermin is a recombinant human platelet-derived growth factor (rhPDGF-BB) that enhances the formation of granulation tissue and promotes wound healing (p.1585). Becaplermin is applied topically as a 0.01% gel in the management of full thickness neuropathic diabetic skin ulcers (see Diabetic Complications, p.433). It is applied once daily, covered by a moist saline gauze dressing, for up to 20 weeks. If no meaningful healing process (decrease in ulcer size of about 30%) is evident after 10 weeks of therapy, treatment should be re-assessed.

Becaplermin should not be applied to ulcers where neoplasms are present or to clinically infected ulcers. If the ulcer becomes infected during therapy, becaplermin should be stopped until the infection has cleared. US licensed product information warns that an increased rate of death from all cancers has been seen in patients treated with 3 or more tubes of becaplermin gel (tube size not specified).

Becaplermin is used with a resorbable synthetic calcium phosphate matrix to promote bone and tissue growth in the treatment of periodontal disease. It is also under investigation in the treatment of osteonecrosis of the jaw, fractures, and osteoporosis, and in the repair of cartilage, ligament, and tendon injuries.

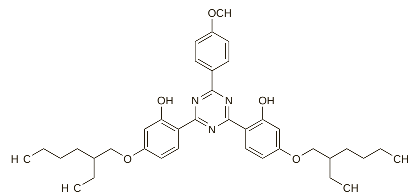
Bemotrizinol *(USAN, rINN)*

Bémotrizinol; Bemotrizinolum; BEMT; Bis-ethylhexyloxyphenol Methoxyphenol Triazine; FAT-70884. 2,2′-[6-(4-Methoxyphenyl)-1,3,5-triazine-2,4-diyl]bis{5-[(2-ethylhexyl)oxy]phenol}.

Бемотризинол

$C_{38}H_{49}N_3O_5$ = 627.8.
CAS — 187393-00-6.



NOTE. Tinosorb S is a trade name that has been used for bemotrizinol.

Profile

Bemotrizinol is used as a sunscreen (p.1576). It is effective against UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

Bentoquatam *(USAN)*

Quaternium 18-bentonite.

Бентокватам

CAS — 1340-69-8.

Profile

Bentoquatam, described as an organoclay compound, is a barrier preparation that is applied topically as a 5% lotion to prevent allergic contact dermatitis caused by poison ivy, poison oak, or poison sumac. The lotion is applied in a sufficient quantity to form a visible coating 15 minutes before possible contact with the plants. If continued protection is required the lotion may be re-applied every 4 hours or at any time if the visible coating is removed.

Preparations

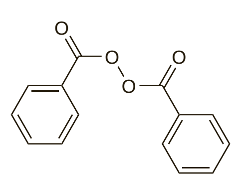
Proprietary Preparations (details are given in Part 3)
USA: Ivy Block.

Benzoyl Peroxide *(USAN)*

Bensoylperoxid; Bentsoyyliperoksidi; Benzoilo peroksidas; Benzoil-peroxid; Benzoyil Peroksit; Benzoylis peroxidum; Benzoylperoxid; NSC-675; Peróxido de benzoilo; Peroxyde de benzoyle. Dibenzoyl peroxide.

Бензоил Пероксид; Пероксид Бензоила

$C_{14}H_{10}O_4$ = 242.2.
CAS — 94-36-0 (anhydrous benzoyl peroxide).
ATC — D10AE01.
ATC Vet — QD10AE01; QD11AX90.



(anhydrous benzoyl peroxide)

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Benzoyl Peroxide, Hydrous). It contains not less than 70% and not more than 77% of anhydrous benzoyl peroxide and not less than 20% of water. It rapidly loses water on exposure to air and may explode if the water content is too low. A white or almost white, amorphous or granular powder. Practically insoluble in water; slightly soluble in alcohol; soluble in acetone; soluble in dichloromethane with separation of water. Store at 2° to 8° in a container that has been treated to reduce static charges and that has a device for the release of excess pressure. Unused material should not be returned to its original container but should be destroyed by the addition of sodium hydroxide solution (10%). Destruction can be considered to be complete if the addition of a crystal of potassium iodide does not result in the release of free iodine after acidification with dilute hydrochloric acid. Protect from light.

USP 31 (Hydrous Benzoyl Peroxide). It contains not less than 65% and not more than 82% of anhydrous benzoyl peroxide with a water content of about 26%. The hydrous form is a white granular powder with a characteristic odour. Sparingly soluble in water and in alcohol; soluble in acetone, in chloroform, and in ether. Store in the original container, treated to reduce static charges. Unused material should not be returned to its original container but should be destroyed by the addition of sodium hydroxide solution (10%). Destruction can be considered to be complete if the addition of a crystal of potassium iodide does not result in the release of free iodine.

Adverse Effects and Precautions

Topical application of benzoyl peroxide may produce skin irritation, particularly at the start of treatment. In some patients the irritation may require reduced frequency of application or temporary suspension of treatment. Skin dryness, peeling, rash, and transient local oedema may also occur. Contact sensitisation has been reported in some patients using preparations containing benzoyl peroxide. Caution is required when applying it near the eyes, the mouth and other mucous membranes, and to the neck and other sensitive areas. Patients should be alerted to benzoyl peroxide's bleaching property.

Body odour. An unusual unpleasant body odour in a patient was attributed to the topical use of benzoyl peroxide.[1]

1. Molberg P. Body odor from topical benzoyl peroxide. *N Engl J Med* 1981; **304:** 1366.

Carcinogenicity. There has been concern at the implications of some *animal* studies showing benzoyl peroxide to possess some tumour-promoting activity.[1] However, a retrospective survey in Canada concluded that there was no indication that the normal use of benzoyl peroxide in the treatment of acne was associated with an increased risk of facial cancer.[2] A comprehensive review[3] that included *in-vitro* and *animal* studies, as well as human data, also concluded that there was no evidence to associate the topical use of benzoyl peroxide with the development of skin cancer in humans. However, the International Agency for Research on Cancer[4] considers that there is inadequate evidence in humans and its overall evaluation is that benzoyl peroxide is not classifiable as to its carcinogenicity to humans.

2. Hogan DJ, *et al.* A study of acne treatments as risk factors for skin cancer of the head and neck. *Br J Dermatol* 1991; **125:** 343–8.
3. Kraus AL, *et al.* Benzoyl peroxide: an integrated human safety assessment for carcinogenicity. *Regul Toxicol Pharmacol* 1995; **21:** 87–107.
4. IARC/WHO. Benzoyl peroxide. *IARC monographs on the evaluation of carcinogenic risks to humans volume 71* 1999. Available at: http://monographs.iarc.fr/ENG/Monographs/vol71/volume71.pdf (accessed 27/09/07)

Handling. Benzoyl peroxide powder may explode if subjected to grinding, percussion, or heat. Hydrous benzoyl peroxide containing water to reduce the risk of explosion may still explode if exposed to temperatures higher than 60° or cause fires in the presence of reducing substances.

Hypersensitivity. Benzoyl peroxide appears to induce contact hypersensitivity quite often when used to treat leg ulcers,[1] but it is unclear how often this occurs when used in the treatment of acne.[2] Patch testing[3,4] in some studies suggests that up to 76% of patients may be hypersensitive to benzoyl peroxide but this does not appear to correlate either with the clinical irritation produced during treatment, which usually resolves on continued use, or with the reported incidence of hypersensitivity.[2,4] In one study 25% of patients were considered to be hypersensitive from patch testing but only 2 of 44 patients developed clinical hypersensitivity.[4] Another study involving 204 patients with acne found that the incidence of false-positive irritant skin reactions to benzoyl peroxide was about 15% but only 1% of the patients had true allergic reactions to the drug on further testing.[5] However, there has been concern that hypersensitivity to benzoyl peroxide may be mistaken for irritation or worsening of the acne.[3]

1. Vena GA, *et al.* Contact dermatitis to benzoyl peroxide. *Contact Dermatitis* 1982; **8:** 338.
2. Cunliffe WJ, Burke B. Benzoyl peroxide: lack of sensitization. *Acta Derm Venereol (Stockh)* 1982; **62:** 458–9.
3. Leyden JJ, Kligman AM. Contact sensitization to benzoyl peroxide. *Contact Dermatitis* 1977; **3:** 273–5.
4. Rietschel RL, Duncan SH. Benzoyl peroxide reactions in an acne study group. *Contact Dermatitis* 1982; **8:** 323–6.
5. Balato N, *et al.* Acne and allergic contact dermatitis. *Contact Dermatitis* 1996; **34:** 68–9.

Pharmacokinetics

◊ Work *in vitro* and in *animals*[1] suggests that although there is some absorption of benzoyl peroxide after topical application, any absorbed drug appears to be metabolised in the skin to benzoic acid and rapidly excreted in the urine.

1. Yeung D, *et al.* Benzoyl peroxide: percutaneous penetration and metabolic disposition II: effect of concentration. *J Am Acad Dermatol* 1983; **9:** 920–4.

Uses and Administration

Benzoyl peroxide has mild keratolytic properties. Its antimicrobial action is probably due to its oxidising effect and activity has been reported against *Staphylococcus epidermidis* and *Propionibacterium acnes*. It is used mainly in the treatment of acne (below), applied once or twice daily in topical preparations usually containing 2.5 to 10%, sometimes with other antimicrobials. For use in young children, see below. It has been used similarly in the treatment of fungal skin infections (p.521), such as tinea pedis although other drugs are usually preferred. A 20% lotion has been applied every 8 to 12 hours in the treatment of decubitus or stasis ulcers. Strengths are expressed as anhydrous benzoyl peroxide although it is used in a hydrous form for safety (see Pharmacopoeias, above).

Benzoyl peroxide is also used as a bleaching agent in the food industry and as a catalyst in the plastics industry.

Acne. Benzoyl peroxide applied topically in concentrations of up to 10% is probably the most widely used first-line drug in the management of mild acne (p.1577). Early studies in *animals* found benzoyl peroxide to be sebosuppressive[1] but later studies demonstrated that sebum excretion rises during the first few months of treatment,[2,3] probably due to the comedolytic action of benzoyl peroxide, and remains at a stable level thereafter. Benzoyl peroxide has been shown to have a significant inhibitory effect on skin microflora, with reductions in surface and follicular micro-organisms within 48 hours of beginning treatment, but clinical improvement took several more days to appear.[4] The combined use of benzoyl peroxide with topical clindamycin or erythromycin can inhibit the development of antibacterial resistance and bring about clinical improvement when resistance already exists.[5]

5. Taylor GA, Shalita AR. Benzoyl peroxide-based combination therapies for acne vulgaris: a comparative review. *Am J Clin Dermatol* 2004; **5:** 261–5.

Administration in children. Benzoyl peroxide has been used topically in the treatment of neonatal and infantile acne, applied once or twice daily starting with lower strength preparations of 2.5%.

Preparations

BP 2008: Benzoyl Peroxide Cream; Benzoyl Peroxide Gel; Benzoyl Peroxide Lotion; Potassium Hydroxyquinoline Sulphate and Benzoyl Peroxide Cream;
USP 31: Benzoyl Peroxide Gel; Benzoyl Peroxide Lotion; Erythromycin and Benzoyl Peroxide Topical Gel.

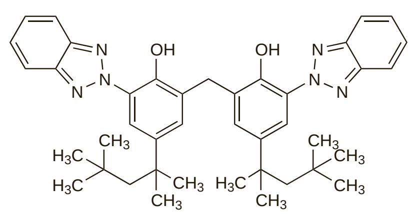
Bisoctrizole *(USAN, rINN)*

Bisoctrizol; Bisoctrizolum; FAT-75634; MBBT; Methylene Bis-Benzotriazolyl Tetramethylbutylphenol. 2,2′-Methylenebis[6-(2*H*-benzotriazol-2-yl)-4-(1,1,3,3-tetramethylbutyl)phenol].

Бизоктризол

$C_{41}H_{50}N_6O_2$ = 658.9.

CAS — 103597-45-1.



NOTE. Tinosorb M is a trade name that has been used for bisoctrizole.

Pharmacopoeias. In *US.*

USP 31 (Bisoctrizole). Store at a temperature of 20° to 25°, excursions permitted between 15° and 30°.

Profile

Bisoctrizole is used as a sunscreen (p.1576). It is effective against UVB and UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

Calamine

Calamina; Kalamin; Prepared Calamine.

Каламин

Pharmacopoeias. In *Br., Chin., Int.,* and *US.*

BP 2008 (Calamine). It is a basic zinc carbonate coloured with ferric oxide. It is an amorphous, impalpable, pink or reddish-brown powder, the colour depending on the variety and amount of ferric oxide present and the process by which it is incorporated. Practically insoluble in water; it dissolves with effervescence in hydrochloric acid.

USP 31 (Calamine). It is zinc oxide with a small proportion of ferric oxide. A pink, odourless, fine powder. Insoluble in water; practically completely soluble in mineral acids.

Profile

Calamine has mild astringent and antipruritic actions and is used as a dusting powder, cream, lotion, or ointment in a variety of skin conditions although its value is uncertain.

Preparations

BP 2008: Aqueous Calamine Cream; Calamine and Coal Tar Ointment; Calamine Lotion; Calamine Ointment;
USP 31: Calamine Topical Suspension; Phenolated Calamine Topical Suspension.

Proprietary Preparations (details are given in Part 3)

Calcipotriol *(BAN, rINN)*

Calcipotriene *(USAN)*; Calcipotriolum; Kalcipotriol; Kalcypotriol; Kalsipotriol; Kalsipotrioli; MC-903. (5*Z*,7*E*,22*E*,24*S*)-24-Cyclopropyl-9,10-secochola-5,7,10(19),22-tetraene-1α,3β,24-triol.

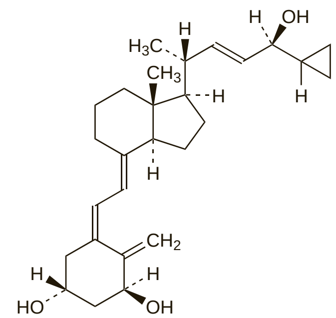
Кальципотриол

$C_{27}H_{40}O_3$ = 412.6.

CAS — 112828-00-9; 112965-21-6.

ATC — D05AX02.

ATC Vet — QD05AX02.



Pharmacopoeias. In *Eur.* (see p.vii), which also includes the monohydrate.

Ph. Eur. 6.2 (Calcipotriol, Anhydrous; Calcipotriolum Anhydricum). A white or almost white, crystalline powder. It is sensitive to heat and light. A reversible isomerisation to pre-calcipotriol takes place in solution, depending on temperature and time. The activity is due to both compounds. Practically insoluble in water; freely soluble in alcohol; slightly soluble in dichloromethane. Store in airtight containers at a temperature of −20° or below. Protect from light.

Ph. Eur. 6.2 (Calcipotriol Monohydrate; Calcipotriolum Monohydricum). A white or almost white, crystalline powder. It is sensitive to light. A reversible isomerisation to pre-calcipotriol takes place in solution, depending on temperature and time. The activity is due to both compounds. Practically insoluble in water; freely soluble in alcohol; slightly soluble in dichloromethane. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

The most frequent adverse effect associated with calcipotriol is skin irritation and it should not therefore be applied to the facial area. Symptoms may include burning, itching, erythema, and dry skin, but stopping therapy is seldom necessary. Aggravation of psoriasis may occur. Hypercalcaemia has occurred during treatment with calcipotriol and although rapidly reversible on withdrawal, it should not be used in patients with disorders of calcium metabolism. Other rare adverse effects may include skin atrophy, hyperpigmentation, and photosensitivity. Patients should limit or avoid excessive exposure to both natural and artificial sunlight, because *animal* studies have suggested that topical calcipotriol may enhance the effect of UV radiation to induce skin tumours.

Effects on calcium homoeostasis. Calcipotriol is a vitamin D derivative and therefore has the potential to cause hypercalcaemia and hypercalciuria. Up to December 1993, when about 150 000 patients in the UK had been treated with calcipotriol, the UK CSM had received 6 reports of hypercalcaemia and 2 of hypercalciuria.[1] Three of the patients with hypercalcaemia either had used doses in excess of the recommended maximum (see Uses and Administration, below) or had pustular or exfoliative psoriasis. Hypercalcaemia and hypercalciuria were reversible on withdrawal of calcipotriol. A study[2] investigating the effect of calcipotriol on urine calcium excretion found that use of the maximum recommended dose for 4 weeks produced increased urine calcium excretion, and the authors suggested that patients requiring the maximum dose of calcipotriol should be monitored for hypercalciuria before and during treatment. A review[3] of the effects of vitamin D analogues on calcium homoeostasis concluded that patients with unstable psoriasis are at particular risk of

The symbol † denotes a preparation no longer actively marketed

toxicity from calcipotriol and that measurement of urine calcium excretion is a more sensitive indicator of toxicity than serum-calcium concentrations.

Hyperpigmentation. Hyperpigmentation occurred at the site of calcipotriol application in 2 patients after use with PUVA-bath therapy (a topical psoralen with UVA irradiation) for psoriasis.[1] The effect persisted for at least 4 months in these patients. Hyperpigmentation of psoriatic plaques was also reported in a patient treated with topical calcipotriol and UVB phototherapy.[2] Abnormal lentiginous pigmentation of psoriatic plaques occurred in a patient treated with topical calcipotriol for psoriasis, which had worsened during chemotherapy for melanoma, and was still present 2 years after stopping chemotherapy and calcipotriol.[3] The authors also noted that melanoma can cause pigment changes and may have played a role in this case.

There has been some interest in the hyperpigmentary effects of calcipotriol for the possible treatment of vitiligo (see Skin Disorders, below).

Uses and Administration

Calcipotriol is a vitamin D_3 derivative. *In vitro* it appears to induce differentiation and to suppress proliferation of keratinocytes.

Calcipotriol is used in a cream or ointment for the management of plaque psoriasis and as a solution in the management of scalp psoriasis; the concentration of calcipotriol used is 0.005%. Applications should be made once or twice daily. No more than 100 g of cream or ointment, or 60 mL of scalp solution, should be applied in one week. If both are used, the limit is 60 g of cream or ointment with 30 mL of scalp solution, or 30 g of cream or ointment with 60 mL of scalp solution.

For the use of calcipotriol in children, see below.

Administration in children. Topical calcipotriol may be used in the management of plaque psoriasis in children. In the UK, the cream or ointment (0.005%) may be applied twice daily. The maximum applied in one week should be 50 g in children aged 6 to 12 years, and 75 g in children more than 12 years of age. The *BNFC* also suggests that under specialist supervision the scalp solution (0.005%) may be applied twice daily to children aged 6 years and over for the treatment of scalp psoriasis; no more than 30 mL of the solution should be applied in one week to those aged 6 to 12 years, with older children receiving a maximum of 45 mL in one week. When preparations are used together, the *BNFC* recommends a maximum total calcipotriol dose of 2.5 mg in any one week for children aged 6 to 12 years (e.g. 20 mL of the scalp solution with 30 g of the cream or ointment); in older children, the maximum is 3.75 mg in any one week (e.g. 30 mL of the scalp solution with 45 g of the cream or ointment). In the UK, the scalp solution is not licensed for use in children and the cream and ointment are not licensed for use in children under 6 years; however, safety and efficacy have been reported in small 8-week studies that have included children as young as 2 years old.[1-3] There are also a few case reports of topical calcipotriol use in infants with psoriasis, aged 3 months[4] and 6 months.[5]

Skin disorders. Topical drugs are the treatment of first choice for *chronic plaque psoriasis* (p.1583). Calcipotriol, dithranol, and coal tar are commonly used for mild to moderate forms of the disorder. Calcipotriol inhibits cell proliferation and increases cell differentiation by binding to vitamin D receptors, thus inhibiting epidermal growth and returning some normality to the skin's structure. It is also possible that calcipotriol affects immunological and inflammatory processes in the skin.[1] Topical calcipotriol has been shown to be effective in mild to moderate chronic plaque psoriasis; it is at least as effective as dithranol, coal tar, and corticosteroids, and has been reported to be superior in a number of studies.[1,2] Calcipotriol is also more cosmetically acceptable than dithranol, which can stain, and coal tar, which can have an unpleasant smell. Benefits have been maintained with long-term use, and repeat courses are effective for the management of relapse. Although there are fewer studies in children, calcipotriol has been reported to be safe and effective in studies including children aged 2 to 15 years[1] (see also Administration in Children, above). Calcipotriol, applied as a topical solution, is also effective for *scalp psoriasis*.[3] When solutions of calcipotriol and betamethasone were compared for mild to moderate scalp psoriasis,[4] calcipotriol produced a satisfactory response, but betamethasone was more effective and was associated with less irritation of the scalp and face. Similar results were reported in a study comparing calcipotriol with clobetasol propionate in moderate to severe scalp psoriasis.[5] In a study of patients with *nail psoriasis* about half received benefit from calcipotriol ointment over a 3 to 5 month treatment period.[6] This result was similar to that found for patients treated with betamethasone and salicylic acid ointment.

Use of calcipotriol with other antipsoriatic drugs may be beneficial. The combination of calcipotriol with a topical corticosteroid is more effective than monotherapy with either of these.[1,7,8] Treatment for up to 4 weeks is usually effective and may be followed by maintenance calcipotriol monotherapy.[9] Topical calcipotriol with systemic therapies has also been tried. There is evidence that the response to oral ciclosporin or acitretin can be improved,[1] as can the response to phototherapy (UVB) or photochemotherapy (PUVA).[1,10] Combination therapy may also reduce the cumulative dose of acitretin, UVB, or PUVA required to achieve clearance or marked improvement of psoriasis, potentially reducing the risk of long-term adverse effects from these treatments.[1,10,11] However, because of the potential for the vehicle of topical calcipotriol preparations to block UV irradiation, they should be applied at least 2 hours before irradiation.[12] Despite promising reports from combination therapy using topical calcipotriol with systemic treatment, phototherapy, or photochemotherapy, a systematic review[13] found that although there can be a measurable additive effect, it may not be clinically significant in patients' own assessments.

A 2-week course of high-dose calcipotriol (up to 360 g of 0.005% ointment weekly) has been used for inpatient treatment of extensive psoriasis, followed by the usual recommended dose (up to 100 g weekly) for residual psoriasis.[14] Asymptomatic hypercalcaemia and hypercalciuria occurred in some patients, and the authors suggested that the monitoring of calcium homoeostasis is mandatory with this regimen (see also Effects on Calcium Homoeostasis, above). Relapse occurred in most patients within one year.

Beneficial results with calcipotriol have also been reported in small numbers of patients with various skin disorders[15] including *acrodermatitis continua of Hallopeau*, *confluent and reticulated papillomatosis*, *congenital ichthyosis*, *inflammatory linear verrucous epidermal nevus*, *lichen amyloidosis*, *morphea or linear scleroderma*, *pityriasis rubra pilaris*, *prurigo nodularis*, and *seborrhoeic dermatitis*. A small open study[16] has indicated that topical calcipotriol may be effective in the treatment of oral *leucoplakia* (see under Bleomycin, p.688). It has also been tried, alone or with UVA or UVB, or a topical corticosteroid, in the treatment of *vitiligo*[17-21] (see Pigmentation Disorders, p.1582), but results have been mixed.

CAS — 18449-41-7 (madecassic acid); 464-92-6 (asiatic acid); 16830-15-2 (asiaticoside).

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).

Ph. Eur. 6.2 (Centella). The dried, fragmented aerial parts of *Centella asiatica*. It contains not less than 6% of total triterpenoid derivatives, expressed as asiaticoside, calculated with reference to dried drug. Protect from light.

Profile

Centella contains madecassic acid, asiatic acid, and asiaticoside. It has been used topically and orally in the management of wounds, ulcers, and keloid scars.

The names gotu kola, gotu cola, and gota kola are used for *Centella asiatica* (=*Hydrocotyle asiatica*) in herbal medicine. Centella is also used in homoeopathic medicine.

Adverse effects. Contact dermatitis has been reported with the topical use of centella.[1] There is also a report of 3 cases of hepatotoxicity associated with ingestion of centella, all presenting with jaundice, painful hepatomegaly, and granulomatous hepatitis with areas of necrosis.[2]

Crotamiton *(BAN, rINN)*

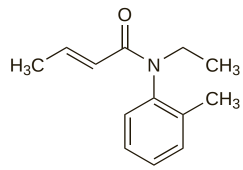
Crotam; Crotamitón; Crotamitonum; Krotamiton; Krotamitonas; Krotamitoni. *N*-Ethyl-*N*-*o*-tolylcrotonamide; *N*-Ethylcrotono-*o*-toluidide; *N*-Ethyl-*N*-(2-methylphenyl)-2-butenamide.

Кротамитон

$C_{13}H_{17}NO$ = 203.3.

CAS — 483-63-6.

ATC Vet — QP53AX04.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Crotamiton). A colourless or pale yellow oily liquid. It solidifies partly or completely at low temperatures. It is mainly the (*E*)-isomer, with not more than 15% of the (*Z*)-isomer. Slightly soluble in water; miscible with alcohol. Protect from light.

USP 31 (Crotamiton). A colourless to slightly yellowish oil with a faint amine-like odour. It is a mixture of *cis*- and *trans*-isomers. Soluble in alcohol and in methyl alcohol. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Topical use of crotamiton occasionally causes irritation. There have been rare reports of hypersensitivity reactions. Crotamiton should not be used in patients with acute exudative dermatitis. It should not be applied near the eyes, mouth, or other mucous membranes or on excoriated skin.

Ingestion of crotamiton may cause burning and irritation of oral, oesophageal, and gastric mucosa with nausea, vomiting, and abdominal pain.

Overdosage. A 23-year-old woman developed tonic-clonic seizures, requiring treatment with diazepam, after ingestion of a crotamiton emulsion.[1] Other hospital treatment included gastric lavage, activated charcoal, and metoclopramide. Crotamiton was detected in serum at a concentration of 34 micrograms/mL and was also detectable with several metabolites in the urine. Reference was also made to a report of a 2½-month-old child who had developed pallor and cyanosis after excessive dermal application of a crotamiton cream.

1. Meredith TJ, *et al.* Crotamiton overdose. *Hum Exp Toxicol* 1990; **9:** 57.

Uses and Administration

Crotamiton is used as an antipruritic (p.1582), although its value is considered uncertain (see also below). It is applied as a 10% cream or lotion 2 or 3 times daily; children aged less than 3 years may receive one application daily.

Crotamiton has also been used as an acaricide in the treatment of scabies but other more effective drugs are usually preferred (p.2035). The 10% cream or lotion is applied, after first bathing and drying, to the whole of the body-surface below the chin, particular attention being paid to body folds and creases. A second application should be applied 24 hours later but it may need to be used once daily up to a total of 5 days to be effective.

Pruritus. A double-blind study in 31 patients[1] found that 10% crotamiton lotion was no more effective an antipruritic than its vehicle.

1. Smith EB, *et al.* Crotamiton lotion in pruritus. *Int J Dermatol* 1984; **23:** 684–5.

Dextranomer *(BAN, rINN)*

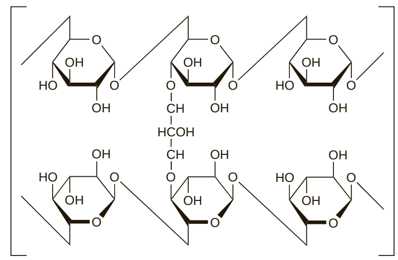
Dekstranomeeri; Dextranomère; Dextranómero; Dextranomerum. Dextran cross-linked with epichlorohydrin (1-chloro-2,3-epoxypropane); Dextran 2,3-dihydroxypropyl 2-hydroxy-1,3-propanediyl ether.

Декстраномер

CAS — 56087-11-7.

ATC — D03AX02.

ATC Vet — QD03AX02.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Dextranomer). White or almost white, spherical beads. Practically insoluble in water. It swells in water and electrolyte solutions

Adverse Effects and Precautions

Dextranomer can cause pain during dressing changes in some patients, and bleeding, blistering, and erythema have been reported occasionally. It should not be used in deep wounds or cavities from which it cannot be easily removed, nor should it be used on dry wounds. Care should be exercised when paste formulations of dextranomer are used near the eyes.

Spillage may render surfaces very slippery.

Viscous gel implants containing dextranomer, injected submucosally around the urethra, can cause transient urinary retention. Injection site reactions including mass, abscess, and pseudocyst formation have been reported.

Uses and Administration

The action of dextranomer as a wound dressing depends upon its ability to absorb up to 4 times its weight of fluid, including dissolved and suspended material of molecular weight up to about 5000.

Dextranomer is used for the cleansing of exudative and infected burns (p.1578), wounds and ulcers (p.1585), and for preparation for skin grafting.

The wound is cleansed with sterile water or saline and allowed to remain wet; dextranomer in the form of spherical beads is sprinkled on to a depth of at least 3 to 6 mm and covered with a sterile dressing. Occlusive dressings are not recommended as they may lead to maceration around the wound. The dextranomer can be renewed up to 5 times daily (usually once or twice daily) when the layer has become saturated with exudate; the old layer is washed off with a stream of sterile water or saline before renewal. All dextranomer must be removed before skin grafting. Dextranomer may also be applied as a paste (either ready-made or prepared by mixing dextranomer beads with glycerol).

Implants containing dextranomer microspheres in a stabilised hyaluronic acid carrier gel (NASHA/Dx) are available for injection. In female stress urinary incontinence (p.2180), 4 injections each containing 35 mg of dextranomer are injected into the submucosa of the urethra. Connective tissue gradually surrounds the microspheres, and the resulting augmented tissue helps to restore urinary continence. A second implantation may be performed if necessary, but no sooner than 6 weeks after the first. In vesicoureteral reflux in children, up to 50 mg may be injected into the submucosa of the ureter, creating a bulge close to the ureteral orifice. The procedure may be repeated after 3 months if necessary.

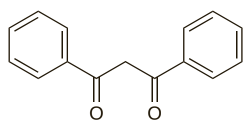
Dibenzoylmethane

Dibenzoilmetano. 1,3-Diphenyl-1,3-propanedione.

Дибензоилметан

$C_{15}H_{12}O_2$ = 224.3.

CAS — 120-46-7.



Profile

Dibenzoylmethane is a sunscreen (p.1576) with actions similar to those of avobenzone (p.1589). It is effective against UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

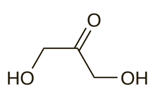
Dihydroxyacetone

DHA; Dihidroxiacetona; Ketotriose. 1,3-Dihydroxypropan-2-one.

Дигидроксиацетон

$C_3H_6O_3$ = 90.08.

CAS — 96-26-4.



NOTE. DHA is also used as a synonym for docosahexaenoic acid (p.1362).

Pharmacopoeias. In *US.*

USP 31 (Dihydroxyacetone). A white to off-white crystalline powder. The monomeric form is freely soluble in water, in alcohol, and in ether; the dimeric form is freely soluble in water, soluble in alcohol, and sparingly soluble in ether. A 5% solution in water has a pH between 4.0 and 6.0. Store at a temperature of 8° to 15° in airtight containers.

Adverse Effects and Precautions

Skin irritation from dihydroxyacetone occurs rarely; rashes and allergic dermatitis have been reported. Contact with eyes, abraded skin, and clothing should be avoided.

Uses and Administration

Application to the skin of preparations containing dihydroxyacetone slowly produces a brown coloration similar to that caused by exposure to the sun, probably due to a reaction with the amino acids of the skin.

A single application may give rise to a patchy appearance; progressive darkening of the skin results from repeated use until a point is reached when the maximum effect is achieved. If the treatment is stopped the colour starts to fade after about 2 days and disappears completely within 8 to 14 days as the external epidermal cells are lost by normal attrition.

Preparations usually contain 5% of dihydroxyacetone and have been used to camouflage vitiligo (see Pigmentation Disorders, p.1582) or to produce an artificial suntan. Some preparations include sunscreens since the pigmentation produced gives no protection against sunburn.

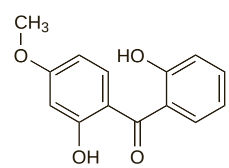
CAS — 131-53-3.



Pharmacopoeias. In *US.*

USP 31 (Dioxybenzone). A yellow powder. Practically insoluble in water; freely soluble in alcohol and in toluene. Store in airtight containers. Protect from light.

Profile

Dioxybenzone, a substituted benzophenone, is a sunscreen (p.1576) with actions similar to those of oxybenzone (p.1608). It is effective against UVB and some UVA light (for definitions, see p.1580).

Preparations

USP 31: Dioxybenzone and Oxybenzone Cream.

Proprietary Preparations some preparations are listed in Part 3.

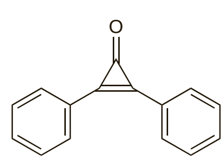
Diphencyprone

Difenciprona. 2,3-Diphenylcyclopropenone-1.

Дифенципрон

$C_{15}H_{10}O$ = 206.2.

CAS — 886-38-4.



Profile

Diphencyprone has been applied as a contact sensitiser for the treatment of alopecia. It has also been tried in warts.

Adverse effects. Diphencyprone is considered to lack serious adverse effects but some patients may not be able to tolerate the induced hypersensitivity reaction. There have been reports of generalised urticaria and dermographism, sometimes severe, following the use of diphencyprone.[1-5] In another case, a severe reaction of urticaria and dermographism, which lasted several months, occurred after the initial sensitisation dose.[6] Allergy to diphencyprone has been reported in medical and nursing staff in spite of taking protective precautions during its application.[7] A patient who received diphencyprone treatment for warts developed a widespread pruritic rash and palpitations due to ventricular extrasystoles.[1] Vitiligo has also been reported in patients treated with diphencyprone[8-10] and it has been suggested that this might be due to unmasking of subclinical vitiligo.[8,9] Erythema multiforme-like eruptions have been associated with the topical application of diphencyprone.[11,12]

Alopecia. Diphencyprone has been used as a contact sensitiser in the treatment of various forms of alopecia (p.1577) including areata, totalis, and universalis. Case series reports generally describe treatment of adults, but some groups have also included adolescents and children, and some have reported solely on treatment in children.[1,2]

Initial sensitisation is usually achieved by applying a 2% solution of diphencyprone in acetone to a small area of scalp, which may be repeated if necessary beneath plastic occlusion if adequate sensitisation is not produced. Thereafter, weaker concentrations are applied once weekly and gradually increased in strength to produce erythema and pruritus for 36 to 48 hours post-therapy. Concentrations that have been used vary between reports and the first treatment application may be as dilute as 0.00001%, with further applications gradually increased to up to 2%. Only one side of the scalp is treated until the optimum concentration is found, in order to prevent a widespread adverse reaction. Once hair regrowth has started on the treated side the applications may be extended to the entire scalp.[1-8] As well as erythema and pruritus, patients usually experience transient eczema and regional lymph node swelling.[2,5,7,8]

Hair regrowth may not start for several months,[4,6,8] and the required duration of therapy can vary considerably; at least 8 months of treatment may be required,[3,6] and up to 12 months[1,2] or more[4,6] has been reported. Not all patients will respond to treatment and reported response rates vary, although these have probably been influenced by the different definitions used for complete, partial, and no response. Overall, however, regrowth of hair can occur in up to about 70% of patients, with around half of these having complete regrowth.[1,4,6-8] Some reports have attempted to determine which factors might be associated with clinical response to diphencyprone. There is disagreement between studies but some possible unfavourable prognostic factors include extensive involvement,[4,6,8] younger age at onset,[8] longer disease duration before treatment,[5,7] and a history of atopic eczema.[4,7] The need for high diphencyprone concentrations and prolonged therapy have also been associated with a less favourable outcome.[8]

Despite these rates of response a significant number of patients will relapse, either during or after stopping treatment, and retreatment may be considered.[4,6,7] The time to relapse can be variable. Remission in a small group of complete responders ranged from 1 month to 2 years after stopping therapy.[4] Another group of patients who achieved total regrowth of hair were able to stop treatment with diphencyprone for a mean of 15 months without relapse[9] while a further group maintained satisfactory hair growth for a mean follow-up period of 19.8 months.[5]

Warts. Diphencyprone has been tried in the treatment of recalcitrant warts. The successful treatment of digital or plantar warts in 42 of 60 patients has been described.[1] The patients were initially sensitised with a 2% topical solution of diphencyprone in acetone, then the warts treated every 1 to 4 weeks with solutions ranging from 0.01 to 6%. In another series,[2] diphencyprone in a paraffin ointment was effective in the clearance of palmar, plantar, palmoplantar, and periungual warts in 135 of 154 patients. A concentration of diphencyprone 2% was used for the initial sensitisation, and concentrations of 0.5 to 4% were used for treatment once every 3 weeks. After initial sensitisation with diphencyprone 2% in acetone, a preparation of diphencyprone with salicylic acid in white soft paraffin applied every night as tolerated was reported to be successful in 44 of 50 patients treated for palmoplantar warts.[3] The concentration of diphencyprone in the ointment ranged from 0.01 to 0.2%, and the concentration of salicylic acid was 15%.

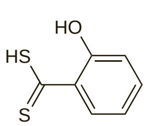
Дитиосалициловая Кислота

$C_7H_6OS_2$ = 170.3.

CAS — 527-89-9.



Profile

Dithiosalicylic acid has been used in multi-ingredient preparations used topically for the treatment of acne and seborrhoeic dermatitis.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ital.:*** Sacnel.

Dithranol *(BAN, rINN)*

Anthralin; Antralin; Dioxyanthranol; Dithranolum; Ditranol; Ditranoli; Ditranolis. 1,8-Dihydroxyanthrone; 1,8-Dihydroxy-9(10*H*)-anthracenone.

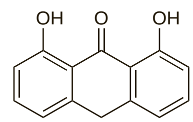
Дитранол

$C_{14}H_{10}O_3$ = 226.2.

CAS — 1143-38-0 (dithranol); 16203-97-7 (dithranol triacetate).

ATC — D05AC01.

ATC Vet — QD05AC01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Dithranol). A yellow or brownish-yellow, crystalline powder. Practically insoluble in water; slightly soluble in alcohol; sparingly soluble in acetone; soluble in dichloromethane; dissolves in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Anthralin). A yellowish-brown, odourless, crystalline powder. Insoluble in water; slightly soluble in alcohol, in ether, and in glacial acetic acid; soluble in acetone, in chloroform, in benzene, and in solutions of alkali hydroxides. The filtrate from a suspension in water is neutral to litmus. Store at a temperature of 8° to 15° in airtight containers. Protect from light.

Stability. The stability of dithranol has been studied in a number of bases and vehicles.[1-4] The weaker preparations of dithranol may be less stable.[1,3,4] Salicylic acid is included in dithranol preparations as an antioxidant and its inclusion in pastes also containing zinc oxide prevents their discoloration due to the inactivation of dithranol by zinc oxide.[5] However, zinc oxide or starch can be omitted from dithranol pastes without loss of effectiveness provided stiffness is maintained.[5] Addition of ascorbic or oxalic acid may improve dithranol's stability in '*Unguentum Merck*' but salicylic acid appears to be ineffective.[1] The effect of salicylic acid on the instability of dithranol in yellow soft paraffin is variable[1,2] and its inclusion has been questioned as it can be irritant and percutaneous absorption can be significant.[1] Dithranol is relatively stable in white soft paraffin.[1]

The application of any type of heat and contact with metal spatulas should be avoided during the manufacture of dithranol pastes[6] and if milling facilities are not available dithranol can be incorporated into Lassar's paste by dissolving it first in chloroform.[5]

Adverse Effects and Precautions

Dithranol may cause a burning sensation especially on perilesional skin. Patients with fair skin may be more sensitive than those with dark skin. It is irritant to the eyes and mucous membranes. Use on the face, skin flexures, and genitals should be avoided. Hands should be washed after use.

Dithranol should not be used for acute or pustular psoriasis or on inflamed skin. It stains skin, hair, some fabrics, plastics, and enamel. Staining of bathroom ware may be less of a problem with creams than ointments. Stains on skin and hair slowly disappear on cessation of treatment.

Handling. Dithranol is a powerful irritant and should be kept away from the eyes and tender parts of the skin.

Uses and Administration

Dithranol is used in the treatment of subacute and chronic psoriasis, usually in one of two ways.

Conventional treatment is commonly started with an ointment or paste containing 0.1% dithranol (0.05% in very fair patients) applied for a few hours; the strength is gradually increased as necessary to 0.5%, occasionally to 1%, and the duration of contact extended to overnight periods or longer. The preparation is sparingly and accurately applied to the lesions only. If, on initial treatment, lesions spread or excessive irritation occurs, the concentration of dithranol or the frequency of application should be reduced; if necessary, treatment should be stopped. After each treatment period the patient should bathe or shower to remove any residual dithranol.

For *short-contact therapy* dithranol is usually applied in a soft basis to the lesions for up to 60 minutes daily, before being washed off. As with conventional treatment the strength used is gradually increased from 0.1 to 2% but strengths up to 5% have been used. Surrounding unaffected skin may be protected by white soft paraffin.

Treatment for psoriasis should be continued until the skin is entirely clear. Intermittent courses may be needed to maintain the response. Treatment schedules often involve coal tar and UV irradiation (preferably UVB) before the application of dithranol (see below). Salicylic acid is included in many topical preparations of dithranol.

A cream containing dithranol triacetate has been used similarly to dithranol in conventional treatment of psoriasis.

Alopecia. Dithranol cream (0.5 to 1%) applied for 20 to 60 minutes to the scalp and then washed off, has been found to be of benefit in the treatment of alopecia areata (p.1577). However, at least 6 months of treatment may be required for a cosmetically acceptable result.[1] The response rate has, however, been difficult to evaluate because of the small number of reports, and although it has been widely prescribed for limited patchy alopecia areata, some guidelines conclude that there is no convincing evidence of efficacy.[2]

1. Meidan VM, Touitou E. Treatments for androgenetic alopecia and alopecia areata: current options and future prospects. *Drugs* 2001; **61:** 53–69.
2. MacDonald Hull SP, *et al.* British Association of Dermatologists. Guidelines for the management of alopecia areata. *Br J Dermatol* 2003; **149:** 692–9. Also available at: http://www.bad.org.uk/healthcare/guidelines/Alopecia_Areata.pdf (accessed 27/09/07)

Psoriasis. Dithranol used alone or with coal tar, (with or without ultraviolet light), continues to be one of the drugs of first-line treatment for psoriasis (p.1583). It is particularly suited to the treatment of stable chronic plaque psoriasis but unlike coal tar, is irritant to healthy skin and care is required to ensure that it is only applied to lesions. Treatment with dithranol is therefore more feasible when the plaques are large, or few in number. Use with coal tar may help to reduce the irritant effects of dithranol without affecting efficacy. Traditional treatment with dithranol is time consuming and more suitable for use on hospital inpatients. Dithranol formulated in stiff preparations such as Lassar's paste to minimise spreading to perilesional skin is left on overnight covered with a suitable dressing and washed off the next day. Treatment is usually started with a concentration of 0.1% (0.05% in fair-skinned patients) and gradually increased according to the response and irritation produced. Cream formulations may be less effective but are more suitable for domestic use. Short-contact therapy in which concentrations of up to 5% of dithranol are applied daily for up to 1 hour is more suitable for use on an outpatient basis and there appears to be little reduction in efficacy; irritation and staining may also be reduced.

Dithranol is also used with UVB phototherapy and there have been many modifications of the original Ingram's regimen in which dithranol is applied after bathing in a tar bath and exposure to ultraviolet light. Inpatient stays of up to 3 weeks may be required but long periods of remission can be obtained.

Reviews.

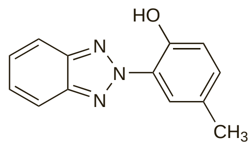
Drometrizole *(USAN, rINN)*

Drométrizol; Drometrizol; Drometrizolum. 2-(2*H*-Benzotriazol-2-yl)-*p*-cresol.

Дрометризол

$C_{13}H_{11}N_3O$ = 225.2.

CAS — 2440-22-4.



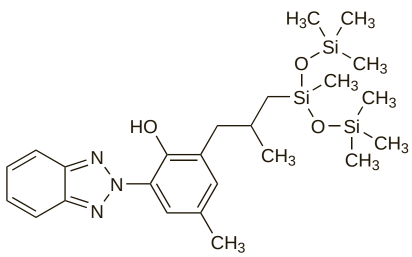
Drometrizole Trisiloxane

2-(2*H*-Benzotriazol-2-yl)-4-methyl-6-(2-methyl-3-{1,3,3,3-tetramethyl-1-[(trimethylsilyl)oxy]-1-disiloxanyl}propyl)phenol.

Дрометризола Трисилоксан

$C_{24}H_{39}N_3O_3Si_3$ = 501.8.

CAS — 155633-54-8.



NOTE. Mexoryl XL and Silatrizole are trade names that have been used for drometrizole trisiloxane.

Profile

Drometrizole trisiloxane is used as a sunscreen (p.1576). It is effective against UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

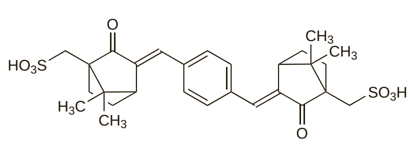
Ecamsule *(USAN, rINN)*

Ecamsul; Écamsule; Ecamsulum. (±)-(3*E*,3′*E*)-3,3′-(*p*-Phenylenedimethylidyne)bis[2-oxo-10-bornanesulfonic acid]; Terephthalylidene-3,3′-dicamphor-10,10′-disulfonic acid.

Экамсул

$C_{28}H_{34}O_8S_2$ = 562.7.

CAS — 92761-26-7.



NOTE. Mexoryl SX is a trade name that has been used for ecamsule.

Profile

Ecamsule, a camphorsulfonic acid derivative, is used as a sunscreen (p.1576). It is effective against UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

Efalizumab *(USAN, rINN)*

Anti-CD11a; Éfalizumab; Efalizumabum; Hu-1124. Immunoglobulin G1, anti-(human antigen CD11a)(human-mouse monoclonal hu1124 γ1-chain), disulfide with human-mouse monoclonal hu1124 light chain, dimer.

Эфализумаб

CAS — 214745-43-4.

ATC — L04AA21.

ATC Vet — QL04AA21.

Adverse Effects and Precautions

The most common adverse affects associated with efalizumab are flu-like symptoms including chills, fever, headache, myalgia, and nausea. These reactions are dose-related in both incidence and severity and usually occur within two days after the first two injections. Other adverse effects include acne, back pain, and an elevation in alkaline phosphatase concentrations. More serious adverse effects of efalizumab include arthritis, interstitial pneumonitis, hypersensitivity reactions, inflammatory polyradiculoneuropathy, and thrombocytopenia. Treatment should be stopped in patients who develop such reactions. Severe haemolytic anaemia, diagnosed 4 to 6 months after the start of efalizumab treatment, has been reported. Treatment should be stopped immediately if haemolytic anaemia occurs. Asymptomatic leucocytosis or lymphocytosis commonly occurs during treatment. Worsening of psoriasis or development of variant forms (pustular, erythrodermic, or guttate) have been reported during and after stopping efalizumab therapy.

As a result of immunosuppression, patients given efalizumab are at increased risk of infection, and might be at increased risk of developing malignancies. It should not be given to patients with pre-existing serious infection and should be used with care in patients with a history of recurring infection or malignancy. Response to vaccines may also be reduced and acellular, live, and live-attenuated vaccines should not be given during efalizumab treatment.

Assessment of the platelet count is advised before starting therapy and monthly during early treatment. Frequency of monitoring may be decreased with ongoing treatment.

Incidence of adverse effects. The safety data from 13 controlled and open-label studies of efalizumab in psoriasis have been analysed.[1] During the first 12 weeks of therapy the most common events in patients treated with efalizumab were headache, fever, chills, nausea, vomiting, or myalgia, starting within 48 hours of dosing. In 4 controlled studies that included 1620 patients treated with efalizumab and 715 with placebo, about a third of efalizumab-treated patients reported headache, while chills, nausea, and pain occurred in around 10%, and fever and myalgia in about 8%. These events usually occurred with the first 1 or 2 doses of efalizumab but by the third and subsequent doses the incidence was similar to that in the placebo group. Atypical or unusual worsening of psoriasis, and the development of variant forms, particularly guttate psoriasis, were reported in 3.2% of patients treated with efalizumab; other forms included psoriatic erythroderma, inverse psoriasis, palmoplantar psoriasis, and pustular psoriasis. In 5 studies of extended therapy for 13 to 60 weeks (1115 patients treated for 13 to 24 weeks and 228 for 60 weeks) the rate of adverse effects remained low, there was no new pattern of serious adverse effects, and there was no evidence of cumulative toxicity. An analysis of infection risk found similar rates of mild to moderate and serious infections in patients treated with either efalizumab or placebo. Nevertheless, efalizumab should not be used in patients with pre-existing serious infection. Anti-efalizumab antibodies were found in 67 of 1063 patients, but there was no apparent effect on efficacy, safety, or pharmacodynamics.

There have been infrequent reports of new onset or recurrent severe arthritis, including psoriatic arthritis, in patients treated with efalizumab. Separate analyses[1,2] of pooled study data both found that the incidence of arthropathy events was low (less than 4%) and similar for patients treated with either efalizumab or placebo. However, there was some suggestion[2] that patients with a history of arthropathy and those who have a poor clinical response to efalizumab may be at higher risk.

1. Papp KA, *et al.* Safety of efalizumab in patients with moderate to severe chronic plaque psoriasis: review of clinical data. *J Cutan Med Surg* 2005; **9:** 313–23.
2. Pincelli C, *et al.* The incidence of arthropathy adverse events in efalizumab-treated patients is low and similar to placebo and does not increase with long-term treatment: pooled analysis of data from phase III clinical trials of efalizumab. *Arch Dermatol Res* 2006; **298:** 329–38.

Carcinogenicity. Efalizumab is an immunosuppressant and as such might increase the risk of malignancy. An analysis[1] of pooled data from clinical studies that included 2980 patients given efalizumab found 51 patients (1.7%) with 67 malignancies. Most cases were of non-melanoma skin cancer (51 cases in 35 patients) and it was found that many had risk factors for skin cancer. Other cases included 3 lymphomas, 12 solid tumours at various sites, and 1 malignant melanoma. However, when compared with patients given placebo and data from 2 external cohorts of psoriasis patients (to allow for the increased risk of skin cancers seen in psoriasis patients compared with the general population) there was no evidence that efalizumab increased the risk of developing a malignancy. Nevertheless, further data are needed to determine whether efalizumab has any long-term effect on the development of malignancies.

1. Leonardi CL, *et al.* A review of malignancies observed during efalizumab (Raptiva) clinical trials for plaque psoriasis. *Dermatology* 2006; **213:** 204–14.

Effects on the blood. Thrombocytopenia has been described in 6 patients given efalizumab.[1] In 5 cases it started 8 to 12 weeks after starting weekly efalizumab. In all cases the platelet counts recovered quickly after efalizumab was stopped; in 5 cases corticosteroids were also given. In another case a woman presented with pancytopenia 4 weeks after starting efalizumab therapy.[2] Efalizumab was stopped and the patient treated with granulocyte colony-stimulating factor, normal immunoglobulin, oral prednisone, platelet transfusion, and darbepoetin alfa. Cell counts returned to normal limits within 4 weeks.

2. Tom WL, *et al.* Efalizumab-induced autoimmune pancytopenia. *Br J Dermatol* 2006; **155:** 1045–7.

Interactions

For a warning concerning the use of live vaccines in patients receiving efalizumab see Adverse Effects and Precautions, above.

Pharmacokinetics

Peak plasma concentrations of efalizumab are reached about 1 to 2 days after subcutaneous injection, with a bioavailability of about 50%. Steady state is reached at week 4 of weekly dosing. Efalizumab is metabolised by intracellular degradation. It is cleared by non-linear saturable elimination and the time to elimination after the last dose is about 25 days.

3. Joshi A, *et al.* An overview of the pharmacokinetics and pharmacodynamics of efalizumab: a monoclonal antibody approved for use in psoriasis. *J Clin Pharmacol* 2006; **46:** 10–20.

Uses and Administration

Efalizumab is a humanised monoclonal antibody that binds to human CD11a on leucocytes to inhibit the activation of T-lymphocytes. It is used for the treatment of chronic moderate to severe plaque psoriasis (p.1583) in patients aged 18 years and over. Efalizumab is given by subcutaneous injection. The initial dose is 700 micrograms/kg, followed by a weekly dose of 1 mg/kg; a single dose should not exceed 200 mg. Treatment is given for 12 weeks, then continued in those who have responded.

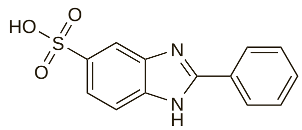
Ensulizole *(USAN, rINN)*

Ensulizol; Ensulizolum; Phenylbenzimidazole Sulphonic Acid. 2-Phenyl-1*H*-benzimidazole-5-sulphonic acid.

Энсулизол

$C_{13}H_{10}N_2O_3S$ = 274.3.

CAS — 27503-81-7.



NOTE. Eusolex 232 and Neo-Heliopan Hydro are trade names that have been used for ensulizole.

Pharmacopoeias. In *US.*

USP 31 (Ensulizole). A white to ivory-coloured, odourless powder. Practically insoluble in water and in oily solvents; soluble in alcohol; its salts are freely soluble in water. Store in airtight containers at a temperature of 8° to 15°.

Profile

Ensulizole is used topically as a sunscreen (p.1576). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

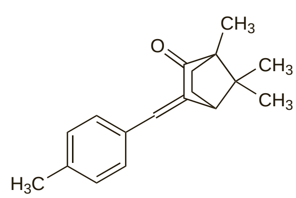
Enzacamene *(USAN, rINN)*

Enzacamène; Enzacameno; Enzacamenum; Methyl Benzylidene Camphor; 3-(4-Methylbenzylidene)bornan-2-one; 3-(4-Methylbenzylidene)camphor. 1,7,7-Trimethyl-3-[(4-methylphenyl)methylene]bicyclo[2.2.1]heptan-2-one.

Энзакамен

$C_{18}H_{22}O$ = 254.4.

CAS — 36861-47-9 (DL-form); 38102-62-4 (form unspecified).



NOTE. Eusolex 6300, Neo-Heliopan MBC, and Parsol 5000 are trade names that have been used for enzacamene.

Pharmacopoeias. In *US.*

USP 31 (Enzacamene). A white, fine crystalline powder. M.p. between 66° and 68°. Practically insoluble in water; freely soluble in alcohol; very soluble in chloroform. Store in airtight containers.

Profile

Enzacamene is a camphor derivative used as a sunscreen (p.1576). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations numerous preparations are listed in Part 3.

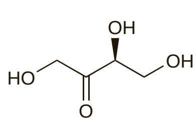
Erythrulose

DL-Glycero-tetrulose. 1,3,4-Trihydroxy-2-butanone.

Эритрулаза

$C_4H_8O_4$ = 120.1.

CAS — 40031-31-0 (DL-erythrulose); 496-55-9 (D-erythrulose); 533-50-6 (L-erythrulose).



Profile

Application to the skin of preparations containing L-erythrulose slowly produces a brown coloration similar to that caused by exposure to the sun, probably due to a reaction with the amino acids of the skin. It is often used with dihydroxyacetone (p.1594) in artificial suntan preparations. Recommended concentrations are up to 5% when used alone or up to 4% with dihydroxyacetone.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Braz.:*** Sunmax Autobronzeador; ***UK:*** ViTicolor.

Etretinate *(BAN, USAN, rINN)*

Etretinaatti; Etretinat; Étrétinate; Etretinato; Etretinatum; Ro-10-9359. Ethyl 3-methoxy-15-apo-ϕ-caroten-15-oate; Ethyl (*all-trans*)-9-(4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethylnona-2,4,6,8-tetra-enoate.

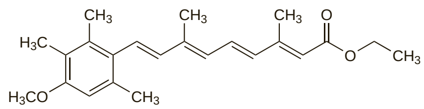
Этретинат

$C_{23}H_{30}O_3$ = 354.5.

CAS — 54350-48-0.

ATC — D05BB01.

ATC Vet — QD05BB01.



Adverse Effects and Precautions

As for Isotretinoin, p.1599.

Donation of blood should be avoided for at least 2 years after cessation of treatment. The period of time during which pregnancy must be avoided after stopping treatment has not been determined; detectable plasma-etretinate concentrations have been reported nearly 3 years after the last dose.

◊ In addition to the references cited below, further references to the adverse effects of etretinate can be found in Isotretinoin, p.1599, under Effects on the Blood, Cardiovascular System, Eyes, Liver, Musculoskeletal System, Serum Lipids, and the Skin, as well as under Vasculitic Syndromes.

Carcinogenicity. A report of 2 patients who developed lymphomas while receiving etretinate[1] prompted a report of 3 other malignancies in patients taking etretinate.[2]

1. Woll PJ, *et al.* Lymphoma in patients taking etretinate. *Lancet* 1987; **ii:** 563–4.
2. Harrison PV. Retinoids and malignancy. *Lancet* 1987; **ii:** 801.

Effects on the kidneys. Rare cases of impaired renal function associated with etretinate have been described.[1,2] In one report[1] it was also noted that in manufacturer-sponsored studies the mean serum-creatinine concentration had been raised in patients receiving etretinate.

1. Horber FF, *et al*. Impaired renal function and hypercalcaemia associated with etretinate. *Lancet* 1984; **ii:** 1093.
2. Cribier B, *et al.* Renal impairment probably induced by etretinate. *Dermatology* 1992; **185:** 266–8.

Oedema. A report of generalised oedema after treatment with etretinate.[1] Five other cases had been reported in the literature and rechallenge in 4 patients had provoked a recurrence. Generalised oedema as part of the capillary leak syndrome has been reported with acitretin (p.1586).

1. Allan S, Christmas T. Severe edema associated with etretinate. *J Am Acad Dermatol* 1988; **19:** 140.

Pregnancy. For further information on the teratogenicity of etretinate, see under Acitretin, p.1586.

Interactions

As for Isotretinoin, p.1602.

Anticoagulants. Etretinate has been reported to reduce the therapeutic efficacy of *warfarin* (see p.1430).

Antiepileptics. Etretinate was ineffective and none of its characteristic mucocutaneous adverse effects occurred in a patient with pityriasis rubra pilaris who was already taking *carbamazepine* and *valproate* for epilepsy. However, there was a clinical response after the carbamazepine had been withdrawn, suggesting that it may have reduced the bioavailability or increased the metabolism of etretinate.[1]

1. Mohammed KN. Unresponsiveness to etretinate during anticonvulsant therapy. *Dermatology* 1992; **185:** 79.

Antineoplastics. The risk of developing hepatotoxicity may be increased when etretinate is used with *methotrexate* (see Retinoids, p.748).

Hormonal contraceptives. For discussion of the potential interactions of retinoids with oral hormonal contraceptives, and the effect this might have on contraceptive choice during retinoid treatment, see p.2068.

Pharmacokinetics

The mean bioavailability of etretinate is about 40% after oral doses but there is a large interindividual variation. Absorption can be increased if taken with milk or fatty food. Etretinate undergoes significant first-pass metabolism and plasma concentrations of the active carboxylic acid metabolite, acitretin (p.1586), may be detected before those of the parent drug; acitretin may itself be metabolised to etretinate (see p.1586). Both etretinate and acitretin are extensively bound to plasma protein. Etretinate appears to accumulate in adipose tissue after repeated dosing and has a prolonged elimination half-life of about 120 days; detectable serum concentrations have been observed up to 3 years after stopping therapy. Up to 75% of a dose is excreted in the faeces mainly as unchanged drug. Etretinate is also excreted in the urine as metabolites. Etretinate crosses the placenta. Although it is not known whether etretinate is distributed into breast milk, this would be expected because of its lipophilicity; acitretin, a metabolite of etretinate, has been found in breast milk when it was given to a lactating woman (see p.1586).

3. Larsen FG. Pharmacokinetics of etretinate and acitretin with special reference to treatment of psoriasis. *Acta Derm Venereol (Stockh)* 1994; **190** (suppl): 1–33.
4. Wiegand UW, Chou RC. Pharmacokinetics of acitretin and etretinate. *J Am Acad Dermatol* 1998; **39** (suppl): S25–S33.

Uses and Administration

Etretinate is a retinoid and is a derivative of tretinoin (p.1618). It has been given orally for the treatment of severe, extensive psoriasis that has not responded to other treatment, especially generalised and palmo-plantar pustular psoriasis. It has also been used in severe congenital ichthyosis, severe Darier's disease (keratosis follicularis) as well as other disorders of keratinisation, and oral lichen planus. Acitretin (p.1586) is now preferred to etretinate.

Therapy is generally started at doses of 0.75 to 1 mg/kg daily in divided oral doses. A maximum dose of 1.5 mg/kg daily should not be exceeded (some licensed product information has suggested a maximum of 75 mg daily). Erythrodermic psoriasis may respond to lower initial doses of 250 micrograms/kg daily, increased at weekly intervals by 250 micrograms/kg daily until optimal response occurs. After the initial response, generally after 8 to 16 weeks of therapy, maintenance doses of 500 to 750 micrograms/kg daily have been given. Therapy should be stopped once lesions have sufficiently resolved.

Preparations

Proprietary Preparations (details are given in Part 3)

Jpn: Tigason.

Fumaric Acid

Acidum Fumaricum; Allomalenic Acid; Boletic Acid; E297; Fumárico, ácido; Kwas fumarowy. *trans*-Butenedioic acid.

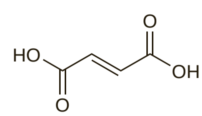
Фумаровая Кислота

$C_2H_2(CO_2H)_2$ = 116.1.

CAS — 110-17-8 (fumaric acid); 624-49-7 (dimethyl fumarate).

ATC — D05AX01.

ATC Vet — QD05AX01.



Pharmacopoeias. In *Pol.* Also in *USNF.*

USNF 26 (Fumaric Acid). White, odourless granules or crystalline powder. Slightly soluble in water and in ether; soluble in alcohol; very slightly soluble in chloroform.

Profile

Fumaric acid and some of its derivatives have been used in the treatment of psoriasis and other skin disorders.

Fumaric acid is also used as an acidifier and flavouring agent in foods.

Skin disorders. Fumaric acid, its sodium salts, and derivatives such as dimethyl fumarate, monoethyl fumarate (ethyl hydrogen fumarate), and octil hydrogen fumarate have been used, both topically and systemically, in the treatment of psoriasis (p.1583) and other skin disorders. Dimethyl fumarate appears to be the most active compound given orally but combination with various salts of monoethyl fumarate has been claimed to improve efficacy.[1-6] However, there have been reports of acute renal failure associated with treatment and the German Federal Office of Health has expressed the opinion that the available evidence did not establish the value of fumaric acid derivatives in psoriasis or other skin disorders.[7] A subsequent retrospective analysis of 41 patients who received fumaric acid esters orally, for between 1 and 14 years, suggested that these drugs might be effective,[8] and a later review suggested that they may be of value in refractory psoriasis.[9] Reported adverse effects in the earlier analysis[8] were generally mild, with only 1 case of elevated serum creatinine; however, lymphocytopenia was noted in 76% of patients and treatment consequently stopped in 4 patients. Other adverse effects with oral therapy have included disturbances of liver function,[3,10] gastrointestinal effects,[2-4,10,11] and flushing.[2-4,10,11] There has been a report of exanthema in a patient receiving dimethyl fumarate for lichen planus.[12]

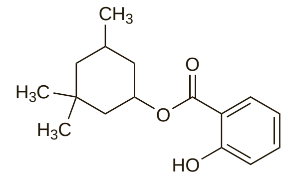
Homosalate *(USAN, rINN)*

Homomenthyl Salicylate; Homosalato; Homosalatum. 3,3,5-Trimethylcyclohexyl salicylate.

Гомосалат

$C_{16}H_{22}O_3 = 262.3.$

CAS — 118-56-9.



NOTE. Eusolex HMS and Neo-Heliopan HMS are trade names that have been used for homosalate.

Pharmacopoeias. In *US.*

USP 31 (Homosalate). Store in airtight containers.

Profile

Homosalate, a substituted salicylate, is a sunscreen (p.1576) with actions similar to those of octisalate (p.1608). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations numerous preparations are listed in Part 3.

Hydroquinone

Hidrokinon; Hidroquinona; Hydrochinon; Hydrochinonum; Quinol. 1,4-Benzenediol.

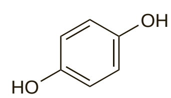
Гидрохинон

$C_6H_6O_2 = 110.1.$

CAS — 123-31-9.

ATC — D11AX11.

ATC Vet — QD11AX11.



NOTE. Do not confuse with Hydroquinine (p.2322).

Pharmacopoeias. In *US.*

USP 31 (Hydroquinone). Fine white needles which darken on exposure to light and air. Soluble 1 in 17 of water, 1 in 4 of alcohol, 1 in 51 of chloroform, and 1 in 16.5 of ether. Store in airtight containers. Protect from light.

Adverse Effects, Treatment, and Precautions

Topical hydroquinone may cause transient erythema and a mild burning sensation. Occasionally hypersensitivity has occurred and US licensed product information recommends skin testing before use. Hydroquinone should not be applied to abraded or sunburnt skin. It should not be used to bleach eyelashes or eyebrows and contact with the eyes should be avoided as it may produce staining and corneal opacities. High concentrations or prolonged use may produce a blue-black hyperpigmentation (ochronosis) or pigmented colloid milium. The systemic effects of hydroquinone and their treatment are similar to those of phenol (see p.1656) but tremors and convulsions may also occur.

Carcinogenicity. There is some evidence from *animal* studies that hydroquinone might be carcinogenic (see Effects on the Skin, below).

Effects on the liver. Toxic hepatitis in a radiographer was attributed to occupational exposure to hydroquinone fumes from the developing medium used in the darkroom.[1] However, it has been pointed out[2] that hydroquinone is not volatile under normal conditions of use and that surveillance of 879 people engaged in the manufacture and use of hydroquinone from 1942 to 1990 found no association between toxic hepatitis and hydroquinone exposure.

1. Nowak AK, *et al.* Darkroom hepatitis after exposure to hydroquinone. *Lancet* 1995; **345:** 1187.
2. O'Donaghue JL, *et al.* Hydroquinone and hepatitis. *Lancet* 1995; **346:** 1427–8.

Effects on the skin. The incidence of exogenous ochronosis (blue-black hyperpigmentation) in a survey of black South African patients was found to be 15% in males and 42% in females with 69% of affected individuals admitting to using hydroquinone-containing preparations.[1] This was considered to be more consistent with a toxic effect of a drug with a low therapeutic index, rather than an idiosyncratic reaction. The data revealed that even preparations with hydroquinone 2% or less with a sunscreen produced ochronosis. Ochronosis usually became apparent after about 6 months of use and, once established, was probably irreversible. Patients may initially use skin lighteners for cosmetic purposes but once ochronosis develops they may fall into the 'skin lightener trap' as they use other hydroquinone preparations to remove the disfigurement.[1] Treatment of exogenous ochronosis is based on stopping the use of hydroquinone, but it may take years for any improvement to be apparent. There are a few reports of benefit from topical tretinoin, dermabrasion, and laser therapy, but these are far from established therapies.[2] Reversible brown discoloration of the nails has also been reported after the use of skin lighteners containing hydroquinone.[3-5]

In addition to the risk of ochronosis it has been suggested that, based on *animal* studies, long-term use of hydroquinone might be carcinogenic.[6] In the USA, preparations containing up to 2% hydroquinone may be sold without prescription, but in 2006, based on data regarding potential carcinogenicity and reports of ochronosis, the FDA proposed to reclassify these products as drugs and make them available by prescription only.[7] In Europe the use of hydroquinone in cosmetic preparations for skin lightening is already banned, but it is still available for prescription as a medicine.[6]

Uses and Administration

Hydroquinone increases melanin excretion from melanocytes and may also prevent its production. Hydroquinone is used topically as a depigmenting agent for the skin in hyperpigmentation conditions (p.1582) such as chloasma (melasma), freckles, and lentigines (liver spots). Concentrations of 2 to 4% are commonly used; higher concentrations may be very irritant and increase the risk of ochronosis. It may be several weeks before any effect is apparent but depigmentation may last for 2 to 6 months after stopping. Application of hydroquinone should stop if there is no improvement after 2 months. Hydroquinone should be applied twice daily only to intact skin which should be protected from sunlight to reduce repigmentation. A preparation containing hydroquinone 4%, tretinoin 0.05%, and fluocinolone acetonide 0.01% may be applied once daily at night in the treatment of chloasma (melasma). Hydroquinone preparations often include a sunscreen or a sunblocking basis.

Hydroquinone is also used as an antoxidant in topical preparations and in photographic developers.

Ichthammol (BAN)

Ammonii Bituminosulfonas; Ammonii Sulfogyrodalas; Ammonio Sulfoittiolato; Ammonium Bithiolicum; Ammonium Bitumenosulfonicum; Ammonium Bituminosulphonate; Ammonium Ichthosulphonate; Ammonium Sulfobituminosum; Ammonium Sulpho-Ichthyolate; Amonowy sulfobituminian; Bithiolate Ammonique; Bithyol; Bitiol; Bitiolato amónico; Bitomol; Bituminol; Ichtammol; Ichtamolis; Ichthammolum; Ichthamol; Ichthosulphol; Ichthyol; Ichthyolammonium; Ictamol; Ictiolsulfonato amónico; Ihtamol; Iktammol; Iktammoli; Sulfobituminato amónico; Sulfoictiolato amónico.

Ихтаммол; Ихтиол

CAS — 8029-68-3.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Ichthammol). A dense blackish-brown liquid. It is obtained by distillation of certain bituminous schists, sulfonation of the distillate, and neutralisation of the product with ammonia. It contains not less than 4.5% and not more than 7.0% of total ammonia, not less than 10.5% of organically combined sulfur, calculated with reference to the dried substance, and not more than 20% of the total sulfur in the form of sulfates.

Miscible with water and with glycerol; slightly soluble in alcohol, in fatty oils, and in liquid paraffin; forms homogeneous mixtures with wool fat and soft paraffin.

USP 31 (Ichthammol). A reddish-brown to brownish-black viscous fluid with a strong characteristic empyreumatic odour. It is obtained by the destructive distillation of a bituminous schist, sulfonation of the distillate, and neutralisation of the product with ammonia. It yields not less than 10.0% of total sulfur and not less than 2.5% of ammonia. Miscible with water, with glycerol, and with fixed oils and fats. Partially soluble in alcohol and in ether.

Incompatibility. Ichthammol is incompatible with wool alcohols.

Profile

Ichthammol has slight bacteriostatic properties and is used in a wide range of topical preparations, for a variety of skin disorders; it has also been used in suppositories for anorectal disorders. Ichthammol is often used with zinc oxide in medicated bandages for chronic lichenified eczema (p.1579). Ichthammol may be slightly irritant to the skin and there have been rare reports of hypersensitivity.

Light Ammonium Bituminosulfonate (Ammoniumbituminosulfonat Hell) is produced from the light distillate fraction of shale oil.

Ammoniumsulfobitol, an ammonium bituminosulfonate similar to ichthammol but with a low sulfur content, was commercially available as Tumenol Ammonium.

Preparations

BP 2008: Zinc and Ichthammol Cream;
USP 31: Ichthammol Ointment.

Ictasol (USAN)

Ichtasol; Ichthyol-Natrium Hell; Light Sodium Bituminosulphonate; Natrium Sulfobituminosum Decoloratum; Sulfobituminato sódico; Sulfobituminato sódico decolorado.

$C_{28}H_{36}Na_2O_6S_3$ = 610.8.
CAS — 12542-33-5; 1340-06-3.
ATC — D10BX01.
ATC Vet — QD10BX01.

Profile

Ictasol is a sodium bituminosulfonate produced from the light distillate fraction of shale oil. Sodium bituminosulfonate is obtained by the destructive distillation of certain bituminous schists, sulfonation of the distillate, and neutralisation of the product with sodium hydroxide.

Ictasol has similar properties to ichthammol (above) and is used in a wide range of preparations for a variety of skin disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Austria: Crino Cordes; Ichthraletten; Lavichthol; ***Ger.:*** Aknichthol Creme; Crino Cordes N†; Dermichthol†; Ichthoderm; Ichtholan T; Ichthosin; Ichthraletten; Leukichtan; Solutio Cordes.

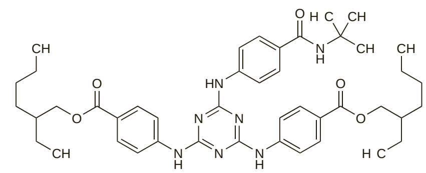
Iscotrizinol (USAN)

Diethylhexyl Butamido Triazone; Diethylhexylbutamido Triazone; Dioctylbutamidotriazone. Bis(2-ethylhexyl) 4,4′-[(6-{[4-(*tert*-butylcarbamoyl)phenyl]amino}-1,3,5-triazine-2,4-diyl)diimino]dibenzoate.

$C_{44}H_{59}N_7O_5$ = 766.0.
CAS — 154702-15-5.



NOTE. Uvasorb HEB is a trade name that has been used for iscotrizinol.

Profile

Iscotrizinol is used as a sunscreen (p.1576). It is effective against UVB light (for definitions, see p.1580).

Preparations

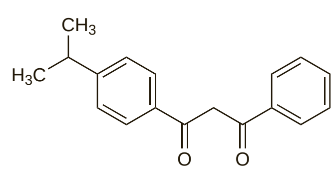
Proprietary Preparations some preparations are listed in Part 3.

Isopropyldibenzoylmethane

Isopropildibenzoilmetano. 1-[4-(1-Methylethyl)phenyl]-3-phenyl-1,3-propanedione.

Изопропилдибензоилметан

$C_{18}H_{18}O_2$ = 266.3.
CAS — 63250-25-9.



Profile

Isopropyldibenzoylmethane, a substituted dibenzoylmethane, is a sunscreen (p.1576) with actions similar to those of avobenzone (p.1589). It is effective against UVA light (for definitions, see p.1580).

Preparations

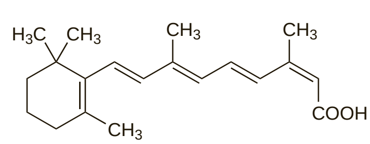
Proprietary Preparations some preparations are listed in Part 3.

Isotretinoin (BAN, USAN, rINN)

Isotretinoiini; Isotretinoína; Isotrétinoïne; Isotretinoinum; Izotretinoin; Izotretinoinas; Izotretynoina; 13-*cis*-Retinoic Acid; Ro-4-3780. (13*Z*)-15-Apo-β-caroten-15-oic acid; (2*Z*,4*E*,6*E*,8*E*)-3,7-Dimethyl-9-(2,6,6-trimethylcyclohex-1-enyl)nona-2,4,6,8-tetraenoic acid.

Изотретиноин

$C_{20}H_{28}O_2$ = 300.4.
CAS — 4759-48-2.
ATC — D10AD04; D10BA01.
ATC Vet — QD10AD04; QD10BA01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Isotretinoin). A yellow or light orange, crystalline powder. Practically insoluble in water; slightly soluble in alcohol; soluble in dichloromethane. It is sensitive to air, heat, and light, especially in solution. Store in airtight containers at a temperature not exceeding 25°. Protect from light. It is recommended that the contents of an opened container be used as soon as possible and that any unused part be protected by an atmosphere of an inert gas.

USP 31 (Isotretinoin). Yellow crystals. Practically insoluble in water; sparingly soluble in alcohol, in isopropyl alcohol, and in macrogol 400; soluble in chloroform. Store in airtight containers under an atmosphere of an inert gas. Protect from light.

Adverse Effects

The adverse effects of isotretinoin and other oral retinoids are similar to those of vitamin A (see p.1971) and are generally reversible and dose-related. The most common are dryness of the mucous membranes and skin, which can often progress to cheilitis, epistaxis, conjunctivitis, localised exfoliation including palmoplantar exfoliation, pruritus, erythematous rash, and skin fragility. Less common effects have included hair thinning (occasionally irreversible), hirsutism, photosensitivity, changes in skin pigmentation, paronychia, nail dystrophy, pyogenic granuloma, and increased sweating. Acne can be exacerbated at the beginning of isotretinoin treatment, and there are very rare reports of acne fulminans occurring. Less common adverse effects on the eyes include corneal opacities, visual disturbances such as blurred vision and colour vision disorders, impaired night vision that may persist, photophobia, and keratitis. Papilloedema, visual disturbances, headache, and nausea and vomiting can be signs and symptoms of benign intracranial hypertension. Arthralgia, myalgia, and back pain are commonly reported, and there have been rare reports of arthritis, osteoporosis, and tendinitis. Hyperostosis and calcinosis have also occurred, particularly in patients treated with high doses of isotretinoin over long periods for keratinisation disorders. Premature closure of the epiphyses has occurred in children treated with isotretinoin. Elevation of serum triglycerides is common, and pancreatitis has occurred in patients with high concentrations; cholesterol concentrations may also be increased. Increases in hepatic enzymes, erythrocyte sedimentation rate, and blood glucose can also occur. Alterations in haematological measures are common; there have also been reports of anaemia, thrombocytopenia, and neutropenia, and very rare reports of agranulocytosis. Other effects that have been reported rarely include gastrointestinal symptoms, hepatitis, hearing impairment, drowsiness, seizures, vasculitis, and hypersensitivity reactions including anaphylaxis. Mood changes, psychotic symptoms, depression, and suicidal behaviour have occurred in patients treated with oral isotretinoin. There may also be an association with skin infections and an inflammatory bowel syndrome.

Isotretinoin and other retinoids are teratogenic.

When isotretinoin is applied topically the adverse effects are similar to those of tretinoin (see p.1618).

Effects on the blood. Serious adverse effects on the blood have been reported rarely with oral retinoids, and are thought to be idiosyncratic in nature. There have been reports of thrombocytopenia in patients taking isotretinoin[1] and etretinate.[2,3] A few cases of agranulocytosis have involved isotretinoin[4] and acitretin.[5] In contrast, there are also reports of transient and asymptomatic thrombocytosis associated with isotretinoin[6] and tretinoin.[7,8] Leucocytosis is often associated with the retinoic acid syndrome caused by tretinoin (p.1618).

Effects on the cardiovascular system. From 1983 to the end of 2005, Health Canada had received 29 reports of adverse cardiovascular effects in patients treated with isotretinoin, including myocardial infarction, stroke, and pulmonary embolism.[1] Thrombotic stroke has also been attributed to the use of acitretin in a woman treated for psoriasis,[2] and rare cases of myocardial ischaemia and infarction have been reported with etretinate.[3] Thromboembolic disorders have also occurred in patients given tretinoin for remission induction in acute promyelocytic leukaemia (see p.1618).

There are rare reports of isotretinoin causing cardiac arrhythmias, such as sinus tachycardia with right branch bundle block[4] and atrial tachycardia.[5]

Effects on the eyes. A number of ocular adverse effects have been reported with oral isotretinoin, and these have been reviewed.[1,2] Using the WHO Causality Assessment Guide of Suspected Adverse Reactions, an analysis[3] of 2449 spontaneous reports found that decreased dark adaptation, ocular sicca, and the ocular signs and symptoms of intracranial hypertension, accounted for most of the reports that were certainly associated with isotretinoin. In some cases of intracranial hypertension the patient had also been taking other drugs, such as tetracyclines, that have also been associated with this effect. There was also a certain association between isotretinoin and abnormal meibomian gland secretion and gland atrophy, blepharoconjunctivitis, corneal opacities, decreased vision, increased tear osmolarity, keratitis, myopia, ocular discomfort and decreased tolerance to contact lenses, and photophobia. There was a probable association with reversible decreased colour vision and permanent loss of dark adaptation. Other effects that had been reported, but only possibly associated with isotretinoin, included corneal ulcers, diplopia, eyelid oedema, optic neuritis, permanent sicca, and subconjunctival haemorrhage.

There are fewer reports of ocular adverse effects with other oral retinoids. Intracranial hypertension with papilloedema, blurred vision, and headache, has been reported with acitretin, etretinate, and tretinoin.[4-6] A 1-year follow-up failed to find any evidence of ocular toxicity attributable to etretinate in 4 patients who had received long-term treatment, including 1 patient who had toxic optic neuropathy due to methotrexate and who was able to continue treatment with etretinate.[7] Ectropion has been associated with etretinate therapy in a patient.[8] Maculopathy occurred in a patient after a year of treatment with acitretin for psoriasis.[9]

Effects on the gastrointestinal tract. A causal association has been suggested in cases of inflammatory bowel disease developing in patients taking oral isotretinoin.[1,2] Between 1997 and 2002 the FDA received 85 reports of Crohn's disease, ulcerative colitis, colitis, or haemorrhagic colitis attributed to isotretinoin;[3] the association was judged probable in 62 cases and possible in 23. Specific treatment, in addition to drug withdrawal, was required in 35 patients, 11 were hospitalised, and 7 underwent surgery. Rechallenge was positive in the 3 reported cases. The mechanism of this adverse effect is unknown, and because young adulthood is the most common age for both the onset of inflammatory bowel disease and the use of isotretinoin, a coincidence could not be ruled out. The authors of this review suggested that isotretinoin should be used with caution in patients with a history of inflammatory bowel disease or symptoms suggestive of the condition and those who might be at increased risk because of a family history. Although there have been patients with inflammatory bowel disease who have received isotretinoin without adverse effect, there are some cases in which the condition was apparently exacerbated by isotretinoin.[1,4]

Effects on the liver. Transient slight elevations of serum concentrations of liver enzymes are common with etretinate, but there have been few reports of acute hepatitis[1,2] or cholestatic jaundice.[3] Acute hepatitis may progress to chronic active hepatitis, despite stopping etretinate therapy[4] but studies of serial liver biopsies from patients receiving long-term etretinate have failed to show any significant chronic liver damage.[5-7] Licensed product information has included reports of hepatic fibrosis, necrosis, and/or cirrhosis.

An overview considered that some form of hepatotoxicity may be seen in up to 20% of patients treated with etretinate and significant liver disease in 1%.[8]

Isotretinoin may also cause mild elevations of liver enzymes and licensed product information states that hepatitis has occurred rarely. There is also a report of fatty liver.[9]

Effects on mental function. Case reports provide evidence of depression, psychotic symptoms, suicide, and suicide attempts occurring as idiosyncratic adverse effects of isotretinoin. However, the high background prevalence of psychiatric illness among adolescents in general, and among patients with acne, are potentially confounding factors. Retrospective studies have not shown a clear cause and effect mechanism and prospective studies have been limited by sample size. Systematic reviews have found no strong evidence for an association between isotretinoin use and depression or suicidal behaviour, but noted that the evidence was not sufficiently compelling to rule out a weak association,[1,2] although other factors were probably more important.[1] In the absence of better evidence, monitoring for depression and other psychiatric effects has been advised for all patients receiving isotretinoin.[3-5]

Two cases of sustained dreaming have also been reported. After 2 to 3 weeks of oral isotretinoin, both patients reported changes in their dreaming pattern with a feeling that they had been 'dreaming all night'. The dreams persisted for 4 to 5 weeks after which they subsided despite continued isotretinoin therapy.[6]

Effects on the musculoskeletal system. Hyperostotic changes (bone spurs) or calcification of tendons and ligaments, resembling *diffuse idiopathic skeletal hyperostosis* (DISH), have been reported with systemic retinoid therapy.[1,2] DISH-like hyperostotic changes are common in the general population and are associated with ageing; the use of chronic retinoid therapy may increase the risk of developing these changes. Reports have particularly involved patients with keratinisation disorders being treated with large doses of retinoids for prolonged periods, and radiographic changes can be found in most patients after long-term treatment. However, minimal bone changes have also been found in radiographic studies of patients treated with isotretinoin in the dose range usually used to treat acne. Changes were also reported in a study of very low doses of isotretinoin used over 3 years to investigate skin cancer prevention. There have been few reports on the skeletal adverse effects of chronic low-dose etretinate and acitretin and results so far have been equivocal;[2] further studies are needed to clarify any effects. *Premature closure of the epiphyses* in children treated with retinoids has also been described.[1] Again, high doses or prolonged therapy were often used. There is limited evidence to suggest that children might also be at increased risk of slender long bones. There have been rare reports of changes in bone mineral density and *osteoporosis* from retinoid therapy, but there is limited evidence to confirm this association.[1] Ongoing clinical surveillance and periodic radiographic skeletal surveys have been recommended during long-term therapy; symptomatic bone spurs may be treated surgically.[1]

There have also been individual reports of *hypercalciuria*[3] or *hypercalcaemia*[4-6] associated with oral retinoid therapy.

Muscular disorders such as myalgia are not uncommon in patients treated with oral isotretinoin. Reversible myopathy with muscle pain, weakness, and raised creatine kinase concentrations has been described in a few patients treated with isotretinoin,[7] etretinate,[8] and acitretin.[9] Asymptomatic muscle damage has also been found in a study of patients given etretinate for at least a year.[10] Rhabdomyolysis and myoglobinuria have been described in a patient given isotretinoin for acne.[11] Myositis, often affecting the lower limbs, has occurred in a few patients given tretinoin for remission induction in acute promyelocytic leukaemia.[12-15] In one case, cardiac myositis also occurred.[14] Symptoms usually had an onset of 2 to 4 weeks and responded to stopping tretinoin and being treated with a corticosteroid. In a few cases, subsequent courses of tretinoin were given without recurrence of symptoms.[14,15] A review[15] suggested that some cases of myositis might have been associated with the retinoic acid syndrome (see under Tretinoin, p.1618) or Sweet's syndrome (see Effects on the Skin, under Tretinoin, p.1618).

Effects on the nervous system. There has been a report[1] of Guillain-Barré syndrome in 2 patients taking oral isotretinoin; both patients required ventilatory support and recovered slowly after treatment with intravenous immunoglobulins. There had been 1 case reported previously to the UK CSM. Intracranial hypertension, causing headaches and papilloedema, can occur with retinoids, including isotretinoin (see Effects on the Eyes, above).

1. Pritchard J, *et al.* Guillain-Barré syndrome seen in users of isotretinoin. *BMJ* 2004; **328:** 1537.

Effects on the respiratory system. There have been reports of exercise-induced wheezing,[1] eosinophilic pleural effusion,[2] and worsening asthma[3,4] associated with isotretinoin therapy. The US manufacturers have records of adverse effects on the lung including worsening asthma, recurrent pneumothorax, interstitial fibrosis, and pulmonary granuloma.[5] A study of healthy subjects confirmed that lung function tests could deteriorate after treatment with isotretinoin.[5]

Effects on serum lipids. The oral retinoids induce dose-dependent changes in serum lipids. There can be increases in very-low-density-lipoprotein cholesterol with smaller increases in low-density-lipoprotein cholesterol and reductions in high-density-lipoprotein cholesterol.[1,2] These effects appear to be unrelated to age or sex. They occur early during treatment and are usually reversible within a few weeks of withdrawal. Overall, the effect of isotretinoin is much greater than that of etretinate. Although the total cholesterol and triglyceride concentrations may remain within normal limits, types IIb and IV hyperlipidaemias are not uncommon among patients receiving oral retinoids. A large retrospective study[3] of patients treated with isotretinoin for acne found that of those who had normal concentrations before treatment, there was an increase in triglycerides in 44% and in total cholesterol in 31% of patients. Pancreatitis may be associated with hypertriglyceridaemia in patients treated with isotretinoin.[4-7]

Retinoids should be used with caution in patients with pre-existing hypertriglyceridaemia or in those at risk of developing hypertriglyceridaemia.[1] Use of fish oil containing eicosapentaenoic acid has been reported to attenuate retinoid-induced increases in serum-cholesterol and serum-triglyceride concentrations.[2,8]

Effects on sexual function. Ejaculatory failure has been reported in 3 men to be associated with isotretinoin treatment.[1] A possible mechanism could be an effect on the goblet cells of the seminal vesicles, an effect similar to the general reduction in body secretions which leads to dry mucous membranes.

1. Coleman R, MacDonald D. Effects of isotretinoin on male reproductive system. *Lancet* 1994; **344:** 198.

Effects on the skin, hair, and nails. Apart from the more common effects of oral retinoids on the skin and hair (see Adverse Effects, above), there have been isolated reports of various other reactions. Stickiness of the skin, particularly of the palms and soles, has been described with etretinate.[1,2] It has also occurred in a patient using topical tretinoin,[3] but not when he had previously taken a course of oral isotretinoin. Papules and pustules on the palms and soles have also been described with etretinate use.[4] In a series of 5 patients being treated for psoriasis, the lesions appeared 5 to 9 days after starting therapy and cleared spontaneously within a few weeks leaving a desquamation, despite continuing etretinate.

Granulomatous nodules or pyogenic granulomas have been reported with isotretinoin,[5,6] etretinate,[7,8] topical tretinoin,[9,10] and topical tazarotene.[11] Pyoderma gangrenosum has occurred in patients treated with isotretinoin.[12-14] Prurigo-like eruptions have been reported with etretinate.[15] Precipitation or exacerbation of erythroderma has been reported with isotretinoin,[16] etretinate,[17] and acitretin.[18]

Reversible chloasma (melasma) has been reported with isotretinoin.[19]

Acne fulminans is an uncommon complication of acne, developing as a sudden onset of ulcerative crusting acne with fever, weight loss, and musculoskeletal pain. Although isotretinoin may be used to treat this condition,[20] there have been reports of acne fulminans being precipitated by isotretinoin.[21,22] In some cases erythema nodosum has also developed,[23,24] but it has been suggested that this might be a manifestation of acne fulminans rather than an adverse effect of isotretinoin.[24] Erythema nodosum has also occurred in patients given oral tretinoin for remission induction in acute promyelocytic leukaemia. In a series of 4 cases, patients were successfully managed with a 5-day course of oral corticosteroid allowing the tretinoin course to be completed.[25] There has been a report of fatal toxic epidermal necrolysis associated with etretinate.[26]

For other reports of eruptions associated with vasculitic syndromes, see below. Painful scrotal ulcers and Sweet's syndrome (acute febrile neutrophilic dermatosis) are other reactions that have been reported with oral tretinoin (see p.1618). Skin erosion after wax depilation has been reported in patients receiving retinoids (see Skin Fragility under Precautions, below).

Curling hair has been described in transplant recipients taking isotretinoin and azathioprine.[27] Oral retinoids have been associated with nail fragility, onycholysis,[28] paronychia, and other forms of nail dystrophy.[29,30]

Effects on taste. Almost complete loss of taste has been reported in a patient given oral isotretinoin 600 micrograms/kg daily for 20 weeks.[1] Sense of taste returned about 6 months after isotretinoin was stopped. Up to September 1994 the UK CSM knew of 5 cases of taste changes, including 4 reports of loss of taste.

Overdosage. Apart from vague abdominal discomfort there were no other symptoms or significant abnormalities in a 15-year-old who was treated with gastric lavage 1.5 hours after ingestion of 350 mg of isotretinoin.[1] The authors noted a similar outcome in 2 other cases of isotretinoin overdosage reported in the literature at that time. In a subsequent report, mild headache, skin that was dry and peeling, and cheilitis occurred in a 29-year-old who ingested 900 mg of isotretinoin.[2]

Vasculitic syndromes. The manufacturer of isotretinoin and etretinate has received isolated reports of vasculitis associated with the use of these oral retinoids; Wegener's granulomatosis has also been reported after the use of isotretinoin.[1,2] The precise mechanism underlying these effects is unknown; in some patients there may have been a direct toxic effect as symptoms developed shortly after the start of treatment, in other patients the onset was long-delayed and may have been triggered by the incidental use of antibacterials. Vasculitis, manifesting as fever and skin lesions, has been reported in patients given oral tretinoin for acute promyelocytic leukaemia.[3]

Precautions

Isotretinoin and other oral retinoids are teratogenic and therefore contra-indicated in pregnant patients. It is advisable for female patients to begin using contraceptive measures 1 month before starting isotretinoin treatment. Pregnancy should be excluded before starting therapy and avoided during treatment and for 1 month after stopping treatment. Patients receiving isotretinoin should not donate blood during, or for 1 month after stopping therapy, because of the potential risk to the fetus of a pregnant transfusion recipient. *Pregnancy or blood donation must be avoided for much longer periods in patients taking acitretin or etretinate.* Isotretinoin is contra-indicated in patients with hepatic impairment, hyperlipidaemias, and hypervitaminosis A. Renal impairment does not affect the pharmacokinetics of isotretinoin but a lower starting dose has been suggested in severe impairment. It is not known whether isotretinoin is distributed into breast milk but its lipophilicity makes this likely; isotretinoin use in breast-feeding women is therefore contra-indicated because of the potential for adverse effects in the infant. Isotretinoin should be used with care in patients with a history of depression and patients taking isotretinoin should be monitored for signs of depressive illness.

Liver function and fasting blood lipids should be measured at the start of therapy, after the first month (or every 1 to 2 weeks for the first 2 months for acitretin), and thereafter as appropriate. Blood glucose should be monitored throughout treatment in patients who either have, or are predisposed to, diabetes mellitus. Some recommend routine radiological evaluation in patients receiving long-term therapy (see under Effects on the Musculoskeletal System, above). Patients may have a reduced tolerance to contact lenses.

Excessive exposure to sunlight and UV light should be avoided.

Dizziness, drowsiness, and visual disturbances may occur rarely, and could affect the performance of skilled tasks such as driving.

When applied topically the precautions described under tretinoin (see p.1618) should be considered.

Pregnancy. The problem of prescribing oral retinoids to women of child-bearing potential has been discussed.[1,2] Intra-uterine exposure to isotretinoin has caused spontaneous abortion and a characteristic pattern of fetal malformations involving craniofacial, cardiac, thymic, and CNS structures.[3,4] Some infants have also shown subnormal intelligence and other neuropsychological impairments.[5] The risk of malformation appears to be high at all therapeutic doses of isotretinoin even when the duration of exposure is short.[6] Despite warnings on the use of retinoids during pregnancy and the need for adequate contraception in women of child-bearing potential, and other strict guidelines on their use, intra-uterine exposure to retinoids has still occurred.[7-10]

Isotretinoin has a relatively short half-life and it has been recommended that conception should be avoided for at least one month after the end of treatment. A survey of women who conceived after the use of isotretinoin (64% within one month of stopping treatment) suggested that the incidence of spontaneous abortion or congenital malformations was no greater than in the general population.[11]

Warnings to avoid conception are similar for oral tretinoin (see p.1618). However, patients taking oral retinoids with longer half-lives must avoid conception for much longer periods; at least 2 years (3 years in the USA) is recommended if patients are taking acitretin although the period of time for patients taking etretinate has not been established (see also Pregnancy under Acitretin, p.1586).

Unless otherwise contra-indicated, oral combined contraceptives have been recommended as the contraceptive method of choice for women undergoing retinoid treatment.[12] Use of an additional form of contraception, such as a barrier method, is also recommended.[2,7] For further information on the use of hormonal contraceptives with retinoids, see p.2068.

Skin fragility. Wax depilation should be avoided in patients receiving retinoids since they cause increased skin fragility and facial and leg erosions have occurred.[1-3] Licensed UK product information also recommends that wax depilation should be avoided for at least 6 months after isotretinoin treatment because of the risk of epidermal stripping. Aggressive chemical dermabrasion and cutaneous laser treatment should also be avoided for a period of 5 to 6 months after treatment because of the risk of hypertrophic scarring in atypical areas and, more rarely, post-inflammatory hypo- or hyperpigmentation in treated areas.

Interactions

Use of isotretinoin with vitamin A (including dietary supplements) should be avoided because of additive toxic effects. Tetracyclines should be avoided as their use with isotretinoin has been associated with the development of benign intracranial hypertension. Skin irritation may be increased if isotretinoin is given with topical keratolytic or exfoliative anti-acne treatments; such use should be avoided.

Antiepileptics. For the effect of isotretinoin on *carbamazepine*, see p.475.

Hormonal contraceptives. For discussion of the potential interactions of retinoids with oral hormonal contraceptives, and the effect this might have on contraceptive choice during retinoid treatment, see p.2068.

Pharmacokinetics

Isotretinoin is absorbed from the gastrointestinal tract and absorption may be increased by food. Minimal systemic absorption occurs after topical application. Peak plasma concentrations occur 1 to 4 hours after oral doses. Oral bioavailability is low, possibly due to metabolism in the gut wall and first-pass metabolism in the liver. Isotretinoin is highly bound to plasma proteins. It is metabolised in the liver to its major metabolite 4-oxo-isotretinoin; there is also some isomerisation of isotretinoin to tretinoin. Several cytochrome P450 isoenzymes are involved in isotretinoin metabolism, including CYP2C8, CYP2C9, CYP3A4, and CYP2B6. Isotretinoin, tretinoin, and their metabolites undergo enterohepatic recycling. The terminal elimination half-life of isotretinoin is 10 to 20 hours, while that of the 4-oxo metabolite may be up to 50 hours; return to physiological levels of retinoids takes about 2 weeks after stopping therapy. Equal amounts of a dose appear in the faeces, mainly as unchanged drug, and in the urine as metabolites.

Isotretinoin crosses the placenta. It is not known whether isotretinoin is distributed into breast milk but its lipophilicity makes this likely.

Uses and Administration

Isotretinoin is a retinoid. It is the *cis* configuration of tretinoin (p.1618), which is the acid form of vitamin A (p.1971). Isotretinoin is given orally for the treatment of severe acne (below) that has not responded to other measures; it is also applied topically in milder forms of acne. It is not indicated for uncomplicated adolescent acne, and is not licensed for prepubertal acne (but see also Administration in Children, below, for use in infantile acne). Isotretinoin has also been tried in a number of other skin disorders and in some forms of neoplastic disease.

In the UK and a number of other countries the initial oral dose of isotretinoin for acne is 500 micrograms/kg daily, although in the USA initial doses of up to 1 mg/kg daily are permitted. The dose is given with food once daily or in two divided doses and adjusted if necessary up to 1 mg/kg daily according to response and adverse effects. Patients intolerant to the initial dose may be able to continue treatment at a lower dose, but there is a higher risk of relapse. Doses up to 2 mg/kg daily are permitted in the USA and some other countries for patients whose disease is very severe or primarily on the body instead of the face. A lower starting dose has been recommended in the UK for patients with severe renal impairment (see below).

Acute exacerbation of acne is occasionally seen during the initial period, but usually subsides within 7 to 10 days on continued treatment. Treatment should continue for 15 to 24 weeks or until the total cyst count has decreased by over 70%. Long-term remission and relapse rates are related to total dose, and additional benefit is not expected beyond a cumulative dose of 120 to 150 mg/kg. Improvement may continue for several months after stopping treatment; prolonged remissions can occur.

Repeat courses are not normally recommended but occasionally they may be required. However, since acne may continue to improve after stopping isotretinoin, there must be at least a 2-month drug-free period before starting repeat treatment.

For the topical treatment of acne a gel containing 0.05% of isotretinoin is applied sparingly once or twice daily. A therapeutic response may not be evident for 6 to 8 weeks.

Acne. The retinoids play an important role in the treatment of acne (p.1577). Isotretinoin reduces sebum excretion with a subsequent reduction in growth of *Propionibacterium acnes*; it also normalises the differentiation of keratinocytes, which has a comedolytic effect, and appears to have a direct anti-inflammatory effect.[1-3] The main indication for oral isotretinoin therapy is severe forms of acne (such as conglobate or nodulocystic acne or acne at risk of permanent scarring) that is unresponsive to other therapy including systemic antibacterials. Some argue,[4,5] however, that oral isotretinoin should be considered for first-line treatment in other cases, such as less severe acne that has the potential to cause scarring or acne that is causing severe psychological distress. Most patients remain free of their disease after a single course of isotretinoin, or have a mild recurrence that responds to other treatments to which it was previously resistant. A minority will relapse and those at higher risk include patients less than 16 years of age, those with severe acne on the trunk, and adult women.[2] Cumulative dose, rather than daily dose, appears to be an important factor in achieving stable remission.[4] To avoid relapse, a course of therapy to a cumulative dose of 120 to 150 mg/kg is required.[2] This usually equates to a course of 5 to 6 months using daily doses of 0.5 to 1 mg/kg. One group suggests[4] that treatment should be continued for 2 months after complete clearing of acne to avoid recurrence, and that higher cumulative doses (up to 200 mg/kg) might be needed in some cases, such as those showing clear signs of ongoing improvement when a cumulative dose of 150 mg/kg has been reached. In patients who do relapse, repeat courses may be indicated.[2,3] However, improvement may continue for several months after withdrawal and at least 2 months should elapse before determining whether further treatment is necessary. There is evidence to suggest that patients who repeatedly relapse after stopping standard isotretinoin therapy may benefit from continuous use of very low doses of isotretinoin, such as 250 or 500 micrograms/kg daily taken every 4th week for 6 months, 100 micrograms/kg daily, or a single dose of 20 mg once or twice a week.[6] Low-dose regimens have also been tried instead of standard isotretinoin doses for persistent moderate or severe acne. A dose of 20 mg daily for 6 months has produced significant improvement or complete remission in moderate acne.[7] However, prolonged use of low-dose regimens is needed to achieve a cumulative dose of 120 mg/kg and reduce the risk of relapse.[8] Isotretinoin has also been used for the treatment of acne associated with immunosuppressive therapy in transplant recipients.[9,10]

Isotretinoin is also used topically for acne. Although it has no sebosuppressive effect and only a weak direct anti-inflammatory effect by this route[1] its comedolytic effect makes unplugged follicles less anaerobic, reducing *P. acnes* growth and associated inflammation.[11] Topical isotretinoin appears to have a similar efficacy to tretinoin, but may be better tolerated.[3]

Isotretinoin is not licensed for the treatment of prepubertal acne because of the risk of adverse effects including early epiphyseal closure, but see also Administration in Children, below.

Administration in children. Oral isotretinoin is licensed in most countries for use from 12 years of age where appropriate, but it is not licensed for the treatment of prepubertal acne because of the risk of adverse effects including early epiphyseal closure. However, it has been used orally with some success in nodulocystic infantile acne when topical preparations and antibacterial therapies have not been effective.[1-4] A range of doses have been used, sometimes influenced by the dosage form available, but in general doses have been similar to those used in older patients, that is, 0.5 to 1 mg/kg daily to cumulative doses of 120 to 150 mg/kg. As there are no suitable licensed oral products for children, isotretinoin liquid capsules have been opened and the contents mixed with a drink[1,2] or soft food[3] immediately before use to make administration easier. One report[3] described freezing the capsule so that it could be cut more easily to the required dose, which could then be concealed in food.

Administration in renal impairment. Although renal impairment does not affect the pharmacokinetics of isotretinoin, licensed UK product information suggests that patients with severe renal impairment being treated with oral isotretinoin for acne should be started at a lower dose, such as 10 mg daily. It may be gradually increased up to 1 mg/kg daily as tolerated.

Malignant neoplasms. Retinoids such as isotretinoin have been studied in the treatment of various neoplastic or preneoplastic disorders. Although oral tretinoin is used for remission induction in acute promyelocytic leukaemia (see p.1619), other retinoids do not have an established role in the treatment of cancer. There may, however, be a place for the use of retinoids in the chemoprevention of some malignancies.

There has been particular interest in the potential for retinoids to prevent the formation of *skin cancers* (p.672) in patients at increased risk. Maintenance immunosuppression may increase the incidence of pre-malignant and malignant skin lesions in solid organ transplant recipients; large numbers of lesions can develop and tend to be more aggressive than those in the general population.[1] Although there has been some investigation in cardiac transplant recipients, most case reports and some small studies have involved renal transplant patients. Oral acitretin has been reported to reduce the number of actinic keratoses and reduce the development of new basal and squamous cell carcinomas in these patients.[1-4] Other patients at increased risk of skin cancers who may benefit from prophylactic retinoid therapy include those with xeroderma pigmentosum and naevoid basal cell carcinoma syndrome; oral isotretinoin, rather than acitretin, has been tried in such patients.[5] Retinoids might also be considered in others who have already developed nonmelanoma skin cancers, such as those with conditions requiring maintenance immunosuppression, chronic lymphocytic leukaemia or non-Hodgkin's lymphoma, severe photodamage of the skin, and those with squamous cell carcinoma at high risk of metastasis or that has already metastasised.[5]

Since retinoids suppress rather than cure skin cancer, rebound occurs when the retinoid is stopped and long-term therapy is needed. There is some concern about the risks of such long-term use, particularly on plasma lipids and bone, and monitoring has been recommended.[1,4,5] The mucocutaneous adverse effects that commonly occur can affect patient acceptance during long-term use; mucocutaneous effects may be more severe with isotretinoin, but hair loss may be more extensive with acitretin.[4,5] Gradual dose escalation to an effective dose can be used to minimise these mucocutaneous effects. One example using isotretinoin starts with a dose of 250 micrograms/kg on alternate days for a month, increased to 250 micrograms/kg daily for the second month, then to 500 micrograms/kg daily for the third month; the dose is then adjusted as tolerated.[5] As there are risks of teratogenicity with retinoids, isotretinoin is preferred for women of child-bearing potential because of its shorter half-life.[4,5] For acitretin doses that have been used, see p.1586.

Topical application of retinoids has also been tried for chemoprevention of skin cancers. Topical tretinoin has been used on actinic keratoses in organ transplant recipients, but results have been mixed and may depend on dose. If squamous cell carcinomas are present, however, systemic retinoids should be considered.[3]

Retinoids have been studied in the chemoprevention of primary disease recurrence and second primary tumours after treatment for *squamous cell carcinoma of the head and neck* (p.666) but results have been mixed and limited by resistance and toxicity.[6] A large placebo-controlled study[7] has also reported that low-dose oral isotretinoin (30 mg daily for 3 years with an additional 4 years of follow-up) did not reduce the rate of second primary tumours or death in patients who had been treated for early stage head and neck squamous cell carcinoma. There has also been some interest in the use of retinoids, given orally (isotretinoin) or topically (isotretinoin or tretinoin), in the management of *oral leucoplakia*, which can be pre-malignant (see under Bleomycin, p.688). However, despite reports of beneficial response, relapse frequently occurs on stopping retinoid therapy.[6,8]

Oral isotretinoin has been studied as continuation therapy in children with high-risk *neuroblastoma* that had responded to intensive chemotherapy. One study[9] found improved survival with 6 cycles of isotretinoin given for 14 days of each 28-day cycle. However, another study[10] using a lower dose given daily for 4 years or until relapse found no additional benefit from isotretinoin.

Skin disorders. Apart from its established role in the treatment of acne (above), isotretinoin has been tried in many other skin disorders not responding to usual therapy.[1,2] Clinical responses to oral isotretinoin have been reported[1] in small numbers of patients with anogenital warts (p.1584), rosacea (p.1583), and lichen planus (p.1580). Benefit has also been reported for keratinisation disorders such as Darier's disease[2] (p.1578), ichthyosis[1,2] (p.1580), and pityriasis rubra pilaris.[1,2] Isotretinoin is less effective than other retinoids for psoriasis[1] (p.1583). Oral isotretinoin may be used for chemoprevention of skin cancers (see Malignant Neoplasms, above).

Topical isotretinoin has been used to reduce some of the signs of photoageing[3] (p.1581).

Keluamid

Keluamida.

Келуамид

Profile

Keluamid has keratolytic properties and has been used in topical preparations for the treatment of seborrhoeic dermatitis and other scaling skin disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Kelual; ***Fr.:*** Kelual.

Multi-ingredient: ***Arg.:*** Kelual Zinc; ***Fr.:*** Kelual DS; Kelual Zinc; Kertyol-S.

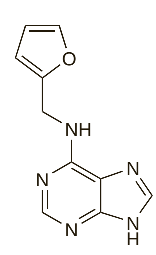
Kinetin

N^6-Furfuryladenine; 6-Furfurylaminopurine.

Кинетин

$C_{10}H_9N_5O = 215.2.$

CAS — 525-79-1.



NOTE. The name kinetin has also been used as a proprietary name for hyaluronidase (p.2321).

Profile

Kinetin is a plant growth hormone that has been promoted in products for the management of photodamaged skin and hyperpigmentation but good evidence of efficacy appears to be lacking.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Kinerase†; ***Braz.:*** Kinerase; ***Hong Kong:*** Kinerase; ***Malaysia:*** Kinerase†; ***Mex.:*** Kinerase; ***Singapore:*** Kinerase; ***USA:*** Kinerase.

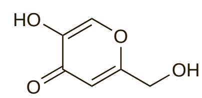
Kojic Acid

Kójico, ácido. 5-Hydroxy-2-hydroxymethyl-4-pyrone.

Койевая Кислота

$C_6H_6O_4 = 142.1.$

CAS — 501-30-4.



Profile

Kojic acid is reported to inhibit melanin production and is used in topical preparations for the treatment of hyperpigmentation disorders (p.1582). Kojic acid is also used as a food additive.

◊ References.

Fumarato de liarozol; Liarozole, Fumarate de; Liarozoli Fumaras; R-85246.

Лиарозола Фумарат

$2C_{17}H_{13}ClN_4,3C_4H_4O_4 = 965.7.$

CAS — 145858-52-2.

Liarozole Hydrochloride *(BANM, USAN, rINNM)*

Hidrocloruro de liarozol; Liarozole, Chlorhydrate de; Liarozoli Hydrochloridum; R-75251.

Лиарозола Гидрохлорид

$C_{17}H_{13}ClN_4, HCl = 345.2.$

CAS — 145858-50-0.

Profile

Liarozole, an imidazole analogue, increases plasma and cutaneous retinoic acid concentrations through inhibition of cytochrome P450 isoenzymes involved in retinoic acid catabolism. It is under investigation for the management of ichthyoses and psoriasis.

◊ References.

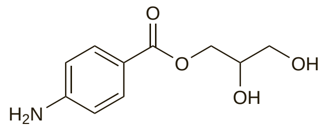
Lisadimate *(USAN, rINN)*

Glyceryl Aminobenzoate; Glyceryl PABA; Lisadimato; Lisadimatum. Glyceryl 1-(4-aminobenzoate).

Лизадимат

$C_{10}H_{13}NO_4$ = 211.2.

CAS — 136-44-7.



Profile

Lisadimate, a substituted aminobenzoate, is a sunscreen (see p.1576) with actions similar to those of aminobenzoic acid (p.1589). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

Lithium Succinate

Litio, succinato de.

Лития Сукцинат

$C_4H_6O_4.xLi$.

CAS — 16090-09-8.

ATC — D11AX04.

ATC Vet — QD11AX04.

Profile

Lithium succinate is reported to have anti-inflammatory properties and is used as an 8% cream or ointment, usually with zinc sulfate. It is applied twice daily initially in the treatment of seborrhoeic dermatitis (p.1584). It should be used with caution in patients with psoriasis as it may exacerbate their condition.

Maggots

Larvas; Sterile Larvae.

Личинки

Profile

Maggots used in wound management are the live sterile larvae of *Lucilia sericata*, the common greenbottle fly. Larval therapy (sometimes called biosurgery) may be used for debridement of infected or necrotic wounds (p.1585), including diabetic foot ulcers. Maggots produce a mixture of proteolytic enzymes that breaks down the necrotic tissue while leaving the healthy tissue unharmed, and kill or prevent the growth of micro-organisms, particularly Gram-positive bacteria. The movement of the maggots also appears to stimulate the growth of granulation tissue.

The maggots are applied to the surface of the wound and kept in place with dressings for up to 3 days. They are removed with the dressing, and the wound is irrigated with sodium chloride solution; any remaining maggots are removed with forceps.

Maggots should not be applied to wounds that have a tendency to bleed easily, or that communicate with a body cavity or any internal organ. Pain has been reported with larval therapy and some patients may require analgesics.

Proprietary Preparations (details are given in Part 3)

UK: LarvE.

Melanin

Меланин

Profile

Melanin is a group of natural pigments found in many plants and animals; they are present in human skin and hair. Natural and synthetic forms of melanin have been used in sunscreen preparations.

Preparations

Proprietary Preparations (details are given in Part 3)

Arg.: Fotobloc.

Multi-ingredient: ***Arg.:*** Fotocrem Ultra; ***Chile:*** ProZone Face; ProZone Gel; ***Mex.:*** ProZone Body; ProZone Face; ProZone Gel; ProZone Ultra; ProZone Ultra Fluido.

Mequinol *(USAN, rINN)*

BMS-181158; *p*-Guaiacol; 4-HA; 4-Hidroxianisol; HQMME; Hydroquinone Monomethyl Ether; *p*-Hydroxyanisole; Hydroxyquinone Methyl Ether; Méquinol; Mequinolum; Metoxifenol; *p*-Metoxifenol. 4-Methoxyphenol.

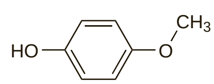
Мехвинол

$C_7H_8O_2$ = 124.1.

CAS — 150-76-5.

ATC — D11AX06.

ATC Vet — QD11AX06.



Profile

Mequinol is used similarly to hydroquinone (p.1598), in concentrations of up to 20%, in the treatment of hyperpigmentation (see Pigmentation Disorders, p.1582). A preparation containing mequinol 2% with tretinoin 0.01% is used for the treatment of solar lentigines (liver spots).

Adverse effects. A report of severe reversible irregular hypopigmentation of the hands, arms, neck, and legs in a West Indian woman who applied a bleaching wax containing mequinol for 2 to 3 months to lighten the colour of her skin.[1]

Austria: Leucobasal; ***Braz.:*** Leucodin; ***Fr.:*** Any; Leucodinine B; ***Gr.:*** Leucodinine-M; ***Spain:*** Novo Dermoquinona.

Multi-ingredient: ***Canad.:*** Solage†; ***USA:*** Solage.

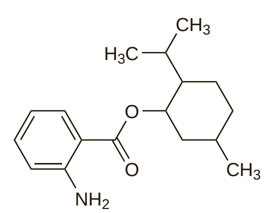
Meradimate *(USAN, rINN)*

Menthyl *O*-Aminobenzoate; Menthyl Anthranilate; Méradimate; Meradimato; Meradimatum. 5-Methyl-2-(1-methylethyl)-cyclohexyl 2-aminobenzoate.

Мерадимат

$C_{17}H_{25}NO_2$ = 275.4.

CAS — 134-09-8.



NOTE. Do not confuse with methyl anthranilate (p.1607). Neo-Heliopan MA is a trade name that has been used for meradimate.

Pharmacopoeias. In *US.*

USP 31 (Meradimate). Store in airtight containers.

Profile

Meradimate is used as a sunscreen (p.1576). It is effective against UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

Ammoniated Mercury

Aminomercuric Chloride; Hydrargyri Aminochloridum; Hydrargyrum Amidochloratum; Hydrargyrum Ammoniatum; Hydrargyrum Praecipitatum Album; Mercuric Amidochloride; Mercuric Ammonium Chloride; Mercurio amoniacal; Mercury Amide Chloride; Mercury Aminochloride; Precipitado blanco (de mercurio); White Precipitate.

Хлористый Меркураммоний

NH_2HgCl = 252.1.

CAS — 10124-48-8.

ATC — D08AK01.

ATC Vet — QD08AK01.

NOTE. 'White Precipitate' has also been used as a name for Precipitated Mercurous Chloride.

Pharmacopoeias. In *US.*

USP 31 (Ammoniated Mercury). A white amorphous powder or pulverulent pieces; odourless. It is stable in air, but darkens on exposure to light. Insoluble in water and in alcohol; readily soluble in warm hydrochloric, nitric, and acetic acids. Protect from light.

Profile

Ammoniated mercury was formerly used topically in the treatment of skin infections and psoriasis but the use of such mercurial preparations is generally deprecated. Frequent or prolonged application to large areas or to broken skin or mucous membranes can cause mercury poisoning (see p.2341) and use on infants has produced acrodynia (pink disease). Ammoniated mercury is also a potent sensitiser and can produce allergic reactions.

Effects on the kidneys. Of 60 patients who were found to have nephrotic syndrome, 32 had used skin-lightening creams containing 5 to 10% of ammoniated mercury.[1] Concentrations of mercury in the urine of these patients were up to 250 nanograms/mL compared with a usual upper limit of 80 nanograms/mL. Of 26 patients followed up for up to 2 years, 13 had no remission or response to treatment; 6 of these had used skin lighteners.

1. Barr RD, *et al.* Nephrotic syndrome in adult Africans in Nairobi. *BMJ* 1972; **2:** 131–4.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Cz.:*** Homeovox; ***Hung.:*** Dermaforine†.

Mesulphen *(BAN)*

Mesulfen *(pINN)*; Dimethyldiphenylene Disulphide; Dimethylthianthrene; Mesulfeeni; Mésulfène; Mesulfeno; Mesulfenum. It consists mainly of 2,7-dimethylthianthrene.

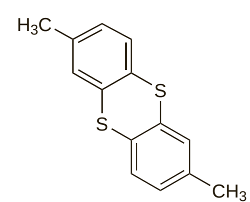
Месульфен

$C_{14}H_{12}S_2$ = 244.4.

CAS — 135-58-0.

ATC — D10AB05; P03AA03.

ATC Vet — QD10AB05; QP53AA01.



Pharmacopoeias. *Jpn* includes thianthol, a mixture of 2,7-dimethylthianthrene and ditolyl disulfide.

Profile

Mesulphen has been used as a parasiticide and antipruritic in a range of skin disorders including acne, scabies, and seborrhoea. Sensitivity to mesulphen has occasionally been reported.

Preparations

Proprietary Preparations (details are given in Part 3)

Ger.: Citemul S†; ***Switz.:*** Soufrol.

Multi-ingredient: ***India:*** Polyderm†.

Methoxsalen (BAN)

Ammoidin; Amoidina; Methoxalenum; 8-Methoxypsoralen; Metoksaleeni; Metoksalen; Metoxalen; Metoxaleno; Metoxipsoraleno; 8-MOP; Xanthotoxin; Xantotoxina. 9-Methoxyfuro[3,2-g]chromen-7-one; 9-Methoxy-7H-furo[3,2-g][1]benzopyran-7-one.

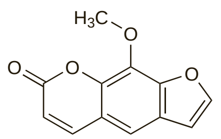
Метоксален

$C_{12}H_8O_4$ = 216.2.

CAS — 298-81-7.

ATC — D05AD02; D05BA02.

ATC Vet — QD05AD02; QD05BA02.



Pharmacopoeias. In *Jpn* and *US.*

USP 31 (Methoxsalen). White to cream-coloured, odourless, fluffy, needle-like crystals. Practically insoluble in water; sparingly soluble in boiling water and in ether; soluble in boiling alcohol, in acetone, in acetic acid, in propylene glycol, and in benzene; freely soluble in chloroform. Protect from light.

Adverse Effects

Methoxsalen given orally commonly causes nausea and less frequently mental effects including insomnia, nervousness, and depression.

Photochemotherapy or PUVA (see under Uses and Administration, below) may cause pruritus and mild transient erythema. Other effects include oedema, dizziness, headache, vesiculation, bulla formation, acneform eruption, and severe skin pain. Overexposure to sunlight or UVA radiation may produce severe burns in patients being treated with psoralens. Hypertrichosis, pigmentation alterations of skin or nails, and onycholysis, have also been reported. PUVA can produce premature ageing of the skin, and may be associated with an increased risk of malignant cutaneous neoplasms.

Carcinogenicity. See under Effects on the Skin, below.

There has been concern about a possible increased risk of noncutaneous malignancies associated with PUVA. However, a long-term study of 1380 patients followed for 20 years reported no overall increase in solid malignancies, lymphoma, or leukaemia.[1]

1. Stern RS, Väkevä LH. PUVA Follow-up Study. Noncutaneous malignant tumors in the PUVA follow-up study: 1975–1996. *J Invest Dermatol* 1997; **108:** 897–900.

Effects on the eyes. Free methoxsalen has been detected in the lens of the eye for at least 12 hours after oral doses.[1] It may become integrated into the structure of the lens if there is exposure to UV light, promoting cataract formation in patients who fail to wear suitable eye protection for 12 to 24 hours after methoxsalen ingestion.[2] However, provided that eye protection is used there appears to be no significant dose-dependent increase in the risk of cataract formation,[3] although a higher risk of developing nuclear sclerosis and posterior subcapsular opacities has been noted in patients who have received more than 100 treatments.[4] Other ocular effects include dose-related transient visual-field defects reported in 3 patients receiving PUVA therapy.[5] Psoralens may also increase the sensitivity of the retina to visible light.[6]

1. Lerman S, *et al.* Potential ocular complications from PUVA therapy and their prevention. *J Invest Dermatol* 1980; **74:** 197–9.
2. Woo TY, *et al.* Lenticular psoralen photoproducts and cataracts of a PUVA-treated psoriatic patient. *Arch Dermatol* 1985; **121:** 1307–8.

4. Stern RS, *et al.* Ocular findings in patients treated with PUVA. *J Invest Dermatol* 1985; **85:** 269–73.
5. Fenton DA, Wilkinson JD. Dose-related visual-field defects in patients receiving PUVA therapy. *Lancet* 1983; **i:** 1106.
6. Souêtre E, *et al.* 5-Methoxypsoralen increases the sensitivity of the retina to light in humans. *Eur J Clin Pharmacol* 1989; **36:** 59–61.

Effects on the hair. Hypertrichosis was noticed in 15 of 23 female patients receiving PUVA therapy compared with 2 of 14 patients treated with UVA alone.[1]

1. Rampen FHJ. Hypertrichosis in PUVA-treated patients. *Br J Dermatol* 1983; **109:** 657–60.

Effects on the immune system. PUVA therapy appears to have immunosuppressive effects and inhibits lymphocytes, polymorphonuclear leucocytes, and Langerhans' cells.[1-3] It is capable of inducing antinuclear antibody formation and a syndrome similar to systemic lupus syndrome has developed during treatment.[4,5] An immunological basis has also been suspected for the development of nephrotic syndrome in one patient who received PUVA therapy.[6]

See also Hypersensitivity, below.

6. Lam Thuon Mine LTK, *et al.* Nephrotic syndrome after treatment with psoralens and ultraviolet A. *BMJ* 1983; **287:** 94–5.

Effects on the skin. *MALIGNANT NEOPLASMS.* Squamous cell carcinoma, basal cell carcinoma, keratoacanthoma, actinic keratosis, Bowen's disease, and malignant melanoma have all been reported during or after cessation of PUVA.[1-3] There have been several large long-term follow-up studies to assess the risk of **non-melanoma** skin cancer in patients receiving PUVA therapy. Early studies from Europe found no clear evidence that PUVA was independently carcinogenic but did find that previous treatment with arsenic, methotrexate, or ionising radiation increased the incidence of skin tumours.[4] Studies from the USA have found an increase in the incidence of basal cell carcinoma and squamous cell carcinoma independent of other treatment,[5] which was dose-related in some studies.[6] Male genitalia appeared to be particularly susceptible.[7] It has been suggested that the differences between the findings might be due to the fact that in Europe higher and fewer doses are used and the median total dose employed may be only 29% of that used in the USA.[8] However, further studies from northern Europe also found a dose-related increase in the risk of developing squamous cell carcinomas.[9-11] One small series suggested that about 50% of the recipients of high-dose PUVA went on to develop squamous cell carcinomas or premalignant lesions.[12] While some European workers have findings that confirm the increased susceptibility of the male genitalia[13] others have failed to find any such evidence.[14,15] Ongoing surveillance of patients is encouraged as US data[16,17] show the risk of skin cancers and genital tumours to persist long-term after stopping PUVA therapy. A few patients have gone on to develop metastatic disease.[18,19]

There are anecdotal reports of **malignant melanomas** occurring in patients who had received PUVA. A prospective study[20] in 1380 patients with psoriasis who were first treated with PUVA in 1975 or 1976 found that the risk of melanoma increases about 15 years after the first treatment with PUVA and that the risk was increased especially in patients who had received 250 treatments or more. The authors suggested that long-term PUVA should therefore be used with caution, especially in younger patients. Further follow-up of this group[21] found the incidence of melanoma to increase over time. However, a similar follow-up study[11] of 4799 patients treated with PUVA found no increase in the risk for malignant melanoma. Comparing their findings with the earlier study, the authors suggested that the results might differ because one-fifth of their cohort had received bath PUVA in which lower UVA doses are used. The comment has also been made[22] that patients receiving long-term therapy should be followed up carefully and that such therapy should not be used in patients at risk for melanoma.

A study[23] of follow-up data on patients who had received trioxysalen bath PUVA did not find an increase in risk of developing either squamous cell carcinoma or malignant melanoma, but the authors suggested that further study is needed to determine the carcinogenicity of trioxysalen PUVA.

NON-MALIGNANT SKIN DISORDERS. Toxic pustuloderma, marked by erythema and superficial pustular lesions, has been reported in a patient given PUVA therapy for mycosis fungoides.[1] There have been a number of reports of bullous pemphigoid occurring, or recurring, in patients treated with PUVA, usually for psoriasis.[2] A case of lichen planus pemphigoides has also been described in a woman treated with topical PUVA.[3] Another effect sometimes associated with PUVA is severe skin pain;[4,5] the pain may respond to treatment with topical capsaicin.[5] Long-term PUVA treatment accelerates ageing of the skin.[6]

Hypersensitivity. Hypersensitivity reactions to methoxsalen and PUVA therapy occur rarely but there have been reports of drug-induced fever,[1] bronchoconstriction,[2] and contact dermatitis.[3] Cases of anaphylaxis have also been attributed to methoxsalen[4] and 5-methoxypsoralen.[5]

Precautions

Methoxsalen should not generally be given to patients with diseases associated with light sensitivity such as porphyria, although it may be used with care in some photosensitivity disorders to decrease sensitivity to sunlight. Other contra-indications include aphakia, melanoma or a history of melanoma, and invasive squamous cell carcinoma. It is generally recommended that PUVA therapy should not be used in children. Methoxsalen should be used with caution in patients with hepatic impairment.

Patients should not sunbathe for 24 hours before and 48 hours after PUVA treatment. They should avoid exposure to sunlight, even through glass or cloud cover for at least 8 hours after methoxsalen ingestion and should wear wrap-around UVA absorbing glasses for 24 hours after ingestion. Photosensitivity is more prolonged after topical application and treated skin should be protected from exposure to sunlight for at least 12 to 48 hours, and possibly for up to a week. Unless specific treatment is required male genitalia should be shielded during PUVA therapy. It has been recommended that patients undergo an ophthalmic examination before starting therapy and at regular intervals thereafter, especially those at increased risk of cataracts. Patients should also receive regular examinations for signs of premalignant or malignant skin lesions. Anti-nuclear antibody titre may be tested before starting therapy, particularly if there is a suggestion of connective tissue disease; frequent evaluation during treatment is probably not necessary for patients with uncomplicated psoriasis, an initial negative test, and no symptoms of connective tissue disease.

Porphyria. Methoxsalen should not be given to patients with porphyria.

Interactions

Methoxsalen should be used with caution with other drugs also known to cause photosensitivity. It inhibits the action of cytochrome P450 isoenzyme CYP2A6, and may increase plasma concentrations of drugs metabolised via this enzyme.

Antiepileptics. Failure of PUVA treatment due to abnormally low serum concentrations of methoxsalen in a patient with epilepsy was probably a result of induction of hepatic enzymes by *phenytoin*.[1]

1. Staberg B, Hueg B. Interaction between 8-methoxypsoralen and phenytoin. *Acta Derm Venereol (Stockh)* 1985; **65:** 553–5.

Emollients. Some emollient preparations may have a photoprotective effect, and if applied immediately before UVA irradiation could interfere with the efficacy of PUVA therapy.[1,2]

1. Hudson-Peacock MJ, *et al.* Photoprotective action of emollients in ultraviolet therapy of psoriasis. *Br J Dermatol* 1994; **130:** 361–5.
2. Otman SGH, *et al.* Modulation of ultraviolet (UV) transmission by emollients: relevance to narrowband UVB phototherapy and psoralen plus UVA photochemotherapy. *Br J Dermatol* 2006; **154:** 963–8.

Food. Some foods, for example, celery, parsnip, and parsley, contain psoralens and eating large quantities may increase the risk of phototoxicity with methoxsalen. A patient[1] who ate a large quantity of celery soup the evening before and 2 hours before undergoing PUVA therapy for atopic eczema developed severe phototoxicity after treatment, which was attributed to the additive effects of methoxsalen and psoralens contained in the celery.

1. Boffa MJ, *et al.* Celery soup causing severe phototoxicity during PUVA therapy. *Br J Dermatol* 1996; **135:** 334.

Xanthines. For mention of the effect of systemic methoxsalen on the metabolism of theophylline, see Methoxsalen, under Interactions of Theophylline, p.1145.

Pharmacokinetics

When taken orally methoxsalen is well but variably absorbed from the gastrointestinal tract and there is considerable interindividual variation in peak serum concentrations. Depending on the oral formulation used increased photosensitivity is present 1 hour after a dose, reaches a peak at about 1 to 4 hours, and disappears after about 8 hours. Methoxsalen is highly protein bound. It appears to be preferentially taken up by epidermal cells. It also diffuses into the lens of the eye. Methoxsalen is almost completely metabolised. About 95% of a dose is excreted in the urine within 24 hours. The photosensitising action of methoxsalen may persist for several days after topical application. The erythema induced by oral or topical PUVA is usually delayed and peaks after 2 to 3 days.

Uses and Administration

Methoxsalen, a psoralen, is a constituent of the seeds of *Ammi majus* and the roots of *Heracleum candicans*. It is a photosensitiser that markedly increases skin reactivity to long-wavelength ultraviolet radiation (320 to 400 nm), an effect used in photochemotherapy or PUVA [psoralen (P) and high-intensity long-wavelength UVA irradiation]. In the presence of UVA methoxsalen bonds with DNA, inhibiting DNA synthesis and cell division, and can lead to cell injury. Recovery from the cell injury may be followed by increased melanisation of the epidermis and thickening of the stratum corneum. Methoxsalen may also increase pigmentation by an action on melanocytes.

PUVA is used to treat idiopathic vitiligo and severe, recalcitrant, disabling psoriasis not adequately responsive to conventional topical therapy. It may also be useful in selected cases of atopic eczema and polymorphic light eruptions and may be used in T-cell lymphomas such as mycosis fungoides.

Methoxsalen is given orally or applied topically in PUVA regimens. *Differing oral dosage forms of methoxsalen may exhibit significantly varying bioavailabilities and times to onset of photosensitisation.* The UVA exposure dose should generally be based on prior measurement of the minimal phototoxic dose although it can be calculated with regard to the skin type of the patient if phototoxic dose testing cannot be carried out.

- To repigment **vitiliginous** areas, methoxsalen is given in a dose of 20 mg or up to 600 micrograms/kg *orally* 2 to 4 hours before measured periods of exposure to UVA, depending on the preparation. Treatment is usually given twice a week or on alternate days, but always at least 48 hours apart.
- Methoxsalen may also be applied *topically* to repigment small, well-defined vitiliginous lesions. Preparations containing up to 1% have been used but dilution to 0.1 or 0.01% may be necessary to avoid adverse cutaneous effects. The surrounding skin should be protected by an opaque sunscreen. Some suggest that the treated area should be exposed to UVA soon after application while others recommend waiting up to 2 hours. After exposure the lesions should be washed and protected from light; protection may be necessary for up to 48 hours or longer. Treatment is repeated usually once weekly. Significant repigmentation may not appear until after 6 to 9 months of treatment.
- For the treatment of **psoriasis** a dose of up to about 600 micrograms/kg *orally* is given 1.5 to 3 hours before UVA, depending on the preparation. Treatment is usually given twice a week although increased frequencies, but with at least 48-hour intervals between doses, have been suggested. If there is no response or only minimal response after the fifteenth PUVA treatment some suggest that the dosage may be increased by 10 mg and that this higher dose be used for the remainder of the course of treatment.
- Methoxsalen may also be used *topically* with UVA exposure for the treatment of psoriasis. For direct application to affected areas of skin a preparation containing approximately 0.15% (or diluted to 0.015% if necessary to avoid adverse cutaneous effects) is applied 15 minutes before UVA exposure. Alternatively the patient may take a whole body bath for 15 minutes in a methoxsalen solution, followed immediately by UVA exposure. UK guidelines (see also Skin Disorders, below) suggest a typical concentration of methoxsalen 2.6 mg/litre for such solutions although higher concentrations (up to about 3.7 mg/litre) have been used. Hand and foot soaks may be used to treat only those affected areas; a solution containing methoxsalen 3 mg/litre may be used with the affected areas immersed for 15 minutes followed by a delay of 30 minutes before UVA exposure. Baths or soaks are generally given twice a week.

Psoralen itself has also been used.

Administration. The dose of methoxsalen is usually calculated on the basis of body-weight. This method of dose calculation produces a considerable difference between the doses received by heavy and light patients. A study in 41 patients with psoriasis[1] suggested that using methoxsalen 25 mg/m^2 gave more consistent plasma concentrations and may reduce the potential for burning in heavy patients and prevent underdosing in light patients undergoing PUVA therapy.

1. Sakuntabhai A, *et al.* Calculation of 8-methoxypsoralen dose according to body surface area in PUVA treatment. *Br J Dermatol* 1995; **133:** 919–23.

PUVA. PUVA combines psoralens with UVA irradiation. The psoralens may be given directly to the patient, either orally or topically, and the patient is then exposed to UVA. In extracorporeal PUVA (extracorporeal photochemotherapy; photopheresis), an oral dose of a psoralen is given, after which the patient's leucocytes are isolated, exposed to UVA extracorporeally, and then reinfused. In another method of extracorporeal photopheresis methoxsalen is added directly to leucocytes that have already been removed from the patient. The mixture is then treated with UVA after which it is returned to the patient; the total dose of methoxsalen used by this method is lower than that used orally. PUVA has been used in a wide range of disorders including skin disorders, mycosis fungoides, and organ and tissue transplant rejection (below).

MYCOSIS FUNGOIDES. PUVA therapy is used in the treatment of the manifestations of cutaneous mycosis fungoides and Sèzary syndrome, two forms of cutaneous T-cell lymphoma (see p.657). Extracorporeal PUVA therapy (photopheresis; see above) has also been used,[1-6] particularly for disease with erythrodermic features. The Photopheresis Expert Group[7] (from the UK and Scandinavia) suggests a usual treatment cycle of 2 consecutive days, which is repeated every 2 to 4 weeks. More frequent treatment may be given to symptomatic patients and those with a high peripheral blood tumour burden. Response is assessed every 3 months and then, when complete or maximal response has occurred, treatment is tapered to every 6 to 12 weeks before stopping. Relapse may be treated with the same schedule. After the first 3 months of therapy, treatment should generally be continued for a further 3 months in patients with stable disease (no response). However, consideration should be given to stopping treatment, or using combination therapy (photopheresis with interferon alfa and/or bexarotene), if there is disease progression. At 6 months and beyond, treatment should be stopped, or combination therapy considered, in patients with stable or progressive disease, but for those already receiving combination therapy, photopheresis should be stopped.

ORGAN AND TISSUE TRANSPLANTATION. PUVA[1,2] and extracorporeal PUVA therapy[3-6] (photopheresis; see above) have been tried in both acute and chronic graft-versus-host disease (GVHD) that is unresponsive to usual treatment (see Haematopoietic Stem Cell Transplantation, p.1811). As well as improvements in GVHD, particularly cutaneous manifestations, PUVA therapies have enabled the doses of corticosteroids and other immunosuppressants to be reduced. The Photopheresis Expert Group[7] (from the UK and Scandinavia) suggests, for chronic GVHD, a usual treatment cycle of 2 consecutive days, repeated every 2 weeks. Response is assessed after 3 months and treatment reduced to once every 4 weeks if there has been a complete or partial response. Treatment is then reassessed every 3 months and tapered or stopped when a complete or maximal response has occurred. It should be stopped if there is no response or disease progression.

Photopheresis has also been tried in treating rejection of solid organ transplants,[3,6,8] particularly after heart transplantation (p.1812). It has also shown promise in a study[9] of the prevention of heart transplant rejection.

SKIN DISORDERS. PUVA has been used in a wide range of skin disorders and guidelines have been published by the British Photodermatology Group,[1,2] which are summarised as follows:

- Indications for PUVA in chronic plaque **psoriasis** include severe extensive psoriasis unresponsive to conventional topical therapies, relapse within 3 to 6 months of successful topical treatment, or patient refusal of topical treatment if UVB phototherapy has failed (see p.1583 for a discussion of the various treatments of psoriasis). Initial UVA exposure should preferably be determined on the basis of prior measurement of the minimal phototoxic dose rather than on the skin type. Increases in UVA irradiation are then calculated as a percentage of previous doses.

  Methoxsalen in an oral dose of 600 micrograms/kg given 2 hours before UVA exposure is the widely accepted standard regimen. Alternatively, 5-methoxypsoralen 1.2 mg/kg, again 2 hours before UVA exposure, can be given and appears to be almost free of the adverse reactions such as nausea, pruritus, and erythema induced by methoxsalen. However, until the clinical efficacy of 5-methoxypsoralen has been clearly shown, methoxsalen should remain the psoralen of choice for most clinical situations.

  Alternatives to oral PUVA are baths or soaks using methoxsalen or trioxysalen. For whole body bathing a concentration of methoxsalen 2.6 mg/litre is typically utilised with the patient bathing for 15 minutes followed by immediate exposure to UVA. For hand and foot soaks a concentration of methoxsalen 3 mg/litre is used with the affected area immersed for 15 minutes followed by a delay of 30 minutes before UVA exposure. For trioxysalen a concentration of about 330 micrograms/litre is used for a 15-minute whole body bath or hand and foot soak followed by immediate UVA exposure for whole body therapy, or a 30 minute delay before hand and foot UVA exposure. Whole body baths or hand and foot soaks are given twice each week.

  Methoxsalen may also be applied topically to the affected areas. A concentration of about 0.15% (or 0.015% if erythema occurs) is used in an emulsion, or 0.005% in an aqueous gel, and applied 15 minutes before UVA exposure.

  PUVA treatment should be stopped as soon as disease clearance is achieved; maintenance PUVA should be avoided to minimise cumulative UVA exposure, but may be considered if there is rapid relapse. A combination of PUVA with acitretin (300 to 700 micrograms/kg orally) or etretinate (0.5 to 1 mg/kg orally) may be considered in patients who have reached 50 treatment sessions or relapsed within 6 months of PUVA. PUVA and methotrexate are also effective for severe psoriasis but should be reserved for such cases because of the possible increased risk of skin cancer
- Oral PUVA twice weekly with methoxsalen 600 micrograms/kg or 5-methoxypsoralen 1.2 mg/kg has been effective in many patients with **vitiligo** (see Pigmentation Disorders, p.1582). If patches are well demarcated topical application of methoxsalen 0.15% may be preferable
- In **mycosis fungoides** PUVA is an effective symptomatic treatment for early disease and a useful adjunct for late-stage disease but optimal regimens have not been established (see above)
- PUVA is effective for atopic **eczema** (p.1579) but clearance is less certain than for psoriasis, twice the number of treatments may be needed, and relapse is more frequent. It should therefore be reserved for severe disease unresponsive to conventional treatments. Optimal regimens have not been established
- In **polymorphic light eruptions** (see Photosensitivity Disorders, p.1581) PUVA is effective in up to 90% of patients but is only indicated in those who are frequently or severely affected despite the regular use of high-protection broad-spectrum sunscreens. Several arbitrary regimens are in use
- Variable results have also been reported in a variety of other disorders but data has been insufficient to establish precise guidelines. Such disorders include actinic prurigo, alopecia areata, aquagenic pruritus, chronic actinic dermatitis, granuloma annulare, lichen planus, nodular prurigo, pityriasis lichenoides, localised scleroderma, solar urticaria, and urticaria pigmentosa. In most cases relapse occurs in the absence of maintenance therapy and PUVA should usually only be tried as a last resort.

Extracorporeal PUVA has been tried in patients with severe epidermolysis bullosa acquisita,[3,4] lichen planus,[5] and scleroderma.[6,7]

Preparations

USP 31: Methoxsalen Capsules; Methoxsalen Topical Solution.

Proprietary Preparations (details are given in Part 3)
Arg.: Oxsoralen Ultra; ***Austral.:*** Oxsoralen; ***Austria:*** Oxsoralen; ***Belg.:*** Mopsoralen; ***Braz.:*** Oxsoralen; ***Canad.:*** Oxsoralen; Ultramop; ***Chile:*** Oxsoralen; ***Cz.:*** Oxsoralen; Uvadex; ***Denm.:*** Geroxalen†; ***Fr.:*** Meladinine; Uvadex; ***Ger.:*** Meladinine; ***Gr.:*** Melaoline; ***Hong Kong:*** Oxsoralen; ***Hung.:*** Geroxalen†; Oxsoralen; ***India:*** Macsoralen†; Manaderm; Melanocyl; ***Indon.:*** Delsoralen; Oxsoralen; ***Irl.:*** Deltasoralen; ***Ital.:*** Oxsoralen†; ***Jpn:*** Oxsoralen; ***Malaysia:*** Meladinine†; Oxsoralen; ***Mex.:*** Dermox; Meladinina; Oxsoralen; ***Neth.:*** Geroxalen; Meladinine; Oxsoralen†; ***Norw.:*** Geroxalen†; ***NZ:*** Oxsoralen; ***Pol.:*** Geralen; Oxsoralen; ***Rus.:*** Oxsoralen (Оксорален); ***S.Afr.:*** Oxsoralen; ***Singapore:*** Oxsoralen; ***Spain:*** Oxsoralen; ***Switz.:*** Meladinine; ***Thai.:*** Meladinine†; ***Turk.:*** Geroxalen; Vitspo; ***UK:*** Puvasoralen; ***USA:*** Oxsoralen; Uvadex.

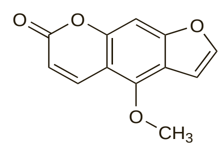
Multi-ingredient: ***India:*** Melanocyl.

5-Methoxypsoralen

Bergapteeni; Bergapten; Bergapteno; Bergaptenum; 5-Metoxipsoraleno; 5-MOP. 4-Methoxy-7*H*-furo[3,2-g]chromen-7-one.

5-Метоксипсорален

$C_{12}H_8O_4$ = 216.2.
CAS — 484-20-8.
ATC — D05BA03.
ATC Vet — QD05BA03.



Profile

5-Methoxypsoralen is a photosensitiser with actions similar to those of methoxsalen (above). It may be given orally in the PUVA therapy (see under Methoxsalen, above) of psoriasis and vitiligo.

5-Methoxypsoralen is included in some cosmetic suntan preparations to enhance tanning but because of its potential phototoxicity this is considered unwise by authorities in Europe and the USA. Photosensitivity caused by 5-methoxypsoralen is sometimes known as Berloque dermatitis.

5-Methoxypsoralen is an ingredient of bergamot oil (p.2265).

◊ References.

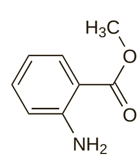
Methyl Anthranilate

Metilo, antranilato de; Metylu antranilan. Methyl 2-aminobenzoate.

Метилантранилат

$C_8H_9NO_2$ = 151.2.
CAS — 134-20-3.



NOTE. Do not confuse with menthyl anthranilate (see Meradimate, p.1604).

Profile

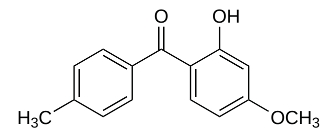
Methyl anthranilate has been used in sunscreen preparations. It is a constituent of several essential oils.

Mexenone *(BAN, pINN)*

Benzofenon-10; Benzophenone-10; Mexenona; Mexénone; Mexenonum. 2-Hydroxy-4-methoxy-4′-methylbenzophenone.

Мексенон

$C_{15}H_{14}O_3$ = 242.3.
CAS — 1641-17-4.



Pharmacopoeias. In *Br.*

BP 2008 (Mexenone). A pale yellow odourless or almost odourless crystalline powder. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone.

Profile

Mexenone, a substituted benzophenone, is a sunscreen (p.1576) with actions similar to those of oxybenzone (p.1608). It is effective against UVB and some UVA light (for definitions, see p.1580)

Preparations

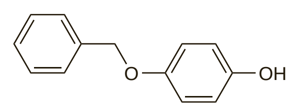
BP 2008: Mexenone Cream.

Monobenzone *(rINN)*

Benoquina; Hydroquinone Monobenzyl Ether; Monobenzona; Monobenzonum. 4-Benzyloxyphenol.

Монобензон

$C_{13}H_{12}O_2$ = 200.2.
CAS — 103-16-2.
ATC — D11AX13.
ATC Vet — QD11AX13.



Pharmacopoeias. In *US.*

USP 31 (Monobenzone). Store at a temperature not exceeding 30° in airtight containers. Protect from light.

Adverse Effects and Precautions

Monobenzone may cause skin irritation and sensitisation. In some patients this is transient and the drug need not be withdrawn. In others, an eczematous sensitisation may occur. Excessive depigmentation may occur even beyond the areas under treatment and may produce unsightly patches.

Monobenzone frequently produces permanent depigmentation and should not be used as a substitute for hydroquinone.

Interactions

Agalsidase. For the recommendation that monobenzone not be used with agalsidase alfa or beta, see p.2252.

Uses and Administration

Monobenzone has actions similar to those of hydroquinone (p.1598) but in some patients it also produces extensive and selective destruction of melanocytes. It is used locally for final, permanent depigmentation of normal skin in extensive vitiligo (see Pigmentation Disorders, p.1582). Monobenzone is not recommended for freckling, chloasma, or hyperpigmentation following skin inflammation or due to photosensitisation after the use of certain perfumes. It has no effect on melanomas or pigmented naevi.

For vitiligo a cream containing monobenzone 20% is applied to the affected areas two or three times daily until a satisfactory response is obtained, and thereafter as necessary, usually about twice weekly. Depigmentation only becomes apparent when the preformed melanin pigments have been lost with the normal sloughing of the stratum corneum and this may take several months. If, however, no improvement is noted after 4 months, treatment should be stopped. Excessive exposure to sunlight should be avoided during treatment. After depigmentation the skin will be sensitive for the rest of the patient's life and a sunscreen must be used during sun exposure.

Preparations

USP 31: Monobenzone Cream.

Proprietary Preparations (details are given in Part 3)
Canad.: Benoquin; ***India:*** Benoquin†; ***USA:*** Benoquin.

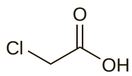
Monochloroacetic Acid

Chloroacetic Acid; Kwas chlorooctowy; Monocloroacético, ácido.

Монохлоруксусная Кислота

$C_2H_3O_2Cl$ = 94.5.

CAS — 79-11-8.



Profile

Preparations containing 50% of monochloroacetic acid are used as a caustic for the removal of plantar warts (p.1584).

Preparations

Proprietary Preparations (details are given in Part 3)
Austria: Warzenmittel; ***Ger.:*** Acetocaustin; ***Switz.:*** Acetocaustine.

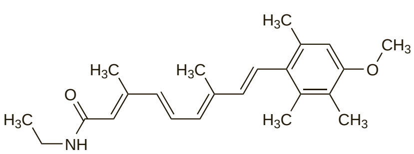
Motretinide *(USAN, rINN)*

Motretinid; Motretinida; Motrétinide; Motretinidi; Motretinidum; Ro-11-1430. (*all-trans*)-*N*-Ethyl-9-(4-methoxy-2,3,6-trimethylphenyl)-3,7-dimethyl-2,4,6,8-nonatetraenamide.

Мотретинид

$C_{23}H_{31}NO_2$ = 353.5.

CAS — 56281-36-8.
ATC — D10AD05.
ATC Vet — QD10AD05.



Profile

Motretinide is a retinoid structurally related to acitretin (p.1586). Motretinide is used topically in the treatment of acne (p.1577). It is applied in preparations containing 0.1%.

Preparations

Proprietary Preparations (details are given in Part 3)
Switz.: Tasmaderm.

Naphthalan Liquid

Naftalan; Naphthalanic Oil; Naphthalanum Liquidum.

Нафталановое Масло

CAS — 37229-16-6.

Profile

Naphthalan liquid is an oil-like complex mixture of naphthene hydrocarbons and tars obtained from the oil fields of Azerbaijan and Croatia. It has analgesic, anti-inflammatory, and emollient properties and is used in the treatment of conditions such as psoriasis and in various musculoskeletal disorders. It is usually applied locally in the form of the oil or as an ointment or alternatively patients may bath in the oil.

◊ References.

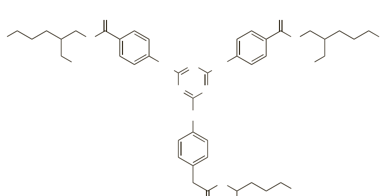
Octil Triazone

Octiltriazona; Octyl Triazone. 2,4,6-Trianilino-*p*-(carbo-2′-ethylhexyl-1′-oxy)-1,3,5-triazine.

Октилтриазон

$C_{48}H_{66}N_6O_6$ = 823.1.

CAS — 88122-99-0.



NOTE. Uvinul T 150 is a trade name that has been used for octil triazone.

Profile

Octil triazone is used as a sunscreen (p.1576). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

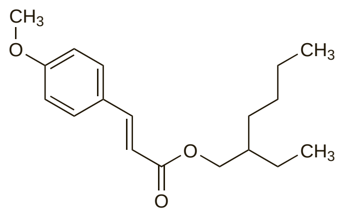
Octinoxate *(USAN, rINN)*

Octinoxato; Octinoxatum; Octyl methoxycinnamate. 2-Ethylhexyl-*p*-methoxycinnamate; 3-(4-Methoxylphenyl)-2-propenoic acid 2-ethylhexyl ester.

Оциноксат

$C_{18}H_{26}O_3$ = 290.4.

CAS — 5466-77-3.
ATC — D02BA02.
ATC Vet — QD02BA02.



NOTE. Escalol 557, Eusolex 2292, Neo-Heliopan AV, Parsol MCX, Tinosorb OMC, Uvinul MC 80, and Uvinul MC 80 N are trade names that have been used for octinoxate.

Pharmacopoeias. In *US.*

USP 31 (Octinoxate). Pale yellow oil. Insoluble in water. Store in airtight containers at a temperature of 8° to 15°.

Profile

Octinoxate, a substituted cinnamate, is used by topical application as a sunscreen (p.1576). Cinnamate sunscreens effectively absorb light throughout the UVB range but absorb little or no UVA light (for definitions, see p.1580). Cinnamate sunscreens may therefore be used to prevent sunburn but are unlikely to prevent drug-related or other photosensitivity reactions associated with UVA light; combination with a benzophenone may give some added protection against such photosensitivity. Cinnamates may occasionally produce photosensitivity reactions.

Preparations

Proprietary Preparations numerous preparations are listed in Part 3.

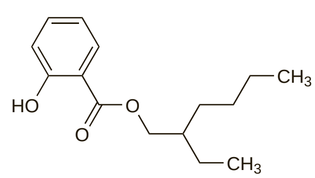
Octisalate *(USAN, rINN)*

Octisalato; Octisalatum; Octyl Salicylate. 2-Ethylhexyl salicylate; 2-Hydroxybenzoic acid 2-ethylhexyl ester.

Октисалат

$C_{15}H_{22}O_3$ = 250.3.

CAS — 118-60-5.



NOTE. Escalol 587, Eusolex OS, and Neo-Heliopan OS are trade names that have been used for octisalate.

Pharmacopoeias. In *US.*

USP 31 (Octisalate). Store in airtight containers.

Profile

Octisalate is a substituted salicylate used topically as a sunscreen (p.1576). Salicylates effectively absorb light throughout the UVB range but absorb little or no UVA light (for definitions, see p.1580). Salicylate sunscreens may therefore be used to prevent sunburn, but are unlikely to prevent drug-related or other photosensitivity reactions associated with UVA light; combination with a benzophenone may give some added protection.

Salicylates may occasionally produce photosensitivity reactions or contact dermatitis.

Preparations

Proprietary Preparations numerous preparations are listed in Part 3.

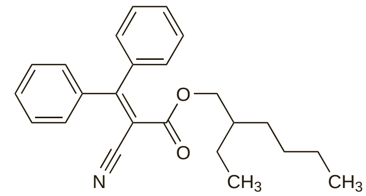
Octocrilene *(rINN)*

2-Ethylhexyl α-cyano-β-phenylcinnamate; Octocrilène; Octocrileno; Octocrilenum; Octocrylene *(USAN)*. 2-Ethylhexyl 2-cyano-3,3-diphenylacrylate.

Октокрилен

$C_{24}H_{27}NO_2$ = 361.5.

CAS — 6197-30-4.



NOTE. Escalol 597, Eusolex OCR, Neo-Heliopan 303, Parsol 340, and Uvinul N 539 T are trade names that have been used for octocrilene.

Pharmacopoeias. In *US.*

USP 31 (Octocrylene). Store in airtight containers.

Profile

Octocrilene, a substituted cinnamate, is a sunscreen (p.1576) with actions similar to those of octinoxate (above). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations numerous preparations are listed in Part 3.

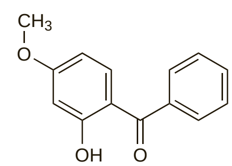
Oxybenzone *(USAN, rINN)*

Benzofenon-3; Benzophenone-3; Oxibenzona; Oxybenzonum. 2-Hydroxy-4-methoxybenzophenone.

Оксибензон

$C_{14}H_{12}O_3$ = 228.2.

CAS — 131-57-7.



NOTE. Escalol 567, Eusolex 4360, Neo-Heliopan BB, Tinosorb B3, and Uvinul M 40 are trade names that have been used for oxybenzone.

Pharmacopoeias. In *US.*

USP 31 (Oxybenzone). A pale yellow powder. Practically insoluble in water; freely soluble in alcohol and in toluene. Store in airtight containers. Protect from light.

Profile

Oxybenzone is a substituted benzophenone used topically as a sunscreen (p.1576). Benzophenones effectively absorb light throughout the UVB range (wavelengths 290 to 320 nm) and also absorb some UVA light with wavelengths of 320 to about 360 nm and some UVC light with wavelengths of about 250 to 290 nm (for definitions, see p.1580). Benzophenones may therefore be used to prevent sunburn and may also provide some protection against drug-related or other photosensitivity reactions associated with UVA light; in practice they are usually combined with a sunscreen from another group.

Photocontact allergic dermatitis can be caused by topical application of benzophenone sunscreens. Oxybenzone is widely used and often found to be a photo-allergen in patients with these reactions. Contact allergy reactions occur less frequently.

Hypersensitivity. Chemical sunscreens are known to cause photosensitivity and contact allergy reactions. Oxybenzone is widely used and reported to be the sunscreen photo-allergen most commonly detected in photopatch testing.[1,2] In a group of 5800 patients with suspected allergic contact dermatitis who were tested for contact allergens,[3] a positive reaction to oxybenzone was recorded in 0.6%. There have also been rare reports of severe allergic reactions to oxybenzone including anaphylaxis; sensitivity was confirmed by patch testing.[4,5] A history of atopy may predispose patients to such reactions.

5. Yesudian PD, King CM. Severe contact urticaria and anaphylaxis from benzophenone-3 (2-hydroxy 4-methoxy benzophenone). *Contact Dermatitis* 2002; **46:** 55–6.

Preparations

USP 31: Dioxybenzone and Oxybenzone Cream.

Proprietary Preparations numerous preparations are listed in Part 3.

Arg.: Biorevit Labial; Lelco; ***Braz.:*** Solaquin.

Padimate *(BAN, rINN)*

Amyl Dimethylaminobenzoate; Isoamyl Dimethylaminobenzoate; Padimate A *(USAN)*; Padimato; Padimatum. A mixture of pentyl, isopentyl, and 2-methylbutyl 4-dimethylaminobenzoates.

Падимат

$C_{14}H_{21}NO_2$ = 235.3.

CAS — 14779-78-3 (pentyl 4-dimethylaminobenzoate); 21245-01-2 (isopentyl 4-dimethylaminobenzoate).

Profile

Padimate, a substituted aminobenzoate, is a sunscreen (p.1576) with actions similar to those of aminobenzoic acid (p.1589). It is effective against UVB light (for definitions, see p.1580).

Preparations

Proprietary Preparations some preparations are listed in Part 3.

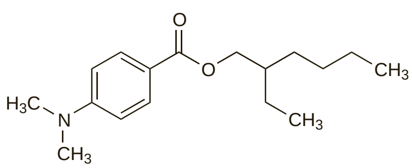
Padimate O *(BANM, USAN)*

Ethylhexyl Dimethyl PABA; Octyl Dimethyl PABA; Padimato O. 2-Ethylhexyl 4-(dimethylamino)benzoate.

Падимат O

$C_{17}H_{27}NO_2$ = 277.4.

CAS — 21245-02-3.



NOTE. Escalol 507 and Eusolex 6007 are trade names that have been used for padimate O.

Pharmacopoeias. In *US.*

USP 31 (Padimate O). A light yellow, mobile liquid with a faint aromatic odour. Practically insoluble in water, in glycerol, and in propylene glycol; soluble in alcohol, in isopropyl alcohol, and in liquid paraffin. Store in airtight containers. Protect from light.

Profile

Padimate O, a substituted aminobenzoate, is a sunscreen (p.1576) with actions similar to those of aminobenzoic acid (p.1589). It is effective against UVB light (for definitions, see p.1580).

Preparations

USP 31: Padimate O Lotion.

Proprietary Preparations some preparations are listed in Part 3.

Pimecrolimus *(BAN, USAN, rINN)*

ASM-981; Pimécrolimus; Pimecrolimús; Pimecrolimusum; Pimekrolimus; Pimekrolimuusi; SDZ-ASM-981. (3*S*,4*R*,5*S*,8*R*,9*E*,12*S*,14*S*,15*R*,16*S*,18*R*,19*R*,26a*S*)-3-{(*E*)-2-[(1*R*,3*R*,4*S*)-4-Chloro-3-methoxycyclohexyl]-1-methylvinyl}-8-ethyl-5,6,8,11,12,13,14,15,16,17,18,19,24,25,26,26a-hexadecahydro-5,19-dihydroxy-14,16-dimethoxy-4,10,12,18-tetramethyl-15,19-epoxy-3*H*-pyrido[2,1-*c*][1,4]oxaazacyclotricosine-1,7,20,21(4*H*,23*H*)-tetrone.

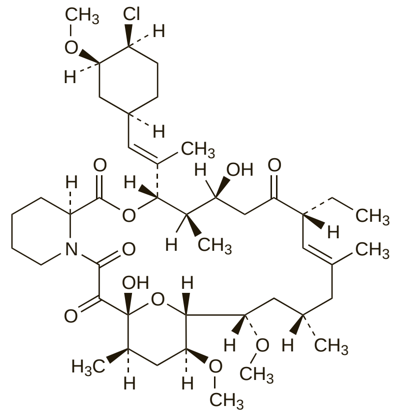
Пимекролимус

$C_{43}H_{68}ClNO_{11}$ = 810.5.

CAS — 137071-32-0.

ATC — D11AX15.

ATC Vet — QD11AX15.



Adverse Effects and Precautions

As for topical tacrolimus (p.1843).

The most frequent adverse effects of topical pimecrolimus are a burning sensation, irritation, pruritus, erythema, and skin infections at the application site. Rarely anaphylactic reactions, sometimes severe, have been reported.

Cases of lymphadenopathy have been reported in patients using pimecrolimus cream. Treatment with pimecrolimus should be stopped in patients who develop lymphadenopathy in the absence of a clear aetiology or in the presence of acute infectious mononucleosis. All patients should be monitored to ensure that the condition resolves.

Carcinogenicity. Carcinogenicity studies in *animals* and reports of malignancies in patients treated with topical calcineurin inhibitors prompted the FDA to issue an alert about the possible risk and to make recommendations about the appropriate use of pimecrolimus and tacrolimus (see under Tacrolimus, p.1843).

Interactions

Alcohol intolerance, described as flushing, rash, burning, itching, or swelling, has occurred rarely after the consumption of alcohol by patients using topical pimecrolimus.

Pharmacokinetics

There is minimal systemic absorption and no accumulation from topical use of pimecrolimus. Studies in *animals* and *in vitro* have found no evidence of metabolism in the skin.

Pimecrolimus is absorbed from the gastrointestinal tract after oral doses, and is about 74 to 87% bound to plasma proteins. It is metabolised in the liver by the cytochrome P450 isoenzyme CYP3A subfamily. About 78% of a single dose is eliminated in the faeces as metabolites and less than 1% as unchanged pimecrolimus. Only about 2.5% of a dose is eliminated in the urine, as metabolites.

Uses and Administration

Pimecrolimus is a macrolactam ascomycin derivative related to tacrolimus (p.1846) that acts as a calcineurin inhibitor and has similar anti-inflammatory and immunosuppressant actions. It is used for short-term and intermittent long-term treatment of mild to moderate atopic eczema (p.1579) in non-immunocompromised patients over the age of 2 years when conventional therapies are ineffective or unsuitable. Pimecrolimus is applied twice daily as a 1% cream until signs and symptoms clear. Treatment should be stopped if there is no improvement after 6 weeks or if eczema is exacerbated.

Oral forms of pimecrolimus are also being investigated for the treatment of psoriasis and atopic eczema.

Administration in infants. A 6-week, double-blind, randomised study of 186 infants between the age of 3 and 23 months, followed by a 20-week open-label phase, showed that 1% pimecrolimus cream, applied twice daily was both safe and effective in mild to moderate atopic eczema.[1] A review[2] of data from 10 studies that included 1133 infants between 3 and 23 months of age who were treated for up to 2 years found that the level of systemic exposure to pimecrolimus was very low and comparable to that observed in older children and adults. Treatment was reported to be effective and there was no evidence of immunosuppression or an increase in the rate of infections. Licensed product information, however, does not recommend its use in patients under 2 years of age as the effect of pimecrolimus cream on the developing immune system in infants is unknown (for concerns about possible carcinogenicity see above).

Lichen. There are a few case reports[1,2] of benefit from pimecrolimus 1% cream in the management of oral *lichen planus* (p.1580). In most cases it was applied twice daily, and in some cases adhesive gel or paste was also used. Improvement in oral lesions occurred within 2 to 4 weeks in 3 cases.[1] In a placebo-controlled study[3] of 20 patients with oral erosive lichen planus, pimecrolimus 1% cream was applied twice daily for 4 weeks. Although pain scores were reduced with pimecrolimus, the reduction in erythema was not maintained. There was also a trend towards an improvement in ulceration but changes in scores were not statistically significant. Topical pimecrolimus has also been tried in the management of genital lichen planus. In a series[4] of 11 women, 9 experienced benefit after 4 to 6 weeks of treatment; with follow-up of up to 10 months, 6 of them had experienced a complete response and 3 a partial response.

The resolution of signs and symptoms of *lichen sclerosus* (p.1580) has been reported in 7 female patients (aged 4 to 48 years) with the use of topical pimecrolimus 1% cream twice daily for 3 to 4 months.[5,6] A poor response was reported in a 62-year-old woman who used the cream less frequently because of burning and stinging.[5]

Psoriasis. Topical pimecrolimus may have some benefit[1] in the treatment of psoriasis (p.1583). Although studies have generally found it to be less effective than topical corticosteroids or topical calcipotriol,[2-4] one study[2] in patients with chronic plaque psoriasis did report that pimecrolimus 1% ointment applied under occlusion had a similar efficacy to clobetasol propionate 0.05% ointment.

Oral pimecrolimus is also under investigation and has reduced disease severity in dose-finding studies in patients with chronic plaque psoriasis.[5,6]

Podophyllum

American Mandrake; May Apple Root; Podófilo; Podofilum; Podoph.; Podophyllum Rhizome; Rizoma de podófilo.

Подофилл щитовидный (*Podophyllum peltatum*)

Pharmacopoeias. In *US.*

USP 31 (Podophyllum). The dried rhizomes and roots of *Podophyllum peltatum* (Berberidaceae). It yields not less than 5% of resin. It has a slight odour.

Indian Podophyllum

Ind. Podoph.; Indian Podophyllum Rhizome; Podófilo indio.

Подофилл гималайский (*Podophyllum emodi*)

Description. The dried fruits or rhizomes and roots of *Podophyllum hexandrum* (*P. emodi*) (Berberidaceae).

Podophyllum Resin

Podofilino; Podoph. Resin; Podophylli Resina; Podophyllin; Resina de podófilo.

Подофиллин

CAS — 8050-60-0.

Pharmacopoeias. In *Int.* and *US* (both from podophyllum only). In *Br.* from Indian podophyllum.

BP 2008 (Podophyllum Resin). The resin obtained from the rhizomes and roots of *Podophyllum hexandrum* (*P. emodi*). It contains not less than 50% of total aryltetralin lignans, calculated as podophyllotoxin.

An amorphous powder, varying in colour from light brown to greenish-yellow or brownish-grey masses, with a characteristic odour; caustic. On exposure to light or to temperatures above 25° it becomes darker in colour.

Partly soluble in hot water but precipitated again on cooling; partly soluble in chloroform, in ether, and in dilute ammonia solution. Protect from light.

USP 31 (Podophyllum Resin). The powdered mixture of resins extracted from podophyllum (the rhizomes and roots of *Podophyllum peltatum*) by percolation with alcohol and subsequent precipitation with acidified water. It contains not less than 40% and not more than 50% of hexane-insoluble matter.

An amorphous caustic powder, varying in colour from light brown to greenish-yellow. On exposure to light or to temperatures above 25° it becomes darker in colour.

Soluble in alcohol with a slight opalescence; partially soluble in chloroform and in ether. A solution in alcohol is acid to litmus. Store in airtight containers. Protect from light.

Podophyllotoxin *(BAN)*

Podofilotoxina; Podofilox *(USAN)*; Podofyllotoksiini; Podofyllotoxin; Podophyllotoxinum. (5*R*,5a*R*,8a*R*,9*R*)-5,5a,6,8,8a,9-Hexahydro-9-hydroxy-5-(3,4,5-trimethoxyphenyl)furo[3′4′:6,7]naphtho[2,3-*d*]-1,3-dioxol-6-one.

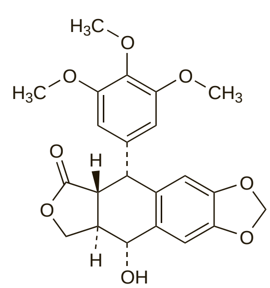
Подофиллотоксин

$C_{22}H_{22}O_8$ = 414.4.

CAS — 518-28-5.

ATC — D06BB04.

ATC Vet — QD06BB04.



Adverse Effects

Podophyllum is very irritant, especially to the eyes and mucous membranes. It can also cause severe systemic toxicity after ingestion or topical application, which is usually reversible but has been fatal. Symptoms of toxicity include nausea, vomiting, abdominal pain, and diarrhoea; there may be thrombocytopenia, leucopenia, renal failure, and hepatotoxicity. Central effects are delayed in onset and prolonged in duration and include acute psychotic reactions, hallucinations, confusion, dizziness, stupor, ataxia, hypotonia, seizures, and coma. EEG changes may persist for several days. Peripheral and autonomic neuropathies develop later and may result in paraesthesias, reduced reflexes, muscle weakness, tachycardia, apnoea, orthostatic hypotension, paralytic ileus, and urinary retention. Neuropathy may persist for several months.

Poisoning. Reports and reviews of podophyllum toxicity.[1-7] A few of the cases followed consumption of herbal preparations containing podophyllum or the related plant bajiaolian (*Dysosma pleianthum*). Death has occurred after ingestion of 10 g of podophyllum.

5. Kao W-F, *et al.* Podophyllotoxin intoxication: toxic effect of bajiaolian in herbal therapeutics. *Hum Exp Toxicol* 1992; **11:** 480–7.
6. Chan TYK, Critchley JAJH. Usage and adverse effects of Chinese herbal medicines. *Hum Exp Toxicol* 1996; **15:** 5–12.
7. Chu CC, *et al.* Sensory neuropathy due to bajiaolian (podophyllotoxin) intoxication. *Eur Neurol* 2000; **44:** 121–3.

Precautions

The risk of systemic toxicity after topical application of podophyllum is increased by the treatment of large areas with excessive amounts for prolonged periods, by the treatment of friable, bleeding, or recently biopsied warts, and by inadvertent application to normal skin or mucous membranes.

Podophyllum should not be used during pregnancy or breast feeding. There are few reports of use during pregnancy and a teratogenic risk cannot be ruled out. Adverse systemic effects in the mother would also be undesirable during pregnancy, and there are other non-drug treatments available for the treatment of anogenital warts. It is not known whether podophyllum is distributed into breast milk.

Handling. Podophyllum resin is strongly irritant to the skin, eyes, and mucous membranes and requires careful handling.

Uses and Administration

Podophyllum resin and podophyllotoxin have an antimitotic action and are used principally as topical treatments for anogenital warts (condylomata acuminata). Podophyllum resin and podophyllotoxin may be used on external genital and perianal warts; podophyllum resin may also be used on urethral meatus warts. However, neither of these compounds should be used to treat warts on mucous membranes, including vaginal, cervical, intra-urethral, intra-anal, and rectal warts.

Podophyllum resin is usually formulated in compound benzoin tincture in strengths of 15% Indian podophyllum resin or 10 to 25% American podophyllum resin. Lower concentrations of American podophyllum resin in alcoholic solutions have been used. The solution is left on the warts for 1 to 6 hours, and then washed off. Only a small area or number of warts should be treated at any one time and care must be taken to avoid application to healthy tissue. This procedure is carried out once a week for up to 3 to 6 weeks. Preparations containing podophyllotoxin 0.5% in alcohol or alcoholic gel or podophyllotoxin 0.15% cream are used similarly. They are applied twice daily for 3 days but not washed off. Treatment may be repeated at weekly intervals for up to a total of 4 or 5 weeks of treatment. Podophyllum resin is also used with other keratolytics for the removal of plantar warts.

Although podophyllum resin and podophyllotoxin preparations are generally not used in children, see below.

When taken orally podophyllum resin is highly irritant to the intestinal mucosa and produces violent peristalsis resulting in a drastic purging action. It has been superseded by less toxic laxatives.

Podophyllum has been used in homoeopathic medicine.

Administration in children. The use of podophyllum resin and podophyllotoxin preparations in children is generally avoided because of the potential for severe local irritation and systemic toxicity. Nonetheless, podophyllotoxin has been used for the treatment of symptomatic, persistent anogenital warts in children.[1] The *BNFC* suggests that, although not licensed for use in children, podophyllum resin and podophyllotoxin preparations may be used in regimens similar to those used in adults (see above) in children 2 years of age and older who are able to cooperate with treatment.

1. Bellew SG, *et al*. Childhood warts: an update. *Cutis* 2004; **73:** 379–84.

Anogenital warts. Podophyllum preparations are one of the treatment choices for anogenital warts caused by human papillomavirus infection (condylomata acuminata) (p.1584). Podophyllum resin preparations have traditionally been applied by a healthcare provider because of the potential local and systemic toxicity associated with inappropriate or excessive use.[1] However, podophyllotoxin may be more effective[2,3] and less toxic[2] than podophyllum resin, and is suitable for self-treatment by the patient.[1,4]

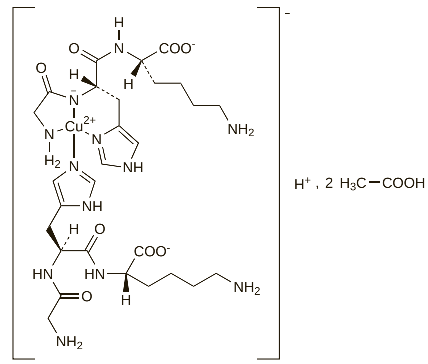
Prezatide Copper Acetate *(USAN, rINN)*

Acetato de prezatida cúprica; Acetato de prezatida de cobre; PC-1020 (prezatide copper); Prézatide Cuprique, Acétate de; Prezatidi Cuprici Acetas. Hydrogen [N^2-(*N*-glycyl-L-histidyl)-L-lysinato][N^2-(*N*-glycyl-L-histidyl)-L-lysinato(2–)]cuprate(1–) diacetate.

Презатида Меди Ацетат

$C_{28}H_{46}CuN_{12}O_8,2C_2H_4O_2 = 862.4.$

CAS — 130120-57-9.



Profile

Prezatide copper acetate is a copper-containing tripeptide that is used topically as a wound-healing agent.

Preparations

Proprietary Preparations (details are given in Part 3)

Braz.: Prezatim†; ***Mex.:*** Iamin; ***USA:*** Iamin Hydrating Gel.

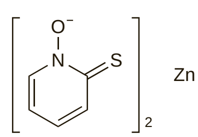
Pyrithione Zinc *(BAN, USAN, rINN)*

Çinko Pirition; Piritiona cíncica; Piritiona de zinc; Pyrithione Zincique; Pyrithionum Zincicum; Zinc 2-Pyridinethiol 1-Oxide; Zinc Pyridinethione. Bis[1-hydroxypyridine-2(1*H*)-thionato]zinc.

Пиритион Цинк

$C_{10}H_8N_2O_2S_2Zn = 317.7.$

CAS — 13463-41-7.
ATC — D11AX12.
ATC Vet — QD11AX12.



Profile

Pyrithione zinc has bacteriostatic and fungistatic properties. It is used similarly to selenium sulfide (p.1613) in usual concentrations of 1 to 2% in the control of seborrhoeic dermatitis and dandruff (p.1584). It is an ingredient of some proprietary shampoos. It has also been used in the treatment of pityriasis versicolor.

Pyrithione magnesium has also been used.

Effects on the nervous system. Peripheral neuritis with paraesthesia and muscle weakness in a patient was associated with the prolonged use of a shampoo containing pyrithione zinc 2%.[1] The muscle weakness had disappeared 3 months after stopping the shampoo and 2 years later the paraesthesia had improved by about 75%.

Studies in *animals* had found signs of neurotoxicity after oral doses of pyrithione zinc but whereas absorption after topical application was found to be 13% for pyrithione sodium it was less than 1% for pyrithione zinc.[2]

1. Beck JE. Zinc pyrithione and peripheral neuritis. *Lancet* 1978; **i:** 444.
2. Parekh CK. Zinc pyrithione and peripheral neuritis. *Lancet* 1978, **i:** 940.

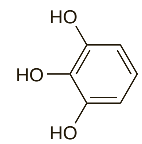
Pyrogallol

1,2,3-Bencenotriol; Pirogálico, ácido; Pirogalol; Pyrogallic Acid; Pyrogallolum. Benzene-1,2,3-triol.

Пирогаллол

$C_6H_6O_3 = 126.1.$

CAS — 87-66-1.



Pharmacopoeias. In *Fr.* and *Pol.*

Profile

Pyrogallol was formerly used topically in the treatment of psoriasis and parasitic skin diseases, but application over large areas or denuded surfaces is dangerous and may produce systemic effects similar to phenol poisoning (see p.1656); methaemoglobinaemia, haemolysis, and kidney damage may also occur.

Pyrogallol stains the skin and hair black.

Preparations

Proprietary Preparations (details are given in Part 3)

USA: Pyrogallic.

Pyroxylin *(rINN)*

Algodão-Polvora; Algodón pólvora; Cellulose Nitrate; Celulosa decanítrica; Colloxylinum; Fulmicoton; Gossypium Collodium; Kollodiumwolle; Nitrato de celulosa; Piroxilina; Pyroxyline; Pyroxylinum; Soluble Guncotton.

Пироксилин

CAS — 9004-70-0.

Pharmacopoeias. In *Br.*, *Jpn*, *Pol.*, and *US.*

BP 2008 (Pyroxylin). A nitrated cellulose obtained by the action of a mixture of nitric and sulfuric acids on wood pulp or cotton linters that have been freed from fatty matter. It must be damped with not less than 25% of isopropyl alcohol or of industrial methylated spirit. White or almost white cuboid granules or fine material resembling absorbent cotton but harsher to the touch and more powdery. It is highly flammable. Soluble in acetone and in glacial acetic acid. Store in well-closed containers, loosely packed, protected from light, and at a temperature not exceeding 15°, remote from fire. The container should be suitably designed to disrupt should the internal pressure reach or exceed 1400 kPa. The amount of damping fluid must not be allowed to fall below 25% w/w; should this happen, the material should be either rewetted or used immediately for the preparation of Collodion.

USP 31 (Pyroxylin). Pyroxylin is obtained by the action of a mixture of nitric and sulfuric acids on cotton and consists chiefly of cellulose tetranitrate $(C_{12}H_{16}N_4O_{18})_n$. It occurs as a light yellow, matted mass of filaments resembling raw cotton but harsher to the touch. It is highly flammable. Store loosely packed, protected from light. When kept in well-closed containers and exposed to light, it decomposes with the evolution of nitrous vapours, leaving a carbonaceous residue.

Profile

Pyroxylin is used in the preparation of collodions which are applied to the skin for the protection of small cuts and abrasions. Collodions are also used as vehicles for the application of drugs when prolonged local action is required.

Handling. Dry pyroxylin is explosive and sensitive to ignition by impact or friction and should be handled carefully.

Preparations

BP 2008: Collodion; Flexible Collodion.
USP 31: Collodion; Flexible Collodion.

Proprietary Preparations (details are given in Part 3)

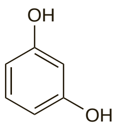
Multi-ingredient: ***UK:*** Dispello.

Resorcinol

m-Dihidroxibenceno; *m*-Dihydroxybenzene; Dioxybenzolum; Resorcin; Resorcina; Résorcinol; Resorcinolum; Resorsinoli; Rezorcin; Rezorcinolis; Rezorcynol. Benzene-1,3-diol.

Резорцинол

$C_6H_6O_2$ = 110.1.
CAS — 108-46-3.
ATC — D10AX02; S01AX06.
ATC Vet — QD10AX02; QS01AX06.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Resorcinol). Colourless or slightly pinkish-grey crystals or crystalline powder. M.p. 109° to 112°. It becomes red on exposure to air and light. Very soluble in water and in alcohol. Protect from light.

USP 31 (Resorcinol). White or practically white, needle-shaped crystals or powder with a faint characteristic odour. M.p. 109° to 111°. It acquires a pink tint on exposure to air and light. Soluble 1 in 1 of water and of alcohol; slightly soluble in chloroform; freely soluble in ether and in glycerol. A 5% solution in water is neutral or acid to litmus. Protect from light.

Incompatibility. Resorcinol is incompatible with ferric salts.

Resorcinol Monoacetate

Acetato de resorcina; Resorcin Acetate; Resorcinol, monoacetato de. 3-Acetoxyphenol.

Резорцинола Моноацетат

$C_8H_8O_3$ = 152.1.
CAS — 102-29-4.
ATC — D10AX02; S01AX06.
ATC Vet — QD10AX02; QS01AX06.

Pharmacopoeias. In *US.*

USP 31 (Resorcinol Monoacetate). A pale yellow or amber, viscous liquid with a faint characteristic odour. Sparingly soluble in water; soluble in alcohol and in most organic solvents. A saturated solution in water is acid to litmus. Store in airtight containers. Protect from light.

Adverse Effects, Treatment, and Precautions

Resorcinol is a mild irritant and may result in skin sensitisation. It should not be applied to large areas of the body, for prolonged periods, or in high concentrations, especially in children, as it is absorbed through intact skin as well as broken skin and may interfere with thyroid function or produce methaemoglobinaemia. Resorcinol may produce hyperpigmentation in patients with dark skins and may darken light-coloured hair. Systemic toxic effects of resorcinol are similar to those of phenol and are treated accordingly (see p.1656) but convulsions may occur more frequently.

Abnormal coloration. Resorcinol could cause green discoloration of the urine.[1]

1. Karlstrand J. The pharmacist and the ostomate. *J Am Pharm Assoc* 1977; **NS17:** 735–8.

Uses and Administration

Resorcinol has keratolytic properties and has been used, usually with sulfur, in topical preparations for the treatment of acne (p.1577) and seborrhoeic skin conditions (p.1584), although other treatments are generally preferred.

Resorcinol has also been used in preparations for the treatment of anorectal disorders often complexed with bismuth compounds (see Haemorrhoids, p.1697).

Resorcinol monoacetate has been used similarly but may provide a milder action with a longer duration.

Dentistry. Resorcinol powder added incrementally to a few drops of formaldehyde 40% solution to saturation and polymerised using 1 or 2 drops of sodium hydroxide 10% solution produces a hard red material, known as "Russian Red". This resin has been used in dentistry in eastern Europe, Russia, and China. Zinc oxide or barium sulfate is often added to the mixture before polymerisation to make it radio-opaque.[1]

1. Schwandt NW, Gound TG. Resorcinol-formaldehyde resin "Russian Red" endodontic therapy. *J Endod* 2003; **29:** 435–7.

Preparations

BPC 1973: Magenta Paint;

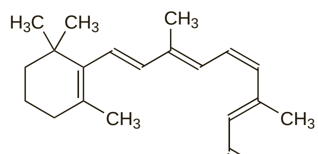
Retinaldehyde

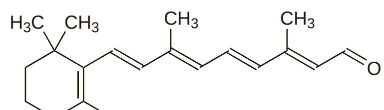
Retinal; Retinene; Vitamin A Aldehyde.

Ретинальдегид

$C_{20}H_{28}O$ = 284.4.
CAS — 116-31-4.



11-*cis* Retinaldehyde



all-*trans* Retinaldehyde

Profile

Retinaldehyde is a derivative of vitamin A (p.1971) that has been used in preparations for skin disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Ystheal; ***Chile:*** Ystheal.

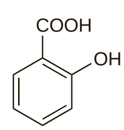
Multi-ingredient: ***Arg.:*** Diacneal; Diroseal; ***Chile:*** Diacneal; Diroseal; ***Fr.:*** Diroseal; ***Venez.:*** Diacneal.

Salicylic Acid

Acide salicylique; Acido Ortóxibenzoico; Acidum salicylicum; Kwas salicylowy; Kyselina salicylová; Salicílico, ácido; Salicilo rūgštis; Salicylsyra; Salisilik Asit; Salisyylihappo; Salizylsäure; Szalicilsav. 2-Hydroxybenzoic acid.

Салициловая Кислота

$C_7H_6O_3$ = 138.1.
CAS — 69-72-7.
ATC — D01AE12; S01BC08.
ATC Vet — QD01AE12; QS01BC08.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Salicylic Acid). White or colourless acicular crystals or a white or almost white, crystalline powder. Slightly soluble in water; freely soluble in alcohol; sparingly soluble in dichloromethane. Protect from light.

USP 31 (Salicylic Acid). White crystals, usually in fine needles or a white, fluffy, crystalline powder. The synthetic form is white and odourless but if prepared from natural methyl salicylate it may have a slightly yellow or pink tint, and a faint, mint-like odour. Soluble 1 in 460 of water, 1 in 15 of boiling water, 1 in 3 of alcohol, 1 in 45 of chloroform, 1 in 3 of ether, and 1 in 135 of benzene.

Adverse Effects and Precautions

Salicylic acid is a mild irritant and application of salicylic acid preparations to the skin may cause dermatitis. Preparations containing high concentrations of salicylic acid can cause skin ulceration or erosion; healthy skin surrounding warts, corns, and calluses should be protected with soft paraffin or specially designed plasters when such preparations are being used. Salicylic acid should be used with care on the extremities of patients with impaired peripheral circulation or diabetes; caution has also been suggested if caustic preparations are used in patients with significant peripheral neuropathy. The drug is readily absorbed through the skin, and symptoms of acute systemic salicylate poisoning (see Aspirin, p.20) have been reported after excessive use; deaths have occurred, mainly in children. To minimise absorption after topical application salicylic acid should not be used for prolonged periods, in high concentrations, on large areas of the body, or on inflamed or broken skin. Contact with mouth, eyes, and other mucous membranes should be avoided.

Uses and Administration

Salicylic acid has **keratolytic** properties and is applied topically in the treatment of hyperkeratotic and scaling skin conditions such as dandruff and seborrhoeic dermatitis (p.1584), ichthyosis (p.1580), psoriasis (p.1583), and acne (p.1577). Preparations usually contain between 2 and 6% salicylic acid, but a wider range of concentrations has been used. It is often used with other drugs, notably coal tar.

Preparations containing up to 60% salicylic acid have been used as a **caustic** for the removal of plantar warts (p.1584), corns, or calluses; surrounding healthy skin should be protected (see above).

Salicylic acid also possesses **fungicidal** properties and is used topically in the treatment of dermatophyte skin infections (see p.521); propyl salicylate and bromosalicylic acid have been used similarly.

Zinc salicylate has been used similarly to salicylic acid in the treatment of seborrhoeic dermatitis and acne.

Preparations

BP 2008: Coal Tar and Salicylic Acid Ointment; Compound Benzoic Acid Ointment; Dithranol Paste; Salicylic Acid Collodion; Salicylic Acid Ointment; Zinc and Salicylic Acid Paste;
BPC 1973: Salicylic Acid and Sulphur Ointment;
USP 31: Benzoic and Salicylic Acids Ointment; Salicylic Acid Collodion; Salicylic Acid Gel; Salicylic Acid Plaster; Salicylic Acid Topical Foam; Zinc Oxide and Salicylic Acid Paste.

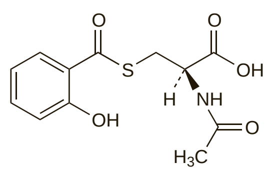
Salnacedin *(USAN, rINN)*

G-201; Salnacedina; Salnacédine; Salnacedinum; SCY. *N*-Acetyl-L-cysteine salicylate.

Сальнацедин

$C_{12}H_{13}NO_5S$ = 283.3.

CAS — 87573-01-1.



Profile

Salnacedin has anti-inflammatory and keratolytic properties and is applied topically in the treatment of seborrhoeic dermatitis and acne.

Preparations

Proprietary Preparations (details are given in Part 3)
Port.: Encaskin Creme†; Encaskin Detergente†; ***Switz.:*** Encaskin Cream; Encaskin Liquid Detergent.

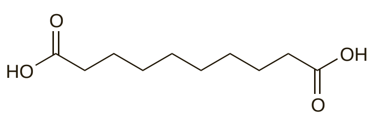
Sebacic Acid

Ácido decanodioico; Sebácico, ácido. Decanedioic acid; Octane-1,8-dicarboxylic acid.

Себациновая Кислота

$C_{10}H_{18}O_4$ = 202.2.

CAS — 111-20-6.



Profile

Sebacic acid may be used as a buffering agent in cosmetic preparations. Some of its esters, such as diethyl sebacate ($C_{14}H_{26}O_4$ = 258.4) and diisopropyl sebacate ($C_{16}H_{30}O_4$ = 286.4) may be used as emollients.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Port.:*** Pirrolfungin†.

Selenium Sulfide

Seleenidisulfidi; Selendisulfid; Seleni Disulfidum; Selenii disulfidum; Selenio, sulfuro de; Sélénium, disulfure de; Selenium Disulphide; Selenium Sulphide; Seleno disulfidas; Sulfid seleničitý; Szelén-diszulfid.

Сульфид Селения

SeS_2 = 143.1.

CAS — 7488-56-4.

ATC — D01AE13.

ATC Vet — QD01AE13.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Selenium Disulphide; Selenium Sulphide BP 2008). A bright orange to reddish-brown powder. Practically insoluble in water.

USP 31 (Selenium Sulfide). A bright orange to reddish-brown powder with not more than a faint odour. Practically insoluble in water and in organic solvents; soluble 1 in 161 of chloroform and 1 in 1667 of ether.

Adverse Effects, Treatment, and Precautions

Topical application of selenium sulfide can produce irritation of the scalp and skin, especially in the genital area and skin folds. Treated areas should be rinsed thoroughly to reduce inflammation, and contact with the eyes should be avoided. Oiliness or dryness of the scalp or hair, hair discoloration, and hair loss have been reported. Selenium sulfide shampoos should not be used within 48 hours of applying hair colours or straightening or waving preparations. Selenium sulfide may discolour metals.

Only traces of selenium sulfide are absorbed through intact skin but prolonged use on broken skin has resulted in systemic toxicity. To minimise absorption it should not be applied to mucous membranes or to skin that is inflamed or damaged. Toxicity is expected to be low from the ingestion of shampoos containing selenium sulfide. Nausea, vomiting, and diarrhoea may occur and gastrointestinal decontamination is generally considered unnecessary, but systemic absorption and toxicity, particularly neurological effects, might develop if large amounts are retained in the gut.

Systemic toxicity. A woman with excoriated eruptions on her scalp developed weakness, anorexia, abdominal pain, vomiting, tremors, sweating, a metallic taste in her mouth, and a garlic-like smell on her breath after using a shampoo containing selenium sulfide 2 or 3 times weekly for 8 months.[1] All symptoms subsided 10 days after the shampoo was stopped.

1. Ransone JW, *et al.* Selenium sulfide intoxication. *N Engl J Med* 1961; **264:** 384–5.

Uses and Administration

Selenium sulfide has antifungal and antiseborrhoeic properties. It is used topically in the treatment of dandruff (pityriasis capitis) and seborrhoeic dermatitis of the scalp (p.1584). Five to 10 mL of a lotion or shampoo containing 2.5% of selenium sulfide is applied to the wet scalp; the hair is rinsed and the application repeated; the preparation should remain in contact with the scalp for 2 to 3 minutes each time. The hair should be well rinsed after the treatment and all traces of the preparation removed from the hands and nails. Applications are usually made twice weekly for 2 weeks, then once weekly for 2 weeks and then only when necessary. Shampoos and lotions containing 1% are also used.

Selenium sulfide is also used as a 2.5% lotion in the treatment of pityriasis versicolor (see Skin Infections, p.521). The lotion may be applied to the affected areas with a small amount of water and allowed to remain for 10 minutes before thorough rinsing. This procedure is repeated once daily for about 7 days. Alternatively undiluted 2.5% lotion has been applied at bedtime and washed off in the morning on 3 separate occasions at 3-day intervals.

Selenium sulfide has also been used as an adjunct to the systemic treatment of tinea capitis (see Dermatophytoses under Skin Infections, p.521).

Preparations

BP 2008: Selenium Sulphide Scalp Application;
USP 31: Selenium Sulfide Topical Suspension.

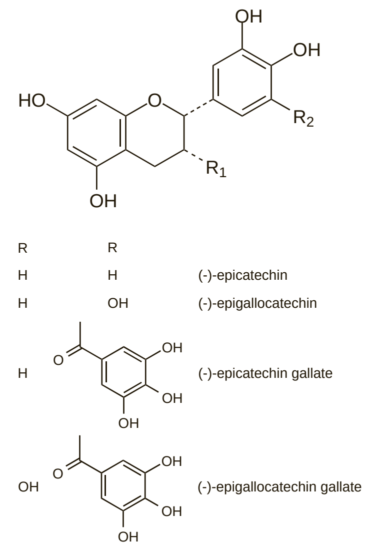
Sinecatechins *(USAN)*

Kunecatechins. A mixture whose major constituents are (−)-epicatechin, (−)-epigallocatechin, the corresponding 3-gallate esters, and their corresponding epimers.

CAS — 811420-59-4 (sinecatechins); 490-46-0 ((−)-epicatechin); 1257-08-5 ((−)-epicatechin 3-O-gallate); 970-74-1 ((−)-epigallocatechin); 989-51-5 ((−)-epigallocatechin 3-O-gallate).



Profile

Sinecatechins is a mixture of complex polyphenols extracted from green tea leaves. Although its mechanism of action is unclear, sinecatechins is used in the treatment of external genital and perianal warts (p.1584). A 15% ointment is applied 3 times daily until complete clearance of all warts, but for no longer than 16 weeks. Local adverse effects are common with the topical application of sinecatechins and include erythema, pruritus, burning, pain or discomfort, erosion or ulceration, oedema, induration, and vesicular rash. Less common effects include urethritis, pigmentation changes, and hyperaesthesia.

Skin Substitutes

Sustitutos de la piel.

Profile

Biological and semisynthetic materials have been developed for use as temporary dressings in burns, ulcers, and other injuries associated with skin loss. The rationale is to prevent fluid and heat loss, to reduce infection, to protect exposed structures, to reduce pain, and to prepare the site for grafting (see Burns, p.1578, and Wounds and Ulcers, p.1585).

Denatured porcine and bovine skin, consisting of the dermal and/or epidermal layers, have been used. More recently bioengineered human skin equivalents have been produced which more closely mimic human skin, as well as human, living dermal replacement products.

Sulfur

Azufre; Enxôfre; Kén; Kükürt; Rikki; Schwefel; Siarka; Síra; Soufre; Sulphur; Sulphurium; Svavel.

Сера

S = 32.065.

CAS — 7704-34-9.
ATC — D10AB02.
ATC Vet — QD10AB02.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US.* Some have monographs for Precipitated Sulfur (Milk of Sulfur), Sublimed Sulfur (Flowers of Sulfur), or both. Some specify it is only for external use.

Ph. Eur. 6.2 (Sulphur for External Use). A yellow powder. The size of most of the particles is not greater than 20 micrometres and that of almost all the particles is not greater than 40 micrometres. Practically insoluble in water; soluble in carbon disulfide; slightly soluble in vegetable oils. Protect from light.

USP 31 (Precipitated Sulfur). A very fine, pale yellow, odourless, amorphous or microcrystalline powder. Practically insoluble in water; very slightly soluble in alcohol; slowly and usually incompletely soluble 1 in 2 of carbon disulfide; soluble 1 in 100 of olive oil.

USP 31 (Sublimed Sulfur). A fine, yellow, crystalline powder with a faint odour. Practically insoluble in water and in alcohol; sparingly soluble in olive oil.

Adverse Effects and Precautions

Topical application of sulfur can cause skin irritation and dermatitis has been reported after repeated application. Contact with the eyes, mouth, and other mucous membranes should be avoided. Contact with sulfur can discolour certain metals such as silver, and application of sulfur with topical mercurial compounds can lead to the generation of hydrogen sulfide which has a foul odour and may stain the skin black.

Handling. Sulfur has been used for the illicit preparation of explosives or fireworks; care is required with its supply.

Uses and Administration

Sulfur is a keratolytic, a mild antiseptic, a mild antifungal, and a parasiticide.

Colloidal sulfur has a smaller particle size than either precipitated or sublimed sulfur. It is sulfur in an aqueous medium containing a colloid such as albumin or gelatin.

Sulfur has been widely used in lotions, creams, or ointments, usually combined with other agents, in concentrations of up to 10% in the treatment of acne, dandruff, seborrhoeic conditions, scabies, and superficial fungal infections, although there are more convenient and effective preparations.

Lotions of precipitated sulfur with lead acetate have been used to darken grey hair.

Sulfur was also formerly used as a mild irritant laxative.

Sulfur is used in homoeopathic medicine.

Sulfurated Lime

Cal sulfurada; Calcium Sulphide; Calx Sulphurata; Sulfuro cálcico; Sulphurated Lime.

Сернистый Кальций (calcium sulfide); Сульфид Кальция (calcium sulfide)

CAS — 8028-82-8 (sulfurated lime solution).

Profile

Sulfurated lime is a mixture containing calcium sulfate and not less than 50% of calcium sulfide (CaS), prepared by heating calcium sulfate with carbonaceous matter. Sulfurated lime solution (Vleminckx's solution) is an aqueous solution containing calcium polysulfides and calcium thiosulfate prepared by boiling sublimed sulfur with calcium hydroxide in water.

Sulfurated lime has been used topically as sulfurated lime solution for acne, scabies, seborrhoeic dermatitis, and pustular infections such as boils and carbuncles. A similar solution known as 'lime-sulphur' is used as a fungicide in horticulture.

An impure grade of calcium sulfide (Hepar Sulphuris; Hepar Sulph.) is used in homoeopathic medicine.

NOTE. The title Hepar Sulfuris is also applied to Sulfurated Potash (see below).

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Cz.:*** Homeovox.

Sulfurated Potash

Foie de Soufre; Hepar Sulfuris; Hígado de azufre; Kalii Sulfidum; Liver of Sulphur; Potasa sulfurada; Potassa Sulphurata; Schwefelleber; Sulphurated Potash.

Серная Печень

CAS — 39365-88-3.

NOTE. The title Hepar Sulphuris is used in homoeopathic medicine for an impure grade of calcium sulfide—see Sulfurated Lime, above.

Pharmacopoeias. In *US.*

USP 31 (Sulfurated Potash). A mixture composed chiefly of potassium polysulfides and potassium thiosulfate, containing not less than 12.8% of sulfur as sulfide. Irregular, liver-brown pieces when freshly made, changing to greenish-yellow. It has an odour of hydrogen sulfide. Soluble 1 in 2 of water, usually leaving a slight residue. Alcohol dissolves only the sulfides. A 10% solution is light brown in colour and alkaline to litmus. Store in small, airtight containers.

Incompatibility. Sulfurated potash is incompatible with acids.

Profile

Sulfurated potash has been used in the treatment of acne and other skin disorders usually in the form of a lotion with zinc sulfate.

Preparations

USP 31: Zinc Sulfide Topical Suspension.

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austria:*** Leukona-Sulfomoor-Bad†.

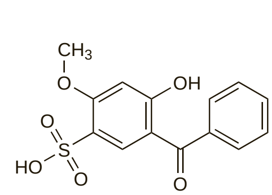
Sulisobenzone *(USAN, rINN)*

Benzofenon-4; Benzophenone-4; NSC-60584; Sulisobenzona; Sulisobenzonum. 5-Benzoyl-4-hydroxy-2-methoxybenzenesulphonic acid.

Сулизобензон

$C_{14}H_{12}O_6S$ = 308.3.

CAS — 4065-45-6.



NOTE. Escalol 577 and Uvinul MS 40 are trade names that have been used for sulisobenzone.

Pharmacopoeias. In *US.*

USP 31 (Sulisobenzone). Light tan powder. M.p. about 145°. Freely soluble in water, in alcohol, and in methyl alcohol; sparingly soluble in ethyl acetate. Store in airtight containers. Protect from light.

Profile

Sulisobenzone, a substituted benzophenone, is a sunscreen (p.1576) with actions similar to those of oxybenzone (p.1608). It is effective against UVB and some UVA light (for definitions, see p.1580).

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Nubevital BB; Nubevital Sunblock Ultra; Refrane Plus; ***Braz.:*** Sunmax Acqua; ***Canad.:*** Hawaiian Tropic Herbal†; ***Chile:*** Hidrafil; Spectraban 55; ***Mex.:*** Spectraban 55; ***USA:*** Hawaiian Tropic Protective Tanning Dry.

T4 Endonuclease V

Bacteriophage T4 Endodeoxyribonuclease V; T4N5. Coliphage T4 endodeoxyribonuclease V.

T4 Эндонуклеаза V

CAS — 52227-85-7.

Profile

T4 endonuclease V is a DNA-repair enzyme that is reported to remove DNA damaged by UV radiation. It is under investigation to reduce the incidence of actinic keratosis and basal cell carcinoma in patients with xeroderma pigmentosum (see Photosensitivity Disorders, p.1581).

◊ References.

Tacalcitol *(BAN, rINN)*

1α,24-Dihydroxycholecalciferol; 1α,24-Dihydroxyvitamin D_3; Tacalcitolum; Takalsitol. (+)-(5*Z*,7*E*,24*R*)-9,10-Secocholesta-5,7,10(19)-triene-1α,3β,24-triol monohydrate.

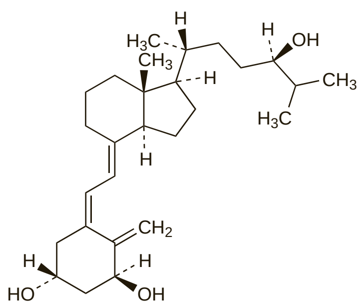
Такальцитол

$C_{27}H_{44}O_3,H_2O$ = 434.7.

CAS — 57333-96-7 (anhydrous tacalcitol); 93129-94-3 (tacalcitol monohydrate).

ATC — D05AX04.

ATC Vet — QD05AX04.



Adverse Effects and Precautions

As for Calcipotriol, p.1591. Paraesthesia may also occur. Tacalcitol may be applied to the face, but care should be taken to avoid the eyes. Tacalcitol may be degraded by UV radiation (see Uses and Administration, below).

Uses and Administration

Tacalcitol is a vitamin D_3 derivative, with actions and uses similar to those of calcipotriol (p.1592).

Tacalcitol is applied topically in the management of plaque psoriasis (p.1583). It is used as the monohydrate, but the concentration is expressed in terms of anhydrous tacalcitol; 4.17 micrograms of tacalcitol monohydrate is equivalent to about 4 micrograms of tacalcitol. It is applied as an ointment containing the equivalent of tacalcitol 4 micrograms/g (0.0004%). Applications are made once daily, preferably at bedtime, and no more than 10 g of ointment should be applied each day. Duration of treatment depends on the severity of the lesions; continuous and intermittent treatments for up to 12 months have been used.

Tacalcitol may be degraded by UV radiation and therefore if combined with UV therapy, the radiation should be given in the morning and tacalcitol applied at bedtime.

Purified Talc

E553(b); Mastek; Powdered Talc; Purified French Chalk; Talc; Talco (esteatita); Talco purificado; Talcum; Talcum Purificatum; Talk; Talkas; Talkki; Talkum.

Очищенный Тальк

CAS — 14807-96-6.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Talc; Purified Talc BP 2008). A powdered, selected, natural, hydrated, magnesium silicate. Pure talc has the formula $Mg_3Si_4O_{10}(OH)_2$; it may contain varying amounts of associated minerals. A light, homogeneous, white or almost white powder, greasy to the touch (non-abrasive). It should be free from asbestos. Practically insoluble in water, in alcohol, and in dilute solutions of acids and of alkali hydroxides.

USP 31 (Talc). A powdered, selected, natural, hydrated magnesium silicate. It may contain variable amounts of associated minerals among which chlorites (hydrated aluminium and magnesium silicates), magnesite (magnesium carbonate), calcite (calcium carbonate), and dolomite (calcium and magnesium carbonate) are predominant. A very fine, white or greyish-white, unctuous crystalline powder, which adheres readily to the skin, and is free from grittiness.

Adverse Effects and Precautions

Contamination of wounds or body cavities with talc is liable to cause granulomas and it should not be used for dusting surgical gloves.

Inhalation of talc can cause respiratory irritation; prolonged exposure may produce pneumoconiosis.

The most common adverse effects of talc pleurodesis are chest pain and fever. More serious complications that can occur include empyema, pneumonitis, dyspnoea, hypoxaemia, pulmonary oedema, pulmonary embolism, acute respiratory distress syndrome, and respiratory failure. Cardiovascular complications such as tachycardia, myocardial infarction, hypotension, hypovolaemia, and asystolic arrest have also occurred in patients treated with talc pleurodesis. However, the role of talc in serious complications is not always clear as the underlying condition of patients with malignant pleural effusion and the procedure itself are likely to be contributing factors.

Talc is liable to be heavily contaminated with bacteria, including *Clostridium tetani, Cl. welchii,* and *Bacillus anthracis.* When used in dusting powders or to treat pneumothorax and pleural effusions, it should be sterilised.

Abuse. Adverse pulmonary and ocular effects have been associated with the presence of talc in abused substances. It may be present as an excipient in oral medications that are crushed then dissolved and injected, or it may have been purposely added as a filler to the abused substance. When injected intravenously, the insoluble talc particles can embolise in small pulmonary vessels causing occlusion and pulmonary hypertension. The particles may also then migrate into the pulmonary interstitium, inducing a foreign-body reaction and fibrosis. Irregular nodules can develop in the lungs, which may coalesce to form conglomerate masses.[1] Talc retinopathy is described as deposits of crystalline talc embolising in the retinal microvasculature after intravenous injection.[2-4] Pulmonary granulomas[5] and talc retinopathy[6] have also been described after nasal inhalation of abused substances containing talc.

Carcinogenicity. A review by a working group of the International Agency for Research on Cancer concluded that there was inadequate evidence to confirm whether purified talc was carcinogenic in humans but there was sufficient evidence to confirm that talc containing asbestiform fibres was carcinogenic to man.[1] There have been suggestions of a link between the use of talc and ovarian cancer[2] but although a case-controlled study suggested an approximate doubling of the risk among women after perineal use of talc the working group noted that information was not available on the asbestos content of the talcs.[1] Further case-controlled studies have also reported a positive association between perineal talc use and ovarian cancer, although others have found no association. A large prospective cohort study[3] that included 78 630 women found little support for an association overall, although from an analysis by histological subtype there appeared to be a modest increase in the risk for serous invasive cancer. A meta-analysis[4] that included this cohort study and 15 case-controlled studies did find a positive association between any exposure to perineal talc and the risk of developing ovarian cancer (relative risk 1.33; 95% confidence interval 1.16 to 1.45). However, the authors highlighted possible selection bias and confounding factors that may have resulted in a false-positive association. There was a lack of a clear dose-response relationship, different results for hospital-based and population-based patients, and the timing of exposure to talc in relation to cancer diagnosis was not always known.

An analysis of epidemiological studies in workers involved in milling the raw mineral (not containing asbestos-like fibres) found no evidence of an increased risk of lung cancer; there was some evidence of an excess among miners or other industrial workers exposed to talc, but these populations were also exposed to other potential carcinogens.[5]

Effects on the lungs. Acute respiratory failure has occurred in patients treated with talc pleurodesis, given either as a slurry or by insufflation. In a series of 338 patients treated with insufflation, 4 developed acute respiratory failure and 3 of them died.[1] In another series[2] of 78 patients who underwent 89 procedures using slurry or insufflation, respiratory complications developed after 24 procedures including acute respiratory distress syndrome after 8 procedures in 7 patients of whom 1 died. In a debate based on these and other reports, including some series in which there were no respiratory complications, it was argued[3] that although the risk of acute respiratory distress is small the use of talc for pleurodesis should be abandoned in favour of other drugs such as tetracyclines or bleomycin, or mechanical abrasion of the pleura. The opposing view[4] was that there were many possible causes for acute respiratory distress in these cases, and that talc was still the best pleurodesis agent available. In a prospective randomised comparison in patients with malignant pleural effusion,[5] respiratory complications were more common with insufflation than slurry. The authors noted that the role of talc in causing acute respiratory complications of pleurodesis is unclear and further study is needed.

It has been suggested that acute respiratory distress syndrome after talc pleurodesis may be related to the talc particle size. There were no such reactions in a study[6] of 558 patients given large-particle (mean size 24.5 μm) talc insufflation, and the authors suggested that reported cases appeared to occur in countries where talc products contained higher concentrations of small particles (less than 5 μm).

For other effects on the lungs, see under Abuse, above and Infant Skin Care, below.

Infant skin care. The routine use of non-medicated powders in the skin care of infants can be hazardous and their use should be discouraged.[1,2] Talc acts as a pulmonary irritant and inhalation of baby-powders by infants has caused severe respiratory difficulties and several deaths have been reported. Careful respiratory monitoring is indicated in children suspected of inhaling talcum powder as the onset of symptoms may be delayed for several hours.[1] There have also been reports of umbilical granulomas resulting from contamination of umbilical stumps with talcum powder used for skin care.[2]

Uses and Administration

Purified talc is used in massage and as a dusting powder to allay irritation and prevent chafing. It is usually mixed with starch, to increase absorption of moisture, and zinc oxide. Talc used in dusting powders should be sterilised. Purified talc is used as a lubricant and diluent in making tablets and capsules and to clarify liquids.

Sterile purified talc is also used as a sclerosant after drainage of malignant pleural effusion and for recurrent spontaneous pneumothorax. It is administered into the pleural cavity as a slurry or by aerosol (insufflation). Doses of about 5 g may be used for pleural effusion and 2 g for pneumothorax.

Pleural effusions. Talc is used as a sclerosant to achieve pleurodesis in the management of benign and malignant pleural effusions (p.659) and recurrent spontaneous pneumothorax.[1-4] It is generally given into the pleural space as a slurry via intercostal tube, or by insufflation (talc poudrage) at thoracoscopy. Most reports have used a dose of 2 to 5 g, but doses have ranged from 1 to 10 g. A study[5] of talc pleurodesis in patients with malignant pleural effusion found both slurry and insufflation to be equally effective. The most common adverse effects associated with this use of talc are pain and fever. Other reported effects have included local infection and empyema, cardiovascular complications, and respiratory failure (see also Effects on the Lungs, above).

Tars and Tar Oils

Breas y aceites de brea.

Birch Tar Oil

Aceite de abedul; Aceite de brea de abedul; Birkenteer; Goudron de Bouleau; Oleum Betulae Albae; Oleum Betulae Empyreumaticum; Oleum Betulae Pyroligneum; Oleum Rusci; Pix Betulae; Pyroleum Betulae.

Масло Берестового Дёгтя

Description. Birch tar oil is obtained by the destructive distillation of the wood and bark of the silver birch, *Betula verrucosa* (*B. pendula*; *B. alba*), and the birch, *B. pubescens* (Betulaceae); the distillate is allowed to stand and the oily upper layer separated from the residual tar.

Cade Oil

Alquitrán de Enebro; Ardıç Katranı; Brea de enebro; Goudron de Cade; Juniper Tar; Juniper Tar Oil; Kad Yağı; Kadeöl; Oleum Cadinum; Oleum Juniperi Empyreumaticum; Pix Cadi; Pix Juniperi; Pix Oxycedri; Pyroleum Juniperi; Pyroleum Oxycedri; Wacholderteer.

Можжевеловое Масло

Description. Cade oil contains guaiacol, ethylguaiacol, creosol, and cadinene.

Pharmacopoeias. In *US.*

USP 31 (Juniper Tar). The empyreumatic volatile oil obtained from the woody portions of *Juniperus oxycedrus* (Pinaceae). It is a dark brown, clear, thick liquid with a tarry odour. Very slightly soluble in water; soluble 1 in 9 of alcohol; soluble 1 in 3 of ether leaving only a slight flocculent residue; partially soluble in petroleum spirit; miscible with amyl alcohol, with chloroform, and with glacial acetic acid. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Coal Tar

Alcatrão Mineral; Alquitrán de hulla; Brea de hulla; Crude Coal Tar; Goudron de Houille; Kamenouhelný dehet; Katran; Oleum Lithanthracis; Pix Carbon.; Pix Carbonis; Pix Lithanthracis; Pix Mineralis; Pyroleum Lithanthracis; Steinkohlenteer.

Каменноугольная Смола

Description. Prepared coal tar is commercial coal tar heated at 50° for 1 hour.

Alcoholic solutions of coal tar or prepared coal tar prepared with the aid of polysorbate have been referred to as Liquor Picis Carbonis and Liquor Carbonis Detergens.

Pharmacopoeias. In *Br., Fr., Int.,* and *US.*

BP 2008 (Coal Tar). A product obtained by the destructive distillation of bituminous coal at a temperature of about 1000°. A nearly black, viscous liquid with a strong characteristic penetrating odour. On exposure to air it gradually becomes more viscous. It burns in air with a luminous sooty flame. Slightly soluble in water; partly soluble in absolute alcohol, in chloroform, in ether, and in volatile oils. A saturated solution is alkaline to litmus.

USP 31 (Coal Tar). The tar obtained by the destructive distillation of bituminous coal at temperatures in the range of 900° to 1100°. It may be processed further either by extraction with alcohol and suitable dispersing agents and maceration times or by fractional distillation with or without the use of suitable organic solvents.

A nearly black, viscous liquid with a characteristic naphthalene-like odour. Slightly soluble in water to which it imparts an alkaline reaction; partially soluble in alcohol, in acetone, in carbon disulfide, in chloroform, in ether, in methyl alcohol, and in petroleum spirit; more soluble in benzene; almost completely soluble in nitrobenzene. Store in airtight containers.

Tar

Alquitrán vegetal; Brea; Brea de pino; Brea vegetal; Goudron Végétal; Nadelholzteer; Pine Tar; Pix Abietinarum; Pix Liquida; Pix Pini; Pyroleum Pini; Wood Tar.

Древесная Смола; Древесный Дёготь

Pharmacopoeias. In *Br.*

BP 2008 (Tar). A bituminous liquid obtained from the wood of various trees of the family Pinaceae by destructive distillation. It is known in commerce as Stockholm Tar. A dark brown or nearly black semi-liquid with a characteristic empyreumatic odour; it is heavier than water. Soluble in alcohol (90%), in chloroform, in ether, and in fixed and volatile oils. The aqueous liquid obtained by shaking 1 g with 20 mL of water for 5 minutes is acidic to litmus paper.

Storage. When stored for some time tar separates into a layer which is granular in character due to minute crystallisation of catechol, resin acids, etc. and a surface layer of a syrupy consistence.

Adverse Effects and Precautions

Tars and tar oils may cause irritation and acne-like eruptions of the skin and should not be applied to inflamed or broken skin, mucosa, or the anogenital area. They should be used with caution on the face and skin flexures. Hypersensitivity reactions are rare but wood tars are more likely to cause sensitisation than coal tar. However, unlike wood tars, coal tar has a photosensitising action. Preparations of refined tar products appear to be less likely than crude tars to stain the skin, hair, and clothing.

Depending on their composition the systemic effects of tars and tar oils are similar to those for phenol (see p.1656).

Carcinogenicity. Coal tar and coal tar distillates contain a number of known and potential carcinogens including benzene, naphthalene, and other polycyclic aromatic hydrocarbons.[1] Studies of occupational exposure (for example, during coke production, coal gasification, and aluminium production) have found systemic absorption of significant amounts of polycyclic aromatic hydrocarbons,[2] and increases in the risks of developing a range of cancers.[1,2] Systemic absorption of polycyclic aromatic hydrocarbons has also been measured after the application of coal tar preparations used in the treatment of skin conditions.[2] However, although an increased risk of skin carcinoma was found[3] in 59 patients with psoriasis who had had very high exposures to tar and/or UV radiation, other cohort studies[4-6] found no increase in the risk of developing cancers from coal tar, even after long-term use.

6. Stern RS, Laird N. The carcinogenic risk of treatments for severe psoriasis. *Cancer* 1994; **73:** 2759–64.

Extemporaneous preparation. Concern about the possible carcinogenic potential of coal tar (see above) led the Health and Safety Executive in the UK to recommend that gloves for chemical protection, as opposed to disposable surgeon's gloves, should be worn during the extemporaneous preparation of formulations containing coal tar.[1]

1. Anonymous. Chemical protection gloves recommended for coal tar ointments. *Pharm J* 1997; **259:** 757.

Uses and Administration

Tars and tar oils can reduce the thickness of the epidermis. They are antipruritic and may be weakly antiseptic. They are used topically in eczema (p.1579), psoriasis (below), dandruff, seborrhoeic dermatitis (p.1584), and other skin disorders. Coal tar preparations have largely replaced the use of wood tars. Ultraviolet (UVB) light increases the efficacy of coal tar in the treatment of psoriasis.

Some wood tars, including creosote (p.1555) have been used in expectorant preparations.

Nonprescription use. After a review of products for safety and efficacy the FDA ruled that cade oil or tar should not be used in nonprescription shampoos[1] and that tar should no longer be included in nonprescription expectorants.[2]

2. Anonymous. FDA announces standards for nonprescription sleep-aid products and expectorants. *Clin Pharm* 1989; **8:** 388.

Psoriasis. Coal tar has long been employed in the treatment of psoriasis (p.1583), and used alone or with dithranol and/or ultraviolet light it continues to be a first-line option, although its use is declining. It is particularly suited to the treatment of stable chronic plaque psoriasis. Its mode of action is unknown but it is considered to have antiproliferative and anti-inflammatory activity, producing a reduction in the thickness of viable epidermis. Crude tar preparations are rather messy and unpleasant; refined products may be more aesthetically acceptable and less likely to stain skin, hair, and clothing although some consider them to be less effective.

Treatments usually start with concentrations equivalent to 0.5 to 1% of crude coal tar with the concentration being increased as necessary every few days up to a maximum of 10%. The higher strength preparations may be required for the management of thicker patches of psoriasis but the British Association of Dermatologists considers that coal tar preparations of between 1 and 5% in white or yellow soft paraffin are as effective as higher concentrations, and that the use of higher concentrations, which has been traditionally advocated, has no evidence-based foundation and is best avoided, especially as it restricts outpatient use.

Coal tar may not clear psoriasis as fast as other agents but extended periods of remission can be obtained with its use. The Goeckerman regimen utilises the enhanced efficacy obtained when coal tar is applied before exposure to ultraviolet (UVB) light. The mechanism for this effect is not known but it does not appear to be due to the photosensitising action of coal tar. In most regimens the coal tar is applied 2 hours before exposure to UVB light. In Ingram's regimen and its modifications the use of coal tar and UVB light is followed by topical treatment with dithranol. It has been suggested that the irritant effects of dithranol treatment can be reduced without loss of efficacy if coal tar is also used.

Tazarotene *(BAN, USAN, rINN)*

AGN-190168; Tatsaroteeni; Tazaroten; Tazarotène; Tazaroteno; Tazarotenum. Ethyl 6-[(4,4-dimethylthiochroman-6-yl)ethynyl]nicotinate.

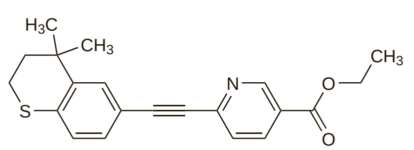
Тазаротен

$C_{21}H_{21}NO_2S$ = 351.5.

CAS — 118292-40-3.

ATC — D05AX05.

ATC Vet — QD05AX05.



Adverse Effects and Precautions

As for Tretinoin, p.1618.

Systemic absorption from tazarotene applied topically is low, and the most frequent adverse effects are on the skin; the incidence of adverse events appears to be concentration related.

Animal studies have indicated that tazarotene is fetotoxic and teratogenic, and licensed product information recommends that tazarotene should not be used during pregnancy or in women planning a pregnancy. Similarly, tazarotene should not be used, or used with caution, during breast feeding, as *animal* data indicate that it may be distributed into breast milk.

Effects on the skin. A 57-year-old man with diabetes and recalcitrant psoriasis on the trunk and limbs developed acute dermatitis[1] in the genital area 2 weeks after starting treatment with topical tazarotene 0.1%. The affected areas became ulcerated over the next few days. It was suspected that accidental contact with the tazarotene that had been applied to the truncal psoriasis was responsible. Pyogenic granuloma has been associated with topical tazarotene and other retinoids given orally or applied topically (see Effects on the Skin, Hair, and Nails, under Isotretinoin, p.1601).

1. Wollina U. Genital ulcers in a psoriasis patient using topical tazarotene. *Br J Dermatol* 1998; **138:** 713–14.

Uses and Administration

Tazarotene is a retinoid used for the topical treatment of mild to moderate acne and plaque psoriasis, and to treat signs of photoageing. Tazarotene is a prodrug that is de-esterified in the skin to its active form, tazarotenic acid. The mode of action is unknown but it appears to modulate cell proliferation and differentiation.

In the treatment of **psoriasis**, tazarotene 0.05% cream or gel is used initially and increased to 0.1% if necessary. It is applied once daily in the evening. In the UK tazarotene is licensed for use in patients with psoriasis affecting up to 10% of the body-surface; in the USA, it may be used on psoriasis involving up to 20% of the body-surface.

In the treatment of **acne**, tazarotene is applied as a 0.1% gel or cream once daily in the evening.

There may be exacerbation of acne during early treatment or of psoriasis at any time during treatment. The treatment period is usually up to 12 weeks, although tazarotene has been used for up to 12 months in the treatment of psoriasis.

A 0.1% cream is used in the topical treatment of certain signs of **photoageing** (facial fine wrinkling, mottled hypo- and hyperpigmentation, and benign facial lentigines). It is applied once daily at bedtime to lightly cover the entire face.

Malignant neoplasms. There has been some interest in the use of topical tazarotene in the treatment of neoplasms affecting the skin. Preliminary studies have reported some lesion regression or clearance in basal cell[1] and squamous cell carcinomas[2] (p.673), and mycosis fungoides[3] (p.657).

Skin disorders. Tazarotene is used for the topical treatment of mild to moderate acne[1,2] (p.1577) and plaque psoriasis[3,4] (p.1583); benefit has also been reported for psoriasis of the nails.[5,6] Improvement has been reported too in keratinisation disorders such as Darier's disease[7,8] (p.1578) and congenital ichthyosis[9-11] (p.1580). Topical tazarotene can also improve some signs of photoageing (p.1581), including fine wrinkling, mottled hyperpigmentation, and lentigines (liver spots).[12-14]

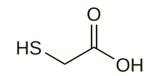
Thioglycollic Acid

Kwas tioglikolowy; Tioglicólico, ácido. Mercaptoacetic acid.

Тиогликолевая Кислота

$C_2H_4O_2S$ = 92.12.

CAS — 68-11-1.



Calcium Thioglycollate

Calcium Mercaptoacetate; Tioglicolato cálcico. Calcium mercaptoacetate trihydrate.

Тиогликолят Кальция

$C_2H_2CaO_2S,3H_2O$ = 184.2.

CAS — 814-71-1.

Profile

Thioglycollic acid is used, usually as the calcium salt, in depilatory preparations. Thioglycollates are also used in hair waving or straightening products with potassium bromate as the neutraliser. There have been reports of skin reactions associated with the use of thioglycollates.

Tioxolone *(BAN, rINN)*

OL-110; Thioxolone; Tioksolon; Tioksoloni; Tioxolon; Tioxolona; Tioxolonum. 6-Hydroxy-1,3-benzoxathiol-2-one; .

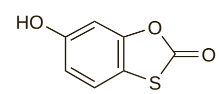
Тиоксолон

$C_7H_4O_3S$ = 168.2.

CAS — 4991-65-5.

ATC — D10AB03.

ATC Vet — QD10AB03.



Pharmacopoeias. In *Pol.*

Profile

Tioxolone has astringent and keratolytic effects, and has been used topically in the treatment of various skin and scalp disorders.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Ger.:*** Loscon†.

Titanium Dioxide

CI Pigment White 6; Colour Index No. 77891; E171; Oxid titaničitý; Titaanidioksidi; Titandioxid; Titán-dioxid; Titane, dioxyde de; Titanii dioxidum; Titanio, dióxido de; Titanium Oxide; Titano dioksidas; Titanyum Dioksit; Tytanu(IV) tlenek.

Двуокись Титана; Диоксид Титана

TiO_2 = 79.87.

CAS — 13463-67-7.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Titanium Dioxide). A white or almost white powder. Practically insoluble in water; it does not dissolve in dilute mineral acids but dissolves slowly in hot concentrated sulfuric acid.

USP 31 (Titanium Dioxide). A white odourless powder. Insoluble in water, in hydrochloric acid, in nitric acid, and in 2N sulfuric acid; dissolves in hot sulfuric acid and in hydrofluoric acid; it is rendered soluble by fusion with potassium bisulfate or with alkali hydroxides or carbonates. A 10% suspension in water is neutral to litmus.

Profile

Titanium dioxide has an action on the skin similar to that of zinc oxide (p.1621) and has similar uses. Titanium peroxide and titanium salicylate are used with titanium dioxide for nappy rash. Titanium dioxide reflects ultraviolet light and is used as a physical sunscreen (p.1576). It is also an ingredient of some cosmetics. It is used to pigment and opacify hard gelatin capsules and tablet coatings and as a delustring agent for regenerated cellulose and other man-made fibres. Specially purified grades may be used in food colours.

Preparations

BP 2008: Titanium Ointment.

Proprietary Preparations numerous preparations are listed in Part 3.

Trafermin *(USAN, rINN)*

CAB-2001; Trafermina; Trafermine; Traferminum. 2-155-Basic fibroblast growth factor (human clone λKB7/λHFL1 precursor reduced).

Трафермин

CAS — 131094-16-1.

Profile

Trafermin is a human recombinant basic fibroblast growth factor (b-FGF) that promotes tissue granulation and the formation of new blood vessels. It is used as a topical liquid spray for the treatment of burns and intractable skin ulcers.

Tretinoin *(BAN, USAN, rINN)*

Ácido retinoico; NSC-122758; Retinoic Acid; Tretinoiini; Tretinoína; Tretinoinas; Trétinoïne; Tretinoinum; Tretynoina; Vitamin A Acid; Vitamina A ácida. *all-trans*-Retinoic acid; 15-Apo-β-caroten-15-oic acid; 3,7-Dimethyl-9-(2,6,6-trimethylcyclohex-1-enyl)nona-2,4,6,8-*all-trans*-tetraenoic acid.

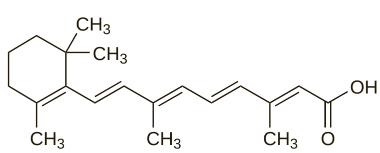
Третиноин

$C_{20}H_{28}O_2$ = 300.4.

CAS — 302-79-4.

ATC — D10AD01; L01XX14.

ATC Vet — QD10AD01; QL01XX14.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Tretinoin). A yellow or light orange crystalline powder. Practically insoluble in water; slightly soluble in alcohol; soluble in dichloromethane. It is sensitive to light, heat, and air, especially in solution. Store in airtight containers at a temperature not exceeding 25°. Protect from light. The contents of an opened container should be used as soon as possible and any unused portion should be protected by an atmosphere of an inert gas.

USP 31 (Tretinoin). A yellow to light-orange crystalline powder. Insoluble in water; slightly soluble in alcohol and in chloroform. Store in airtight containers, preferably under an atmosphere of an inert gas. Protect from light.

Adverse Effects

Tretinoin is a skin irritant. Topical application may cause transitory stinging and a feeling of warmth, and in normal use it produces some erythema, dryness, pruritus, and peeling similar to that of mild sunburn. Sensitive individuals may experience oedema, blistering, and crusting of the skin. Excessive application can cause severe erythema, peeling, and discomfort with no increase in efficacy. Photosensitivity may occur. Temporary hypopigmentation and hyperpigmentation have been reported.

Oral doses of tretinoin may produce similar adverse effects to those of isotretinoin (see p.1599). Adverse cardiovascular effects have also been reported; the most common were arrhythmias, flushing, hypotension, hypertension, and heart failure. Less common events were cardiac arrest, myocardial infarction, cardiomegaly, heart murmur, ischaemia, stroke, myocarditis, pericarditis, pulmonary hypertension, and secondary cardiomyopathy. A potentially life-threatening 'retinoic acid syndrome' (see below) has been described after oral use.

Carcinogenicity. Studies in *mice* suggested that tretinoin could enhance photocarcinogenesis.[1] However, other studies refuted this[2] and evidence indicates that topical tretinoin is not carcinogenic in humans.

Effects on the blood. Transient and asymptomatic thrombocytosis has been reported with the use of oral tretinoin, see under Isotretinoin, p.1599.

Effects on the cardiovascular system. Tretinoin given for induction remission rapidly improves the coagulopathy associated with acute promyelocytic leukaemia, but there are associated reports of arterial and venous thromboembolism. In a number of cases the combination of tretinoin with an antifibrinolytic drug such as tranexamic acid may have increased the risk of thrombosis.[1-3] In other cases,[2,4] thrombosis occurred in the absence of tranexamic acid and appeared to be related to the retinoic acid syndrome (below). An assessment of 124 patients, including 11 who developed thrombosis, found that the expression of particular phenotypic and genotypic features of leukaemic cells may indicate an increased risk of thrombotic events in patients given tretinoin.[5]

For reports associated with other retinoids, see under Isotretinoin, p.1600.

4. Torromeo C, *et al.* Intraventricular thrombosis during all-trans retinoic acid treatment in acute promyelocytic leukemia. *Leukemia* 2001; **15:** 1311–13.
5. Breccia M, *et al.* Occurrence of thrombotic events in acute promyelocytic leukemia correlates with consistent immunophenotypic and molecular features. *Leukemia* 2007; **21:** 79–83.

Effects on the eyes. Papilloedema, retinal haemorrhage and visual changes as a result of benign intracranial hypertension have been associated with oral tretinoin;[1] children appear to be particularly sensitive. For further information about oral retinoids, including tretinoin, causing benign intracranial hypertension, see Effects on the Eyes under Isotretinoin, p.1600.

1. Mahmoud HH, *et al.* Tretinoin toxicity in children with acute promyelocytic leukaemia. *Lancet* 1993; **342:** 1394–5.

Effects on the musculoskeletal system. For reports of myositis occurring in patients receiving oral tretinoin, see under Isotretinoin, p.1600.

Effects on the nervous system. Neurotoxicity (ataxia, dysarthria, and headache) has been reported in a woman with liver impairment using topical tretinoin 0.025% for acne.[1]

1. Bernstein AL, Leventhal-Rochon JL. Neurotoxicity related to the use of topical tretinoin (Retin-A). *Ann Intern Med* 1996; **124:** 227–8.

Effects on the skin. Painful scrotal ulcers, often accompanied by fever, have occurred in men receiving oral tretinoin for acute promyelocytic leukaemia.[1-5] The appearance of the ulcers ranged from days 9 to 30 of the tretinoin course and improved after it was stopped (either at complete remission or because of the ulceration or other adverse effects). Management of the ulcers often included an intravenous or topical corticosteroid and in some cases an antibacterial ointment. Genital ulcers have also been reported in 2 women;[3] an 8-year-old girl developed ulcers 5 days after finishing a course of tretinoin.[6]

Sweet's syndrome (acute febrile neutrophilic dermatosis) has been reported in at least 12 patients treated with oral tretinoin for acute promyelocytic leukaemia.[7] In some cases there was also systemic involvement affecting muscle, kidneys, and lungs, and in a few cases patients also had retinoic acid syndrome (below). Most patients responded to systemic corticosteroid treatment and in some cases the course of tretinoin therapy could be continued as a result. There has also been a report[8] of Sweet's syndrome with myalgia and arthralgia in a child treated with oral tretinoin for acute myeloid leukaemia.

Details of other skin reactions to oral and topical retinoids, including tretinoin, are described under Isotretinoin, p.1601.

Retinoic acid syndrome. A syndrome consisting primarily of fever and respiratory distress developed in 9 of 35 patients between 2 and 21 days after starting induction therapy with oral tretinoin for suspected acute promyelocytic leukaemia.[1] Other symptoms included weight gain, oedema of the lower extremities, pleural or pericardial effusions, and episodic hypotension. Symptoms were life-threatening in 5 patients, 3 of whom subsequently died of multi-system failure. Leucocytosis was frequently, although not invariably, associated with development of the syndrome. Experience showed that early treatment with high-dose corticosteroids should be given to these patients irrespective of the leucocyte count. There have also been a few reports of thrombosis occurring with the retinoic acid syndrome (see Effects on the Cardiovascular System, above).

Reviews[2,3] of this syndrome, known as the 'retinoic acid syndrome', reported that it occurs in about 25% of patients with acute promyelocytic leukaemia treated with tretinoin and that the median time to onset is 10 to 12 days after the start of treatment; the severity of the syndrome varies greatly. A high leucocyte count at diagnosis or a rapidly-increasing count on initiation of therapy appears to increase the likelihood of the syndrome occurring. Close monitoring of leucocyte counts and clinical signs is recommended; high-dose intravenous corticosteroids, and possibly antineoplastic drugs, should be given if symptoms appear or the leucocyte count increases rapidly.

A similar syndrome has been reported in patients with acute promyelocytic leukaemia treated with arsenic trioxide (see p.2260). A capillary leak syndrome, similar to retinoic acid syndrome, has also been described with acitretin (see p.1586).

3. Larson RS, Tallman MS. Retinoic acid syndrome: manifestations, pathogenesis, and treatment. *Best Pract Res Clin Haematol* 2003; **16:** 453–61.

Vasculitic syndromes. For a report of vasculitis associated with oral tretinoin, see under Isotretinoin, p.1601.

Precautions

Contact of tretinoin with the eyes, mouth, or other mucous surfaces should be avoided. It should not be applied to eczematous, sunburnt, or abraded skin and the effects of other topical treatment, especially with keratolytics, should be allowed to subside before topical use of tretinoin. Exposure to UV light and excessive exposure to sunlight should be avoided.

Absorption does not seem to occur to any great extent with topical use. Nevertheless, because of teratogenicity in *animal* studies and isolated cases of congenital abnormalities (see below), licensed product information suggests that the use of topical tretinoin should be avoided during pregnancy. It is not known whether tretinoin is distributed into breast milk, and it should therefore be used topically with caution in breast-feeding mothers.

When tretinoin is given by mouth the precautions described under isotretinoin (see p.1601) should be adopted. Oral tretinoin is contra-indicated in pregnancy and in breast-feeding mothers.

Pregnancy. Although there have been isolated reports[1-4] of congenital abnormalities in infants born to mothers who used tretinoin topically before and during pregnancy, studies involving a total of 415 women[5-7] showed no increased risk for major congenital disorders in infants who had been exposed in the first trimester.

As a characteristic pattern of fetal malformation has been described with the use of oral retinoids, particularly isotretinoin (see p.1601), licensed product information warns that oral tretinoin is contra-indicated during pregnancy and that conception should be avoided for at least one month after the end of treatment. Nevertheless, the outcomes of up to 20 cases have been reviewed,[8,9] in which a course of tretinoin was generally given in the second or third trimester for promyelocytic leukaemia; some women were also given cytotoxic chemotherapy. There were reports of transient pulmonary and cardiac complications in some infants, but no congenital malformations were described. In one case[10] tretinoin was started in the first trimester and continued throughout the pregnancy to avoid the use of cytotoxic chemotherapy. The small-for-date infant was born by caesarean section at week 32 with jaundice and respiratory distress syndrome, which both resolved within 11 days. At 15 months of age the infant had normal growth and development.

Skin fragility. As with other retinoids (see under Isotretinoin, p.1602) the use of depilatory products should be avoided in patients treated with tretinoin. Erosions of the skin occurred in 2 patients after the use of wax depilation on facial areas also being treated topically with tretinoin.[1]

1. Goldberg NS, Zalka AD. Retin-A and wax epilation. *Arch Dermatol* 1989; **125:** 1717.

Interactions

As for Isotretinoin, p.1602.

Tretinoin is metabolised by the hepatic cytochrome P450 isoenzyme system, therefore there is a potential for interaction between oral tretinoin and inhibitors or inducers of these enzymes.

Antifibrinolytics. Thrombotic events have occurred in patients being treated with tretinoin and *tranexamic acid* (see Effects on the Cardiovascular System, above). Licensed product information for tretinoin used in the treatment of acute promyelocytic leukaemia advises caution when it is given with drugs such as *aminocaproic acid*, *aprotinin*, and tranexamic acid, particularly in the first month of treatment.

Minoxidil. For the effect of tretinoin on the percutaneous absorption of minoxidil, see p.1342.

Pharmacokinetics

After oral doses tretinoin is well absorbed from the gastrointestinal tract, and peak plasma concentrations are obtained after 1 to 2 hours. Oral bioavailability is about 50%. Minimal systemic absorption occurs after topical application. Tretinoin is highly bound to plasma proteins. It undergoes metabolism in the liver by the cytochrome P450 isoenzyme system. Metabolites include isotretinoin, 4-oxo-*trans*-retinoic acid, and 4-oxo-*cis*-retinoic acid. The terminal elimination half-life of tretinoin is 0.5 to 2 hours. Tretinoin is excreted in the bile and the urine. There is some evidence that tretinoin induces its own metabolism.

Uses and Administration

Tretinoin is a retinoid and is the acid form of vitamin A (p.1971).

Tretinoin is used primarily in the topical treatment of **acne vulgaris** when comedones, papules, and pustules predominate. It appears to stimulate mitosis and turnover of follicular epithelial cells and reduce their cohesiveness thereby facilitating the extrusion of existing comedones and preventing the formation of new ones. It also appears to have a thinning effect on the stratum corneum. Tretinoin is applied as a cream, gel, or alcoholic solution, usually containing 0.01 to 0.1%. The skin should be cleansed to remove excessive oiliness and dried before applying tretinoin lightly, once or twice daily according to response and irritation; some patients may require less frequent applications. Other topical preparations (including skin moisturisers) should not be applied at the same time as tretinoin is applied, and caution is required if other local irritants are used concurrently. There may be apparent exacerbations of the acne during early treatment and a therapeutic response may not be evident for 6 to 8 weeks. When the condition has resolved maintenance therapy should be less frequent.

Preparations containing 0.02 or 0.05% tretinoin are available for the treatment of mottled hyperpigmentation, roughness, and fine wrinkling of **photodamaged skin**. It is applied once daily at night. Effects may not be seen until about 6 months after starting treatment.

Tretinoin is also used to induce remission in acute promyelocytic **leukaemia**. A daily dose of 45 mg/m^2 is given orally in 2 divided doses with food. Treatment is continued until 30 days after complete remission or 90 days of treatment have been given, whichever occurs first. Dose reduction has been recommended in hepatic or renal impairment (see below).

For the use of tretinoin in children, see below.

A liposomal formulation of tretinoin for intravenous use is under investigation in T-cell non-Hodgkin's lymphoma, and acute and chronic leukaemia.

Administration in children. Although topical tretinoin is not licensed for infantile acne in the UK, the *BNFC* suggests that it may be used under specialist supervision.

The use of oral tretinoin to induce remission in acute promyelocytic leukaemia (see Malignant Neoplasms, below) in children has been studied.[1-3] Although there is less experience than in adults, a similar dosage regimen of 45 mg/m^2 daily (see also above) has been used in children ranging in age from 1 to 16 years. Dose reduction should be considered if severe toxicity, particularly intractable headache, occurs. Although a lower dose of 25 mg/m^2 daily might reduce neurotoxicity[2,3] the two doses have not been directly compared.

Administration in hepatic and renal impairment. Although dosage adjustment has not been studied in patients with hepatic or renal impairment, licensed UK product information suggests that oral doses of tretinoin for acute promyelocytic leukaemia should be reduced to 25 mg/m^2 daily.

There is a report[1] of 2 patients who required dialysis during tretinoin treatment for acute promyelocytic leukaemia and who achieved remission; one was given a dose of 20 mg/m^2 daily in 2 divided doses and the other received 35 mg/m^2 daily in 3 divided doses.

1. Takitani K, *et al.* Pharmacokinetics of all-trans retinoic acid in acute promyelocytic leukemia patients on dialysis. *Am J Hematol* 2003; **74:** 147–8.

Malignant neoplasms. Tretinoin differentiation therapy has become the established treatment for acute promyelocytic leukaemia (APL), a subtype of acute myeloid leukaemia (p.652). Tretinoin is effective in APL because the characteristic chromosomal abnormalities result in an abnormal retinoic acid receptor. When given *orally*, it has produced complete remissions in more than 90% of patients.[1-4] However, the duration of remission is short unless consolidation, usually with an anthracycline- and cytarabine-based regimen, is given concurrently or subsequently. The combination of tretinoin and chemotherapy has been shown to result in improved survival compared with chemotherapy alone.[1,5,6] Prolonged maintenance therapy including intermittent tretinoin also appears to reduce the rate of relapse.[6] Although benefit has been reported with continuous tretinoin maintenance[7] this is generally considered to lead to resistance.[8] A life-threatening syndrome has developed in some patients who have received oral tretinoin for APL (see Retinoic Acid Syndrome, under Adverse Effects, above). Children seem particularly sensitive to the adverse effects of oral tretinoin on the CNS (see also Effects on the Eyes, and Administration in Children, above). A lipid-based *intravenous* formulation of tretinoin is under investigation for the treatment of APL.

Tretinoin has also been tried for *topical* chemoprevention in patients at increased risk of skin cancers, and in the management of oral leucoplakia (see Malignant Neoplasms under Isotretinoin, p.1603).

Skin disorders. Topical treatment with tretinoin has been tried with varying success in a wide range of cutaneous conditions. Its use in acne (p.1577) is well established. Some benefit has also been reported in rosacea[1] (p.1583), in keratinisation disorders such as Darier's disease (p.1578), and in pigmentation disorders (p.1582) such as chloasma.[2] Healing of diabetic foot ulcers (see Diabetic Complications, p.433) was improved in a small placebo-controlled study of topical tretinoin.[3] The 0.05% solution was applied topically for 10 minutes of every day for 4 weeks.

Topical tretinoin is used to improve some of the signs of photoageing (p.1581). Studies have found that tretinoin can improve fine facial wrinkling, with some reduction in coarse wrinkles, tactile roughness, sallowness, irregular pigmentation, and actinic lentigines.[4-6] Tretinoin appears to prevent and repair collagen damage and reduce epidermal melanin content; there is also increased epidermal proliferation and thickening, compaction of the stratum corneum, and deposition of mucinous material.[5] The previous suggestion that skin irritation might be the mechanism behind tretinoin's effects on photodamaged skin has not been supported by clinical study.[4,5] It can take up to 4 months of treatment for a response to develop and the maximum response can be reached between 8 and 12 months. Continued use is necessary to maintain the effect of tretinoin, although it may be used less often.[5,6]

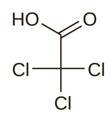
Трихлоруксусная Кислота

$C_2HCl_3O_2$ = 163.4.

CAS — 76-03-9.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Trichloroacetic Acid). A very deliquescent white or almost white crystalline mass or colourless crystals. Very soluble in water, in alcohol, and in dichloromethane. Store in airtight containers.

Adverse Effects and Treatment

As for Hydrochloric Acid, p.2322.

Uses and Administration

Trichloroacetic acid is caustic and astringent. When used as an escharotic for warts it is applied as a strong solution; a range of concentrations have been used including 50% and 80%. The surrounding areas of skin should be protected. Trichloroacetic acid has also been used for the removal of tattoos and in cosmetic surgery for chemical peeling of the skin.

Tattoo removal. References to the use of trichloroacetic acid in the removal of tattoos.

Trioxysalen *(rINN)*

NSC-71047; 4,5′,8-Trimethylpsoralen; Trioksisaleeni; Trioxisalen; Trioxisaleno; Trioxsalen *(USAN)*; Trioxysalène; Trioxysalenum. 2,5,9-Trimethyl-7*H*-furo[3,2-*g*][1]benzopyran-7-one.

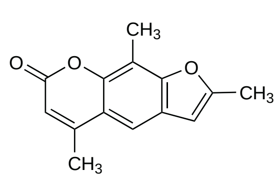
Триоксизален

$C_{14}H_{12}O_3$ = 228.2.

CAS — 3902-71-4.

ATC — D05AD01; D05BA01.

ATC Vet — QD05AD01; QD05BA01.



Pharmacopoeias. In *US.*

USP 31 (Trioxsalen). A white to off-white or greyish, odourless, crystalline solid. Practically insoluble in water; soluble 1 in 1150 of alcohol, 1 in 84 of chloroform, 1 in 43 of dichloromethane, and 1 in 100 of methyl isobutyl ketone. Protect from light.

Profile

Trioxysalen, a psoralen, is a photosensitiser used similarly to methoxsalen in photochemotherapy or PUVA therapy (p.1606).

Trioxysalen is used in idiopathic vitiligo to enhance pigmentation or increase the tolerance to sunlight in selected patients. In vitiligo an oral dose of 10 mg daily is given 2 to 4 hours before exposure to sunlight or ultraviolet radiation; prolonged therapy may be necessary. To increase tolerance to sunlight a dose of 10 mg daily is given 2 hours before exposure; treatment should not be continued for longer than 14 days.

Trioxysalen may also be used topically in the PUVA treatment of psoriasis.

Urea ⊗

Carbamida; Carbamide; E927b; Karbamid; Karbamidi; Močovina; Mocznik; Üre; Urée; Ureia; Urėja; Ureum. Carbonic acid diamide.

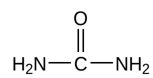
Карбамид; Мочевина

$NH_2.CO.NH_2$ = 60.06.

CAS — 57-13-6.

ATC — B05BC02; D02AE01.

ATC Vet — QB05BC02; QD02AE01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Urea). Transparent, slightly hygroscopic, crystals or a white or almost white, crystalline powder. Very soluble in water; soluble in alcohol; practically insoluble in dichloromethane. Store in airtight containers.

USP 31 (Urea). Colourless or white, practically odourless, prismatic crystals, or white crystalline powder or pellets. May gradually develop a slight odour of ammonia on prolonged standing. Soluble 1 in 1.5 of water, 1 in 10 of alcohol, and 1 in 1 of boiling alcohol; practically insoluble in chloroform and in ether. Solutions are neutral to litmus. Store at a temperature of 25°, excursions permitted between 15° and 30°.

Incompatibility. Urea can cause haemolysis when mixed with blood and should never be added to whole blood for transfusion or given through the same set by which blood is being infused.

Adverse Effects and Precautions

As for Mannitol, p.1330. Urea should also be used with caution in liver impairment as blood-ammonia concentrations can rise, and should be avoided in liver failure.

Urea is reported to be more irritant than mannitol, and intravenous use may cause venous thrombosis or phlebitis at the site of injection; extravasation may cause sloughing or necrosis. Only large veins should be used for infusion, and urea should not be infused into veins of the lower limbs of elderly patients. Extreme care is essential to prevent accidental extravasation of urea infusions.

Rapid intravenous injection of solutions of urea can cause haemolysis; the risk is reduced by using glucose or invert sugar solutions as diluent. Urea should not be mixed with whole blood.

Topical applications may be irritant to sensitive skin.

Infants and neonates. High plasma-urea concentrations have been reported[1,2] in neonates after topical application of emollient creams containing urea. Since there was no evidence of dehydration[2,3] absorption of urea through the skin was the likely cause. Raised plasma-urea concentrations have been reported[4] in infants with erythematous skin conditions who had not been treated with urea cream and this was attributed to dehydration due to increased insensible water loss through the damaged skin.

4. Garty BZ. High plasma urea concentration in babies with lamellar ichthyosis. *Arch Dis Child* 1986; **61:** 1245.

Pregnancy. There have been reports of women suffering coagulopathy associated with urea treatment given for termination of pregnancy.[1,2]

1. Grundy MFB, Craven ER. Consumption coagulopathy after intra-amniotic urea. *BMJ* 1976; **2:** 677–8.
2. Burkman RT, *et al.* Coagulopathy with midtrimester induced abortion: association with hyperosmolar urea administration. *Am J Obstet Gynecol* 1977; **127:** 533–6.

Pharmacokinetics

Urea is fairly rapidly absorbed from the gastrointestinal tract but causes gastrointestinal irritation. Urea is distributed into extracellular and intracellular fluids including lymph, bile, CSF, and blood. It is reported to cross the placenta, and penetrate the eye. It is excreted unchanged in the urine.

Uses and Administration

Urea promotes hydration and is mainly applied topically in the treatment of ichthyosis and hyperkeratotic skin disorders (p.1580). Used intravenously it has osmotic diuretic properties similar to mannitol (p.1331) and has been used in the treatment of acute increases in intracranial pressure (p.1181), due to cerebral oedema, and to decrease intra-ocular pressure in acute glaucoma (p.1873), but has been largely superseded by mannitol. Urea has also been given intra-amniotically for the termination of pregnancy (p.2004).

When applied topically urea has hydrating and keratolytic properties. In the management of ichthyosis and other dry skin disorders it is applied in creams or lotions containing 5 to 25% urea; higher concentrations of 30% and 40% have also been used in severe cases. A preparation containing 40% may be used for nail destruction.

For the reduction of raised intracranial or intra-ocular pressure, urea is given intravenously, as an infusion of a 30% solution in glucose 5 or 10% or invert sugar 10%, at a rate not exceeding 4 mL/minute, in a dose of 0.5 to 1.5 g/kg to a maximum of 120 g daily. Doses used in children are based on the same regimen, but see also below. Rebound increases in intracranial and intra-ocular pressure may occur after about 12 hours.

Solutions of urea 40 to 50% have been given by intra-amniotic injection for the termination of pregnancy.

Urea labelled with carbon-13 (p.2277) is used in the *in vivo* diagnosis of *Helicobacter pylori* infection (see Peptic Ulcer Disease, p.1702). The test involves collecting a breath sample before and after oral ingestion of a single dose of ^{13}C-urea. *H. pylori* produces urease which hydrolyses the urea to carbon dioxide and ammonia; therefore, an excess of carbon-13-labelled carbon dioxide in the sample, compared with a baseline sample, indicates infection. Doses of ^{13}C-urea include 50 mg, 75 mg, or 100 mg depending on the kit being used. Urea labelled with the radionuclide carbon-14 (p.2053) is also used in a urea breath test for *H. pylori* detection.

Administration in children. For the reduction of raised intracranial or intra-ocular pressure in children, urea is given intravenously in dosage regimens similar to those used in adults (see above). However, for children under 2 years of age, a dose of 100 mg/kg may be adequate.

Breath test kits containing ^{13}C-urea for the diagnosis of *Helicobacter pylori* infection are available for children. However, the *BNFC* states that the appropriateness of testing in children has not been established, and that endoscopy with biopsy is more accurate than *in vivo* breath testing, which is frequently unreliable in children.

Ustekinumab *(USAN, pINN)*

CNTO-1275; Ustékinumab; Ustekinumabum. Immunoglobulin G1, anti-(human interleukin-12 subunit beta (IL-12B, CLMF p40, NKSF2))(human monoclonal CNTO 1275 γ1-chain), disulfide with human monoclonal CNTO 1275 κ-chain, dimer.

Устекинумаб

CAS — 815610-63-0.

Profile

Ustekinumab is a human monoclonal antibody that binds to interleukins 12 and 23. It is under investigation in the treatment of psoriasis.

Zinc Carbonate *(USAN)*

Zinc, carbonato de.

Карбонат Цинка; Углекислый Цинк

$ZnCO_3$ = 125.4.

CAS — 3486-35-9.

Basic Zinc Carbonate

Zinc, carbonato básico de.

Основный Карбонат Цинка; Основный Углекислый Цинк

NOTE. The names zinc carbonate, hydrated zinc carbonate, zinc subcarbonate, and zinc carbonate hydroxide have all been applied to basic zinc carbonate of varying composition occurring naturally or produced by the reaction of a soluble zinc salt with sodium carbonate.

Pharmacopoeias. In *US.*

USP 31 (Zinc Carbonate). It corresponds to $3Zn(OH)_2.2ZnCO_3$ containing the equivalent of not less than 70% ZnO. Store in airtight containers.

Profile

Zinc carbonate is mildly astringent and protective to the skin and is used topically, mainly in the form of calamine (p.1591), in a variety of skin conditions. In the USA the name calamine is used for zinc oxide (rather than zinc carbonate) with a small proportion of ferric oxide.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Fr.:*** Pygmal†.

Zinc Oxide

Blanc de Zinc; Blanco de zinc; Cinko oksidas; Çinko Oksit; Cinkoxid; Cynku tlenek; Flores de zinc; Flowers of Zinc; Oxid zinečnatý; Sinkkioksidi; Zinc, óxido de; Zinc, oxyde de; Zinci oxidum; Zinci Oxydum; Zincum Oxydatum; Zinkoxid.

Окись Цинка; Цинк Оксид

ZnO = 81.38.

CAS — 1314-13-2.

NOTE. 'Zinc White' is a commercial form of zinc oxide used as a pigment.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

US also includes a neutral zinc oxide.

Ph. Eur. 6.2 (Zinc Oxide). A white or faintly yellowish-white, soft, amorphous powder, free from gritty particles. Practically insoluble in water and in alcohol; it dissolves in dilute mineral acids.

USP 31 (Zinc Oxide). A white or yellowish-white, odourless, amorphous, very fine powder, free from grittiness. It gradually absorbs carbon dioxide from air. Insoluble in water and in alcohol; soluble in dilute acids.

USP 31 (Zinc Oxide, Neutral). It is for use in sunscreen preparations only.

Incompatibility. Black discoloration has been reported when zinc oxide and glycerol are in contact in the presence of light.

Profile

Zinc oxide is mildly astringent and is used topically as a soothing and protective application in eczema and slight excoriations, in wounds, and for haemorrhoids. It is also used with coal tar (p.1616) or ichthammol (p.1599) in the treatment of eczema. Zinc oxide reflects ultraviolet radiation and is used as a physical sunscreen (see p.1576).

In the USA the name calamine is used for zinc oxide with a small proportion of ferric oxide.

Zinc oxide is used as the basis for the production of a number of dental cements. Mixed with phosphoric acid it forms a hard material composed largely of zinc phosphate; mixed with clove oil or eugenol, it is used as temporary dental filling.

For further details of zinc and its salts, see p.1999.

Complications of dental use. Solitary aspergillosis of the maxillary sinus in 29 of 30 patients was associated with zinc oxide from overfilled teeth.[1] Treatment consisted of removal of the fungal ball containing the zinc oxide; no antifungal treatment was necessary. Zinc oxide has been shown to accelerate the growth of *Aspergillus fumigatus*. Further cases have been reported, and adjunctive systemic antifungal treatment has been used.[2]

This chapter describes those antimicrobial agents that are used for chemical methods of disinfection, antisepsis, preservation, and sterilisation. There is some overlap between these procedures and some agents may be used as both disinfectants and preservatives. Iodine (p.2169), not in this chapter, is also used for its disinfectant properties.

Definition of terms. There is often confusion between the terms disinfectant and antiseptic.

- The term **disinfectant** is applied to a chemical agent that destroys or inhibits the growth of pathogenic micro-organisms in the non-sporing or vegetative state; disinfectants do not necessarily kill all micro-organisms, but reduce them to a level that is harmful neither to health nor the quality of perishable goods. The term is applicable to agents used to treat inanimate objects and materials and may also be applied to agents used to treat the skin and other body membranes and cavities
- An **antiseptic** is a disinfectant that is used on skin and other living tissues thereby limiting or preventing infection
- **Sterilisation** is the total removal or destruction of all living micro-organisms; a few disinfectants (such as ethylene oxide) are capable of producing sterility under suitable conditions but, in general, sterility is produced by heat or radiation methods, with filtration being used for some heat-labile materials. Sterilisation by heating with a bactericide is no longer a recommended practice
- A **preservative** is one of a number of chemical agents that are included in preparations to prevent deterioration from oxidation **(antoxidants)** or to kill or inhibit the growth of micro-organisms inadvertently introduced during manufacture or use **(antimicrobial preservatives)**.

Use of disinfectants. Disinfectants are used in hospitals, industrial establishments, public buildings, on farms, and in the home for control and prevention of infection.

The choice of disinfectant depends on the purpose for which it is used and the likely contaminating organisms. In addition to vegetative bacteria, many common disinfectants could be expected to kill some fungi and lipid-containing viruses. Gram-negative bacteria, mycobacteria, and bacterial spores are generally more resistant to disinfectants, and some disinfectants are less effective against non-lipid enveloped viruses, for example the enteroviruses including polio and coxsackie. Prions are generally resistant to many disinfectants (see Disinfection in Creutzfeldt-Jakob Disease, below). Other factors affecting the effectiveness of disinfectants include the contact time, concentration of the disinfectant, the pH of the system, the number and accessibility of the contaminating micro-organisms, and the presence of interfering substances including lipids, organic matter, rubber, and plastics. Aqueous solutions of disinfectants, particularly quaternary ammonium compounds (such as benzalkonium chloride and cetrimide), chlorhexidine, and phenols, may be susceptible to contamination with micro-organisms. To reduce this risk many preparations are provided for clinical use in a sterile form for single use.

Use of preservatives. Antimicrobial preservatives are used in sterile preparations such as eye drops and multidose injections to maintain sterility during use. They may also be added to aqueous injections that cannot be sterilised in their final containers and have to be prepared using aseptic precautions, unless the volume to be injected as a single dose exceeds 15 mL. Antimicrobial preservatives are also used in cosmetics, foods, and non-sterile pharmaceutical products such as oral liquids and creams to prevent microbial spoilage. They should not be used indiscriminately. Preparations that should *not* contain preservatives include those for injection into the CSF, eye, or heart. Generally, the antimicrobial preservatives that may be added to foods, animal feeding stuffs, and cosmetics are controlled.

Preservatives used as antoxidants may be classified in 3 groups:

- ***true antoxidants***, or anti-oxygens, which probably inhibit oxidation by reacting with free radicals blocking the chain reaction. Examples are the alkyl gallates, butylated hydroxyanisole, butylated hydroxytoluene, nordihydroguaiaretic acid, and the tocopherols (see Vitamin E Substances, p.1992)
- ***reducing agents***, which are substances having a lower redox potential than the drug or adjuvants that they are intended to protect and are therefore more readily oxidised. Reducing agents may act also by reacting with free radicals. Examples are ascorbic acid (p.1983) and the potassium and sodium salts of sulfurous acid (see Sulfites and Sulfur Dioxide)
- ***antoxidant synergists***, which usually have little antoxidant effect themselves but probably enhance the action of antoxidants in the first group by reacting with heavy-metal ions which catalyse oxidation. Examples of synergists are citric acid (p.2284), edetic acid and its salts (p.1445), lecithin (p.2332), and tartaric acid (p.2395)

Contact lens care

Wearers of contact lenses are at increased risk of corneal infections. Factors that predispose the cornea to infection include surface abrasions that may occur during normal wear, extended wear of soft (hydrogel) lenses, accidental trauma during insertion of a lens, and anoxia. In addition, the lens may provide a medium for introducing pathogens into the eye, especially if handling, cleaning, and disinfecting procedures are not followed. The most common pathogens are bacteria, in particular *Pseudomonas aeruginosa, Serratia marcescens, Staphylococcus aureus, Staph. epidermidis,* and *Streptococcus pneumoniae.* Fungi rarely cause lens-related keratitis, although contamination of soft lenses has been reported. *Acanthamoeba* can cause rare but serious corneal infections (p.822) mainly associated with soft contact lens wear; these protozoa are resistant to some commonly used disinfection systems and can colonise lens storage cases.

Lens care systems for **rigid** (hard or gas-permeable) lenses typically entail cleansing and disinfection stages.

- Daily cleansing with solutions containing surfactants and sometimes mild abrasives can substantially reduce microbial contamination as well as removing organic material which can compromise the activity of the disinfection stage. Cleansing solutions frequently contain substances that are irritant to the eye and should be removed by rinsing and soaking the lens.
- Soaking solutions also maintain lens hydration, disinfect the lens, and prevent contamination during storage. Although not intended for use in the eye, soaking solutions should be non-irritant.
- Commonly used disinfectants include benzalkonium chloride and chlorhexidine. Thiomersal is also used but has been associated with a high incidence of hypersensitivity reactions.
- Wetting or rewetting solutions are used to improve the comfort of the lens and, since they are applied to the eye, must be non-irritant. They commonly contain hypromellose, hyetellose, polyvinyl alcohol, or povidone, although a simple sodium chloride 0.9% solution may be used.

Initially chemical disinfection for **soft** contact lenses required 4 steps; cleaning, rinsing, soaking in a disinfectant, and final rinsing. The introduction of multipurpose solutions containing small amounts of surfactant cleaner and disinfectant have reduced the number of steps required.

- Soft contact lenses contain a high proportion of water and are liable to absorb substances from solution. For this reason some disinfectants, notably benzalkonium chloride, are not suitable for inclusion in solutions for soft lenses. Soft lenses may be disinfected by heating in a suitable unit, usually in isotonic saline solution, but this can shorten the life of the lens by denaturing the polymer or causing deposits of denatured protein, minerals, or preservatives from the saline solution. Stabilised hydrogen peroxide is suitable for cold disinfection of soft lenses and is particularly useful for preventing *Acanthamoeba* infections. However, it is irritant to the cornea and must be neutralised before the lens is inserted into the eye. Other disinfectants for soft lenses may include chlorhexidine and polihexanide.
- Cleansers for soft lenses may contain surfactants or enzymes, such as papain or pancreatin, that remove protein deposits.
- Wetting solutions may be used similarly to rigid lenses.

Disinfection in Creutzfeldt-Jakob disease

Creutzfeldt-Jakob disease is a transmissible spongiform encephalopathy believed to be caused by infection of the nervous system with prions. The agent causing Creutzfeldt-Jakob disease (CJD) is resistant to many disinfection procedures including dry heat, ultraviolet irradiation, alcohols, ethylene oxide, eusol, formaldehyde, glutaral, hydrogen peroxide, iodine or iodophores, peracetic acid, phenolics, and propiolactone. Furthermore, aldehyde-type disinfectants have fixative proprieties and could anchor prion and other proteins to equipment and make them more difficult to remove by other means.[1] No sterilisation procedure can be guaranteed to be completely effective under all circumstances and for disposable instruments and materials the safest method is to destroy them by incineration.[2] Neurosurgical and ophthalmic instruments should also be destroyed by incineration if used in patients with confirmed or suspected CJD. WHO[2] has developed guidelines for control of transmissible spongiform encephalopathies which include measures for the decontamination and cleaning of instruments and materials designed for re-use. They recommend that contaminated instruments and material should be kept moist between the time of use and decontamination and that one of the following methods of decontamination be used for heat-resistant instruments (listed in increasing order of severity):

- immerse in 1N sodium hydroxide and heat in a gravity displacement autoclave at 121° for 30 minutes then clean, rinse in water, and continue with routine sterilisation processes
- immerse in 1N sodium hydroxide or sodium hypochlorite (providing 20 000 ppm available chlorine) for 1 hour then transfer the instruments to water, heat in a gravity displacement autoclave at 121° for 1 hour, then clean and continue with routine sterilisation processes
- immerse in 1N sodium hydroxide or sodium hypochlorite (providing 20 000 ppm available chlorine) for 1 hour then remove and rinse in water, transfer to an open pan and heat in a gravity displacement (121°) or porous load (134°) autoclave for 1 hour, then clean and continue with routine sterilisation processes

- immerse in 1N sodium hydroxide and boil for 10 minutes at atmospheric pressure then clean, rinse in water, and continue with routine sterilisation processes
- immerse in sodium hypochlorite (providing 20 000 ppm available chlorine) (preferred) or 1N sodium hydroxide (alternative) at ambient temperature for 1 hour then clean, rinse in water, and continue with routine sterilisation processes
- autoclave at 134° for 18 minutes

Heat sensitive instruments and surfaces should be decontaminated by flooding with 2N sodium hydroxide or undiluted sodium hypochlorite and left to stand for 1 hour, then mopped up and rinsed with water. If these agents cannot be tolerated then thorough cleaning with a diluted solution or other partially effective agent is advised.[2] In the UK, it is recommended[1] that if it is the intention to reuse an endoscope that has been employed in patients with suspected or confirmed CJD or has been used for invasive procedures in those at risk of CJD (e.g. haemophiliacs), then the endoscope should be disinfected with a non-aldehyde disinfectant (preferably single use) separately from other endoscopes and quarantined for use only in those with confirmed CJD.

Recommendations for disinfection and sterilisation in CJD have also been published in the UK[3] and USA.[4]

Disinfection in dental practice

Dental patients and healthcare staff can be exposed to viruses and bacteria that are present in blood or colonise or infect the oral cavity and respiratory tract, such as CMV, hepatitis B and C viruses, herpes simplex virus types 1 and 2, HIV, *Mycobacterium tuberculosis*, staphylococci, and streptococci. For information on endocarditis prophylaxis, see p.168. These organisms can be transmitted in dental settings through direct or indirect contact with blood, oral fluids, or other body matter; by indirect contact with contaminated objects (e.g. instruments, equipment, or environmental surfaces), or inhalation of airborne micro-organisms (which can remain suspended in the air for long periods).

Guidelines have been developed in the USA for preventing and controlling infectious diseases and managing personnel health and safety concerns related to infection control in dental settings.[1] **Hand hygiene** (see below) substantially reduces potential pathogens on the hands and is considered a critical measure for reducing the risk of transmitting organisms to patients and healthcare workers. For routine dental examinations and nonsurgical procedures, handwashing and hand antisepsis is achieved by using a plain or antimicrobial soap and water. If the hands are not visibly soiled, an alcohol-based hand rub may be used. Before surgical procedures an antimicrobial soap or alcohol hand rub with persistent activity should be used. This extended antimicrobial activity is needed to prevent the introduction of organisms, which can colonise the hands underneath gloves and enter the wound if gloves become punctured or torn.

Patient-care items such as dental instruments, devices, and equipment should be **cleaned** to remove debris as well as organic and inorganic contamination, before proceeding with disinfection and sterilisation. If manual cleaning cannot be done immediately, the instruments should be placed in a puncture-resistant container and soaked in a detergent, a disinfectant/detergent, or an enzymatic cleaner. Use of a liquid chemical sterilant/high-level disinfectant (e.g. glutaral) as a holding solution is not recommended.

Heat-tolerant dental instruments usually are **sterilised** by autoclaving, dry heat, or unsaturated chemical vapour. Three levels of **disinfection** are used for patient-care devices that do not require sterility:

- high (e.g. glutaral, hydrogen peroxide, hydrogen peroxide with peracetic acid, *o*-phthaldialdehyde, peracetic acid, and phenol with glutaral)
- intermediate (e.g. chlorine-containing products, iodophores, phenolics, and quaternary ammonium compounds with alcohol)
- low (e.g. quaternary ammonium compounds, some phenolics, and some iodophores)

Patient-care items are categorised as critical, semicritical, or noncritical, depending on the potential risk for infection associated with their intended use. Heat sterilisation is used for critical items (used to penetrate soft tissue or bone) also for semicritical items that touch mucous membranes or non-intact skin. Semicritical items that are heat-sensitive should be processed with high-level disinfection. Noncritical patient-care items, contacting only intact skin, just require cleaning, or if visibly soiled, cleaning followed by disinfection. When the item is visibly contaminated with blood or other potentially infectious material a disinfectant thought to be effective against tubercle bacilli (intermediate-level disinfectant) should be used.

Clinical contact surfaces can become contaminated from patient materials either by direct spray or spatter generated during dental procedures or by contact with dental healthcare workers' gloved hands. Two levels of disinfection, intermediate and low, are used for environmental surfaces. If protective barriers are not used, surfaces should be cleaned and disinfected between patients by using disinfectants effective against HIV or hepatitis B virus (low-level disinfectant) or a tuberculocidal disinfectant (intermediate-level disinfectant) if the surface is visibly contaminated with blood or other potentially infectious material. General cleaning and disinfection are recommended for clinical contact surfaces, dental unit surfaces, and countertops at the end of daily work activities and are required if surfaces have become contaminated since their last cleaning. Spills of blood and other body fluids should be removed with absorbent material (e.g. disposable paper towels). Nonporous surfaces should be cleaned and then decontaminated with disinfectant effective against hepatitis B virus and HIV (low-level disinfectant) or a tuberculocidal disinfectant (intermediate-level disinfectant).

Disinfection of endoscopes

Whenever possible, medical equipment that comes into intimate contact with the body should be heat sterilised, but some equipment, notably endoscopes, will not withstand high temperatures. Low-temperature steam and formaldehyde or ethylene oxide will achieve sterilisation, but may not be practical in a clinical setting. Satisfactory chemical disinfection of endoscopes and other heat-sensitive instruments relies on initial thorough cleansing of the instrument and choice of an appropriate high-level disinfectant which should be rapidly active against a wide range of pathogens including vegetative bacteria, bacterial spores, mycobacteria, and viruses. The disinfectant should not damage the instrument or discolour the optical components, and it should not leave a toxic residue. Instruments should be rinsed after disinfection with water or alcohols, such as isopropyl alcohol,[1] and dried with forced air.[2,3]

Glutaral 2% is commonly used.[2] To achieve sterilisation, immersion in glutaral 2% for 3 hours is necessary, but high-level disinfection, achieved by immersion for 20 minutes, is usually considered adequate for most endoscopes.[1,2,4,5] Immersion for a minimum of 20 minutes is required for elimination of tubercle bacilli, but immersion for 4 minutes may be adequate for gastroscopes, except those for use on immunocompromised patients. For specific information relating to hepatitis and HIV viruses, see below.

A disadvantage of glutaral is that it is irritant and may cause sensitisation. In addition, longer contact times are needed to eliminate atypical mycobacteria and glutaral-resistant strains of *M. chelonae* have been isolated from endoscope disinfecting equipment.[6,7] It should also be noted that in the UK it is recommended that units should move away from the use of aldehyde-based disinfectants because of their fixative properties, which in theory could anchor prion and other protein within endoscopes.[1] The use of aldehydes as the primary disinfectant should also be avoided in units serving groups at risk of CJD, such as haemophilia centres (see also Disinfection in Creutzfeldt-Jakob Disease, above). Alternative disinfectants include peracetic acid, chlorine dioxide, *o*-phthaldialdehyde, and superoxidised water (hypochlorous acid).[1,5,7] Other alternatives include peroxygen compounds, quaternary ammonium compounds, glucoprotamine, electrolysed acid water, succinic dialdehyde, and alcohol 70%.[1,2,5,7] However, peracetic acid and chlorine dioxide produce irritant fumes, peroxygen-containing compounds and quaternary ammonium compounds have questionable activity against mycobacteria and viruses, and alcohol has a number of practical limitations.[1,5,7]

Disinfection in hepatitis and HIV infection

Hepatitis viruses and HIV are susceptible to heat and the methods recommended for sterilisation of equipment in the UK[1] are conventional procedures using moist or dry heat. Heat-labile articles and surfaces may undergo chemical disinfection but only in the absence of a satisfactory alternative. Although various publications have claimed efficacy against HIV for a wide range of disinfectants and detergents, the evidence for some claims is equivocal.

Fresh aqueous solutions of sodium hypochlorite or troclosene sodium are recommended for general surface disinfection. If contaminated by blood, the concentration must be equivalent to 10 000 ppm of available chlorine. For non-corrosive disinfection of delicate items such as fibreoptic endoscopes, freshly activated alkaline glutaral 2% may be used following thorough washing (but see also Disinfection of Endoscopes, above). If a sterile body cavity will be entered the endoscope must be immersed for a minimum of 3 hours; otherwise a minimum of 30 minutes is sufficient, or 1 hour if the presence of *Mycobacterium tuberculosis* is suspected.

Disinfection of water

Travellers to regions of the world where water is not disinfected at source should be advised to boil or chemically sterilise water for drinking, cleaning teeth, and washing fruit and vegetables.[1] Chlorine and chlorine-releasing disinfectants including tosylchloramide sodium, halazone, sodium hypochlorite, and troclosene sodium are commonly used to sterilise **drinking water**. Iodine-releasing disinfectants such as tetraglycine hydroperiodide, or iodine itself may be useful for short-term or emergency disinfection of small volumes of water.[2] Organic material suspended in the water may reduce the available halogen concentration, and cloudy water should be filtered or allowed to settle and decanted before treatment. Emergency treatment of drinking water with lemon juice has been suggested during epidemics of waterborne gastro-enteritis.[3]

Chlorine and chlorine-releasing disinfectants are also used for recreational and therapeutic **bathing** pools, often with ozone.[4,5] Bromine-based disinfectants and ultraviolet radiation may also be used.

Legionnaires' disease (p.176) is commonly transmitted via cooling water in **air conditioning** systems or **hot water** supplies. Hyperchlorination has been attempted to eradicate the organism from contaminated water sources but has been largely ineffective[6,7] and is no longer recommended. Other disadvantages of using chlorine-based systems at these temperatures and concentrations are corrosion of the plumbing system[7] and the production of potentially carcinogenic byproducts.[8] Effective disinfection can be achieved by raising and maintaining the water temperature above 50°, ultraviolet light, and copper-silver ionisation.

Haemodialysis patients are exposed to large quantities of municipal drinking water as it is used for the production of **dialysis** fluids and may also be used for dialyser rinsing and reuse. Many of the chemical substances in the water, such as calcium, sodium, aluminium, chloramines, fluoride, copper, zinc, sulfates, and nitrates are potentially dangerous for dialysis patients, and can lead to acute or chronic poisoning. There is also a microbiological risk associated with the control of bacterial growth in the water treatment and distribution system. Contaminants are therefore removed by water purification systems. Water is pretreated with activated carbon filters to remove chlorine and its derivatives and other suspended particles, and the hardness of the water is decreased with sodium exchange cationic resins, which remove calcium and magnesium. The final purification process then involves the removal of dissolved salts, bacteria, and endotoxins by reverse osmosis. Reverse osmosis membranes need to be regularly disinfected with chemical agents (such as hypochlorite and peracetic acid), heat, or ozone.[9]

Hand hygiene

Hospital-acquired infections, including those due to multidrug-resistant pathogens, such as meticillin-resistant *Staphylococcus aureus*, vancomycin-resistant *Staph. aureus*, and vancomycin-resistant enterococci, are a major problem in health care facilities.[1] Hand hygiene is one of the most important factors in preventing such infections, as it prevents transmission of pathogens by contact and the faecal-oral route. However, healthcare workers frequently do not wash their hands, and compliance rarely exceeds 40%.[2] A randomised study[3] to compare the efficacy of an alcohol-based solution for hand rubbing with hand washing with a medicated soap in reducing bacterial hand contamination during routine patient care found that the alcohol-based solution was significantly more effective (83% reduction versus 58%). The authors considered that the difference in efficacy might have been due to the duration of hand washing. Participants rubbed or washed their hands for about 30 seconds, but the recommended duration for hand washing is 30 seconds to 1 minute, a time that was adhered to in less than 35% of instances.

Authorities recommend[1,2] that alcohol-based hand rubs should replace hand washing as the standard for hand hygiene in all situations in which the hands are not visibly soiled. The basis for this is that hand rubbing requires less time, is microbiologically more effective, and is less irritating to skin than traditional hand washing with soap and water. The CDC in the USA advises[4] hand washing with a non-antimicrobial or antimicrobial soap and water when hands are visibly dirty or contaminated with proteinaceous material, blood, or other body fluids and if exposure to *Bacillus anthracis* is suspected or proven. Alcohols, chlorhexidine, iodophores, and other antiseptic agents are not recommended for *B. anthracis* contamination as they have poor activity against the spores. If hands are not visibly soiled, an alcohol-based hand rub may be used. Decontamination of the hands with an antiseptic hand rub or hand wash should occur before direct contact with patients, and before putting on sterile gloves when inserting catheters or other invasive devices that do not require a surgical procedure. Decontamination of the hands should also occur after contact with a patient's intact or non-intact skin, body fluids, mucous membranes, and wound dressings if hands are not visibly soiled. Hands should be decontaminated if moving from a contaminated body site to a clean body site during patient care, after contact with inanimate objects (including medical equipment) in the immediate vicinity of the patient, and after removing gloves. When performing surgical procedures hand hygiene with either an antimicrobial soap or an alcohol-based hand rub with persistent activity is recommended before putting on sterile gloves.

The CDC[4] considers that the best antimicrobial efficacy can be achieved with alcohol (ethanol), isopropyl alcohol, and propyl alcohol, as their activity is broad and they are fast acting. Ethanol at high concentrations is the most effective treatment against non-enveloped viruses, whereas propyl alcohol seems to be more effective against the resident bacterial flora. Combinations of alcohols may have a synergistic effect. The antimicrobial efficacy of chlorhexidine (2 to 4%) and triclosan (1 to 2%) is both lower and slower. Bacterial resistance may occur, although the risk is higher for chlorhexidine than triclosan. Even if used in conjunction with hand washing, they are still less effective than the alcohols. Plain soap and water has the lowest efficacy of all.

Injection site and catheter care

The need to disinfect the skin before injection is controversial.[1] Routine skin preparation of the injection site by swabbing with antiseptic has been reported to be both ineffective and unnecessary.[2,3] Central venous and arterial catheters, however, require the application of strict aseptic technique and injection site antisepsis to reduce the chance of infection.[4] Disinfection of catheter insertion sites with aqueous chlorhexidine 2% has been reported to be associated with fewer local and systemic infections than site preparation with either 10% povidone-iodine solution or 70% isopropyl alcohol,[5] although this has been challenged.[6] A subsequent study reported lower rates of catheter colonisation and catheter-related infection with an alcoholic solution of chlorhexidine 0.25% and benzalkonium chloride 0.025% than with povidone-iodine 10%.[7] In a study in preterm infants, technique had greater influence on bacterial counts at injection sites than the antiseptic used; chlorhexidine 0.5% in isopropyl alcohol and aqueous povidone-iodine 10% were equally effective, but cleansing with alcoholic chlorhexidine for 30 seconds or for two 10-second periods was more effective than cleansing for 5 or 10 seconds.[8]

The use of catheters impregnated with antiseptics or antibacterials has also been studied. Catheters impregnated with chlorhexidine and sulfadiazine silver on the external luminal surface, appear to be effective in reducing both catheter colonisation and related bloodstream infection in high-risk patients when used within 14 days.[9] Central venous catheters impregnated with minocycline and rifampicin have been reported to be associated with a lower infection rate than standard silicone catheters[10] and those impregnated with chlorhexidine and sulfadiazine silver.[11]

Guidelines have been produced for the prevention of infection associated with both peripheral intravascular and central venous catheterisation.[12-14]

Pre-operative skin disinfection

Skin preparation with antiseptics before surgery is generally carried out in an attempt to reduce the risks of surgical infection (see p.195), but the evidence base for the practice is conflicting. The CDC recommends[1] pre-operative cleaning of skin at the incision site with either iodophores (e.g. povidone-iodine), alcohol-containing products, or chlorhexidine gluconate. While alcohol is considered to be the most effective and rapidly acting skin antiseptic, there are no appropriate studies to assess comparative efficacy. Furthermore, an analysis[2] of randomised studies comparing the use of pre-operative skin antiseptics with no antiseptics and studies comparing different skin antiseptics, found that there was insufficient evidence to conclude whether pre-operative skin antiseptics were effective in preventing postoperative surgical wound infection.

Wound disinfection

Antiseptic preparations are widely used to treat or prevent superficial infections and wounds, but their usefulness on broken skin and wounds has been questioned.[1] For further information on wound care, see p.1585. Chlorine-releasing antiseptic solutions are generally regarded as irritant and although there is little direct evidence in patients there is concern that they may delay wound healing. Cetrimide,[2] tosylchloramide sodium,[3] hydrogen peroxide 3%,[4] iodophores,[4] and sodium hypochlorite solutions[2] are all reported to be cytotoxic *in vitro* or in *animal* models. Long-term or repeated use of these antiseptics for wound cleaning should probably be avoided. Chlorhexidine is relatively non-toxic.[2,3]

Acridine Derivatives

Acridina, derivados.

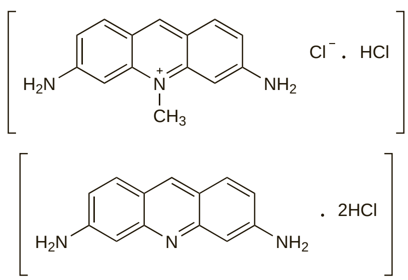
Description. Acridine derivatives are a group of quinoline antimicrobial dyes structurally related to acridine.

Acriflavinium Chloride *(rINN)*

Acriflavine; Acriflavine Hydrochloride; Acriflavinii Chloridum; Acriflavinii Dichloridum; Acriflavinium, Chlorure d'; Akriflavinium-chlorid; Cloruro de acriflavinio. A mixture of 3,6-diamino-10-methylacridinium chloride hydrochloride and 3,6-diaminoacridine dihydrochloride.

Акрифлавиния Хлорид

CAS — 8063-24-9; 65589-70-0.
ATC — R02AA13.
ATC Vet — QG01AC90; QR02AA13.



NOTE. The nomenclature is confusing. Acriflavinium Chloride is *rINN* but also the *BP* name for Acriflavinium Monochloride (see below).

Acriflavinium Monochloride

Acriflavinii monochloridum; Acriflavinio, monocloruro de; Acriflavinium, monochlorure d'; Akriflavinio monochloridas; Akriflaviniummonoklorid; Akriflaviniummonokloridi; Euflaviini; Euflavin; Euflavine; Euflavinum; Neutral Acriflavine; Neutroflavin. A mixture of 3,6-diamino-10-methylacridinium chloride and 3,6-diaminoacridine monohydrochloride. The latter is usually present to the extent of between 30 and 40%.

CAS — 68518-47-8.
ATC — D08AA03.
ATC Vet — QD08AA03.

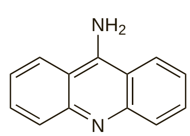
NOTE. The nomenclature is confusing. Although the *BP* name was Acriflavinium Chloride this is also *rINN* for a related compound (see above).

Aminoacridine Hydrochloride *(BANM, rINNM)*

Aminacrine Hydrochloride *(USAN)*; Aminoacridine, Chlorhydrate d'; Aminoacridini Hydrochloridum; Hidrocloruro de aminoacridina; NSC-7571. 9-Aminoacridine hydrochloride monohydrate.

Аминоакридина Гидрохлорид

$C_{13}H_{10}N_2,HCl,H_2O$ = 248.7.
CAS — 90-45-9 (aminoacridine); 134-50-9 (anhydrous aminoacridine hydrochloride).
ATC — D08AA02.
ATC Vet — QD08AA02.



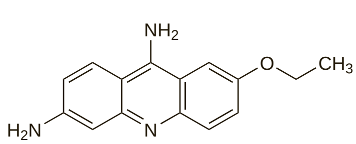
(aminoacridine)

Ethacridine Lactate *(BANM, rINNM)*

Acrinol; Aethacridinium Lacticum; Etakridiinilaktaatti; Etakridinlaktat; Etakridin-laktát; Etakridino laktatas; Etakrydyny mleczan; Éthacridine, lactate d'; Ethacridini lactas; Ethakridin-laktát; Lactato de etacridina; Lactoacridine. 6,9-Diamino-2-ethoxyacridine lactate.

Этакридина Лактат

$C_{15}H_{15}N_3O,C_3H_6O_3$ = 343.4.
CAS — 442-16-0 (ethacridine); 1837-57-6 (ethacridine lactate); 6402-23-9 (ethacridine lactate monohydrate).
ATC — B05CA08; D08AA01.
ATC Vet — QB05CA08; QD08AA01.



(ethacridine)

Pharmacopoeias. *Chin.*, *Eur.* (see p.vii), and *Jpn* describe the monohydrate.

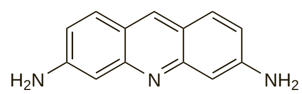
Ph. Eur. 6.2 (Ethacridine Lactate Monohydrate). A yellow crystalline powder. Sparingly soluble in water; very slightly soluble in alcohol; practically insoluble in dichloromethane. A 2% solution in water has a pH of 5.5 to 7.0. Protect from light.

Proflavine Hemisulfate

Proflavine Hemisulphate *(pINNM)*; Hemisulfato de proflavina; Neutral Proflavine Sulphate; Proflavine, Hémisulfate de; Proflavini Hemisulfas. 3,6-Diaminoacridine sulphate dihydrate.

Профлавина Гемисульфат

$(C_{13}H_{11}N_3)_2,H_2SO_4,2H_2O$ = 552.6.
CAS — 92-62-6 (proflavine).



(proflavine)

Profile

The acridine derivatives are slow-acting antiseptics. They are bacteriostatic against many Gram-positive bacteria but less effective against Gram-negative bacteria. They are ineffective against spores. Their activity is increased in alkaline solutions and is not reduced by tissue fluids.

The acridine derivatives have been used for the treatment of infected wounds or burns and for skin disinfection, although they have been largely superseded by other antiseptics or suitable antibacterials. Prolonged treatment may delay healing. They have also been used for the local treatment of ear, oropharyngeal, and genito-urinary infections.

Aminoacridine is reported to be non-staining and is used as the hydrochloride as eye drops in the treatment and prophylaxis of superficial eye infections.

Ethacridine lactate is included in some preparations for the treatment of diarrhoea. It has also been given by extra-amniotic injection for the termination of pregnancy (p.2004) but other methods are usually preferred.

Other acridine derivatives covered elsewhere in *Martindale* include mepacrine (p.836), which is used in the treatment of giardiasis, and pyronaridine (p.612), which is used to treat malaria. Amsacrine (p.681) is a 9-anilinoacridine drug that is used in the treatment of adult leukaemias. Other acridine derivatives are also under investigation as anticancer drugs because of the ability of the acridine chromophore to intercalate DNA and inhibit topoisomerase enzymes.

Hypersensitivity to acridine derivatives has been reported.

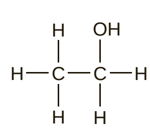
Alcohol ⊗

Aethanolum; Alcool; Alkol; Etanol; Etanol (96%); Etanol bezwodny; Etanoli; Etanolis; Éthanol; Ethanol; Ethanolum; Ethyl Alcohol.

Алкоголь; Этанол

C_2H_5OH = 46.07.
CAS — 64-17-5.
ATC — D08AX08; V03AB16; V03AZ01.
ATC Vet — QD08AX08; QV03AB16; QV03AZ01.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of alcohol:

Booze; Drinks; Grog; Juice; Jungle juice; Liq; Liquor; Lunch head; Moonshine; Piss; Sauce; Schwillins.

Pharmacopoeias. Various strengths are included in *Br.*, *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, *US*, and *Viet.* Also in *USNF.*

In *Martindale* the term alcohol is used for alcohol 95 or 96% v/v.

Ph. Eur. 6.2 (Ethanol, Anhydrous; Ethanolum Anhydricum; Ethanol BP 2008). It contains not less than 99.5% v/v or 99.2% w/w of C_2H_5OH at 20°. A colourless, clear, volatile, flammable, hygroscopic liquid; it burns with a blue, smokeless flame. B.p. about 78°. Miscible with water and with dichloromethane. Protect from light.

The BP 2008 gives Absolute Alcohol and Dehydrated Alcohol as approved synonyms.

Ph. Eur. 6.2 (Ethanol (96 per cent)). It contains not less than 95.1% v/v or 92.6% w/w and not more than 96.9% v/v or 95.2% w/w of C_2H_5OH at 20°, and water. A colourless, clear, volatile, flammable, hygroscopic liquid; it burns with a blue, smokeless flame. B.p. about 78°. Miscible with water and with dichloromethane. Protect from light.

The BP 2008 gives Alcohol (96 per cent) as an approved synonym.

BP 2008 (Dilute Ethanols). The monograph describes several dilute alcohols containing between 20 and 90% v/v of C_2H_5OH, and one of these, ethanol (90%), is also known as rectified spirit.

USP 31 (Alcohol). It contains not less than 92.3% w/w or 94.9% w/v and not more than 93.8% w/w or 96.0% w/v of C_2H_5OH at 15.56°. A clear, colourless, mobile, volatile liquid with a characteristic odour and burning taste; it is flammable. B.p. about 78°. Miscible with water and with almost all other organic solvents. Store in airtight containers. Protect from light.

USP 31 (Dehydrated Alcohol). It contains not less than 99.5% v/v or 99.2% w/w of C_2H_5OH (sp. gr. not more than 0.7962 at 15.56°). Store in airtight containers. Protect from light.

USNF 26 (Diluted Alcohol). It contains 48.4 to 49.5% v/v or 41 to 42% w/w of C_2H_5OH. Store away from fire in airtight containers.

Alcoholic strength. This is expressed as a percentage by volume of alcohol. It was previously often expressed in terms of *proof spirit*. Proof spirit contained about 57.1% v/v or 49.2% w/w of C_2H_5OH, and was defined as 'that which at the temperature of 51°F weighs exactly twelve-thirteenths of an equal measure of distilled water'. Spirit of such a strength that 100 volumes contained as much ethyl alcohol as 160 volumes of proof spirit was described as '60 OP' (over proof). Spirit of which 100 volumes contained as much alcohol as 40 volumes of proof spirit was described as '60 UP' (under proof).

An alternative method of indicating spirit strength was used on the labels of alcoholic beverages in the UK when the strength was given as a number of degrees, proof spirit being taken as 100°. In the USA alcoholic strength is expressed in degrees, the value of which is equal to twice the percentage by volume. Thus 70° proof (old UK system) is equivalent to 40% v/v, and therefore to 80° proof (USA system).

Adverse Effects

Adverse effects of alcohol arise chiefly from the intake of alcoholic beverages. The concentration of alcohol in the blood producing a state of intoxication varies between individuals.

- Low concentrations (up to 180 mg per 100 mL) of alcohol may result in impaired vision, reaction time, and coordination and emotional lability.
- At low to moderate concentrations (180 to 350 mg per 100 mL), alcohol acts as an apparent stimulant; depression of cortical function causes loss of judgement, slurred speech, diplopia, blurred vision, ataxia, lack of coordination, blackouts, sweating, tachycardia, nausea, vomiting, and incontinence. Alcohol inhibits the release of antidiuretic hormone resulting in enhanced diuresis. Acidosis (especially in children), hypoglycaemia, and hypokalaemia may occur.
- High concentrations (350 to 450 mg per 100 mL) of alcohol result in cold clammy skin, hypothermia, hypotension, stupor, coma, dilated pupils, and depressed or absent tendon reflexes. Severe hypoglycaemia, convulsions, respiratory depression, and metabolic acidosis may occur. Cardiac arrhythmias such as atrial fibrillation and AV block have been recorded.

The median lethal blood-alcohol concentration is generally estimated to be about 400 to 500 mg per 100 mL. Death may occur at lower blood-alcohol concentrations due to inhalation of vomit during unconsciousness.

Chronic excessive consumption of alcohol may cause damage to many organs, particularly the brain and the liver. Possible direct toxic effects of alcohol on the brain, as well as thiamine deficiency, may lead to Wernicke-Korsakoff syndrome. Fat deposits may occur in the liver and there may be a reduction in various blood-cell counts. Nutritional diseases may occur due to inadequate diet. High alcohol consumption has been associated with pancreatitis, and an increased risk of cardiovascular disease, although some consider that moderate consumption might have a protective effect against ischaemic heart disease.

Alcohol consumption has also been associated with an increased risk of some types of cancer.

The term '**alcoholism**' may be used to denote dependence on alcohol, which is of the barbiturate-alcohol type (see Amobarbital, p.962) and usually involves tolerance to other sedatives and anaesthetics. After prolonged periods of excessive alcohol consumption, a drop in blood-alcohol concentration may precipitate a withdrawal syndrome characterised by tremor, agitation, feelings of dread, nausea, vomiting, and sweating; hallucinations, seizures, and delirium tremens may also develop.

A **fetal alcohol syndrome** has been identified in some infants born to some alcoholic mothers; such infants have a distinctive set of facial anomalies, growth retardation, and significant learning and/or behavioural problems. There have been some reports of the syndrome and other adverse effects on the fetus being associated with moderate alcohol intake in pregnancy. It is therefore generally suggested that alcohol is avoided, or at least intake limited, during pregnancy (see Pregnancy, below).

Frequent application of alcohol to the skin produces irritation and dry skin.

Effects on the skin. A 70% solution of alcohol, containing povidone-iodine, caused partial thickness chemical burns beneath tourniquets in 3 young children.[1] Other adverse effects on the skin reported with the topical application of alcohols have included necrosis after skin cleansing of preterm neonates with methylated spirits[2,3] and haemorrhagic skin necrosis due to the alcohol content of chlorhexidine in spirit used as a disinfectant in umbilical artery catheterisation in preterm infants.[4]

Treatment of Adverse Effects

Treatment of acute poisoning with alcohol should include hydration with intravenous fluids, control of nausea and vomiting, and correction of electrolyte imbalances, such as hypomagnesaemia. Protection of the airway is crucial and ventilation may be required in cases of respiratory depression. Glucose is indicated for patients with hypoglycaemia, while thiamine supplementation should be considered for chronic alcoholics. Hypothermia and hypotension should be corrected. Convulsions may be controlled with intravenous benzodiazepines or phenytoin. Haemodialysis is of value in severe alcohol poisoning. Gut decontamination and activated charcoal are unlikely to be of benefit due to the rapid absorption of alcohol through intestinal mucosa. The use of intravenous infusions of fructose to treat severe alcohol poisoning is not recommended.

The management of the alcohol withdrawal syndrome and long-term abstinence following withdrawal are discussed below.

Alcohol withdrawal and abstinence. The alcohol withdrawal syndrome presents in the early stages as a classical hyperadrenergic state with tremor, tachycardia, sweating, and hypertension. Sometimes this is accompanied by mild disorientation, anxiety, impaired concentration, depression, agitation, and gastrointestinal symptoms. Insomnia, nightmares, and transient hallucinations can also be present. The condition may be self-limiting without the need for therapeutic intervention or it may progress to the severe and potentially fatal condition of delirium tremens (DTs), often characterised by delirium, disorientation, and hallucinations. In some cases generalised tonic-clonic seizures occur within 24 hours of alcohol withdrawal and are followed by delirium tremens.

The general management of the alcohol **withdrawal** syndrome and maintenance of abstinence have been the subject of many reviews and discussions.[1-15] In most cases symptoms do not require treatment and disappear within a few days, but more severe cases may require managed withdrawal from alcohol to avoid complications.

Benzodiazepines are usually the drugs of first choice because of their sedative, anxiolytic and anticonvulsant properties. If given promptly, benzodiazepines can prevent progression to seizures and delirium tremens. Longer-acting drugs such as chlordiazepoxide or diazepam may be more effective against withdrawal seizures and provide smoother withdrawal, while shorter-acting ones such as lorazepam or oxazepam have a smaller risk of producing oversedation and may be more suitable for use in the elderly and, since they do not rely on hepatic enzymes for their metabolism, for patients with liver disease. Because of the risk of dependence benzodiazepines should only be given in short courses. Some advocate that benzodiazepine dosage should be adjusted according to the severity of symptoms with special care being paid to patients with a history of withdrawal seizures, comorbid conditions, or those using sedative or hypnotic medication. This reduces the amount of drug required and the duration of treatment but entails regular monitoring by trained nursing staff. For mild to moderate symptoms, standard anxiolytic or muscle-relaxing oral doses of benzodiazepines may be sufficient. For severe symptoms, or for the treatment of delirium tremens, higher doses and use of the intravenous route may be required. *Clomethiazole* appears to be an effective alternative to the benzodiazepines (but see under Interactions of Clomethiazole, p.978); although widely used in Europe, it is not available in the USA. Some centres use phenobarbital but *barbiturates* are generally not recommended for the treatment of alcohol withdrawal syndrome.

Antipsychotics are not usually recommended for use in the control of symptoms of alcohol withdrawal since they do not reduce delirium tremens and some may reduce the seizure threshold. However, they might be considered for use as adjuncts in patients requiring treatment of marked agitation or hallucinations.

The generalised tonic-clonic seizures associated with alcohol withdrawal are usually self-limiting and patients who experience only one or two seizures do not usually require any specific treatment beyond continuing therapy with benzodiazepines or clomethiazole. For recurrent seizures or status epilepticus (p.469) a benzodiazepine may be given intravenously. Other types of seizure may be associated with head trauma or pre-existing seizure disorders (p.465) and should be treated accordingly. Other *antiepileptics* such as carbamazepine have been tried in the treatment of alcohol withdrawal seizures and may be of use as adjuncts in controlling other symptoms of alcohol withdrawal syndrome. As benzodiazepines are effective in preventing withdrawal seizures, other prophylactic drugs are not usually indicated.

Beta blockers can reduce symptoms of autonomic overactivity such as tachycardia, hypertension, tremor, and agitation but because they can mask these symptoms of withdrawal and do not prevent the development of more serious complications they should not be used alone. Some beta blockers such as propranolol that penetrate the CNS may produce CNS effects that complicate therapy. The $alpha_2$-adrenoceptor agonist *clonidine* may be of similar benefit as an adjunct.

Other drugs that have been reported to be of benefit in alcohol withdrawal syndrome include nitrous oxide and gamma-hydroxybutyric acid.

It is essential that in all cases of alcohol withdrawal syndrome hypoglycaemia, dehydration, electrolyte disturbances (in particular magnesium), and vitamin deficiencies be corrected. However, hydration should be undertaken with care as alcoholics may be more prone to develop cerebral oedema, the management of which is discussed under Raised Intracranial Pressure on p.1181. It is usually recommended that all patients should be given thiamine because of their increased risk of developing Wernicke-Korsakoff syndrome (p.1977). It should be noted that giving intravenous glucose before thiamine may precipitate Wernicke's encephalopathy in thiamine-deficient patients.

Abstinence. Once the initial acute withdrawal of alcohol is achieved treatment may be required to maintain long-term abstinence. Pharmacotherapy should only be used as an adjunct to psychotherapy and supportive care. Drugs used to modify alcohol seeking behaviour either sensitise the patient to alcohol (aversive drugs) or reduce or alleviate the craving for alcohol. The main ones used for aversive therapy have historically been *disulfiram* and *calcium carbimide*. A patient who ingests alcohol after taking an adequate dose of one of these drugs will experience a severe and unpleasant reaction (see Adverse Effects of Disulfiram, p.2296). However, the deterrent value of aversive drugs, and their potential toxicity, has long been a matter of debate. Such treatment is likely to be of little use unless it is undertaken with the willing cooperation of the patient and is used with psychotherapy, and even then there is no evidence that it has any effect on the long-term course of alcoholism.

Of those drugs that have been reported to reduce alcohol craving *acamprosate* and *naltrexone* have been the most promising as adjuncts for management of alcohol dependence and have been shown to improve abstinence and reduce relapse rates. Whether benefit is maintained long-term after treatment is stopped is unclear. *Other drugs* tried with varying benefit include aripiprazole, tiapride, gamma-hydroxybutyric acid, bromocriptine, nalmefene, and topiramate. Experimental evidence suggests that serotonin plays a role in the impulsivity and craving and is partly responsible for alcohol dependence. However, studies with SSRIs in alcohol dependence have been disappointing and it would appear that the benefit is in treating underlying depression rather than influencing drinking behaviour. Similar results have been noted with other drugs acting at serotonin receptors such as buspirone, ritanserin, and nefazodone. However, studies with ondansetron have shown some efficacy on drinking frequency and intake.

Precautions

Excessive alcohol intake should be avoided. In the UK, the Department of Health advises that men should not drink more than 3 to 4 units of alcohol per day, and women not more than 2 to 3 units of alcohol per day, regardless of whether one drinks every day, once or twice a week, or occasionally. A unit of alcohol is defined as 10 mL of pure alcohol. A normal measure of spirits in a public house contains about 1 unit of alcohol. A pint of ordinary strength lager or cider, a pint of bitter, or 175 mL glass of wine contain about 2 units of alcohol, while a pint of strong lager contains about 3 units of alcohol. Women and the elderly may be more susceptible to the adverse effects of alcohol ingestion.

Alcohol may aggravate peptic ulcer disease or hepatic impairment and impair control of diabetes mellitus or epilepsy. Ingestion of alcohol during pregnancy or breast feeding is not advisable. In chronic alcoholics there may be tolerance to the effects of other CNS depressants including general anaesthetics.

All processes requiring judgement and coordination are affected by alcohol and these include the driving of any form of transport and the operating of machinery. It is an offence in many countries for motorists to drive when the blood-alcohol concentration is above a stated value while in some countries any detectable concentration is an offence. The alcohol concentration in urine and expired air can be used to estimate the blood-alcohol concentration.

It should be remembered that alcohol may be present in a number of pharmaceutical preparations such as elixirs and mouthwashes, and that children may be particularly susceptible to its hypoglycaemic effects.

Breast feeding. The American Academy of Pediatrics[1] states that, although usually compatible with breast feeding, ingestion of large amounts of alcohol by a breast-feeding mother may cause drowsiness, diaphoresis, deep sleep, weakness, decrease in linear growth, and abnormal weight gain in the infant; maternal ingestion of 1 g/kg or more daily decreases the milk ejection reflex.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 15/03/06)

Driving. In addition to the legal maximum blood-alcohol concentration permitted for motorists, in the UK there are restrictions on holding a driving licence for those who persistently misuse alcohol, have alcohol dependency, have had an alcohol-related seizure, or have an alcohol-related disorder.[1]

Porphyria. Alcohol has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Pregnancy. Alcohol crosses the placenta and is both teratogenic and fetotoxic in humans.[1,2] Binge drinking or excessive alcohol intake is associated with low birth-weight, behavioural and intellectual difficulties later in life, and fetal alcohol syndrome (see Adverse Effects, above). It is therefore generally agreed that pregnant women should avoid or limit their intake of alcohol although guidance from professional bodies is slightly inconsistent. In the UK, the Royal College of Obstetricians and Gynaecologists[2] states that while the safest approach may be to avoid any alcohol intake during pregnancy, there is no evidence of harm from infrequent or low levels of alcohol intake (no more than one or two units once or twice a week) particularly after the first trimester. NICE[1] suggests limiting alcohol intake to no more than one unit per day. However, in the USA, the Surgeon General's Office[3] and the American Academy of Pediatrics[4] advise women who are pregnant or women who are planning a pregnancy to avoid alcohol use.

Interactions

Reports of interactions between alcohol and other drugs are not consistent, possibly because acute alcohol intake may inhibit drug metabolism while chronic alcohol intake can enhance the induction of drug-metabolising enzymes in the liver.

Alcohol can enhance the acute effects of CNS depressants, such as hypnotics, antihistamines, opioid analgesics, antiepileptics, antidepressants, antipsychotics, and sedatives. In addition 'dose dumping', rapid and potentially fatal release of high doses from modified-release formulations, has occurred when some opioid preparations were taken with alcohol.

Unpleasant reactions, similar to those occurring with disulfiram (p.2296), may occur when alcohol is taken with chlorpropamide, griseofulvin, mepacrine, metronidazole and other nitroimidazoles, the nitrofuran derivatives furazolidone and nifuratel, procarbazine, or some cephalosporins. Alcoholic beverages containing tyramine may cause reactions when taken by patients receiving MAOIs.

Alcohol can cause hypoglycaemic reactions in patients receiving sulfonylurea antidiabetics or insulin, and orthostatic hypotension in patients taking drugs with a vasodilator action. It may enhance the hypotensive effects of antihypertensives and has also increased the sedative effect of indoramin. Alcohol may increase gastric bleeding caused by analgesics and can have a variable effect on oral anticoagulants. It may decrease the antidiuretic effect of vasopressin.

Cycloserine. Increased blood-alcohol concentrations have been reported in patients receiving cycloserine.[1]

1. Glass F, *et al.* Beobachtungen und untersuchungen über die gemeinsame wirkung von alkohol und D-cycloserin. *Arzneimittelforschung* 1965; **15:** 684–8.

H_2-antagonists. The existence of an interaction between H_2-antagonists and alcohol is controversial and has not been established. While some studies suggest that *cimetidine*[1-3] and *nizatidine*[3] can increase peak blood-alcohol concentrations the effects of *ranitidine*[2,4] have been variable; *famotidine* appears to have no significant effect.[2] Later studies report that any interaction between H_2-antagonists and alcohol is minor and unlikely to be of clinical importance.[5-8]

Paracetamol. The effects of paracetamol poisoning may be exacerbated by chronic alcohol consumption (see p.108).

Verapamil. When verapamil has been taken with alcohol there has been a reported increase in peak blood-alcohol concentrations of about 17%.[1] Such an interaction may extend the toxic effects of alcohol and raise its blood concentration above the legal limit for driving.[2]

Pharmacokinetics

Alcohol is rapidly absorbed from the gastrointestinal tract and is distributed throughout the body fluids. It readily crosses the placenta. Alcohol vapour can be absorbed through the lungs. Absorption through intact skin is said to be negligible.

The rate of absorption of alcohol from the gastrointestinal tract may be modified by such factors as the presence of food, the concentration of alcohol, carbonation of the alcoholic beverage, and the period of time during which it is ingested.

Alcohol is mainly metabolised in the liver; it is converted by alcohol dehydrogenase to acetaldehyde and is then further oxidised to acetate. A hepatic microsomal oxidising system is also involved. About 90 to 98% of alcohol is oxidised and the remainder is excreted unchanged by the kidneys and the lungs. It also appears in breast milk, sweat, and other secretions.

The rate of metabolism may be accelerated after repeated excessive intake and by certain substances including insulin.

Uses and Administration

Alcohol has been used and abused for many thousands of years, in the form of alcoholic beverages, for its effects on the CNS. However, it also has pharmaceutical applications.

Alcohol is bacteriostatic at low concentrations but has bactericidal activity at higher concentrations; it does not, however, destroy bacterial spores. The mechanism of action appears to be denaturation of proteins. In the total absence of water, proteins are not denatured as rapidly as when water is present. Its bactericidal activity drops sharply when diluted below a 50% concentration and the optimal bactericidal concentration is 60 to 90% by volume. Alcohol also exhibits some fungicidal and virucidal activity. It is used to disinfect skin before injection, venepuncture, or surgical procedures. It is also used to disinfect hands and clean surfaces. A concentration of 70%, often as methylated spirits (p.1652), is commonly used for disinfection. Alcohol should not be used for disinfection of surgical or dental instruments because of its low efficacy against bacterial spores and inability to penetrate protein-rich materials.

Alcohol also has anhidrotic, rubefacient, and astringent and haemostatic properties. It is sometimes used for its skin-cooling properties and to harden the skin. It is an ingredient of several topical preparations used for skin disorders.

Alcohol is widely used as a solvent and preservative in pharmaceutical preparations.

Alcohol may be used as a neurolytic in the management of severe and chronic pain.

Alcohol is given intravenously in the treatment of acute poisoning from ethylene glycol (p.2300) and methyl alcohol (p.2024).

Alcohol is also used in sclerotherapy.

Pain. The use of alcohol as a neurolytic to produce destructive nerve block (see under Pain, p.1852) has produced variable results, and some consider the risk of complications outweighs the benefits. However, alcohol has been injected into the pituitary gland for relief of severe pain of the head and neck;[1,2] doses of 1 mL of absolute alcohol have been used.[1] It may be useful in coeliac plexus block, and has been injected into the muscle sheath to relieve painful muscle spasms in patients with multiple sclerosis.[1] Alcohol 50 to 100% may be used for peripheral or central nerve block in terminally ill patients with pain that does not respond to drug therapy;[3,4] the block produced by alcohol may occasionally last up to 2 years, even longer than that produced by phenol. However, larger volumes of alcohol than phenol are required, which means that blockade may be less precise due to leakage to proximal sites;[4] in addition, alcohol may exacerbate local pain on injection, because of its irritant effect on the tissues, and injection of a local anaesthetic beforehand, or giving the alcohol combined with a local anaesthetic, may be necessary.[4,5]

Intrathecal injection of alcohol has also been used for the intractable pain of spasticity (p.1887); early use, as soon as spasticity becomes painful and disabling, has been advocated.[6]

Sclerotherapy. Alcohol has been used successfully as a sclerosant in a variety of conditions including aldosterone-producing adenoma,[1] parathyroid adenomas,[2] thyroid nodules,[3,4] advanced rectal cancer,[5] hepatocellular carcinoma,[6,7] dysphagia associated with oesophogastric cancer,[8,9] hepatic[10] or renal[11] cysts, and gallbladder obstruction.[12] It has also been used in the sclerotherapy of oesophageal varices,[13,14] although the safety of this procedure has been questioned after a report of complications developing in 13 of 17 patients, 2 of whom died.[15] Other conditions in which alcohol has been used as a sclerosant include bleeding from ruptured hepatomas[16] and in peptic ulcer disease,[17] vascular malformations,[18] and obstructive cardiomyopathies[19] resistant to usual treatment.

Other sclerosants used in oesophageal varices are discussed on p.2346.

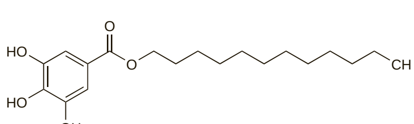
Alkyl Gallates

Galatos de alquilo.

Dodecyl Gallate

Dodecilo galatas; Dodécyle, gallate de; Dodecylgallat; Dodecylgallát; Dodecylis gallas; Dodekyyligallaatti; E312; Galato de dodecilo; Lauryl Gallate; Laurylum Gallicum. Dodecyl 3,4,5-trihydroxybenzoate.

$C_{19}H_{30}O_5$ = 338.4.
CAS — 1166-52-5.

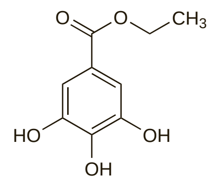


Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Dodecyl Gallate). A white or almost white crystalline powder. M.p. about 96°. Very slightly soluble or practically insoluble in water; freely soluble in alcohol; slightly soluble in dichloromethane. Store in nonmetallic containers. Protect from light.

Ethyl Gallate

Galato de etilo. Ethyl 3,4,5-trihydroxybenzoate.

$C_9H_{10}O_5$ = 198.2.
CAS — 831-61-8.



Pharmacopoeias. In *Br.*
BP 2008 (Ethyl Gallate). A white to creamy-white, odourless or almost odourless, crystalline powder. Slightly soluble in water; freely soluble in alcohol and in ether; practically insoluble in arachis oil. Protect from light. Avoid contact with metals.

Octil Gallate

E311; Galato de octilo; Octyl Gallate; Octyle, gallate d'; Octylis gallas; Oktilo galatas; Oktylgallat; Oktyl-gallát; Oktyyligallaatti. Octyl 3,4,5-trihydroxybenzoate.

$C_{15}H_{22}O_5$ = 282.3.
CAS — 1034-01-1.

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Octyl Gallate). A white or almost white crystalline powder. Practically insoluble in water and in dichloromethane; freely soluble in alcohol. Store in nonmetallic containers. Protect from light.

Propyl Gallate

E310; Galato de propilo; Propil-gallát; Propilo galatas; Propyle, gallate de; Propylgallat; Propyl-gallát; Propylis gallas; Propylu galusan; Propylum Gallicum; Propyyligallaatti. Propyl 3,4,5-trihydroxybenzoate.

$C_{10}H_{12}O_5$ = 212.2.
CAS — 121-79-9.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Propyl Gallate). A white or almost white, crystalline powder. Very slightly soluble in water; freely soluble in alcohol; dissolves in dilute solutions of alkali hydroxides. Protect from light.
USNF 26 (Propyl Gallate). A white crystalline powder with a slight characteristic odour. Slightly soluble in water; freely soluble in alcohol. Store in airtight containers. Avoid contact with metals. Protect from light.

Adverse Effects and Precautions

The alkyl gallates may cause contact sensitivity and skin reactions.

Effects on the blood. Methaemoglobinaemia associated with the antoxidants (butylated hydroxyanisole, butylated hydroxytoluene, and propyl gallate) used to preserve the oil in a soybean infant feed formula has been reported.[1] Propyl gallate was suspected of being the most likely cause because its chemical structure is similar to pyrogallol (p.1611), a methaemoglobinaemia inducer.

1. Nitzan M, *et al.* Infantile methemoglobinemia caused by food additives. *Clin Toxicol* 1979; **15:** 273–80.

Uses

The alkyl esters of gallic acid (3,4,5-trihydroxybenzoic acid) have antoxidant properties and are used as preservatives in pharmaceuticals and cosmetics. Alkyl gallates are also used as antoxidants in foods and are useful in preventing deterioration and rancidity of fats and oils. They are used in concentrations of 0.001 to 0.1%.

To improve acceptability and efficacy, the alkyl gallates are frequently used with other antoxidants such as butylated hydroxyanisole or butylated hydroxytoluene and with sequestrants and synergists such as citric acid and zinc salts.

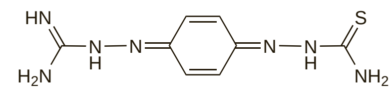
The alkyl gallates have also been reported to have limited antibacterial and antifungal activity.

Ambazone *(BAN, rINN)*

Ambatsoni; Ambazon; Ambazona; Ambazonum. 4-Amidinohydrazonocyclohexa-1,4-dien-3-one thiosemicarbazone monohydrate.

Амбазон

$C_8H_{11}N_7S,H_2O$ = 255.3.
CAS — 539-21-9 (anhydrous ambazone); 6011-12-7 (ambazone monohydrate).
ATC — R02AA01.
ATC Vet — QR02AA01.



Profile

Ambazone is an antiseptic that is used in the form of lozenges for minor infections of the mouth and pharynx.

Preparations

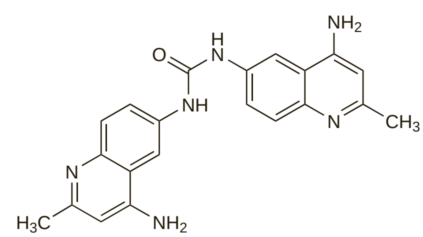
Proprietary Preparations (details are given in Part 3)
Cz.: Faringosept†; ***Hung.:*** Faringosept†; ***Pol.:*** Faringosept; ***Rus.:*** Faringosept (Фарингосепт).

Aminoquinuride Hydrochloride *(rINNM)*

Aminoquinuride, Chlorhydrate d'; Aminoquinuridi Hydrochloridum; Hidrocloruro de aminoquinurida. 1,3-Bis(4-amino-2-methyl-6-quinolyl)urea dihydrochloride.

Аминохинурида Гидрохлорид

$C_{21}H_{20}N_6O,2HCl$ = 445.3.
CAS — 3811-56-1 (aminoquinuride); 5424-37-3 (aminoquinuride hydrochloride).



(aminoquinuride)

Profile

Aminoquinuride hydrochloride is an antiseptic that has been used in topical preparations for the treatment of mouth and skin disorders.

Preparations

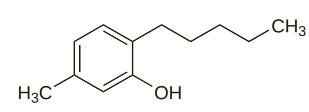
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Austria:*** Herviros; ***Ger.:*** Herviros†.

Amylmetacresol *(BAN, rINN)*

Amilmetacresol; Amilmetakrezol; Amylmétacrésol; Amylmetacresolum; Amylmetakresol; Amyylimetakresoli. 6-Pentyl-*m*-cresol; 5-Methyl-2-pentylphenol.

Амилметакрезол

$C_{12}H_{18}O$ = 178.3.
CAS — 1300-94-3.



Pharmacopoeias. In *Br.*
BP 2008 (Amylmetacresol). A clear or almost clear liquid or a solid crystalline mass with a characteristic odour, colourless or slightly yellow when freshly prepared; it darkens on keeping. F.p. about 22°. Practically insoluble in water; soluble in alcohol, in ether, and in fixed and volatile oils. Protect from light.

Profile

Amylmetacresol is a phenolic antiseptic used chiefly as an ingredient of lozenges in the treatment of minor infections of the mouth and throat.

Preparations

Proprietary Preparations (details are given in Part 3)
UK: Antiseptic Throat Lozenges; Throaties Anti-Bacterial Pastilles.

Multi-ingredient: ***Austral.:*** Sore Throat Chewing Gum†; Strepsils; Strepsils Plus; ***Austria:*** Coldangin; Neo-Angin; ***Belg.:*** Strepsils; Strepsils + Lidocaine; Strepsils Menthol; Strepsils Vit C; ***Canad.:*** Strepsils; Strepsils Cherry†; ***Cz.:*** Neo-Angin; Strepsils; Strepsils Menthol a Eucalyptus; Strepsils Plus; Strepsils Vitamin C; ***Denm.:*** Strepsils; ***Fin.:*** Strepsils; Strepsils Menthol;

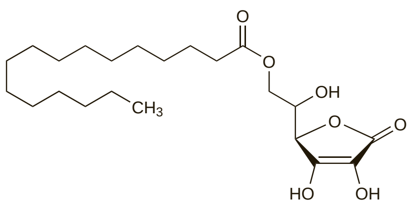
Ascorbyl Palmitate

Ascorbilo, palmitato de; Ascorbyle, palmitate d'; Ascorbylis palmitas; Askorbilo palmitatas; Askorbylpalmitat; Askorbylpalmitát; Askorbylu palmitynian; Askorbyylipalmitaatti; Aszkorbilpalmitát; Vitamin C Palmitate. L-Ascorbic acid 6-hexadecanoate; L-Ascorbic acid 6-palmitate; 3-Oxo-L-gulofuranolactone 6-palmitate.

$C_{22}H_{38}O_7$ = 414.5.

CAS — 137-66-6.



NOTE. The code E304 is used for fatty acid esters of ascorbic acid, which include ascorbyl palmitate.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Ascorbyl Palmitate). A white or yellowish-white powder. Practically insoluble in water; freely soluble in alcohol and in methyl alcohol; practically insoluble in dichloromethane and in fatty oils. Store in airtight containers. Protect from light.

USNF 26 (Ascorbyl Palmitate). A white to yellowish-white powder with a characteristic odour. Very slightly soluble in water, in chloroform, in ether, and in vegetable oils; soluble 1 in 125 of alcohol. Store at 8° to 15° in airtight containers.

Profile

Ascorbyl palmitate is an antoxidant used as a preservative in pharmaceutical products and foods. It is often used with alpha tocopherol (p.1992), and this combination shows marked synergy. As it is a fat-soluble derivative of vitamin C (ascorbic acid, p.1983), ascorbyl palmitate is sometimes used as a source of vitamin C in nutritional supplements.

Preparations

Proprietary Preparations (details are given in Part 3)
Chile: Neolucid-C.

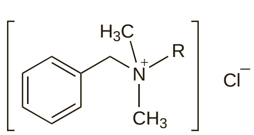
Бензалкония Хлорид

CAS — 8001-54-5.

ATC — D08AJ01; D09AA11; R02AA16.

ATC Vet — QD08AJ01; QD09AA11; QR02AA16.



R = C_8H_{17} to $C_{18}H_{37}$

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.,* and *Jpn.* Also in *USNF.* Some pharmacopoeias also have a monograph for a solution.

Chin. also includes benzalkonium bromide.

Ph. Eur. 6.2 (Benzalkonium Chloride). A mixture of alkylbenzyldimethylammonium chlorides, the alkyl groups having chain lengths of C_8 to C_{18}. It contains not less than 95% and not more than 104% of alkylbenzyldimethylammonium chlorides, calculated as $C_{22}H_{40}ClN$ with reference to the anhydrous substance.

A white or yellowish-white powder, or gelatinous yellowish-white pieces, hygroscopic and soapy to the touch. It forms a clear molten mass on heating. It contains not more than 10% of water. Very soluble in water and in alcohol. An aqueous solution froths copiously when shaken.

USNF 26 (Benzalkonium Chloride). A mixture of alkylbenzyldimethylammonium chlorides of the general formula $[C_6H_5.CH_2.N(CH_3)_2.R]Cl$, in which R represents a mixture of the alkyls having chain lengths from C_8 to C_{16}. It contains not less than 40% of the $C_{12}H_{25}$ compound, calculated on the anhydrous substance, not less than 20% of the $C_{14}H_{29}$ compound, and not less than 70% of the 2 compounds together.

A white or yellowish-white, thick gel, or gelatinous pieces with a mild aromatic odour. It contains not more than 15% of water. Very soluble in water and in alcohol; the anhydrous form is soluble 1 in 100 of ether and 1 in 6 of benzene. A solution in water is usually slightly alkaline and foams strongly when shaken. Store in airtight containers.

Incompatibility. Benzalkonium chloride is incompatible with soaps and other anionic surfactants, citrates, iodides, nitrates, permanganates, salicylates, silver salts, tartrates, and zinc oxide and sulfate. Incompatibilities have been demonstrated with ingredients of some commercial rubber mixes or plastics. Incompatibilities have also been reported with other substances including aluminium, cotton dressings, fluorescein sodium, hydrogen peroxide, hypromellose, kaolin, hydrous wool fat, and some sulfonamides.

Adverse Effects, Treatment, and Precautions

As for Cetrimide, p.1634. Because some rubbers are incompatible with benzalkonium chloride silicone rubber teats should be used on eye drop containers unless the suitability has been established.

Catheters and cannulas. For reference to benzalkonium chloride used in the manufacturing process of heparin-bonded catheters interfering with determination of serum concentrations of sodium and potassium, see under Precautions for Heparin, p.1303.

Effects on the eyes. Benzalkonium chloride is one of the most disruptive ophthalmic additives to the stability of the lipid film and to corneal epithelial membranes;[1] toxicity studies have tended to be carried out using relatively high concentrations of benzalkonium chloride[2] but damage to the tear film and corneoconjunctival surface have been noted in patients receiving regular long-term treatment for glaucoma with eye drops preserved with benzalkonium chloride in usual concentrations.[3,4]

Corneal toxicity has also been reported in patients inadvertently exposed to benzalkonium chloride as a preservative in viscoelastic material during cataract surgery.[5] The use of preservatives in eye drops should generally be avoided and the formulation of such preparations in single-dose containers is desirable.[1,2] Benzalkonium chloride is not suitable for use in solutions for storing and washing hydrophilic soft contact lenses, as it can bind to the lenses and may later produce ocular toxicity when the lenses are worn.[6] Similarly, benzalkonium chloride use in anaesthetic eye drops is discouraged, as the anaesthetic component reduces the blink reflex and increases the contact time with the eye drops which may consequently result in increased toxicity due to the preservative. Patients with dry eye syndrome are also at increased risk of toxicity as the corneal epithelium is exposed to the full strength of the eye drops, in addition to which these patients do not produce enough tears to dilute the preservative in the eye drops.

6. Gasset AR. Benzalkonium chloride toxicity to the human cornea. *Am J Ophthalmol* 1977; **84:** 169–71.

Effects on the respiratory tract. Hypersensitivity to benzalkonium chloride, used as a preservative in nasal drops, was confirmed in a patient by a challenge that produced nasal congestion and irritation of the eyes and throat lasting 48 hours.[1] A review[2] of 18 studies (14 *in vivo*, 4 *in vitro*) where benzalkonium chloride was used as the preservative in multidose nasal products found that 8 studies (all *in vivo*) found no toxic effects, while 10 reported degenerative changes to the nasal epithelia or exacerbation of rhinitis medicamentosa. However, in only 2 of these 10 studies were the differences between benzalkonium chloride and control groups found to be significant, and both of these included the use of oxymetazoline, which is known to cause rhinitis medicamentosa.

Benzalkonium chloride used as a preservative in nebulised solutions of anti-asthma drugs has been reported to cause dose-related bronchoconstriction especially in asthmatic patients,[3] and has been associated with the precipitation of respiratory arrest.[4]

4. Boucher M, *et al.* Possible association of benzalkonium chloride in nebulizer solutions with respiratory arrest. *Ann Pharmacother* 1992; **26:** 772–4.

Interactions

Benzalkonium chloride is not suitable for use in eye drops containing local anaesthetics (see Effects on the Eyes, above).

Uses and Administration

Benzalkonium chloride is a quaternary ammonium antiseptic and disinfectant with actions and uses similar to those of the other cationic surfactants (see Cetrimide, p.1634). It is also used as an antimicrobial preservative for pharmaceutical products. Benzalkonium bromide and benzalkonium saccharinate have also been used.

Solutions of benzalkonium chloride 0.01 to 0.1% are used for cleansing skin, mucous membranes, and wounds. More dilute solutions of 0.005% are suitable for irrigation of deep wounds. A 0.02 to 0.05% solution has been used as a vaginal douche. An aqueous solution containing 0.005 to 0.02% has been used for irrigation of the bladder and urethra and a 0.0025 to 0.005% solution for retention lavage of the bladder.

Creams containing benzalkonium chloride are used in the treatment of napkin rash and other dermatoses.

A 0.2 to 0.5% solution has been used as a shampoo in seborrhoeic dermatitis.

Lozenges containing benzalkonium chloride are used for the treatment of superficial infections of the mouth and throat.

Benzalkonium chloride is used as a preservative in ophthalmic solutions at a concentration of 0.01 to 0.02%, and in nasal and otic solutions at a concentration of 0.002 to 0.02%. Benzalkonium chloride is used for disinfecting rigid contact lenses (p.1622) but is unsuitable as a preservative in solutions for washing and storing hydrophilic soft contact lenses (see also Effects on the Eyes, above).

Benzalkonium chloride is also used as a spermicide.

Solutions of 0.13% are used for disinfection and storage of surgical instruments, sometimes with the addition of sodium nitrite to inhibit rust.

Action. The antibacterial effect of benzalkonium chloride 0.003% was enhanced by 0.175% of benzyl alcohol, phenylpropanol, or phenethyl alcohol.[1] For the use of phenethyl alcohol with benzalkonium chloride as a preservative for ophthalmic solutions, see Antimicrobial Action, under Phenethyl Alcohol, p.1655.

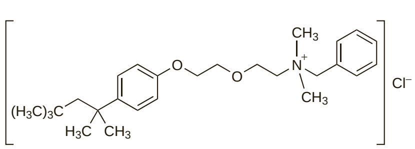
$C_{27}H_{42}ClNO_2$ = 448.1.
CAS — 121-54-0.
ATC — R02AA09.
ATC Vet — QR02AA09.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Benzethonium Chloride). A white or yellowish-white powder. Very soluble in water and in alcohol; freely soluble in dichloromethane. An aqueous solution froths copiously when shaken. Protect from light.

USP 31 (Benzethonium Chloride). White crystals with a mild odour. Soluble 1 in less than 1 of water, of alcohol, and of chloroform, and 1 in 6000 of ether. A 1% solution in water is slightly alkaline to litmus. Store in airtight containers. Protect from light.

Incompatibility. Benzethonium chloride is incompatible with soaps and other anionic surfactants.

Profile

Benzethonium chloride is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used as a preservative in pharmaceutical and cosmetic products. It has also been used as a vaginal spermicide.

◊ Benzethonium chloride, which produced mild skin irritation at a concentration of 5% but not lower, was not considered to be a sensitiser, and was considered to be safe at a concentration of 0.5% in cosmetics applied to the skin and at a maximum concentration of 0.02% in cosmetics used in the eye area.[1]

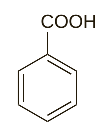
Benzoates

Benzoatos.

Benzoic Acid

Acide benzoïque; Acidum benzoicum; Bensoesyra; Bentsoehappo; Benzoesäure; Benzoesav; Benzoico, ácido; Benzoinė rūgštis; Dracylic Acid; E210; Kwas benzoesowy; Kyselina benzoová.

$C_6H_5.CO_2H$ = 122.1.
CAS — 65-85-0.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Benzoic Acid). A white or almost white, crystalline powder or colourless crystals, odourless or with a very slight characteristic odour. Slightly soluble in water; soluble in boiling water; freely soluble in alcohol and in fatty oils. M.p. 121° to 124°.

USP 31 (Benzoic Acid). White crystals, scales, or needles, with a slight characteristic odour. Soluble 1 in 300 of water, 1 in 3 of alcohol, 1 in 5 of chloroform, and 1 in 3 of ether; freely volatile in steam. Congealing range 121° to 123°.

Incompatibility. The incompatibilities of benzoic acid are described under Sodium Benzoate, below.

Sodium Benzoate

Benzoan sodný; Benzoato sódico; E211; Natrii benzoas; Natrio benzoatas; Natrium Benzoicum; Natriumbensoat; Natriumbentsoaatti; Nátrium-benzoát; Sodii Benzoas; Sodium, benzoate de; Sodu benzoesan; Sodyum Benzoat.

$C_6H_5.CO_2Na$ = 144.1.
CAS — 532-32-1.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *Viet.* Also in *USNF.*

Ph. Eur. 6.2 (Sodium Benzoate). A white or almost white, slightly hygroscopic, crystalline or granular powder or flakes. Freely soluble in water; sparingly soluble in alcohol (90% v/v).

USNF 26 (Sodium Benzoate). A white, odourless or practically odourless, granular or crystalline powder. Soluble 1 in 2 of water, 1 in 75 of alcohol, and 1 in 50 of alcohol 90%.

Incompatibility. Benzoic acid and its salts are incompatible with quaternary compounds, calcium salts, ferric salts, and salts of heavy metals. Their activity is also diminished by nonionic surfactants or due to absorption by kaolin. They are relatively inactive above a pH of about 5.

Adverse Effects and Precautions

The benzoates can cause hypersensitivity reactions, but there have also been reports of non-immunological contact urticaria. The acid can be irritant to skin, eyes, and mucous membranes.

Infants given large doses of sodium benzoate have suffered vomiting. Symptoms of overdosage reported in this group have included vomiting, irritability and, in more severe cases, renal tubular dysfunction, hypokalaemia, hypocalcaemia, and metabolic acidosis.

Premature infants have been reported to be at risk of metabolic acidosis and kernicterus.

Hypersensitivity. Respiratory reactions to benzoates may occur, especially in patients susceptible to aspirin-induced asthma.[1,2] Urticarial reactions have also been associated with these compounds,[3,4] though at a lower incidence[5] and they can be non-immunological.[6] However, these reports have to be balanced against a controlled study[7] that showed no difference in the incidence of urticaria or atopic symptoms between patients given benzoic acid and those given lactose placebo. A retrospective study[8] of 47 patients who had previously shown a hypersensitivity reaction after ingesting food or products containing benzoate sodium found that the incidence of a repeat episode of acute urticaria or angioedema on re-challenge was very low (2%).

Anaphylactoid reactions have been reported in 2 patients.[9,10]

Erythema multiforme has been observed in several patients.[11]

Neonates. Serious metabolic disturbances in premature neonates given intravenous fluids with benzyl alcohol as a preservative have been attributed to the accumulation of benzoic acid, a metabolite of benzyl alcohol (see p.1632). This risk led to the recommendation that Caffeine and Sodium Benzoate Injection (USP), which has been given as a respiratory stimulant, should not be used in neonates.[1]

Sodium benzoate has been tried in the treatment of some neonatal metabolic disorders (see Uses and Administration, below). However, benzoates can also displace bound bilirubin from albumin putting neonates at risk of kernicterus.[2] Three cases of toxicity have been reported after accidental high doses of intravenous sodium benzoate and sodium phenylacetate were given to children with hyperammonaemia.[3] All the children initially became agitated and confused, had Kussmaul respiration (rapid, deep breathing) and developed a partial metabolic acidosis with an increased anion gap. Two patients subsequently developed cerebral oedema and hypotension and died while the third survived after haemodialysis.

2. Schiff D, *et al.* Fixed drug combinations and the displacement of bilirubin from albumin. *Pediatrics* 1971: **48:** 139–41.
3. Praphanphoj V, *et al.* Three cases of intravenous sodium benzoate and sodium phenylacetate toxicity occurring in the treatment of acute hyperammonaemia. *J Inherit Metab Dis* 2000; **23:** 129–36.

Pharmacokinetics

The benzoates are absorbed from the gastrointestinal tract and conjugated with glycine in the liver to form hippuric acid, which is rapidly excreted in the urine.

Neonates. References.

1. Green TP, *et al.* Disposition of sodium benzoate in newborn infants with hyperammonemia. *J Pediatr* 1983; **102:** 785–90.

Uses and Administration

Benzoates have antibacterial and antifungal properties. Their antimicrobial activity is due to the undissociated benzoic acid and is therefore pH-dependent. They are relatively inactive above a pH of about 5.

Benzoates are used as preservatives in pharmaceutical formulations including oral preparations; benzoic acid and sodium benzoate are typically used in concentrations of up to 0.2% and 0.5%, respectively. They are used as preservatives in foods, (and are also present naturally in some foods), and at similar concentrations in cosmetics.

Benzoic acid 6% with salicylic acid 3%, as Compound Benzoic Acid Ointment (BP 2008) (Whitfield's Ointment) has a long history of use as an antifungal (see Skin Infections, p.521). Benzoic acid has also been used in desloughing preparations and has been given as a urinary antiseptic.

An injection of caffeine and sodium benzoate has been used as a CNS stimulant, but see Neonates, under Adverse Effects and Precautions, above for a caution against its use in neonates.

Sodium benzoate is used as part of the treatment of hyperammonaemia that occurs in inborn errors of the urea cycle. It has also been reported to be effective in reducing plasma-glycine concentrations in nonketotic hyperglycinaemia (p.2393), although it may not be effective in preventing mental retardation.

Sodium benzoate is a common ingredient of cough preparations.

Hyperammonaemia. Sodium benzoate is used for treatment of hyperammonaemia (p.1929).[1-3] It is given with sodium phenylacetate (see p.2390 for doses) and a combined preparation is available in some countries.

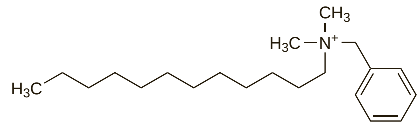
Benzododecinium Bromide

Benzododecinio, bromuro de. Benzyldodecyldimethylammonium bromide.

$C_{21}H_{38}BrN$ = 384.4.
CAS — 10328-35-5 (benzododecinium); 7281-04-1 (benzododecinium bromide).
ATC — D09AA05.
ATC Vet — QD09AA05.



(benzododecinium)

Pharmacopoeias. In *Fr.*

Benzododecinium Chloride *(rINN)*

Benzododecinii Chloridum; Benzododécinium, Chlorure de; Cloruro de benzododecinio; Lauralkonium Chloride. Benzyldodecyldimethylammonium chloride.

Бензододециния Хлорид
$C_{21}H_{38}ClN$ = 340.0.
CAS — 139-07-1.
ATC — D09AA05.
ATC Vet — QD09AA05.

NOTE. The name Lauralkonium Chloride is also a *rINN* for another quaternary ammonium compound ($C_{29}H_{44}ClNO_2$; CAS – 19486-61-4).

Profile

Benzododecinium bromide is a quaternary ammonium antiseptic with properties similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used in mouthwashes, eye preparations, and nasal sprays and solutions for the treatment of minor infections. It has also been used as a spermicide. Benzododecinium chloride has also been used.

Preparations

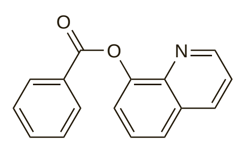
Proprietary Preparations (details are given in Part 3)
Cz.: Ajatin; ***Fr.:*** Rhinedrine.

Multi-ingredient: ***Cz.:*** Ophtal; ***Fr.:*** Prorhinel; Sedacollyre; ***Switz.:*** Kemerhinose; Prorhinel.

Benzoxiquine *(USAN, rINN)*

Benzoxiquina; Benzoxiquinum; NSC-3951. 8-Quinolinol benzoate (ester).

Бензоксихин
$C_{16}H_{11}NO_2$ = 249.3.
CAS — 86-75-9.



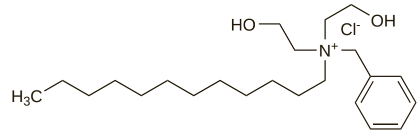
Profile

Benzoxiquine is an antiseptic that has been included in cosmetic products and multi-ingredient preparations used topically for the treatment of fungal infections. The salicylate has also been used.

Benzoxonium Chloride *(rINN)*

Benzoxonii Chloridum; Benzoxonium, Chlorure de; Cloruro de benzoxonio. Benzyldodecylbis(2-hydroxyethyl)ammonium chloride.

Бензоксония Хлорид
$C_{23}H_{42}ClNO_2$ = 400.0.
CAS — 19379-90-9.
ATC — A01AB14; D08AJ05.
ATC Vet — QA01AB14; QD08AJ05.



Profile

Benzoxonium chloride is a quaternary ammonium antiseptic used for disinfection of the skin and mucous membranes. It is also used for instrument disinfection. Allergic contact dermatitis from benzoxonium chloride has been reported.

Preparations

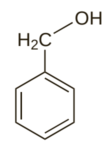
Proprietary Preparations (details are given in Part 3)
Belg.: Orofar; ***Chile:*** Bialcol; ***Gr.:*** Orocil; ***Ital.:*** Bactofen; Bialcol.

Multi-ingredient: ***Belg.:*** Orofar Lidocaine; ***Chile:*** Alcolex; ***Cz.:*** Orofar; ***Ger.:*** Loscon†; ***Gr.:*** Orocil Lido; ***Hung.:*** Mebucain; Vita-Merfen†; ***Israel:*** Merfen; Vita-Merfen NF; ***Philipp.:*** Orofar-L; ***Pol.:*** Orofar; ***Port.:*** Orofar†; ***Rus.:*** Theraflu Lar (Терафлю Лар); ***Switz.:*** Mebucalets f; Merfen; Orofar; Vita-Merfen.

Benzyl Alcohol *(rINN)*

Alcohol bencílico; Alcohol benzylicus; Alcoholum Benzylicum; Alcool Benzylique; Alkohol benzylowy; Bensylalkohol; Bentsyylialkoholi; Benzenemethanol; Benzil-alkohol; Benzilo alkoholis; Benzylalkohol; Benzylique, alcool; Fenilmetanol; Phenylcarbinol; Phenylmethanol.

Бензиловый Спирт
$C_6H_5.CH_2OH$ = 108.1.
CAS — 100-51-6.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Benzyl Alcohol). A clear colourless, oily liquid. Soluble in water; miscible with alcohol, and with fatty and essential oils. Store under nitrogen in airtight containers at a temperature of 2° to 8°. Protect from light.

USNF 26 (Benzyl Alcohol). A clear, colourless, oily liquid. Sparingly soluble in water; freely soluble in alcohol (50%); miscible with alcohol, with chloroform, and with ether. It is neutral to litmus.

Incompatibility. Benzyl alcohol is incompatible with oxidising agents and strong acids. The antimicrobial activity may be reduced by nonionic surfactants and benzyl alcohol may be lost from solutions stored in polyethylene containers.

Stability. Benzyl alcohol oxidises to produce benzaldehyde and benzoic acid and oxidation may take place slowly on exposure to air. Benzaldehyde may also be produced on autoclaving.

Adverse Effects and Precautions

There have been a few reports of hypersensitivity reactions to benzyl alcohol when used as a preservative.

The pure alcohol is irritant and requires handling with care; ingestion or inhalation can cause nausea, vomiting, diarrhoea, headache, and vertigo. Overexposure results in respiratory failure and CNS depression. However, concentrations of benzyl alcohol normally used for preservation are not associated with such effects.

There have been some instances of neurotoxic effects in patients given intrathecal injections that contained benzyl alcohol.

A fatal toxic syndrome in premature infants was attributed to benzyl alcohol present as a preservative in solutions used to flush intravenous catheters. This has led to restriction on the use of benzyl alcohol in neonates and young children, (see below).

Effects on the lungs. Severe bronchitis and haemoptysis was reported in a patient with obstructive pulmonary disease who, over a period of 2 years, had inhaled salbutamol nebuliser solution diluted with a bacteriostatic sodium chloride solution containing benzyl alcohol.[1]

1. Reynolds RD. Nebulizer bronchitis induced by bacteriostatic saline. *JAMA* 1990; **264:** 35.

Effects on the nervous system. Rapid development of flaccid areflexic paraplegia, total anaesthesia below the groin, and radicular abdominal pain occurred in a 64-year-old man after a lumbar intrathecal injection of cytarabine that contained 1.5% benzyl alcohol.[1] The patient recovered fully after 100 mL of CSF was replaced with sodium chloride 0.9% and 40 mg of methylprednisolone. Intrathecal injections of cytarabine dissolved in sterile distilled water before and after the episode of paraplegia caused no neurologic symptoms. On reviewing 20 other cases of paraparesis associated with methotrexate or cytarabine intrathecal injections, benzyl alcohol had been used as a preservative in

7. Of these, 4 developed neurotoxicity immediately; in the other 3 it did not develop for between 6 and 48 hours. The duration varied. One patient did not improve, one made a partial recovery, a third took 6 weeks to recover, another took 5 days; yet 2 patients recovered within 1 ⁄ to 2 ⁄ hours while the final patient experienced only transient effects.

1. Hahn AF, *et al.* Paraparesis following intrathecal chemotherapy. *Neurology* 1983; **33:** 1032–8.

Hypersensitivity. Hypersensitivity reactions to benzyl alcohol have been reported.[1-3]

1. Grant JA, *et al.* Unsuspected benzyl alcohol hypersensitivity. *N Engl J Med* 1982; **306:** 108.
2. Shmunes E. Allergic dermatitis to benzyl alcohol in an injectable solution. *Arch Dermatol* 1984; **120:** 1200–1.
3. Wilson JP, *et al.* Parenteral benzyl alcohol-induced hypersensitivity reaction. *Drug Intell Clin Pharm* 1986; **20:** 689–91.

Neonates. During 1981 and 1982 reports were published from 2 centres in the USA[1-3] of 20 deaths in low-birth-weight neonates attributed to the use of benzyl alcohol as a preservative in solutions used to flush their umbilical catheters and in some cases also to dilute their medication. The neonates suffered a toxic syndrome whose features included metabolic acidosis, symptoms of progressive encephalopathy, intracranial haemorrhage, and respiratory depression with gasping.

These deaths prompted the FDA[4] to recommend that benzyl alcohol should not be used in such flushing solutions; sodium chloride injection 0.9% without preservative should be used instead. The FDA had also advised against the use of benzyl alcohol or any preservative in fluids being used for the dilution or reconstitution of medicines for the newborn.

Those reporting the deaths[2,3] considered that the toxic syndrome could have been caused by the accumulation of the benzoic acid metabolite of benzyl alcohol, which could not be handled effectively by the immature liver; given the very low weight of the neonates they would have been receiving a comparatively high dose of benzyl alcohol. In commenting on the problem, the American Academy of Pediatrics[5] agreed that the FDA's warning was warranted, but pointed out that there was no evidence from controlled studies to confirm that benzyl alcohol was responsible.

1. Gershanik JJ, *et al.* The gasping syndrome: benzyl alcohol (BA) poisoning? *Clin Res* 1981; **29:** 895A.
2. Brown WJ, *et al.* Fatal benzyl alcohol poisoning in a neonatal intensive care unit. *Lancet* 1982; **i:** 1250.
3. Gershanik J, *et al.* The gasping syndrome and benzyl alcohol poisoning. *N Engl J Med* 1982; **307:** 1384–8.
4. Anonymous. Benzyl alcohol may be toxic to newborns. *FDA Drug Bull* 1982; **12:** 10–11.
5. American Academy of Pediatrics. Benzyl alcohol: toxic agent in neonatal use. *Pediatrics* 1983; **72:** 356–7.

Pharmacokinetics

Benzyl alcohol is metabolised to benzoic acid. This is conjugated with glycine in the liver to form hippuric acid which is excreted in the urine. Benzaldehyde and benzoic acid are degradation products *in vitro*.

Uses

Benzyl alcohol is used as an antimicrobial preservative. It is bacteriostatic mainly against Gram-positive organisms and some fungi. It is used in a range of pharmaceutical preparations in concentrations up to 2%. Concentrations of 5% or more are employed when it is used as a solubiliser. Benzyl alcohol is used as a preservative in foods and cosmetics. It is also used as a disinfectant at a concentration of 10%.

In addition to its antiseptic properties, concentrations of benzyl alcohol of up to 10% possess weak local anaesthetic and antipruritic activity.

Preparations

Proprietary Preparations (details are given in Part 3)
Canad.: Babys Own Teething Gel†; Zilactin Cold Sore Gel; ***USA:*** Zilactin.

Multi-ingredient: ***Arg.:*** Standard XXI; ***Austral.:*** Coso; Soothe'n Heal; ***Austria:*** Dermaspray; ***Belg.:*** Dermaspray†; Purigel Crisp; Purigel NF; ***Chile:*** Aucusik; Medikem†; Medisept†; ***Denm.:*** Doloproct Comp; ***Fr.:*** Biseptine; Codotussyl Maux de Gorge; Dermaspraid Antiseptique; Pastilles Medicinales Vicks; ***Ger.:*** Autoderm Extra; Gelipur; Spitacid; ***India:*** Dicloran MS; ***Israel:*** Otomycin; ***Ital.:*** Borocaina; Foille Scottature; Foille Sole; Pitiren; Prurex; Skab 2; ***Singapore:*** Saak†; ***Spain:*** Acerbiol; Pastillas Antisep Garg M; ***UK:*** Sudocrem; ***USA:*** Itch-X; MouthKote O/R; Oragesic; Super Ivy Dry; Topic; Tucks.

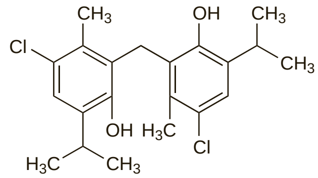
Biclotymol *(rINN)*

Biclotimol; Biclotymolum. 2,2′-Methylenebis(6-chlorothymole).

Биклотимол

$C_{21}H_{26}Cl_2O_2$ = 381.3.
CAS — 15686-33-6.



Profile

Biclotymol is a phenolic antiseptic that is used in lozenges and sprays for mouth and throat infections. It is also an ingredient of cough preparations.

Preparations

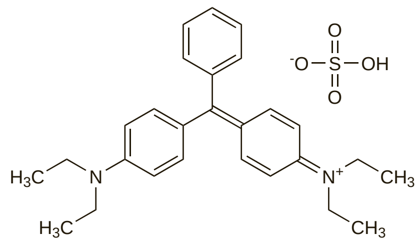
Proprietary Preparations (details are given in Part 3)
Cz.: Hexaspray†; ***Fr.:*** Hexaspray; Humex; Rhinathiol maux de gorge†; Sagadreps†; Sagaspray; Solutricine Maux de Gorge; ***Hong Kong:*** Hexaspray; ***Port.:*** Hexaspray; ***Rus.:*** Hexaspray (Гексаспрей).

Multi-ingredient: ***Fr.:*** Hexalyse; Hexapneumine; Hexarhume; ***Hong Kong:*** Hexalyse; Hexapneumine; ***Rus.:*** Hexalyse (Гексализ).

Brilliant Green

CI Basic Green 1; Colour Index No. 42040; Diamond Green G; Emerald Green; Ethyl Green; Malachite Green G; Solid Green; Verde brillante; Viride Nitens. 4-(4-Diethylaminobenzhydrylidene)cyclohexa-2,5-dien-1-ylidenediethylammonium hydrogen sulphate.

$C_{27}H_{34}N_2O_4S$ = 482.6.
CAS — 633-03-4.



NOTE. The name Emerald Green has also been used for copper acetoarsenite.

Profile

Brilliant green is a triphenylmethane antiseptic dye with actions similar to those of methylrosanilinium chloride (p.1653). Its activity is greatly reduced in the presence of serum.

A gel containing brilliant green 0.5% with lactic acid was formerly used in the treatment of skin ulcers.

An alcoholic solution of brilliant green 0.5% and methylrosanilinium chloride 0.5% (Bonney's Blue) was formerly used for disinfecting the skin, but concern over evidence of *animal* carcinogenicity with methylrosanilinium chloride has led to a decline in its use. A solution of the two disinfectants has been used for marking incisions before surgery.

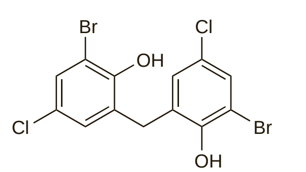
There have been occasional reports of sensitivity to brilliant green.

Adverse effects. For a report of necrotic skin reactions after application of a 1% solution of brilliant green to stripped skin, see under the Adverse Effects of Methylrosanilinium Chloride, p.1653.

Bromchlorophen

Bromchlorophene; Bromochlorophane; Bromoclorofeno. 2,2′-Methylenebis[6-bromo-4-chlorophenol].

$C_{13}H_8Br_2Cl_2O_2$ = 426.9.
CAS — 15435-29-7.



Profile

Bromchlorophen is a halogenated bisphenol antiseptic more active against Gram-positive than Gram-negative bacteria. It is used for disinfection of the hands and skin. It has also been used in deodorants and toothpastes.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Ger.:*** Dibromol.

Bromsalans

Bromosalicilanilidas.
CAS — 55830-61-0.

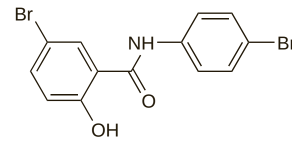
Description. Bromsalans are a series of brominated salicylanilides that possess antimicrobial activity.

Dibromsalan *(USAN, pINN)*

Dibromsalán; Dibromsalanum; NSC-20527. 4′,5-Dibromosalicylanilide; 5-Bromo-*N*-(4-bromophenyl)-2-hydroxybenzamide.

Дибромсалан

$C_{13}H_9Br_2NO_2$ = 371.0.
CAS — 87-12-7.

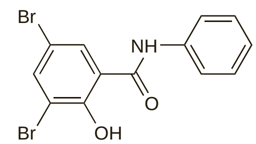


Metabromsalan *(USAN, pINN)*

Métabromsalan; Metabromsalán; Metabromsalanum; NSC-526280. 3,5-Dibromosalicylanilide; 3,5-Dibromo-2-hydroxy-*N*-phenylbenzamide.

Метабромсалан

$C_{13}H_9Br_2NO_2$ = 371.0.
CAS — 2577-72-2.

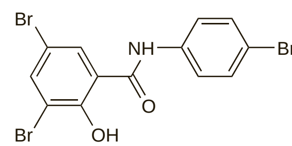


Tribromsalan *(BAN, USAN, rINN)*

ET-394; NSC-20526; TBS; Tribromsalán; Tribromsalanum. 3,4′,5-Tribromosalicylanilide; 3,5-Dibromo-*N*-(4-bromophenyl)-2-hydroxybenzamide.

Трибромсалан

$C_{13}H_8Br_3NO_2$ = 449.9.
CAS — 87-10-5.



Profile

Bromsalans have antibacterial and antifungal activity and have been used in medicated soaps, but there have been many reports of photosensitivity arising from this use.

Preparations

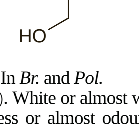
Proprietary Preparations (details are given in Part 3)
Ital.: Bergamon Sapone.

Bronopol *(BAN, rINN)*

Bronopolum. 2-Bromo-2-nitropropane-1,3-diol.

Бронопол

$C_3H_6BrNO_4$ = 200.0.
CAS — 52-51-7.
ATC Vet — QD01AE91.



Pharmacopoeias. In *Br.* and *Pol.*

BP 2008 (Bronopol). White or almost white crystals or crystalline powder, odourless or almost odourless. Freely soluble in water and in alcohol; slightly soluble in glycerol and in liquid paraffin. A 1% solution in water has a pH of 5.0 to 7.0. Protect from light.

Incompatibility. The activity of bronopol can be reduced by sodium metabisulfite, sodium thiosulfate, cysteine hydrochloride, and compounds with a thiol group. Incompatibility with unprotected aluminium affects packaging.

Stability. The stability of bronopol is affected by increases in temperature and by increases in pH above 8.

Creams and shampoos containing bronopol 0.01% as a preservative were found to contain free nitrite and, as a result of amines present in the preparations, nitrosamines.[1] It was recommended that nitrosamine formation could be reduced in preparations containing amines and bronopol by limiting the bronopol concentration to 0.01% and inclusion of alpha tocopherol 0.2% or butylated hydroxytoluene 0.05%.

1. Dunnett PC, Telling GM. Study of the fate of bronopol and the effects of antioxidants on N-nitrosamine formation in shampoos and skin creams. *Int J Cosmet Sci* 1984; **6:** 241–7.

Adverse Effects

Bronopol may be irritant when applied topically and cases of contact dermatitis have been reported.

Pharmacokinetics

Bronopol is absorbed following topical use.

Uses

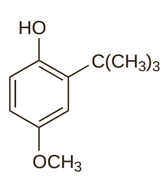
Bronopol is active against a wide range of bacteria, including *Pseudomonas aeruginosa*, but is less active against moulds and yeasts. Bronopol is used as a preservative in shampoos, cosmetics, and both topical and oral pharmaceutical preparations; concentrations in pharmaceutical preparations range from 0.01 to 0.1%, with the usual concentration being 0.02%. It is also used for its antimicrobial properties in various industrial applications, including in air conditioning systems.

Butylated Hydroxyanisole *(BAN)*

BHA; Butilhidroksianizolas; Butilhidroxianisol; Butil-hidroxianizol; Butilidrossianisolo; Butylhydroxianisol; Butylhydroxyanisol; Butylhydroxyanisole; Butylhydroxyanisolum; Butylohydroksyanizol; Butyylihydroksianisoli; E320. 2-*tert*-Butyl-4-methoxyphenol; 2-(1,1-dimethylethyl)-4-methoxyphenol.

$C_{11}H_{16}O_2$ = 180.2.

CAS — 25013-16-5.



Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*

Ph. Eur. 6.2 (Butylhydroxyanisole; Butylated Hydroxyanisole BP 2008). A white, yellowish, or slightly pinkish, crystalline powder. It contains not more than 10% of 3-(1,1-dimethylethyl)-4-methoxyphenol. Practically insoluble in water; freely soluble in alcohol and in fatty oils; very soluble in dichloromethane; it dissolves in dilute solutions of alkali hydroxides. Protect from light.

USNF 26 (Butylated Hydroxyanisole). A white, or slightly yellow, waxy solid with a faint characteristic odour. Insoluble in water; soluble 1 in 4 of alcohol, 1 in 2 of chloroform, and 1 in 1.2 of ether; freely soluble in propylene glycol.

Incompatibility. Butylated hydroxyanisole is incompatible with oxidising agents and ferric salts. Traces of metals can cause loss of activity.

Adverse Effects

Butylated hydroxyanisole can be irritant to the eyes, skin, and mucous membranes and can cause depigmentation. There are also reports of contact urticaria.

Carcinogenicity. There has been concern as to whether butylated hydroxyanisole may be a carcinogen.[1,2] These concerns stem from a study in which *rodents* given food containing 1 to 2% butylated hydroxyanisole developed squamous cell carcinoma of the forestomach. No similar malignancies were found in studies with *animals* that do not have a forestomach. The International Agency for Research on Cancer has concluded[2] that there is sufficient evidence for the carcinogenicity of butylated hydroxyanisole in *animals* but that there is no data on its carcinogenicity in humans.

2. IARC/WHO. Some naturally occurring and synthetic food components, furocoumarins and ultraviolet radiation. *IARC monographs on the evaluation of the carcinogenic risk of chemicals to humans volume 40* 1986. Available at: http://monographs.iarc.fr/ENG/Monographs/vol40/volume40.pdf (accessed 23/05/06)

Effects on the blood. For a report of methaemoglobinaemia associated with the antoxidants (butylated hydroxyanisole, butylated hydroxytoluene, and propyl gallate) used to preserve the oil in a soybean infant feed, see under Adverse Effects in Alkyl Gallates (p.1628).

Pharmacokinetics

Butylated hydroxyanisole is absorbed from the gastrointestinal tract, then metabolised and conjugated, and excreted in the urine; less than 1% is excreted in the urine as unchanged drug within 24 hours of ingestion.

Uses

Butylated hydroxyanisole is an antoxidant with some antimicrobial activity. It is used as a preservative in cosmetics and foods as well as pharmaceutical preparations, particularly to delay or prevent oxidative rancidity of fats and oils in concentrations of up to 0.02%; higher concentrations have been used for essential oils. It is also used to prevent the loss of activity of oil-soluble vitamins. To improve efficacy, butylated hydroxyanisole is frequently used with other antoxidants such as butylated hydroxytoluene or an alkyl gallate and with sequestrants or synergists such as citric acid.

Commercial supplies of butylated hydroxyanisole used in food technology consist of mixtures of the 2-*tert* and 3-*tert* isomers.

Use in food. In the UK the Food Advisory Committee has recommended that the use of butylated hydroxyanisole and butylated hydroxytoluene should no longer be permitted as additives for infant formulas as they are no longer required for the economic manufacture of vitamin A and vitamin A esters.[1]

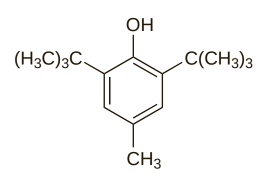
1. MAFF. Food Advisory Committee: report on the review of the use of additives in foods specially prepared for infants and young children. *FdAC/REP/12.* London: HMSO, 1992.

Butylated Hydroxytoluene *(BAN)*

BHT; Butilhidroksitoluenas; Butilhidroxitolueno; Butil-hidroxitoluol; Butylhydroxitoluen; Butylhydroxitoluenum; Butylhydroxytoluen; Butylhydroxytoluène; Butylhydroxytoluene; Butylhydroxytoluenum; Butylohydroksytoluen; Butyylihydroksitolueeni; E321. 2,6-Di-*tert*-butyl-*p*-cresol.

$C_{15}H_{24}O$ = 220.4.

CAS — 128-37-0.



Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*

Ph. Eur. 6.2 (Butylhydroxytoluene; Butylated Hydroxytoluene BP 2008). A white or yellowish-white, crystalline powder. F.p. 69° to 70°. Practically insoluble in water; freely soluble in alcohol and in vegetable oils; very soluble in acetone.

USNF 26 (Butylated Hydroxytoluene). A white crystalline solid with a faint characteristic odour. Insoluble in water and in propylene glycol; soluble 1 in 4 of alcohol and 1 in 1.1 of chloroform and of ether.

Incompatibility. Butylated hydroxytoluene is incompatible with oxidising agents and ferric salts. Traces of metals can cause loss of activity.

Adverse Effects

As for Butylated Hydroxyanisole, p.1633.

Effects on the blood. For a report of methaemoglobinaemia associated with the antoxidants (butylated hydroxyanisole, butylated hydroxytoluene, and propyl gallate) used to preserve the oil in a soybean infant feed formula, see under Adverse Effects in Alkyl Gallates, p.1628.

Poisoning. A 22-year-old woman experienced severe epigastric cramping, nausea and vomiting, and generalised weakness, followed by dizziness, confusion, and a brief loss of consciousness after ingesting 4 g of butylated hydroxytoluene. She recovered after conservative treatment, which was given 2 days later. The antoxidant had been taken as an unauthorised remedy for genital herpes simplex.[1]

1. Shlian DM, Goldstone J. Toxicity of butylated hydroxytoluene. *N Engl J Med* 1986; **314:** 648–9.

Pharmacokinetics

Butylated hydroxytoluene is readily absorbed from the gastrointestinal tract. It is excreted in the urine mainly as glucuronide conjugates of oxidation products.

Uses

Butylated hydroxytoluene is an antoxidant with uses similar to those of Butylated Hydroxyanisole, p.1633.

Preparations

Proprietary Preparations (details are given in Part 3)
Belg.: Proseptine-Plus.

Multi-ingredient: *Fr.:* Cinq sur Cinq.

Cadexomer-Iodine *(BAN)*

Cadexomer Iodine *(USAN)*; Cadexomerjod; Cadexómero yodado; Cadexomerum Iodum; Kadeksomeerijodi. 2-Hydroxymethylene cross-linked (1→4)-α-D-glucan carboxymethyl ether containing iodine.

CAS — 94820-09-4.
ATC — D03AX01.
ATC Vet — QD03AX01.

Adverse Effects and Precautions

As for Povidone-Iodine, p.1659. Some patients have experienced stinging and erythema on application of cadexomer-iodine to their ulcers. Free iodine is released during exposure of cadexomer-iodine preparations to wound exudate and absorption of iodine may occur. Prolonged treatment with cadexomer-iodine should be given with caution in patients with thyroid disorders.

Uses and Administration

Cadexomer-iodine, like povidone-iodine (p.1659), is an iodophore that releases iodine. It is used for its absorbent and antiseptic properties in the management of venous leg ulcers and pressure sores. It is applied as a powder, ointment, or paste containing iodine 0.9%; sufficient powder or ointment should be applied to form a layer about 3 mm thick. Treatment should not usually be continued for more than 3 months.

Preparations

Proprietary Preparations (details are given in Part 3)

Calcium Peroxide

Calcium Dioxide; E930.

Пероксид Кальция

CaO_2 = 72.08.

CAS — 1305-79-9;.

Profile

The action of calcium peroxide is similar to that of hydrogen peroxide (p.1647). Calcium peroxide is used in dental products for tooth whitening. It is also used as a flour bleaching and improving agent.

Preparations

Proprietary Preparations (details are given in Part 3)

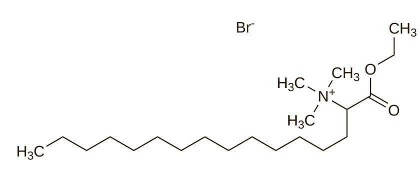
Multi-ingredient: *Arg.:* Hexiben.

Carbaethopendecinium Bromide

Carbethopendecinii Bromidum; Carbethoxypentadecyltrimethylammonium Bromide; Karbethopendecinium bromid. 1-Ethoxy-*N,N,N*-trimethyl-1-oxo-2-hexadecanaminium bromide.

$C_{21}H_{44}NO_2Br$ = 422.5.

CAS — 10567-02-9.



Profile

Carbaethopendecinium bromide is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used in topical preparations for disinfection of skin and mucous membranes.

Preparations

Proprietary Preparations (details are given in Part 3)
Cz.: Mukoseptonex; Ophthalmo-Septonex; Septonex.

Multi-ingredient: *Cz.:* Mesocain; Mukoseptonex E; N-Septonex†; Ophthalmo-Septonex; Paradentol†; Septonex; Septonex Plus; Triamcinolon-Ivax.

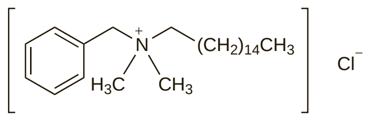
Cetalkonium Chloride *(BAN, USAN, rINN)*

Cetalkonii Chloridum; Cétalkonium, Chlorure de; Cloruro de cetalconio; NSC-32942. Benzylhexadecyldimethylammonium chloride.

Цеталкония Хлорид

$C_{25}H_{46}ClN$ = 396.1.

CAS — 122-18-9.



Profile

Cetalkonium chloride is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used in a variety of topical preparations in the treatment of minor infections of the mouth and throat. It has also been used in the treatment of eye infections. Cetalkonium bromide has also been used.

Preparations

Proprietary Preparations (details are given in Part 3)

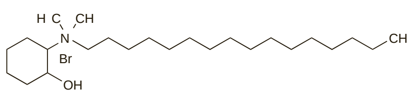
Multi-ingredient: ***Arg.:*** Pansoral; ***Austral.:*** Bonjela; ***Austria:*** Mundisal; ***Braz.:*** Pondicilina; ***Canad.:*** Bionet; ***Cz.:*** Mundisal; ***Fr.:*** Pansoral; ***Ger.:*** Mundisal†; ***Gr.:*** Mundisal; ***Hong Kong:*** Bonjela; ***Hung.:*** Mundisal; ***Irl.:*** Bonjela; ***Israel:*** Baby Gum; Bonjela; ***Malaysia:*** Bonjela; ***NZ:*** Bonjela; ***Pol.:*** Sachol zel Stomatologiczny; ***Rus.:*** Cholisal (Холисал); Pansoral (Пансорал); ***S.Afr.:*** AAA†; Bonjela; ***Singapore:*** Bonjela; ***Switz.:*** Mundisal; Pansoral; Tenderdol; ***Thai.:*** Bonjela; ***UK:*** Bonjela; Bonjela Teething Gel; ***USA:*** Babee.

Cethexonium Bromide

Cetexonio, bromuro de. Hexadecyl(2-hydroxycyclohexyl)dimethylammonium bromide.

$C_{24}H_{50}BrNO$ = 448.6.

CAS — 6810-42-0 (cethexonium); 1794-74-7 (cethexonium bromide); 58703-78-9 (cethexonium chloride).



NOTE. Cethexonium Chloride is *rINN*.

Profile

Cethexonium bromide is a quaternary ammonium antiseptic with properties similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used in preparations for the local treatment of minor infections of the eye, nose, and throat.

Preparations

Proprietary Preparations (details are given in Part 3)

Fr.: Biocidan.

Multi-ingredient: ***Fr.:*** Biocidan.

Cetrimide *(BAN, rINN)*

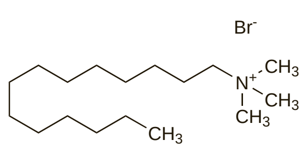
Cetrimid; Cetrimida; Cetrimidas; Cétrimide; Cetrimidum; Cetrymid; Setrimid; Setrimidi.

Цетримид

CAS — 1119-97-7 (trimethyltetradecylammonium bromide); 1119-94-4 (dodecyltrimethylammonium bromide); 8044-71-1 (cetrimide).

ATC — D08AJ04; D11AC01.

ATC Vet — QD08AJ04; QD11AC01.



(trimethyltetradecylammonium bromide)

NOTE. The name cetrimonium bromide was often formerly used for cetrimide. Cetrimonium bromide (see below) is hexadecyltrimethylammonium bromide.

Pharmacopoeias. In *Eur.* (see p.vii) and *Int.*

Br. also includes strong cetrimide solution.

Ph. Eur. 6.2 (Cetrimide). It consists of trimethyltetradecylammonium bromide (=tetradonium bromide (*rINN*)) and may contain smaller amounts of dodecyltrimethylammonium bromide and hexadecyltrimethylammonium bromide (=cetrimonium bromide, p.1635). A white or almost white, voluminous, free-flowing powder. Freely soluble in water and in alcohol. A 2.0% solution in water froths copiously when shaken.

BP 2008 (Strong Cetrimide Solution). It is an aqueous solution of cetrimide. It contains 20 to 40% w/v of cetrimide, calculated as $C_{17}H_{38}BrN$ and up to 10% alcohol or isopropyl alcohol, or both; alcohol may be replaced by industrial methylated spirit. It may be perfumed and may contain colouring matter. Store at a temperature above 15°.

Incompatibility. Cetrimide is incompatible with soaps and other anionic surfactants, bentonite, iodine, phenylmercuric nitrate, and alkali hydroxides. Aqueous solutions react with metals.

Adverse Effects and Treatment

At the concentrations used on the skin, solutions of cetrimide and other quaternary compounds do not generally cause irritation, but some patients become hypersensitive to cetrimide after repeated applications. Cetrimide powder is reported to be irritant. There have been rare reports of burns with concentrated solutions of cetrimide.

If ingested, cetrimide and other quaternary ammonium compounds cause nausea and vomiting; strong solutions may cause oesophageal damage and necrosis. They have depolarising muscle relaxant properties and toxic symptoms include dyspnoea and cyanosis due to paralysis of the respiratory muscles, possibly leading to asphyxia. CNS depression (sometimes preceded by excitement and convulsions), hypotension, coma, and death may also occur. Accidental intra-uterine or intravenous administration may cause haemolysis and pulmonary embolism.

Treatment of poisoning is symptomatic; demulcents and diluents may be given if necessary but emesis and lavage should be avoided, particularly if concentrated solutions have been ingested. Activated charcoal may be considered if the patient presents within an hour of ingestion. CNS stimulants and cholinesterase inhibitors are reported not to reverse paralysis due to cetrimide intoxication although sympathomimetics have been tried. Corticosteroids may reduce oropharyngeal oedema.

Effects after cyst irrigation. Adverse effects after irrigation with cetrimide solutions in the treatment of hydatid cysts have included chemical peritonitis,[1] methaemoglobinaemia with cyanosis,[2] and metabolic acidosis.[3]

1. Gilchrist DS. Chemical peritonitis after cetrimide washout in hydatid-cyst surgery. *Lancet* 1979; **ii:** 1374.
2. Baraka A, *et al.* Cetrimide-induced methaemoglobinaemia after surgical excision of hydatid cyst. *Lancet* 1980; **ii:** 88–9.
3. Momblano P, *et al.* Metabolic acidosis induced by cetrimonium bromide. *Lancet* 1984; **ii:** 1045.

Poisoning. The fatal dose of quaternary ammonium compounds was estimated to be 1 to 3 g.[1]

1. Arena JM. Poisonings and other health hazards associated with use of detergents. *JAMA* 1964; **190:** 56–8.

Precautions

Prolonged and repeated applications of cetrimide to the skin are inadvisable as hypersensitivity may occur. Contact with the eyes, brain, meninges, and middle ear should be avoided. Cetrimide is for external use only and should not be used in body cavities or as an enema.

Quaternary ammonium compounds are not reliable for sterilising surgical instruments and heat-labile articles. The antimicrobial activity of quaternary ammonium compounds may be reduced through absorption, or through combination with organic matter, or by reducing pH.

Solutions of quaternary ammonium compounds should not be used for disinfection of soft contact lenses.

Aqueous solutions of cetrimide or other quaternary ammonium disinfectants may be susceptible to contamination with micro-organisms. To reduce this risk, a sterilised preparation should be used or, where necessary, solutions must be freshly prepared at the recommended concentration and appropriate measures should be taken to prevent contamination during storage or dilution.

Handling. Cetrimide powder is irritant; it has been recommended that the nose and mouth should be protected by a mask when working with the powder[1] and eyes should be protected by goggles.

1. Jacobs JY. Work hazards from drug handling. *Pharm J* 1984; **233:** 195–6.

Uses and Administration

Cetrimide is a quaternary ammonium antiseptic with actions and uses typical of cationic surfactants. These surfactants dissociate in aqueous solution into a relatively large and complex cation that is responsible for the surface activity and a smaller inactive anion. In addition to emulsifying and detergent properties, quaternary ammonium compounds have bactericidal activity against Gram-positive and, at a higher concentration, against some Gram-negative bacteria. Some *Pseudomonas* spp. are particularly resistant as are strains of *Mycobacterium tuberculosis*. They are ineffective against bacterial spores, have variable antifungal activity, and are effective against some viruses.

Quaternary ammonium compounds are most effective in neutral or slightly alkaline solution and their bactericidal activity is appreciably reduced in acid media; their activity is enhanced by alcohols.

Like other quaternary ammonium compounds, notably benzalkonium chloride (p.1629), cetrimide has been employed for cleansing skin, wounds (but see under Wound Disinfection, p.1624), and burns. For these purposes it has been used as a 0.1 to 1.0% aqueous solution, generally prepared by dilution of a more concentrated solution, or as a cream or spray containing 0.5%. However, a mixture of cetrimide with chlorhexidine (p.1635) has often been preferred to cetrimide alone. This combination is also used in a lotion for acne (p.1577).

Solutions containing up to 10% of cetrimide have been used as shampoos to remove the scales in seborrhoeic dermatitis (p.1584).

Cetrimide solution 0.5 or 1% has been used as a scolicide to irrigate hydatid cysts during surgery (see Echinococcosis, p.136) but systemic adverse effects have been reported (see above).

Cetrimide and benzalkonium chloride are also used as preservatives in cosmetics and pharmaceutical formulations including eye drops and in disinfecting solutions for hard contact lenses; neither compound should be used for disinfection of soft contact lenses.

Cetrimide is also present in some emulsifying preparations such as Cetrimide Emulsifying Ointment (BP 2008).

Preparations

BP 2008: Cetrimide Cream; Cetrimide Emulsifying Ointment; Cetrimide Solution.

Multi-ingredient: ***Arg.:*** Desenfriol Caramelos†; Ernex Duo; Oral-B Enjuague Bucal†; Periodil; Solumerin; ***Austral.:*** Cepacaine; Cepacol Anaesthetic; Cepacol Antibacterial; Cepacol Cough & Sore Throat; Difflam Anti-inflammatory Lozenges with Cough Suppressant; Difflam Lozenges; Difflam Mouth Gel; Duro-Tuss Cough Lozenges; Gentlees; Seda-Gel†; ***Austria:*** Coldistan; Dentinox; Gurfix; Paididont; Tetesept; ***Braz.:*** Cepacaina; Cepacol Menta; Cetildrops†; Dentalivio†; Fenotricin†; Lima C; Limao Bravo com Vitamina C†; Limao Bravo†; Malvona†; Neopiridin; Pondicilina; Proplax†; Psiu; Sanilin; ***Canad.:*** Cepacol Extra Strength; Cepacol with Fluoride; Green Antiseptic Mouthwash & Gargle; Kank-A; Oral Plan†; Oral-B Anti-Bacterial with Fluoride; Throat Lozenges; ***Chile:*** Halita; Kank-Eze; Oralfresh Menta; Pancrit; Perio-Aid c Cloruro de Cetilpiridinio; Vitis Encias Colutorio; Vitis Encias Pasta; ***Cz.:*** Brand- und Wundgel†; Calgel; Neoseptolete; Panlid; Stas†; Tetesept Angidin†; ***Fin.:*** Bafucin; ***Fr.:*** Alodont; Broncorinol maux de gorge†; Lysopaine; Parogencyl prevention gencives; ***Ger.:*** Biogelt†; Brand- und Wund-Gel Eu Rho†; Broncho-Tyrosolvetten†; Dolo-Dobendan; Emmedical†; Frubienzym; Frubizin Forte†; Nordathricin N†; Trachiform†; Tyrosolvetten-C†; Tyrosolvetten†; Tyrosur; Wick Sulagil; ***Hong Kong:*** Dentinox Teething Gel; Difflam Anti-inflammatory Lozenges; Difflam Mouth Gel; Pharynx; Setronges†; ***Hung.:*** Mebucain; Tyrosur; ***Indon.:*** Sentril; ***Irl.:*** Anbesol; Merocaine; ***Israel:*** Cepadont; Kank-A; ***Ital.:*** Delta 80; Delta 80 Plus; Farmagola†; Ginvapast; Gola Action; Neo-Stomygen; Oral-B Collutorio per la Protezione di Denti e Gengive; Orosanyl†; Ridiodent; Rikospray; Stomygen; ***Malaysia:*** Cetylpyridinium B; Dentinox Teething Gel; Difflam Anti-inflammatory Lozenges (with Antibacterial); Difflam Anti-Inflammatory Lozenges (with cough suppressant); Difflam Mouth Gel; Orregel; Pharynx; Setronges†; ***Mex.:*** Cepacaina; Mentalgina; Trociletas B; ***Neth.:*** Agre-Gola; ***Norw.:*** Aselli; ***NZ:*** Cepacaine; Cepacol Anaesthetic; Cepacol Cough Discs; Difflam Cough; Difflam Mouth Gel; Duro-Tuss Lozenges; ***Philipp.:*** Xylorinse; ***Pol.:*** Calgel; Lidodent; Septolete Plus; Tetesept; Undofen; ***Port.:*** Anbegele†; Biofluor Ortodoncia†; Biofluor Sensitive†; Dropcina; Mebocaina; ***Rus.:*** Calgel (Калгель); Septolete Plus (Септолете Плюс); ***S.Afr.:*** Anbesol; Andolex-C; Cepacaine; Cepacol; Cepacol Cough Discs; Cetoxol; Colphen; Endcol Lozenges; Medi-Kain†; Medi-Keel A; Prodol; Vagarsol; Vicks Acta Plus; Vicks Cough Syrup; ***Singapore:*** Dentinox Teething Gel; Difflam Anti-inflammatory Anti-Bacterial Lozenges; Difflam Mouth Gel; Duro-Tuss Cough Lozenges; Pharynx; Soragel; ***Spain:*** Alcohocel; Alcohol Cetil†; Alcohol Cetilpi Cuve†; Babysiton; Farmalcohol; Pastillas Antisep Garg L; Pastillas Antisep Garg M; Silidermil†; Vicks Formula 44†; ***Swed.:*** Bafucin; ***Switz.:*** Alodont†; Angina MCC; Anginazol; Desaquick forte†; Flavangin†; Hextriletten; Hextrimint; Lidazon; Mebucaine; Nasex†; Neo-Angin Lido; Otothricinol; Pharmacard Family Maux de gorge†; Wulnasin; ***Thai.:*** Sentril; Sore Mouth Gel; ***Turk.:*** Calgel; Nesgarin; ***UAE:*** B-Cool; New B-Cool; ***UK:*** Adult Meltus for Chesty Coughs & Catarrh; Allens Dry Tickly Cough; Anbesol; Calgel; Dentinox Teething Gel; Kilkof; Listermint with Fluoride; Macleans Mouthguard; Meltus Expectorant; Meltus Junior Expectorant; Merocaine; Merocets Plus; Rinstead; Rinstead Teething Gel†; Woodwards Teething Gel; ***USA:*** Cepacol Anesthetic; Cepacol Maximum Strength Sore Throat; Cepacol Regular Strength; Cylex; MouthKote O/R; MouthKote P/R†; Orajel Mouth Aid; ***Venez.:*** Borogin; Calgel†; Cepacol-BE; Isospray; Lafarcaina; Solunovar Compuesto.

Chlorhexidine *(BAN, rINN)*

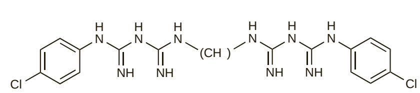
Chlorhexidinum; Clorhexidina; Klooriheksidiini; Klorheksidin; Klorhexidin.

Хлоргексидин

CAS — 55-56-1.

ATC — A01AB03; B05CA02; D08AC02; D09AA12; R02AA05; S01AX09; S02AA09; S03AA04.

ATC Vet — QA01AB03; QB05CA02; QD08AC02; QD09AA12; QR02AA05; QS01AX09; QS02AA09; QS03AA04.



Chlorhexidine Acetate *(BANM, rINNM)*

Acetato de clorhexidina; Chlorheksidino diacetatas; Chlorhexidin-diacetát; Chlorhexidine, Acétate de; Chlorhexidine Diacetate; Chlorhexidine, diacétate de; Chlorhexidini Acetas; Chlorhexidini diacetas; Chloroheksydyny octan; Klooriheksidiinidiasetaatti; Klorhexidindiacetat; Klórhexidin-diacetát. 1,1′-Hexamethylenebis[5-(4-chlorophenyl)biguanide] diacetate.

Хлоргексидина Ацетат

$C_{22}H_{30}Cl_2N_{10},2C_2H_4O_2 = 625.6.$

CAS — 56-95-1.

ATC — A01AB03; B05CA02; D08AC02; D09AA12; R02AA05; S01AX09; S02AA09; S03AA04.

ATC Vet — QA01AB03; QB05CA02; QD08AC02; QD09AA12; QR02AA05; QS01AX09; QS02AA09; QS03AA04.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Int.*

Ph. Eur. 6.2 (Chlorhexidine Diacetate). A white or almost white, microcrystalline powder. Sparingly soluble in water; soluble in alcohol; slightly soluble in glycerol and in propylene glycol.

Incompatibility. The incompatibilities of chlorhexidine salts are discussed under Chlorhexidine Hydrochloride, below.

Stability. The stability of chlorhexidine salts is discussed under Chlorhexidine Hydrochloride, below.

Chlorhexidine Gluconate *(BANM, USAN, rINNM)*

Chlorheksidino digliukonato tirpalas; Chlorhexidin-diglukonát; Chlorhexidine Digluconate; Chlorhexidine, digluconate de; Chlorhexidine, Gluconate de; Chlorhexidini digluconas; Chlorhexidini Digluconatis Solutio; Chlorhexidini Gluconas; Chloroheksydyny diglukonianu roztwór; Gluconato de clorhexidina; Klooriheksidiinidiglukonaattiliuos; Klorheksidin Glukonat; Klorhexidindiglukonatlösning; Klórhexidin-diglükonát-oldat. 1,1′-Hexamethylenebis[5-(4-chlorophenyl)biguanide] digluconate.

Хлоргексидина Глюконат

$C_{22}H_{30}Cl_2N_{10},2C_6H_{12}O_7 = 897.8.$

CAS — 18472-51-0.

ATC — A01AB03; B05CA02; D08AC02; D09AA12; R02AA05; S01AX09; S02AA09; S03AA04.

ATC Vet — QA01AB03; QB05CA02; QD08AC02; QD09AA12; QR02AA05; QS01AX09; QS02AA09; QS03AA04.

Pharmacopoeias. *Chin.*, *Eur.* (see p.vii), and *US* include a solution which contains 19 to 21% of chlorhexidine gluconate.

Ph. Eur. 6.2 (Chlorhexidine Digluconate Solution; Chlorhexidini Digluconatis Solutio; Chlorhexidine Gluconate Solution BP 2008). An aqueous solution which contains not less than 190 g/litre and not more than 210 g/litre of chlorhexidine gluconate. An almost colourless or pale-yellowish liquid. Miscible with water, with not more than 5 parts of alcohol, and with not more than 3 parts of acetone. A 5% v/v dilution in water has a pH of 5.5 to 7.0. Protect from light.

USP 31 (Chlorhexidine Gluconate Solution). An aqueous solution which contains not less than 19% and not more than 21% of chlorhexidine gluconate. An almost colourless or pale yellow, clear liquid. Miscible with water and with glacial acetic acid; miscible with five times its volume of dehydrated alcohol and with three times its volume of acetone; further addition of dehydrated alcohol or of acetone yields a white turbidity. A 5% v/v dilution in water has a pH of 5.5 to 7.0. Store in airtight containers. Protect from light.

Incompatibility. The incompatibilities of chlorhexidine salts are discussed under Chlorhexidine Hydrochloride, below.

Stability. The stability of chlorhexidine salts is discussed under Chlorhexidine Hydrochloride, below.

Sterilisation. Dilutions of commercial concentrated solutions may be sterilised by autoclaving.

Chlorhexidine Hydrochloride *(BANM, USAN, rINNM)*

AY-5312; Chlorheksidino dihidrochloridas; Chlorhexidin-dihydrochlorid; Chlorhexidine, Chlorhydrate de; Chlorhexidine, dichlorhydrate de; Chlorhexidine Dihydrochloride; Chlorhexidini dihydrochloridum; Chlorhexidini Hydrochloridum; Hidrocloruro de clorhexidina; Klooriheksidiinidihydrokloridi; Klorheksidin Hidroklorür; Klórhexidin-dihidroklorid; Klorhexidindihydroklorid. 1,1′-Hexamethylenebis[5-(4-chlorophenyl)biguanide] dihydrochloride.

Хлоргексидина Гидрохлорид

$C_{22}H_{30}Cl_2N_{10},2HCl = 578.4.$

CAS — 3697-42-5.

ATC — A01AB03; B05CA02; D08AC02; D09AA12; R02AA05; S01AX09; S02AA09; S03AA04.

ATC Vet — QA01AB03; QB05CA02; QD08AC02; QD09AA12; QR02AA05; QS01AX09; QS02AA09; QS03AA04.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *Jpn.*

Ph. Eur. 6.2 (Chlorhexidine Dihydrochloride; Chlorhexidine Hydrochloride BP 2008). A white or almost white, crystalline powder. Sparingly soluble in water and in propylene glycol; very slightly soluble in alcohol.

Incompatibility. Chlorhexidine salts are incompatible with soaps and other anionic materials. Activity may be reduced in the presence of suspending agents such as alginates and tragacanth, insoluble powders such as kaolin, and insoluble compounds of calcium, magnesium, and zinc. Chlorhexidine acetate is incompatible with potassium iodide. At a concentration of 0.05%, chlorhexidine salts are incompatible with borates, bicarbonates, carbonates, chlorides, citrates, nitrates, phosphates, and sulfates, forming salts of low solubility which may precipitate out of solution. At dilutions of 0.01% or more, these salts are generally soluble. Insoluble salts may form in hard water. Chlorhexidine salts are inactivated by cork.

Stability. Chlorhexidine and its salts are stable at normal storage temperatures but when heated may decompose with the production of trace amounts of 4-chloroaniline. Chlorhexidine hydrochloride is less readily decomposed than chlorhexidine acetate and may be heated at 150° for 1 hour without appreciable production of 4-chloroaniline. Aqueous solutions of chlorhexidine salts decompose with the formation of trace amounts of 4-chloroaniline. This decomposition is increased by heating and alkaline pH.

Adverse Effects and Treatment

Skin sensitivity to chlorhexidine has occasionally been reported. Severe hypersensitivity reactions, including anaphylactic shock, have been reported rarely after topical use of chlorhexidine. Strong solutions may cause irritation of the conjunctiva and mucous membranes. The use of chlorhexidine dental gel and mouthwash has been associated with reversible discoloration of the tongue, teeth, and silicate or composite dental restorations. Transient taste disturbances and a burning sensation of the tongue may occur on initial use. Oral desquamation and occasional parotid gland swelling have been reported with the mouthwash. If desquamation occurs, 50% dilution of the mouthwash with water and less vigorous rinsing may allow continued use.

The main consequence of ingestion is mucosal irritation and systemic toxicity is rare due to minimal absorption from the gastrointestinal tract (see Poisoning, below). Haemolysis has been reported after accidental intravenous administration. Gastric lavage with demulcents has been suggested for acute ingestion.

Effects on the eyes. Corneal damage was reported in 4 patients after use of chlorhexidine gluconate for pre-operative preparation of facial skin.[1] Severe corneal endothelium damage occurred in a further 3 patients[2] when chlorhexidine was inadvertently used as an intra-ocular irrigating solution and 2 of the patients subsequently required penetrating keratoplasty. Other adverse effects included pronounced iris atrophy, anterior chamber flattening, and a retrocorneal membrane; one patient developed raised intra-ocular pressure. In another case progressive ulcerative keratitis and almost total loss of the corneal epithelium was reported[3] after use of chlorhexidine gluconate 0.02% and propamidine 0.1% eye drops for 8 weeks for *Acanthamoeba* keratitis. In 2 patients[4] treated similarly for 4 to 6 months, deep marginal ulceration of the cornea developed, in each case requiring a penetrating graft; a mature cataract and an atrophic iris were seen in each patient after removal of the cornea. Due to the similarity of both cases, it was suggested that these complications were caused by the drugs rather than by amoeba-induced inflammation.

4. Ehlers N, Hjortdal J. Are cataract and iris atrophy toxic complications of medical treatment of acanthamoeba keratitis? *Acta Ophthalmol Scand* 2004; **82:** 228–31.

Effects on the nose. Temporary hyposmia (reduced sense of smell) in some patients after transsphenoidal pituitary adenoma operation was assumed to be caused by pre-operative disinfection of the nasal cavity with chlorhexidine gluconate solution.[1]

1. Yamagishi M, *et al.* Impairment of olfactory epithelium treated with chlorhexidine digluconate (Hibitane). *Pract Otol* 1985; **78:** 399–409.

Hypersensitivity. Both immediate and delayed hypersensitivity reactions have been reported after topical use of chlorhexidine[1] and from the use of chlorhexidine-containing urethral lubricants.[2] However, the incidence is low given the frequent use of chlorhexidine. Delayed hypersensitivity reactions such as contact dermatitis, fixed drug eruptions, and photosensitivity reactions are more common than immediate hypersensitivity reactions (acute urticaria, angioedema, and bronchospasm which may progress to anaphylactic shock).[1,3]

Immediate hypersensitivity reactions have also occurred with surgical disinfection. Signs appear 15 to 45 minutes after the start of surgery and include hypotension, urticaria, tachycardia, bronchospasm, and sometimes anaphylactic shock, cardiovascular collapse, or cardiac arrest.[3,4] In 1998 the FDA issued a public notice[5] warning of potential hypersensitivity reactions to chlorhexidine-impregnated intravenous catheters, topical antimicrobial skin dressings, and implanted antimicrobial surgical mesh, based on reports of adverse events that had occurred in the USA and other countries.

Occupational asthma has been attributed to an alcoholic chlorhexidine spray.[6]

Poisoning. Reports of adverse effects after ***ingestion*** of chlorhexidine salts include a neonate who developed multiple episodes of cyanosis and bradycardia;[1] the infant's mother had sprayed chlorhexidine onto her breasts to prevent mastitis. In contrast an 89-year-old woman only experienced mild giddiness, unusual laughter, and an increased appetite after mistakenly drinking 30 mL of a solution containing chlorhexidine gluconate 4% and isopropyl alcohol 4%.[2] A review[3] of 7 adult cases of deliberate ingestion of a commercially available mixture of cetrimide 3% and chlorhexidine gluconate 0.3%, concluded that symptoms were generally mild and included nausea, vomiting, sore throat, and abdominal pain. There has also been a report of a patient who developed gastritis after ingesting a pre-operative skin preparation containing chlorhexidine gluconate 4% when using it as a mouthwash.[4]

Another person had much more serious effects after drinking about 150 mL of chlorhexidine gluconate solution, corresponding to about 30 g of the pure substance.[5] Besides pharyngeal oedema and necrotic oesophageal lesions, the patient had aminotransferase concentrations that rose to 30 times normal 5 days after ingestion and were still 8 times normal one week later. After one month the serum aspartate aminotransferase was returning to normal while the serum alanine aminotransferase was still 3 times normal. Six months after ingestion the aminotransferase levels were normal. A liver biopsy performed soon after the peak in aminotransferase levels showed diffuse fatty degeneration and lobular hepatitis suggesting that chlorhexidine was absorbed from the gastrointestinal tract in a concentration high enough to produce liver necrosis. An 80-year-old woman had spontaneous vomiting and aspiration followed by acute respiratory distress syndrome within 5 hours of accidental ingestion of 200 mL of a chlorhexidine gluconate 5% solution .[6] Despite supportive treatment, the patient's condition continued to deteriorate and she developed shock and metabolic acidosis and died from cardiac arrest 12 hours after ingestion.

Accidental ***intravenous*** administration of 4 mL of a 20% chlorhexidine gluconate solution in a 67-year-old man undergoing a colectomy resulted in the sudden development of acute respiratory distress syndrome.[7] Respiratory failure progressed despite plasma exchange therapy over 3 consecutive days. Veno-arterial extracorporeal membrane oxygenation was started on the third day and after 72 hours improvement was noted and the patient subsequently recovered completely.

Precautions

Since chlorhexidine is irritant it is recommended that it should not be used on the brain, meninges, middle ear, or other sensitive tissues. Contact with the eye should be avoided except for dilute solutions expressly for use in the eyes. Chlorhexidine may be adsorbed by some soft contact lenses and cause eye irritation, although it may be suitable for use with others (see Contact Lens Care, p.1622). Syringes and needles that have been immersed in chlorhexidine solutions should be thoroughly rinsed with sterile water or saline before use.

Aqueous solutions of chlorhexidine salts may be susceptible to contamination with micro-organisms. To reduce this risk, a sterilised preparation should be used or, where necessary, solutions must be freshly prepared at the recommended concentration and appropriate measures should be taken to prevent contamination during storage or dilution.

Aqueous solutions of chlorhexidine used for instrument storage should contain sodium nitrite 0.1% to inhibit metal corrosion, and should be changed every 7 days. Commercial 5% concentrate contains a nonionic surfactant to prevent precipitation on dilution with hard water and is not suitable for use in body cavities or for disinfection of instruments containing cemented glass components; dilutions of the 20% concentrate should be used for this purpose.

Contamination. *Ralstonia pickettii* (*Burkholderia pickettii*; *Pseudomonas pickettii*) septicaemia developed in 6 patients after the use of aqueous chlorhexidine 0.05%, prepared with contaminated twice-distilled water, for skin disinfection before venepuncture and it was considered that unsterilised 0.05% solutions should not be used for such skin preparation.[1] Positive blood cultures of *Burkholderia cepacia* (*Pseudomonas cepacia*) were found in 2 patients after inappropriate use of a chlorhexidine handwash for the same purpose.[2] Further studies showed that the handwash supported pseudomonal growth only when diluted.[3]

2. Gosden PE, Norman P. Pseudobacteraemia associated with contaminated skin cleansing agent. *Lancet* 1985; **ii** 671–2.
3. Norman P, *et al.* Pseudobacteraemia associated with contaminated skin cleansing agent. *Lancet* 1986; **i:** 209.

Neonates. Haemorrhagic skin necrosis associated with umbilical artery catheterisation in a premature infant was attributed to damage by the alcohol from the use of chlorhexidine 0.5% in spirit 70% as a disinfectant.[1]

For reference to the percutaneous absorption of chlorhexidine following topical use in neonates and infants, see Pharmacokinetics, below.

1. Harpin V, Rutter N. Percutaneous alcohol absorption and skin necrosis in a preterm infant. *Arch Dis Child* 1982; **57:** 477–9.

Oral hygiene. As toothpastes may contain anionic surfactants such as sodium laurilsulfate, which are incompatible with chlorhexidine, it has been recommended that at least 30 minutes should be allowed to elapse between the use of toothpaste and oral chlorhexidine preparations.[1]

1. Barkvoll P, *et al.* Interaction between chlorhexidine digluconate and sodium lauryl sulfate in vivo. *J Clin Periodontol* 1989; **16:** 593–5.

Washing precautions. Fabrics that have been in contact with chlorhexidine solution may develop a brown stain if bleached with a hypochlorite. A peroxide bleach may be used instead.

Pharmacokinetics

Chlorhexidine is poorly absorbed from the gastrointestinal tract and skin.

Neonates. Occasional reports of the percutaneous absorption of chlorhexidine in neonates and infants include a study in which chlorhexidine was detected in low concentrations in the venous blood of 5 of 24 infants after washing them with a preparation containing chlorhexidine gluconate 4% (*Hibiscrub*); no adverse effects were observed.[1] Low concentrations have been found[2] in the venous blood of neonates following the topical use of a powder containing chlorhexidine 1%. Percutaneous absorption of chlorhexidine was reported in preterm neonates (but not full-term infants) treated with chlorhexidine 1% in alcohol for neonatal cord care; no such absorption occurred when a dusting powder containing chlorhexidine 1% and zinc oxide 3% was used.[3]

2. Alder VG, *et al.* Comparison of hexachlorophane and chlorhexidine powders in prevention of neonatal infection. *Arch Dis Child* 1980; **55:** 277–80.
3. Aggett PJ, *et al.* Percutaneous absorption of chlorhexidine in neonatal cord care. *Arch Dis Child* 1981; **56:** 878–91.

Uses and Administration

Chlorhexidine is a bisbiguanide antiseptic and disinfectant that is bactericidal or bacteriostatic against a wide range of Gram-positive and Gram-negative bacteria. It is more effective against Gram-positive than Gram-negative bacteria, and some species of *Pseudomonas* and *Proteus* have low susceptibility. It is relatively ineffective against mycobacteria. Chlorhexidine inhibits some viruses and is active against some fungi. It is inactive against bacterial spores at room temperature. Chlorhexidine is most active at a neutral or slightly acid pH. Combinations of chlorhexidine with cetrimide (p.1634) or in alcoholic solution are used to enhance efficacy.

Chlorhexidine is formulated as lotions, washes, and creams for disinfection and cleansing of skin and wounds (p.1585), and as oral gels, sprays, and mouthwashes for mouth infections including candidiasis and to reduce dental plaque accumulation. It has also been used with neomycin to eliminate nasal carriage of staphylococci (p.195) and for disinfection of some contact lenses (but see Precautions, above). It has been suggested for use with propamidine isetionate for the treatment of Acanthamoeba keratitis and in spermicides to prevent transmission of HIV infection (p.858).

For pre-operative skin disinfection and hand-washing, chlorhexidine is used as a 0.5% solution of the acetate or gluconate in alcohol (70%) or as a 2 or 4% detergent solution of the gluconate. For disinfection of wounds, burns, or other skin damage or disorders chlorhexidine is used as a 0.05% aqueous solution of the acetate or gluconate, as a tulle dressing impregnated with chlorhexidine acetate 0.5%, or as a cream or powder containing chlorhexidine acetate or gluconate 1%. Preparations containing chlorhexidine acetate or gluconate 0.015% and cetrimide 0.15% are also used for cleansing and disinfection of skin and wounds. In obstetrics, chlorhexidine gluconate is used as a 0.05% aqueous solution or a 1% cream. The cream is also used as a barrier against bacterial hand infection.

Chlorhexidine gluconate is used in a 1% dental gel, 0.2% oral spray, and 0.1 to 0.2% mouthwash for the prevention of plaque and the prevention and treatment of gingivitis and in the treatment of oral candidiasis. A slow-release formulation containing 2.5 mg of chlorhexidine gluconate for insertion into periodontal pockets is also available.

A 0.02% solution may be used as a bladder irrigation in some urinary-tract infections. A gel containing 0.25% chlorhexidine gluconate solution and lidocaine hydrochloride has been used in catheterisation and cystoscopy.

For the emergency disinfection of clean instruments, a 2-minute immersion in chlorhexidine acetate or gluconate 0.5% in alcohol (70%) is used; for the storage and disinfection of clean instruments a 30-minute immersion in a 0.05% aqueous solution containing 0.1% sodium nitrite to inhibit metal corrosion is used.

As an antimicrobial preservative, chlorhexidine is used at a concentration of 0.01% of the acetate or gluconate in eye drops. Solutions containing 0.002 to 0.006% of chlorhexidine gluconate have also been used for disinfection of hydrophilic contact lenses.

Acanthamoeba infections. As discussed on p.822, the optimal antiamoebic therapy for *Acanthamoeba* keratitis has yet to be determined. Propamidine isetionate is commonly used, usually in combinations including a biguanide. A multicentre study[1] evaluated the efficacy of a combination of topical chlorhexidine 0.02% and propamidine 0.1% in 12 contact lens-wearing patients with confirmed *Acanthamoeba* keratitis. Patients were treated for between 2 to 6 months and resolution of signs occurred gradually over 5 to 28 weeks (mean 11 weeks). Resolution of symptoms occurred within 1 to 7 weeks (mean 3 weeks); patients noted a reduction of pain, photophobia and lid oedema after 3 weeks of treatment. No drug toxicity was noted in any of the patients. However, concern has been expressed over the possible toxicity of chlorhexidine at this concentration on the cornea (see Adverse Effects and Treatment, above).

Chlorhexidine is also an effective disinfectant against *Acanthamoeba* cysts and most bacteria found in contact lens storage cases.[2]

Chlorhexidine has also been used to treat skin lesions associated with disseminated *Acanthamoeba* infection[3] as an adjunct to systemic therapy (see p.822).

Contraception. Bisbiguanides of the chlorhexidine type are reported to have the ability to diffuse into cervical mucus and render it impenetrable to sperm at concentrations as low as 1 mg/mL.[1] Higher concentrations of chlorhexidine structurally modify the mucus, producing a barrier to both the entry of sperm and chlorhexidine. The potency[1] of chlorhexidine in inhibiting sperm motility *in vitro* is identical to that of nonoxinol 9, but unlike spermicides containing nonoxinol 9, which tend to trickle out, the clearance of chlorhexidine from the vagina is delayed.[2] Chlorhexidine also has potential for reducing transmission of HIV infection as it does not disrupt the vaginal epithelium and has activity *in vitro* against the HIV virus in low concentrations.[2]

For a review of contraception, including the view that spermicides are not a particularly effective method unless used with other means of contraception, see p.2070.

2. Anonymous. Multipurpose spermicides. *Lancet* 1992; **340:** 211–13.

Disinfection. Viable bacterial counts on the hands were reduced by a mean of 97.9% by the application of chlorhexidine gluconate 0.5% in alcohol 95%.[1] The reduction was not so substantial with a 0.5% chlorhexidine aqueous solution (65.1% reduction in bacterial count) or a 4% detergent solution (86.7%). Hand disinfection with chlorhexidine gluconate 4% appeared to be more effective than the use of isopropyl alcohol 60% and soap in preventing nosocomial infections in a study conducted in intensive care units but this may have been partly due to better compliance with hand-washing instructions when using chlorhexidine.[2] In another study,[3] pre-operative total body bathing with a 4% detergent did not decrease the risk of wound infection in patients compared with bathing in detergent alone.

Chlorhexidine 1% nasal cream failed to control an epidemic of meticillin-resistant *Staphylococcus aureus* in a neurosurgical ward[4] and handwashing with chlorhexidine soap failed to control an outbreak of infection with *Staph. aureus* resistant to meticillin and gentamicin in a neonatal intensive care unit.[5] The organisms were subsequently eradicated by the use of nasal mupirocin and hexachlorophene handwashing, respectively.

INJECTION SITE AND CATHETER CARE. See p.1624.

Endocarditis. Antiseptics applied immediately before dental procedures may reduce postextraction bacteraemia. Chlorhexidine mouthwash or gel may be used as an adjunct to antibacterial prophylaxis in dental patients at risk of bacterial endocarditis.[1,2] The protective cover required for such patients is discussed on p.168.

1. Dajani AS, *et al*. Prevention of bacterial endocarditis: recommendations by the American Heart Association. *JAMA* 1997; **277:** 1794–1801. Also available at: http://circ.ahajournals.org/cgi/content/full/96/1/358 (accessed 07/03/06)
2. Simmons NA, *et al*. Antibiotic prophylaxis and infective endocarditis. *Lancet* 1992; **339:** 1292–3.

Mouth disorders. Chlorhexidine mouthwashes, sprays, and gels are used to prevent accumulation of dental plaque (see Mouth Infections, p.180). Early studies[1-4] generally showed chlorhexidine mouthwash 0.1 to 0.2% used 2 or 3 times daily to be effective in reducing plaque accumulation and gingivitis and provided limited evidence of effectiveness in preventing caries in permanent teeth of children and adolescents. A retrospective review[5] of 22 controlled studies of chlorhexidine for caries prevention, found the evidence inconclusive in schoolchildren and adolescents with active caries and regular fluoride exposure; there was also no good evidence that it arrested root caries in patients with dry mouth and in frail elderly subjects. However, chlorhexidine varnishes showed a preventative effect for fissure caries compared with no treatment in children with low fluoride exposure. Other studies have shown that chlorhexidine reduces gingivitis by 60 to 90% but its use is limited by its unpleasant taste and staining properties; special circumstances in which chlorhexidine is helpful include management of acute gingivitis, control of periodontal involvement in immunocompromised patients, and promotion of healing after periodontal treatment.[6]

Chlorhexidine gluconate may be useful in controlling secondary bacterial infections of aphthous ulcers (see Mouth Ulceration, p.1700). Local application of chlorhexidine has been reported to reduce the incidence[7] and duration and severity[8] of recurrent ulcers, although one study showed no benefit compared with placebo.[9] However, a retrospective review[10] of 7 studies comparing chlorhexidine with placebo or no treatment found no evidence that chlorhexidine prevents oral mucositis in patients receiving cancer treatment.

Chlorhexidine may be a useful adjunct to antifungal treatment of oral candidiasis[11] (p.518).

For the need for a delay when using chlorhexidine with other oral hygiene preparations, see under Precautions, above.

Obstetric use. Disinfection of the birth canal with chlorhexidine gluconate 0.05 to 0.4% during labour has been investigated as a method for reducing mother-to-child transmission of infections, including early-onset group B streptococcal infection and HIV.[1-6] Studies have shown that it has not reduced perinatal transmission of HIV except when membranes were ruptured for more than 4 hours before delivery[1] or if used before the membranes rupture and at higher concentrations.[4] A systematic review of 5 studies[5] to determine the efficacy of chlorhexidine vaginal disinfection for preventing early-onset group B streptococcal infection concluded that, although there was a statistically significant reduction in colonisation there was no significant reduction in early-onset infection, morbidity or mortality. Comparable results have been reported with the use of chlorhexidine gluconate 1% obstetric cream at each examination during labour.[3] A systematic review of 3 studies[6] to determine the efficacy of chlorhexidine vaginal disinfection for preventing perinatal transmission of infections other than group B streptococcal infection and HIV found no evidence to support its use. However, a study[2] conducted in Malawi reported a reduction in neonatal morbidity and mortality from other neonatal infections.

Urinary catheter-related infection. Chlorhexidine solutions have been used in the management of catheter-related bladder infections and for urinary catheter maintenance. Twice-daily bladder irrigation with chlorhexidine acetate 0.02% did not produce a reduction in urinary bacterial counts in geriatric patients with indwelling catheters, and there was a tendency for overgrowth of *Proteus* spp. in patients given chlorhexidine.[1] In patients undergoing prostatectomy, intermittent pre-operative bladder irrigation with chlorhexidine gluconate 0.05% reduced the incidence of bacteraemia and severe wound infection, although urinary infections were eradicated in only 3 of the 13 patients treated.[2]

Addition of chlorhexidine to catheter drainage bags was not shown to reduce the frequency of urinary infections,[3] but infection rates were reduced by combining this technique with the use of a catheter lubricant containing chlorhexidine, disinfection of the urethral meatus, and aseptic nursing procedures.[4] The use of lubricating gel containing chlorhexidine did not reduce the risk of urinary-tract infections associated with short-term catheterisation,[5] and in general external disinfection of the periurethral area alone does not seem to be of benefit in reducing the rate of catheter-related bacteriuria.[6,7]

The treatment of urinary-tract infections is discussed on p.199.

Chlorinated Lime

Bleaching Powder; Cal clorada; Calcaria Chlorata; Calcii Hypochloris; Calcium Hypochlorite; Calcium Hypochlorosum; Calx Chlorata; Calx Chlorinata; Chloride of Lime; Chlorkalk; Chlorure de Chaux; Cloruro de Cal; Desmanche.

CAS — 7778-54-3.

Pharmacopoeias. In *Br.* and *Jpn.*

BP 2008 (Chlorinated Lime). A dull white powder with a characteristic odour, containing not less than 30.0% w/w of 'available chlorine'. It becomes moist and gradually decomposes on exposure to air, carbon dioxide being absorbed and chlorine evolved. Partly soluble in water and in alcohol.

Adverse Effects, Treatment, and Precautions

As for Sodium Hypochlorite, p.1661.

Uses and Administration

Chlorinated lime is a disinfectant and antiseptic with the general properties of chlorine (p.1638).

Its action is rapid but brief, the 'available chlorine' soon being exhausted by combination with organic material. It is used to disinfect faeces, urine, and other organic material, and as a cleansing agent for lavatories, drains, and effluents.

Chlorinated lime is used in the preparation of Surgical Chlorinated Soda Solution (BPC 1973) (Dakin's Solution) which has been employed as a wound disinfectant, and Chlorinated Lime and Boric Acid Solution (BP 1993), (Eusol), which has been used as a disinfectant lotion and wet dressing, sometimes with equal parts of liquid paraffin. However, such solutions are irritant when applied undiluted, and are no longer recommended for use in this way. In addition, there is some evidence that such chlorine-releasing solutions may delay wound healing (see Disinfection, Wounds under Uses and Administration of Sodium Hypochlorite, p.1662).

Preparations

BPC 1973: Surgical Chlorinated Soda Solution.

Chlorine

925; Chlor; Chlore; Chlorium; Cloro; Klor.

Хлор

Cl_2 = 70.906.

CAS — 7782-50-5.

Description. Chlorine is a greenish-yellow gas with a suffocating odour; commonly available as a pressurised liquid.

Adverse Effects and Treatment

Chlorine gas is irritant and corrosive producing inflammation, burns, and necrosis. Inhalation may result in coughing, choking, headache, dyspnoea, dizziness, expectoration of frothy white sputum (which may be blood stained), a burning chest pain, and nausea. Bronchospasm, laryngeal oedema, acute pulmonary oedema with cyanosis, and hypoxia may occur. There may be vomiting and development of acidosis. Death may result from hypoxia.

Some of the toxicity of chlorine may be due to its dissolution in tissue water to produce hydrochloric acid and hypochlorite. After exposure to chlorine, conjunctivitis may require a topical anaesthetic and frequent irrigations of water or saline. Respiratory distress should be treated with inhalations of humidified oxygen and bronchodilators; mechanical ventilation may be required. Corticosteroids have been given in an attempt to minimise pulmonary damage but their benefit is unproven. Acidosis may require the intravenous use of sodium bicarbonate or other suitable alkalising agent.

◊ Experience gained from 186 cases of acute chlorine exposure indicated that medical support was required for only a short time even when exposure was repeated;[1] late sequelae were not seen, even in patients with abnormal respiratory function tests or blood gases on admission. Thirteen children who were accidentally exposed to chlorine products and gas at a community swimming pool complained of eye and throat irritation, chest pain and tightness, shortness of breath, wheezing, and anxiety and 5 children with hypoxia required hospital admission. These children received humidified oxygen, salbutamol, and, in 4 patients, methylprednisolone, and all were discharged 1 to 2 days later.[2] Another report on 76 children with chlorine poisoning revealed that the longest period of hospitalisation was 12 hours after treatment with oxygen and corticosteroids.[3] A 14-year-old boy with a history of asthma exposed to chlorine gas developed acute respiratory distress syndrome and required intubation, ventilatory support, salbutamol, and corticosteroids. He was extubated after 19 days and recovered well.[4] There have been reports of deliberate inhalation of chlorine,[5,6] in one instance for pleasure,[5] leading to severe adverse effects. Some individuals may be unduly insensitive to chlorine-induced irritation and workers should be warned that concentrations of chlorine which can be tolerated for short periods without undue discomfort can still cause serious injury which may not be immediately apparent.[6]

Guidelines[7,8] have been issued for the management of chlorine exposure.

Effects on the eyes. Eye examinations of 50 subjects immediately before and after swimming in a chlorinated pool (chlorine range 1.0 to 1.5 ppm) showed that 68% had symptoms of corneal oedema and 94% had corneal epithelial erosions. No subject had a measurable decrease in visual acuity.[1]

Precautions

The antimicrobial activity of chlorine disinfectants is reduced by the presence of organic material and by increasing pH. Hypochlorite solutions may delay wound healing (see Disinfection: Wounds under Uses and Administration of Sodium Hypochlorite, p.1662).

Uses and Administration

Chlorine is a disinfectant with a rapid potent brief bactericidal action. It is capable of killing most bacteria, and some fungi, yeasts, algae, viruses, and protozoa. It is slowly active against spores.

It is used for the treatment of water (p.1623), but for most other purposes it is used in the form of hypochlorites, organic and inorganic chloramines, chlorinated hydantoins, chlorinated isocyanurates, and similar oxidising compounds capable of releasing chlorine. In the presence of water these compounds produce hypochlorous acid (HOCl) and hypochlorite ion (OCl^-) and it is generally considered that the lethal action on micro-organisms is due to chlorination of cell protein or enzyme systems by nonionised hypochlorous acid, although the hypochlorite ion may also contribute.

The activity of most of the compounds decreases with increase of pH, the activity of solutions of pH 4 to 7 being greater than those of higher pH values. However, stability is usually greater at an alkaline pH.

The potency of chlorine disinfectants is expressed in terms of **available chlorine**. This is based on the concept of chlorine gas (Cl_2) as the reference substance. Two atoms of chlorine (2 × Cl) yield in water only one molecule of hypochlorous acid (on which activity is based), while hypochlorites and chloramines yield one molecule of hypochlorous acid for each atom of chlorine as shown in the following equations:

$$Cl_2 + H_2O \leftrightarrow HOCl + H^+ + Cl^-$$
$$NaOCl + H_2O \leftrightarrow HOCl + NaOH$$

Thus the assayed chlorine in such compounds has to be multiplied by 2 to produce 'available chlorine'. The term 'active chlorine' has been used confusingly for either 'available chlorine' (Cl_2) or 'combined chlorine' (Cl).

Because they have relatively low residual toxicity, chlorine compounds are useful for the disinfection of relatively clean impervious surfaces, such as babies' feeding bottles, baths, and food and dairy equipment. A concentration of 100 to 300 ppm of 'available chlorine' is used; a detergent may be added to ensure wetting of the surface. Solutions containing 1000 ppm 'available chlorine' are recommended for minor surface contamination and as part of general good hygiene practice. Solutions containing 10 000 ppm 'available chlorine' are used to disinfect surfaces contaminated with spilled blood or body fluids; this strength is effective against viruses including human immunodeficiency virus (HIV) and hepatitis B virus (p.1623). A concentration providing 20 000 ppm 'available chlorine' is used for material from patients with Creutzfeldt-Jakob disease (p.1622).

On a large scale, chlorine gas is used to disinfect public water supplies. On a smaller scale, the use of chlorine compounds is more convenient and sodium hypochlorite, tosylchloramide sodium, chlorinated lime, chlorine dioxide, or halazone are used. After satisfying the chlorine demand (the amount of chlorine needed to react with organic matter and other substances), a free-residual content of 0.2 to 0.4 ppm 'available chlorine' should be maintained, though more is required for alkaline waters with a pH of 9 or more. For the disinfection of potentially contaminated water a concentration of 1 ppm is recommended. Excessive residual chlorine may be removed by adding a little citric acid or sodium thiosulfate.

For use in small swimming pools, sodium or calcium hypochlorite may be added daily to maintain a free-residual 'available chlorine' concentration of 1 to 3 ppm. Tosylchloramide sodium, chlorinated lime, and the isocyanurates (see Troclosene, p.1665) may also be used. To minimise irritation of the eyes, maintain disinfectant activity, prevent precipitation of salts, and prevent metal corrosion, a pH of 7.2 to 7.8 should be maintained.

Solutions of chlorine-releasing compounds are also used in wound desloughing and disinfection (but see Disinfection: Wounds, under Sodium Hypochlorite, p.1662).

Chlorine Dioxide

926; Cloro, dióxido de.

ClO_2 = 67.45.

CAS — 10049-04-4.

Profile

Chlorine dioxide is a strong oxidising agent with the general properties of chlorine (p.1638). It is rapidly active against vegetative bacteria, including mycobacteria, and viruses and is also sporicidal. It is used for disinfection of medical equipment either in gaseous form or in a solution that requires activation before use and yields 700 to 1100 ppm 'available chlorine' (see p.1638). Chlorine dioxide is irritant to the skin, eyes, and respiratory tract and should be stored in sealed containers. It is potentially corrosive to many materials and solutions may contain corrosion inhibitors.

Chlorine dioxide is also used for treatment and disinfection of water supplies.

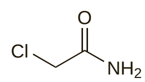
Belg.: Retardex; ***Philipp.:*** Oracare; ***UK:*** Retardex.

Chloroacetamide

Chloracetamide; Cloroacetamida. 2-Chloroacetamide.

C_2H_4ClNO = 93.51.

CAS — 79-07-2.



Profile

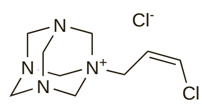
Chloroacetamide is a preservative that has been used in topical pharmaceutical preparations and cosmetics.

N-(3-Chloroallyl)hexaminium Chloride

N-(3-Cloroalil)hexaminio, cloruro de; Quaternium-15. 1-(3-Chloroallyl)-3,5,7-triaza-1-azoniaadamantane chloride.

$C_9H_{16}Cl_2N_4$ = 251.2.

CAS — 4080-31-3.



Profile

N-(3-Chloroallyl)hexaminium chloride is an antimicrobial preservative used in pharmaceutical preparations and cosmetics. Skin reactions have been reported.

Chlorobutanol *(BAN, rINN)*

Acetone-Chloroforme; Alcohol Trichlorisobutylicus; Chlorbutanol; Chlorbutanolum; Chlorbutol; Chloretone; Chlorobutanolis; Chlorobutanolum; Clorobutanol; Klooributanoli; Klorbutanol; Klorobutanol; Trichlorbutanolum. 1,1,1-Trichloro-2-methylpropan-2-ol.

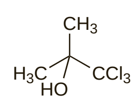
Хлоробутанол

$C_4H_7Cl_3O$ = 177.5.

CAS — 57-15-8 (anhydrous chlorobutanol); 6001-64-5 (chlorobutanol hemihydrate).

ATC — A04AD04.

ATC Vet — QA04AD04.



Pharmacopoeias. *Eur.* (see p.vii), *Int.*, and *USNF* allow either the anhydrous form or the hemihydrate; *Eur.* includes them as separate monographs. *Chin.* specifies the hemihydrate. *Jpn* permits up to 6% of water.

Ph. Eur. 6.2 (Chlorobutanol Hemihydrate; Chlorobutanol BP 2008). A white or almost white, crystalline powder or colourless crystals. It sublimes readily. M.p. about 78°. Slightly soluble in water; very soluble in alcohol; soluble in glycerol (85%). Store in airtight containers.

Ph. Eur. 6.2 (Chlorobutanol, Anhydrous). A white or almost white, crystalline powder or colourless crystals. It sublimes readily. M.p. about 95°. Slightly soluble in water; very soluble in alcohol; soluble in glycerol (85%). Store in airtight containers.

USNF 26 (Chlorobutanol). It is anhydrous or contains not more than one-half molecule of water of hydration. Colourless or white crystals with a characteristic, somewhat camphoraceous odour. M.p. about 76° for the hemihydrate and about 95° for the anhydrous form. Soluble 1 in 125 of water, 1 in 1 of alcohol, and 1 in 10 of glycerol; freely soluble in chloroform, in ether, and in volatile oils. Store in airtight containers.

Incompatibility and stability. The activity of chlorobutanol can be adversely affected by the presence of other compounds as well as by the packaging material. There may be sorption onto substances like magnesium trisilicate, bentonite, carmellose,[1] polyethylene,[2,3] or polyhydroxy-ethylmethacrylate that has been used in soft contact lenses.[4] Increasing heat[2,3] or pH[5,6] can reduce stability and activity.

Hypersensitivity. A delayed, cellular type of hypersensitivity reaction to chlorobutanol used to preserve heparin injection after subcutaneous injection has been reported.[1] Pruritus from intranasal desmopressin has been attributed to the chlorobutanol preservative.[2]

1. Dux S, *et al.* Hypersensitivity reaction to chlorbutanol-preserved heparin. *Lancet* 1981; **i:** 149.
2. Itabashi A, *et al.* Hypersensitivity to chlorobutanol in DDAVP solution. *Lancet* 1982; **i:** 108.

Uses and Administration

Chlorobutanol has antibacterial and antifungal properties and it is used at a concentration of 0.5% as a preservative in injections and in eye drops as well as cosmetics.

Chlorobutanol has been used as a mild sedative and local analgesic but other compounds are preferred. It has been used in preparations for inflammatory and painful conditions of the ear and oropharynx.

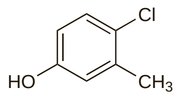
Chlorocresol *(USAN, rINN)*

Chlorkresol; Chlorkresolum; Chlorocrésol; Chlorocresolum; Chlorokrezolis; Clorocresol; Kloorikresoli; Klorkresol; Klorokrezol; Parachlorometacresol; PCMC. *p*-Chloro-*m*-cresol; 4-Chloro-3-methylphenol.

Хлорокрезол

C_7H_7ClO = 142.6.

CAS — 59-50-7.



Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*

Ph. Eur. 6.2 (Chlorocresol). A white or almost white, crystalline powder or compacted crystalline masses supplied as pellets or colourless or white crystals. M.p. 64° to 67°. Slightly soluble in water; very soluble in alcohol; freely soluble in fatty oils. It dissolves in solutions of alkali hydroxides. Protect from light.

USNF 26 (Chlorocresol). Colourless or practically colourless crystals or crystalline powder with a characteristic nontarry odour; it is volatile in steam. M.p. 63° to 66°. Soluble 1 in 260 of water; more soluble in hot water; soluble 1 in 0.4 of alcohol; soluble in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides. Store in airtight containers. Protect from light.

Incompatibility. Chlorocresol has long been recognised to be incompatible with a range of compounds including: calcium chloride, codeine phosphate, diamorphine hydrochloride, papaveretum, quinine hydrochloride,[1] methylcellulose,[2] and nonionic surfactants[3,4] such as cetomacrogol 1000 and polysorbate 80.

1. McEwan JS, Macmorran GH. The compatibility of some bactericides. *Pharm J* 1947; **158:** 260–2.
2. Harris WA. The inactivation of cationic antiseptics by bentonite suspensions. *Australas J Pharm* 1961; **42:** 583–8.
3. *PSGB Lab Report P/70/15* 1970.
4. Yousef RT, *et al.* Effect of some pharmaceutical materials on the bactericidal activities of preservatives. *Can J Pharm Sci* 1973; **8:** 54–6.

Adverse Effects, Treatment, and Precautions

As for Phenol, p.1656. The antimicrobial activity of chlorocresol may be reduced by incompatibility (see above), adsorption, increasing pH, or through combination with organic matter (including oils and fats) or nonionic surfactants.

Chlorocresol is less toxic than phenol. Sensitisation reactions may follow application to the skin and hypersensitivity has occurred after systemic use of injections containing chlorocresol as a preservative.

Uses and Administration

Chlorocresol is a potent chlorinated phenolic disinfectant and antiseptic. It has bactericidal activity against Gram-positive and Gram-negative bacteria and is effective against fungi but has little activity against bacterial spores except at high temperatures. It is more active in acid than in alkaline solution.

Chlorocresol is used in preparations for disinfection of the skin and wounds. It is also used as a preservative in cosmetics and in creams and other preparations for external use that contain water.

Chlorocresol is used as a preservative in aqueous injections issued in multidose containers. It may also be added to aqueous preparations that cannot be sterilised in their final containers and have to be prepared using aseptic precautions. Concentrations of 0.1% have generally been used. Injections prepared with chlorocresol should not be injected into the CSF, the eye, or the heart. Also such injections should generally not be given in volumes greater than 15 mL. Sterilisation by heating with a bactericide such as chlorocresol is no longer a recommended practice.

Preparations

BPC 1973: Proflavine Cream.

Proprietary Preparations (details are given in Part 3)

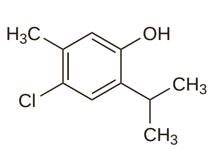
Multi-ingredient: ***Arg.:*** Perfungol†; ***Austria:*** Ulcurilen; ***Chile:*** Perfungol; ***Cz.:*** Cyteal; ***Fr.:*** Cicatryl; Cyteal; ***Ger.:*** Bomix; Helipur; Ulcurilen N†; ***Gr.:*** Lyoderm; Octrene; ***Irl.:*** Anbesol; Valderma†; ***Ital.:*** Helipur; Hygienist†; ***Port.:*** Anbegele†; Cyteal; ***Rus.:*** Cyteal (Цитеал); ***S.Afr.:*** Anbesol; ***Singapore:*** Cyteal; ***UK:*** Anbesol; Cymex; Cyteal; Valderma.

Chlorothymol

Clorotimol; Monochlorothymol. 6-Chlorothymol; 4-Chloro-2-isopropyl-5-methylphenol.

$C_{10}H_{13}ClO$ = 184.7.

CAS — 89-68-9.



Profile

Chlorothymol is a chlorinated phenolic antiseptic used as an ingredient of preparations for hand and skin disinfection and topical treatment of fungal infections. It has also been used in preparations for anorectal disorders, cold symptoms, and mouth disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Ital.: Pioral Pasta.

Chloroxylenol *(BAN, USAN, rINN)*

Chloroxylénol; Chloroxylenolum; Cloroxilenol; Parachlorometaxylenol; PCMX. 4-Chloro-3,5-xylenol; 4-Chloro-3,5-dimethylphenol.

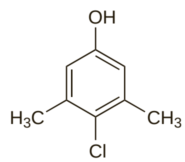
Хлороксиленол

C_8H_9ClO = 156.6.

CAS — 88-04-0.

ATC — D08AE05.

ATC Vet — QD08AE05.



Pharmacopoeias. In *Br.* and *US.*

BP 2008 (Chloroxylenol). White or cream crystals or crystalline powder with a characteristic odour; volatile in steam. Very slightly soluble in water; freely soluble in alcohol; soluble in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides.

USP 31 (Chloroxylenol). White crystals or crystalline powder with a characteristic odour; volatile in steam. Very slightly soluble in water; freely soluble in alcohol, in ether, in terpenes, in fixed oils, and in solutions of alkali hydroxides.

Incompatibility. Chloroxylenol has been reported to be incompatible with nonionic surfactants and methylcellulose.

Adverse Effects and Precautions

Chloroxylenol in the recommended dilutions is generally non-irritant but skin sensitivity has occurred. There have been isolated reports of poisoning. Symptoms include corrosion of the oral mucosa, larynx, and the gastrointestinal tract, bradycardia, hypotension, and renal failure. Large amounts may cause CNS depression. Pulmonary aspiration of chloroxylenol-based disinfectants may result in pneumonia, acute respiratory distress syndrome, and cardiorespiratory arrest.

The antimicrobial activity of chloroxylenol may be diminished through combination with organic matter. Aqueous solutions of chloroxylenol may be susceptible to contamination with micro-organisms. To reduce this risk, solutions must be freshly prepared at the recommended concentration and appropriate measures should be taken to prevent contamination during storage or dilution.

Poisoning. Reports of fatal or severe self-poisoning with chloroxylenol solution.[1-5]

1. Meek D, *et al.* Fatal self-poisoning with Dettol. *Postgrad Med J* 1977; **53:** 229–31.
2. Joubert P, *et al.* Severe Dettol (chloroxylenol and terpineol) poisoning. *BMJ* 1978; **1:** 890.
3. Chan TYK, *et al.* Chemical gastro-oesophagitis, upper gastrointestinal haemorrhage and gastroscopic findings following Dettol poisoning. *Hum Exp Toxicol* 1995; **14:** 18–19.
4. Chan TY, Critchley JA. Pulmonary aspiration following Dettol poisoning: the scope for prevention. *Hum Exp Toxicol* 1996; **15:** 843–6.
5. Joynt GM, *et al.* Delayed upper airway obstruction: a life-threatening complication of Dettol poisoning. *Anaesthesia* 1997; **52:** 261–3.

Uses and Administration

Chloroxylenol is a chlorinated phenolic antiseptic that is bactericidal against most Gram-positive bacteria but less active against staphylococci and Gram-negative bacteria, and is often inactive against *Pseudomonas* spp. Its activity against *Ps. aeruginosa* appears to be increased by the addition of edetic acid. It is inactive against bacterial spores.

Chloroxylenol Solution (BP 2008) is used for skin and wound disinfection, and chloroxylenol is used as a preservative in a variety of other topical formulations.

Preparations

BP 2008: Chloroxylenol Solution.

Proprietary Preparations (details are given in Part 3)

Ital.: Golamed†.

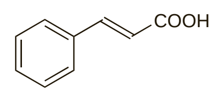
Multi-ingredient: ***Ital.:*** Golamed Due†; Pastiglie Valda†.

Cinnamic Acid

Cinámico, ácido; Cinnamylic Acid. *trans*-3-Phenylpropenoic acid.

$C_6H_5.CH{:}CH.CO_2H$ = 148.2.

CAS — 621-82-9.



Pharmacopoeias. In *Br.*

BP 2008 (Cinnamic Acid). Colourless crystals with a faint balsamic odour. Very slightly soluble in water; freely soluble in alcohol; soluble in chloroform and in ether.

Profile

Cinnamic acid has preservative properties. It is used with benzoic acid and other substances to simulate the flavour of tolu.

Preparations

BP 2008: Tolu-flavour Solution.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***UK:*** Hemocane; Potters Gees Linctus; Sanderson's Throat Specific.

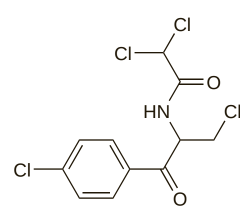
Cloponone *(BAN, rINN)*

Clopona; Clopononum. (*RS*)-2,2-Dichloro-*N*-[4-chloro-α-(chloromethyl)phenacyl]acetamide.

Клопонон

$C_{11}H_9Cl_4NO_2$ = 329.0.

CAS — 15301-50-5.



Profile

Cloponone is an antiseptic included in multi-ingredient preparations intended for the topical treatment of vaginal infections.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Hong Kong:*** Ginetris†.

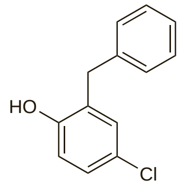
Clorophene *(USAN)*

Clorofene *(pINN)*; Clorfene; Clorofène; Clorofeno; Clorofenum; NSC-59989; Septiphene. 2-Benzyl-4-chlorophenol.

Клорофен

$C_{13}H_{11}ClO = 218.7$.

CAS — 120-32-1.



Profile

Clorophene is a chlorinated phenolic antiseptic stated to be active against a wide range of bacteria, fungi, protozoa, and viruses. It is used as a skin disinfectant and for surface and instrument disinfection. Clorophene sodium has also been used.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Belg.:*** Neo-Sabenyl; ***Ger.:*** Bomix; Freka-Derm; Freka-Sept 80; Helipur; ***Ital.:*** Helipur; Hygienist†; ***Switz.:*** Frekaderm†; ***UAE:*** Radol; ***USA:*** BTK-Plus.

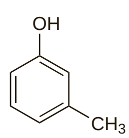
Cresol

Crésol brut (cresol, crude); Cresolum; Cresolum crudum (cresol, crude); Cresylic Acid; Kresol; Kresol, rå (cresol, crude); Kresoli, raaka (cresol, crude); Kresolum Venale; Krezol; Krezolis, negrynintas (cresol, crude); Metacresol *(BAN)*; Tricresol; Trikresolum. Methylphenol.

Крезол

$C_7H_8O = 108.1$.

CAS — 1319-77-3; 95-48-7 (o-cresol); 108-39-4 (m-cresol); 106-44-5 (p-cresol).



NOTE. Some grades of mixed cresols may be equivalent to Tar Acids (p.1663).

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *Jpn.* Also in *USNF.*

Eur. also includes metacresol.

Ph. Eur. 6.2 (Cresol, Crude; Cresolum Crudum). A mixture of *o*-, *m*-, and *p*-methylphenol. A colourless or pale brown liquid. Relative density 1.029 to 1.044. Sparingly soluble in water; miscible with alcohol and with dichloromethane. Protect from light.

Ph. Eur. 6.2 (Metacresol; Metacresolum). A colourless or yellowish liquid. Relative density about 1.03. M.p. about 11°. Sparingly soluble in water; miscible with alcohol and with dichloromethane. Store in airtight containers. Protect from light.

USNF 26 (Cresol). A mixture of cresol isomers obtained from coal tar or petroleum. A colourless, yellowish to brownish-yellow, or pinkish, highly refractive liquid, becoming darker with age or on exposure to light, with a phenol-like, sometimes empyreumatic odour. Specific gravity 1.030 to 1.038. Sparingly soluble in water, usually forming a cloudy solution; miscible with alcohol, with ether, and with glycerol; dissolves in solutions of fixed alkali hydroxides. A saturated solution in water is neutral or slightly acid to litmus. Store in airtight containers. Protect from light.

Profile

Cresol is a disinfectant with a similar action to phenol (p.1656); suitable precautions should be taken to prevent absorption through the skin.

It has been used as Cresol and Soap Solution (BP 1968) (Lysol) as a general disinfectant but it has been largely superseded by other, less irritant, phenolic disinfectants. Cresol has been used in dentistry, alone or with formaldehyde, but is caustic to the skin and unsuitable for skin and wound disinfection. The cresols have been widely used in disinfectants for domestic and hospital use. Cresol is also used as an antimicrobial preservative in parenteral pharmaceutical preparations and in some topical formulations.

Preparations

Proprietary Preparations (details are given in Part 3)

Ital.: Creolina.

Multi-ingredient: ***Arg.:*** Algiodent; Sulfanoral T; ***Austral.:*** Formo-Cresol Mitis; ***Canad.:*** Gernel; ***Spain:*** Tifell†; ***USA:*** Cresylate.

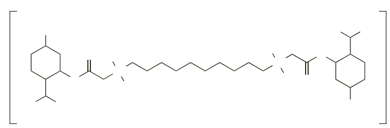
Decamethoxine

Dekametoksin. *N,N,N′,N′*-Tetramethyl-*N,N′*-bis(2-{[5-methyl-2-(1-methylethyl)-cyclohexyl]oxy}-2-oxoethyl)-1,10-decanediaminium dichloride.

Декаметоксин

$C_{38}H_{74}Cl_2N_2O_4 = 693.9$.

CAS — 38146-42-8.



Profile

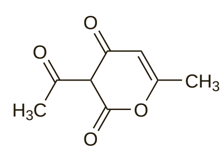
Decamethoxine is a quaternary ammonium antiseptic and disinfectant with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). It is used topically for disinfection of the skin and mucous membranes and for disinfection of equipment. Decamethoxine is also used as a gargle for infections of the oral cavity and has been used topically or as an irrigation for infections of the skin and various body cavities.

Dehydroacetic Acid

Deshidroacético, ácido; Methylacetopyronone. 3-Acetyl-6-methyl-2*H*-pyran-2,4(3*H*)-dione (keto form); 3-Acetyl-4-hydroxy-6-methyl-2*H*-pyran-2-one (enol form).

$C_8H_8O_4 = 168.1$.

CAS — 520-45-6 (keto form); 771-03-9 (enol form).



(keto form)

Pharmacopoeias. In *USNF.*

USNF 26 (Dehydroacetic Acid). A white or nearly white, crystalline powder. Very slightly soluble in water; soluble in aqueous solutions of alkalis. One g dissolves in about 35 mL of alcohol and in 5 mL of acetone.

Sodium Dehydroacetate

Deshidroacetato sódico. The sodium salt of 3-acetyl-6-methyl-2*H*-pyran-2,4(3*H*)-dione.

$C_8H_7NaO_4 = 190.1$.

CAS — 4418-26-2.

Pharmacopoeias. In *USNF.*

USNF 26 (Sodium Dehydroacetate). A white or practically white, odourless powder. Freely soluble in water, in glycerol, and in propylene glycol.

Incompatibility. The activity of sodium dehydroacetate may be reduced by alkaline pH or interaction with nonionic surfactants.

Profile

Dehydroacetic acid and sodium dehydroacetate have some antifungal activity and have been used in the preservation of cosmetics and oral preparations.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Venez.:*** Photoderm AKN.

Dequalinium Chloride *(BAN, rINN)*

BAQD-10; Cloruro de decualinio; Decalinium Chloride; Decaminum; Dekalinyum Klorür; Dekvalinio chloridas; Dekvalinium dichlorid; Dekvaliniumklorid; Dekvalinium-klorid; Dekvaliniumkloridi; Dequalinii chloridum; Dequalinii Dichloridum; Déqualinium, chlorure de. *N,N*-Decamethylenebis(4-amino-2-methylquinolinium chloride).

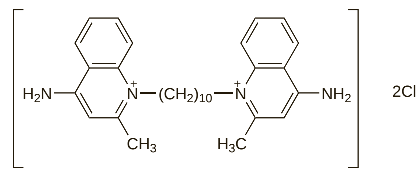
Деквалиния Хлорид

$C_{30}H_{40}Cl_2N_4 = 527.6$.

CAS — 6707-58-0 (dequalinium); 522-51-0 (dequalinium chloride); 4028-98-2 (dequalinium acetate); 16022-70-1 (dequalinium salicylate).

ATC — D08AH01; G01AC05; R02AA02.

ATC Vet — QD08AH01; QG01AC05; QR02AA02.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Dequalinium Chloride). A white or yellowish-white, hygroscopic powder. Slightly soluble in water and in alcohol. Store in airtight containers.

Incompatibility. Dequalinium chloride is incompatible with soaps and other anionic surfactants, with phenol, and with chlorocresol.

Profile

Dequalinium chloride is a bisquaternary quinolinium antiseptic, bactericidal against many Gram-positive and Gram-negative bacteria, and effective against fungi. It is mainly used in the form of lozenges in the treatment of minor infections of the mouth and throat. It has been applied topically in the treatment of skin and vaginal infections.

Dequalinium salicylate and undecenoate have also been used.

Preparations

Proprietary Preparations (details are given in Part 3)

Austria: Dequavagyn; Evazol; Sorot; Tonsillol; ***Belg.:*** Anginol; Laryngarsol; ***Canad.:*** Dequadin; ***Chile:*** Larylin†; ***Ger.:*** Evazol; Fluomycin N; Gurgellosung-ratiopharm; Maltyl†; Sorot; Stada Gurgellosung†; ***Hong Kong:*** Delin; Dequadin; Roxine; ***Indon.:*** Decamedin; Degirol; SP Troches; ***Irl.:*** Dequadin; ***Ital.:*** Dequadin; Dequosangola; Faringina; Goladin; Osangin; Pumilsan; ***Malaysia:*** Delin; Denium†; DQM; SP Troches; Synti†; Uphadeq†; ***Mex.:*** Apocatil†; ***Neth.:*** Gargilon; Natterman Streptofree; ***Philipp.:*** Dequadin; ***S.Afr.:*** Dequadin†; ***Singapore:*** Beacons DQ; Dequa-loz; Dequadin; SP Troches; ***Spain:*** Dequadin†; ***Switz.:*** Decatylene; Fluomizin; Pastilles pour la gorge formule 535†; ***Thai.:*** Decho; Deo; Dequadin; V Day Lozenges†; ***Turk.:*** Dequadin; ***UK:*** Dequadin; Labosept; ***Venez.:*** Dequadin; Laimolin.

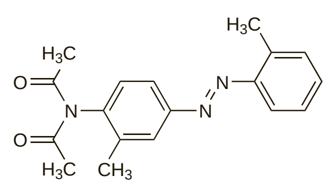
Diacetylaminoazotoluene

Diacetazotol; Diacetilaminoazotoluene; Pellidol. 4-Diacetylamino-2′,3-dimethylazobenzene.

$C_{18}H_{19}N_3O_2 = 309.4$.

CAS — 83-63-6.



Profile

Diacetylaminoazotoluene is an antiseptic that has been used topically to promote wound healing.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austria:*** Dermowund.

Dibrompropamidine Isetionate *(BANM, rINNM)*

Dibromipropamidiinidi-isetionaatti; Dibromopropamidine Isethionate; Dibromopropamidyny diizetionian; Dibrompropamidindiisetionat; Dibrompropamidin-diisetionát; Dibrompropamidine Diisetionate; Dibrompropamidine, diisétionate de; Dibrompropamidine, Isétionate de; Dibrompropamidini diisetionas; Dibrompropamidini Isetionas; Isetionato de dibrompropamidina. 3,3′-Dibromo-4,4′-trimethylenedioxydibenzamidine bis(2-hydroxyethanesulphonate).

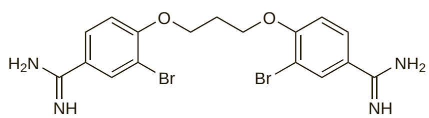
Дибромпропамидина Изетионат

$C_{17}H_{18}Br_2N_4O_2,2C_2H_6O_4S$ = 722.4.

CAS — 496-00-4 (dibrompropamidine); 614-87-9 (dibrompropamidine isetionate).

ATC — D08AC01; S01AX14.

ATC Vet — QD08AC01; QS01AX14.



(dibrompropamidine)

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Dibrompropamidine Diisetionate). A white or almost white, crystalline powder. Freely soluble or soluble in water; slightly soluble in alcohol; practically insoluble in dichloromethane. A 5% solution in water has a pH of 5.0 to 6.0.

Profile

Dibrompropamidine isetionate is an aromatic diamidine antiseptic similar to propamidine (p.1660). It is bactericidal against Gram-positive bacteria but is less active against Gram-negative bacteria and spore-forming organisms. It also has antifungal properties. It is available as topical preparations for the local treatment of minor eye and skin infections.

Preparations

Proprietary Preparations (details are given in Part 3)

Austral.: Brolene; Brulidine; ***Irl.:*** Brolene; ***Norw.:*** Brulidine; ***NZ:*** Brolene; ***UK:*** Brolene; Brulidine; Golden Eye Ointment; Pickles Antiseptic Cream.

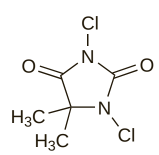
Multi-ingredient: ***UK:*** Healthy Feet; No-Sor Nose Balm; RBC; Swarm.

Dichlordimethylhydantoin

Diclorodimetilhidantoína. 1,3-Dichloro-5,5-dimethylhydantoin; 1,3-Dichloro-5,5-dimethylimidazolidine-2,4-dione.

$C_5H_6Cl_2N_2O_2$ = 197.0.

CAS — 118-52-5.



Profile

Dichlordimethylhydantoin is a disinfectant used as a source of chlorine, for sterilising food and dairy equipment and as a bleach. It contains about 72% w/w of 'available chlorine' (see p.1638).

Bromochlorodimethylhydantoin ($C_5H_6N_2O_2BrCl$ = 241.5) is a closely related bromine-releasing compound used for the disinfection of swimming-pool water.

Dichlorobenzyl Alcohol

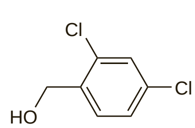
Alcohol diclorobencílico; 2,4-Dichlorbenzyl-alcoholum; Dichlorophenylcarbinol; 2,4-Diklooribentsyyli-alkoholi; 2,4-Diklorbensylalkohol; Diklorobenzil Alkol. 2,4-Dichlorobenzyl alcohol.

$C_7H_6Cl_2O$ = 177.0.

CAS — 1777-82-8.

ATC — R02AA03.

ATC Vet — QR02AA03.



Profile

Dichlorobenzyl alcohol is an antiseptic used chiefly as an ingredient of lozenges in the treatment of minor infections of the mouth and throat.

Preparations

Proprietary Preparations (details are given in Part 3)

Ital.: Neo Borocillina Collutorio; Neo Borocillina Spray.

Multi-ingredient: ***Austral.:*** Ayrton's Antiseptic; Logicin Rapid Relief; Sore Throat Chewing Gum†; Strepsils; Strepsils Plus; ***Austria:*** Coldangin; Neo-Angin; Sulgan 99; ***Belg.:*** Neofenox; Strepsils; Strepsils + Lidocaine; Strepsils Menthol; Strepsils Vit C; ***Canad.:*** Strepsils; Strepsils Cherry†; ***Chile:*** Cornina†; Hansaplast Antimicotico; ***Cz.:*** Neo-Angin; Strepsils; Strepsils Menthol a Eucalyptus; Strepsils Plus; Strepsils Vitamin C; ***Denm.:*** Strepsils; ***Fin.:*** Bafucin; Strepsils; Strepsils Menthol; ***Fr.:*** Strepsils; Strepsils Lidocaine; Strepsils Miel-Citron; Strepsils Vitamine C; Strepsilspray Lidocaine; ***Ger.:*** Dobendan Synergie; Neo-Angin; ***Gr.:*** Strepsils; ***Hong Kong:*** Logicin Rapid Relief; Strepsils; Strepsils Dual Action; ***Hung.:*** Neo-Angin; Strepsils; Strepsils Menthol and Eucalyptus; Strepsils Plus; Strepsils Vitamin C; ***India:*** Cofsils†; ***Irl.:*** Strepsils; Strepsils +Plus Anaesthetic; Strepsils Dual Action; Strepsils Vitamin C; ***Israel:*** Strepsils; Strepsils Plus; Strepsils with Menthol and Eucalyptus; Strepsils with Vitamin C; ***Ital.:*** Arscolloid; Benagol; Benagol Mentolo-Eucaliptolo; Benagol Vitamina C; Bio-Arscolloid; Corti-Arscolloid; Farmagola†; Neo Borocillina; Neo Borocillina Balsamica; Neo Borocillina C; Neo Borocillina Tosse Compresse; ***Malaysia:*** Chericof; Strepsils; Strepsils Dual Action; ***Neth.:*** Strepsils; Strepsils Menthol en Eucalyptus; Strepsils Sinaasappel en Vitamine C; ***NZ:*** Strepsils; Strepsils Plus Anaesthetic; Strepsils with Vitamin C; ***Philipp.:*** Strepsils; ***Pol.:*** Neo-Angin; Strepsils; ***Port.:*** Benoral; Dropcina; ***Rus.:*** Astrasept (Астрасепт); Coldact Lorpils (Колдакт Лорпилс)†; Rinza Lorsept (Ринза Лорсепт); Strepsils (Стрепсилс); Strepsils Plus (Стрепсилс Плюс); Suprima-Lor (Суприма-Лор); ***S.Afr.:*** Strepsils; Strepsils Eucalyptus Menthol; Strepsils Orange-C; Strepsils Plus; Strepsils Soothing Honey & Lemon; ***Singapore:*** Strepsils; Strepsils Dual Action; ***Spain:*** Strepsils; Strepsils con Vitamina C; Strepsils Lidocaina; ***Swed.:*** Bafucin; Strepsils; ***Switz.:*** Anginazol; Hextriletten; Lidazon; Neo-Angin au miel et citron; Neo-Angin avec vitamin C sans sucre; Neo-Angin sans sucre; Sulgan N; ***Thai.:*** Strepsils Butter Menthol Capsicum; Strepsils Plus Anaesthetic; Strepsils Plus Vit C; Strepsils Sugar Free; Throatsil; ***Turk.:*** Strepsils; Strepsils C; Strepsils Mentollu; ***UK:*** Strepsils; Strepsils with Vitamin C.

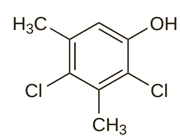
Dichloroxylenol *(BAN, rINN)*

DCMX; Dichlorometaxylenol; Dichloroxylénol; Dichloroxylenolum; Dicloroxilenol. 2,4-Dichloro-3,5-xylenol; 2,4-Dichloro-3,5-dimethylphenol.

Дихлороксиленол

$C_8H_8Cl_2O$ = 191.1.

CAS — 133-53-9.



Profile

Dichloroxylenol is a chlorinated phenolic antiseptic.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***India:*** Fairgenol†; ***UAE:*** Radol.

Didecyldimethylammonium Chloride

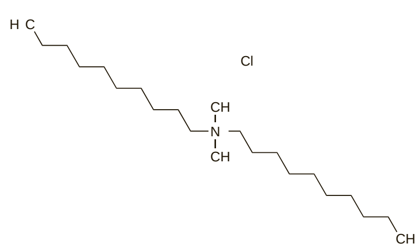
DideciIdimetilamonio, cloruro de; Didecyldimonium Chloride. *N*-Decyl-*N*,*N*-demethyl-l-decanaminium chloride.

$C_{22}H_{48}ClN$ = 362.1.

CAS — 7173-51-5.

ATC — D08AJ06.

ATC Vet — QD08AJ06.



Profile

Didecyldimethylammonium chloride is a quaternary ammonium disinfectant used in preparations for disinfection of the skin and mucous membranes. It is also used to disinfect instruments and surfaces.

Preparations

Proprietary Preparations (details are given in Part 3)

Ger.: Amosept; Fungisept; ***Ital.:*** Alfa; Farmasept; ***Thai.:*** Deconex 50FF†.

Multi-ingredient: ***Fr.:*** Aniospray 29; Aniospray 41; Aniosyme; Bacterianos D†; Chlorispray†; Hexanios G+R; Oxitou; Sanytol†; Surfanios; ***Ger.:*** Almyrol; Baccalin†; Bacillocid rasant†; Desoform†; Freka-Nol; Fugisept†; Gercid forte†; Gigasept Med†; Hexaquart L†; Hexaquart plus; Hexaquart S; Inova†; Kohrsolin FF; Korsolex Extra; Korsolex FF; Korsolex Plus; Lysoformin 3000; Lysoformin spezial; Meliseptol Rapid; Melsept SF; Melsitt; Quatohex; Teta Extra; ***Ital.:*** Melsept SF; ***Switz.:*** Desamon; ***Thai.:*** Deconex 53IN†; ***USA:*** Vi Rid-Ready.

1,6-Dihydroxy-2,5-dioxahexane

Ethylene Glycol Bis(semiformal); (Ethylenedioxy)dimethanol. [1,2-Ethanediylbis(oxy)]bismethanol.

$C_4H_{10}O_4$ = 122.1.

CAS — 3586-55-8.

Profile

1,6-Dihydroxy-2,5,-dioxahexane is an aldehyde that slowly releases formaldehyde. It is used for the disinfection of surfaces and of medical and surgical instruments.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ger.:*** Bacillol; Kohrsolin; Korsolex basic; Korsolex Extra.

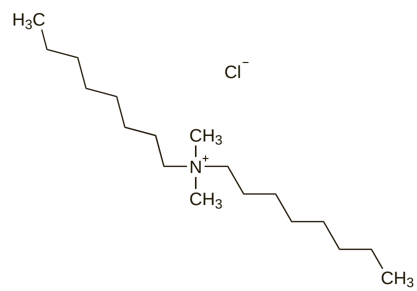
Dioctyldimethylammonium Chloride

Dimethyldioctylammonium Chloride; Dioctyl Dimethyl Ammonium Chloride. *N*,*N*-Dimethyl-*N*-octyl-1-octanaminium chloride.

Диоктилдиметиламмония Хлорид

$C_{18}H_{40}ClN$ = 306.0.

CAS — 5538-94-3.



Profile

Dioctyldimethylammonium chloride is a quaternary ammonium disinfectant used in preparations for disinfection of surfaces.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***USA:*** Vi Rid-Ready.

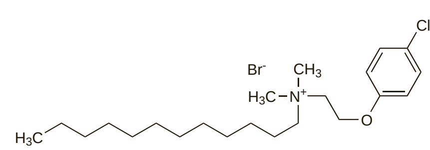
Dodeclonium Bromide *(rINN)*

Bromuro de dodeclonio; Dodeclonii Bromidum; Dodéclonium, Bromure de; GR-412. [2-(*p*-Chlorophenoxy)ethyl]dodecyldimethylammonium bromide.

Додеклония Бромид

$C_{22}H_{39}BrClNO$ = 448.9.

CAS — 15687-13-5.



Profile

Dodeclonium bromide is an antiseptic that has been included in multi-ingredient preparations intended for the treatment of skin and anorectal disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Belg.:*** Biogaze; ***Fr.:*** Sedorrhoide.

Domiphen Bromide *(BAN, USAN, rINN)*

Bromuro de domifeno; Domifeenibromidi; Domifenbromid; Domiphène, Bromure de; Domipheni Bromidum; NSC-39415; PDDB; Phenododecinium Bromide. Dodecyldimethyl-2-phenoxyethylammonium bromide.

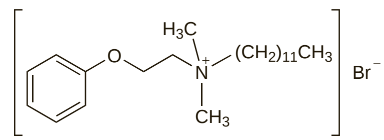
Домифена Бромид

$C_{22}H_{40}BrNO = 414.5.$

CAS — 13900-14-6 (domiphen); 538-71-6 (domiphen bromide).

ATC — A01AB06.

ATC Vet — QA01AB06.



Pharmacopoeias. In *Br. Chin.* includes the monohydrate.

BP 2008 (Domiphen Bromide). Colourless or faintly yellow, crystalline flakes. Freely soluble in water and in alcohol; soluble in acetone.

Incompatibility. Domiphen bromide is incompatible with soaps and other anionic surfactants.

Profile

Domiphen bromide is a quaternary ammonium antiseptic with actions and uses similar to those of other cationic surfactants (see Cetrimide, p.1634). Preparations containing domiphen bromide are used in the treatment of minor infections of the mouth and throat.

Preparations

Proprietary Preparations (details are given in Part 3)
Canad.: Antiseptique Pastilles; Bronchodex Pastilles; ***Ital.:*** Bradoral; ***Malaysia:*** Domidin; ***Port.:*** Neobradoral.

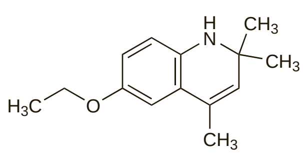
Multi-ingredient: ***Austria:*** Bepanthen; Bradosol; ***Canad.:*** Nupercainal; ***Chile:*** Oralfresh Menta; ***Fr.:*** Fluoselgine; ***Ital.:*** Inalar; ***Pol.:*** Viosept.

Ethoxyquin

Etoxiquina. 6-Ethoxy-1,2-dihydro-2,2,4-trimethylquinoline.

$C_{14}H_{19}NO = 217.3.$

CAS — 91-53-2.



Profile

Ethoxyquin has been used as an antoxidant for the prevention of common scald of apples and pears during storage and as an additive to animal feeds. Concern has been expressed over the toxicity of ethoxyquin and its residues on foodstuffs and its use is limited or restricted in some countries.

Ethylene Oxide

Dimethylene oxide; Epoxietano; 1,2-Epoxyethane; Etylenu tlenek; Óxido de etileno; Oxirane; Oxirano; Oxirano.

Окись Этилена; Этиленоксид

$C_2H_4O = 44.05.$

CAS — 75-21-8.

Description. Ethylene oxide is a colourless flammable gas at room temperature and atmospheric pressure.

Stability. Mixtures of ethylene oxide with oxygen or air are explosive but the risk can be reduced by the addition of carbon dioxide or fluorocarbons.

Adverse Effects and Precautions

Ethylene oxide irritates the eyes and respiratory tract and may also cause nausea and vomiting, diarrhoea, headache, vertigo, CNS depression, dyspnoea, and pulmonary oedema. Liver and kidney damage and haemolysis may occur. Fatalities have occurred. Excessive exposure of the skin to liquid or solution causes burns, blistering, irritation, and dermatitis; percutaneous absorption may lead to systemic effects.

Many materials including plastics and rubber adsorb ethylene oxide. If such materials are being sterilised with ethylene oxide all traces of the gas must be removed before the materials can be used; removal may be by ventilation or more active means. Hypersensitivity reactions, including anaphylaxis, have been associated with ethylene oxide-contaminated materials. Ethylene oxide may also react with materials being sterilised to produce substances such as ethylene chlorohydrin (with chloride) or ethylene glycol (with water); these may contribute to any toxicity.

Pharmaceutical manufacturers within the EU have been advised to use ethylene oxide only when there is no alternative. Ethylene oxide has been shown to have carcinogenic and mutagenic properties and there is evidence of increased risk of neoplasms following occupational exposure.

Carcinogenicity. Exposure of workers to ethylene oxide has been associated with the development of lymphatic and haematopoietic cancer and there is concern that it may be linked to breast cancer. In order to evaluate the carcinogenicity of ethylene oxide the National Institute for Occupational Safety and Health (NIOSH), in the mid 1980s, assembled a cohort of about 18 000 workers exposed to ethylene oxide.[1-3] Results of the initial cohort followed up to 1987 showed no overall excess of haematopoietic cancer, but did find a significant excess of non-Hodgkin's lymphoma among men.[1] Based on limited clinical evidence from humans and from significant evidence in *animal* studies, the International Agency for Research on Cancer concluded in 1994 that there was sufficient evidence to classify ethylene oxide as a definite human carcinogen.[4] A later evaluation[3] of the NIOSH cohort from 1987 to 1998 indicated that, despite 2852 deaths as opposed to 1177 deaths in the earlier study, there was little evidence of cancer excesses for ethylene oxide exposed workers versus the general population, with the exception of bone cancer (6 deaths), and no conclusion could be drawn from this small number. However, exposure-response analyses found statistically significant evidence of an association between increased exposure and some types of haematopoietic cancer (non-Hodgkin's lymphoma and lymphocytic leukaemia), particularly for males.[2,3] There was also some evidence for a positive exposure-response for breast cancer. Follow-up of a cohort of 2876 workers exposed to ethylene oxide in the UK[5] found no statistically significant increase in mortality from cancer overall, or from any specific category of tumour. A study[6] of a cohort of 7576 female workers exposed to ethylene oxide suggested that ethylene oxide was associated with breast cancer. However, the authors indicated weaknesses in the study that could have influenced the findings.

Effects on the nervous system. Four men exposed to ethylene oxide at a concentration of greater than 700 ppm developed neurological disorders. One experienced headaches, nausea, vomiting, and lethargy followed by major motor seizures. The others had headaches, limb numbness and weakness, increased fatigue, trouble with memory and thought processes, and slurred speech. Three also developed cataracts, and one required bilateral cataract extractions.[1] Rash, followed a few months later by hand numbness and weakness, headaches, and cognitive impairment, has been reported[2] in a cluster of 12 surgical nurses and technicians after exposure for 5 months to ethylene oxide-contaminated surgical gowns. Several patients showed signs of peripheral and CNS dysfunction and one patient had signs of axonal injury.

Hypersensitivity. Anaphylactoid reactions in dialysis patients have resulted from the use of dialysis equipment sterilised with ethylene oxide.[1-3] There have also been reports of hypersensitivity[4] and anaphylactoid[5] reactions in plateletpheresis donors caused by residues of ethylene oxide in components of apheresis kits. The most common adverse reactions reported have been dyspnoea, wheezing, urticaria, flushing, headache, and hypotension, but acute severe bronchospasm, circulatory collapse, cardiac arrest, and death have also occurred. It was noted[6] that where severe, sometimes fatal, anaphylactoid reactions have occurred at the beginning of dialysis, ethylene oxide has almost universally been implicated, although exposure to cuprammonium cellulose (cuprophane) dialysis membranes may also have been involved.

It has been reported that there may be an increased risk of ethylene oxide-induced anaphylactic shock in children undergoing surgery for spina bifida.[7] Such children might be at increased risk of sensitisation and anaphylaxis, and came into frequent contact with ethylene oxide through multiple operations and catheterisations.

Occupational asthma and contact dermatitis have been attributed to residual ethylene oxide in surgical gloves.[8]

Pregnancy. A study[1] of female staff responsible for sterilising instruments was carried out in all general hospitals in Finland. The incidence of spontaneous abortion (analysed according to employment at the time of conception and corrected for maternal age, parity, decade of pregnancy, smoking, and consumption of alcohol and coffee) was significantly increased in those exposed to ethylene oxide during pregnancy compared with those not so exposed. This study provoked criticism,[2,3] and the authors conceded that the study was not large enough to compare abortion rates and known ethylene oxide concentrations.[4] A retrospective analysis[5] of 32 dental assistants who had been exposed to ethylene oxide during pregnancy suggested that, after adjusting for age, the risk of spontaneous abortions and preterm or post-term births may have been more than doubled.

Pharmacokinetics

Ethylene oxide gas is rapidly absorbed through the lungs and distributed throughout the body. Percutaneous absorption can occur from aqueous solutions. It is rapidly metabolised by hydrolysis or conjugation with glutathione.

Uses

Ethylene oxide is a bactericidal and fungicidal gaseous disinfectant that is effective against most micro-organisms, including viruses. It is also sporicidal. It is used for the gaseous sterilisation of heat-labile pharmaceutical and surgical materials that cannot be sterilised by other means.

Ethylene oxide forms explosive mixtures with air; this may be overcome by using mixtures containing 10% ethylene oxide in carbon dioxide, or by removing at least 95% of the air from the apparatus before admitting either ethylene oxide or a mixture of 90% ethylene oxide in carbon dioxide. Alternatively, non-flammable mixtures of dichlorodifluoromethane and trichlorofluoromethane with 9 to 12% w/w of ethylene oxide have been employed, but restrictions on the release of fluorocarbons or CFCs limit their use.

Effective sterilisation by ethylene oxide depends on exposure time, temperature, humidity, the amount and type of microbial contamination, and the partial pressure of the ethylene oxide in the exposure chamber. Concentrations of between 400 and 1000 mg/litre are usually used for sterilisation and the process time may vary from 30 minutes to 10 hours. The material being sterilised must be permeable to ethylene oxide if occluded micro-organisms are present. The bactericidal action is accelerated by increase of temperature; the average temperature used is between 40° and 50°.

Moisture is essential for sterilisation by ethylene oxide. In practice, dry micro-organisms need to be rehydrated before ethylene oxide can be effective; humidification is normally carried out under vacuum prior to introduction of ethylene oxide. Relative humidities of 40 to 60% are used.

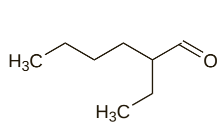
Control of physical factors does not assure sterility, and the process should be monitored usually by using standardised suspensions of aerobic spores such as those of *Bacillus subtilis* var. *niger.*

Ethylhexanal

2-Ethylcaproaldehyde; 2-Ethylhexylaldehyde; Octylaldehyde. 2-Ethylhexanal.

$C_8H_{16}O = 128.2.$

CAS — 123-05-7.



Profile

Ethylhexanal is an aldehyde disinfectant used for instrument disinfection.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ger.:*** Buraton 10 F; Helipur H plus N; Lysetol FF†; Sekucid konz†.

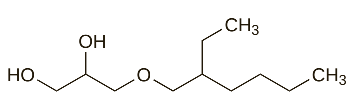
Ethylhexylglycerin

Octoxyglycerin. 3-[(2-Ethylhexyl)oxy]-1,2-propanediol.

Этилгексилглицерин

$C_{11}H_{24}O_3 = 204.3.$

CAS — 70445-33-9.



Profile

Ethylhexylglycerin is a disinfectant used in a concentration of 0.3% in topical deodorant preparations. It is also used in products for disinfection of the hands.

Multi-ingredient: ***Braz.:*** Effidrate†; ***Chile:*** Uriage Desodorante Tri-Actif.

Formaldehyde

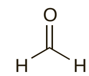
Formaldehid; Formaldehído; Formaldehyd.

Формальдегид

$CH_2O = 30.03.$

CAS — 50-00-0.

ATC Vet — QP53AX19.



Formaldehyde Solution

Formaldehído, solución de; Formaldehido tirpalas; Formaldehidoldat; Formaldehyd roztok; Formaldéhyde, solution de; Formaldehydi solutio; Formaldehydiliuos; Formaldehydlösning; Formaldehydu roztwór.

NOTE. The names formalin and formol have been used for formaldehyde solution but in some countries they are trade marks.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Formaldehyde Solution (35 per cent); Formaldehyde Solution BP 2008). It contains 34.5 to 38.0% w/w of formaldehyde with methyl alcohol as a stabiliser. It is a clear, colourless, liquid. Miscible with water and with alcohol. It may be cloudy after storage. Store at a temperature between 15° and 25°. Protect from light.

USP 31 (Formaldehyde Solution). It contains not less than 34.5% w/w of formaldehyde with 9 to 15% methyl alcohol added to prevent polymerisation. It is a clear, colourless, or practically colourless liquid with a pungent, irritating odour. Miscible with water and with alcohol. Store at a temperature above 15° in airtight containers. It may become cloudy on standing due to the separation of paraformaldehyde, especially if the solution is kept in a cold place; the cloudiness disappears on warming.

Strength of solutions. Formaldehyde solution is sometimes known simply as formaldehyde and this has led to confusion in interpreting the strength and the form in which formaldehyde is being used. In practice formaldehyde is available as formaldehyde solution which is diluted before use, the percentage strength being expressed in terms of formaldehyde solution rather than formaldehyde. For example, in the UK, formaldehyde solution 3% consists of 3 volumes of Formaldehyde Solution (35 Per Cent) (Ph. Eur. 6.2) diluted to 100 volumes with water and thus contains 1.04 to 1.14% w/w of formaldehyde; it is ***not*** prepared by diluting Formaldehyde Solution (35 Per Cent) (Ph. Eur. 6.2) to arrive at a solution containing 3% w/w of formaldehyde.

Incompatibility. Formaldehyde reacts with protein and this may diminish its antimicrobial activity.

Adverse Effects and Precautions

Concentrated formaldehyde solutions applied to the skin cause whitening and hardening. Contact dermatitis and sensitivity reactions have occurred after the use of conventional concentrations and after contact with residual formaldehyde in resins.

Ingestion of formaldehyde solution causes intense burning pain in the mouth, throat, chest, and stomach, with inflammation, ulceration, and necrosis of mucous membranes. There may be nausea, vomiting, haematemesis, blood-stained diarrhoea, haematuria, and anuria; metabolic acidosis, vertigo, convulsions, loss of consciousness, and circulatory and respiratory failure may occur. Death has occurred after the ingestion of the equivalent of about 30 mL of formaldehyde solution. If the patient survives 48 hours, recovery is probable. Formaldehyde vapour is irritant to the eyes, nose, and upper respiratory tract, and may cause coughing, dysphagia, spasm and oedema of the larynx, bronchitis, pneumonia, and rarely, pulmonary oedema. Asthma-like symptoms have been reported after repeated exposure.

Carcinogenicity. There is controversy as to the risk formaldehyde presents as a carcinogen. Studies on the occupational exposure of medical personnel and industrial workers[1-3] to formaldehyde have generally concluded that although the risk is small or non-existent, the possibility that formaldehyde is a human carcinogen cannot be excluded. Reanalyses of some studies have led to different interpretations of the results, with some workers concluding that the risk of cancer from formaldehyde is greater than originally thought.[4] Analysis of mortality data[5] for a cohort of 25619 workers exposed to formaldehyde in the USA found some evidence of an association with nasopharyngeal cancer and possibly cancers at other upper respiratory-tract sites. Based on the results of this large cohort study and supported by evidence from other epidemiological and *animal* studies, the International Agency for Research on Cancer (IARC) concluded,[6] in 2004, that occupational exposure to formaldehyde does cause nasopharyngeal cancer. Furthermore, they found strong, but not sufficient, evidence to establish a causal link with leukaemia and limited evidence to suggest it causes sinonasal cancer. IARC has concluded that formaldehyde is a definite human carcinogen.[6]

Effects on the blood. Haemolysis during chronic haemodialysis was due to formaldehyde eluted from filters.[1]

1. Orringer EP, Mattern WD. Formaldehyde-induced hemolysis during chronic hemodialysis. *N Engl J Med* 1976; **294:** 1416–20.

Effects on the urinary tract. Adverse effects have resulted from intravesical instillation of formaldehyde solutions, ranging in strength from 1 to 10%, in the treatment of haemorrhagic cystitis. They include dysuria, suprapubic pain, ureteric and bladder fibrosis, hydronephrosis, vesicoureteral reflux, bilateral ureteral obstruction, papillary necrosis, bladder rupture, and acute tubular necrosis. Intraperitoneal spillage through a fistula, leading to adverse systemic effects, has also occurred.[1] Fatalities have resulted from cardiac arrest and acute renal failure.[1-3] See also Haemorrhagic Cystitis under Uses, below.

There has also been a report[4] of 4 patients exposed to high levels of atmospheric formaldehyde who developed membranous nephropathy, suggesting that there may be genetic susceptibility for this effect.

Hypersensitivity. Hypersensitivity to formaldehyde has had several manifestations. Effects on the skin have included acute exacerbation of eczema after injection of hepatitis B vaccine containing formaldehyde up to 20 micrograms/mL.[1] In another case, formaldehyde sensitivity was characterised by pruritus, burning, and redness within minutes of exposure to sunlight.[2] Painful, enlarged, and haemorrhagic gingival margins have occurred after the use of a toothpaste containing a solution of formaldehyde.[3] There is conflicting evidence of the respiratory effects of formaldehyde: although a low concentration has been reported not to trigger an asthma attack in patients with severe bronchial hyperresponsiveness,[4] occupational asthma has been documented.[5] More severe manifestations of hypersensitivity include 7 cases of shock of possible toxic or anaphylactic aetiology that occurred after the use of formaldehyde solutions during surgical removal of hydatid cysts.[6]

For mention of an allergic response to root canal paste containing paraformaldehyde, see p.1655.

6. Galland MC, *et al.* Risques thérapeutiques de l'utilisation des solutions de formol dans le traitement chirurgical des kystes hydatiques du foie. *Therapie* 1980; **35:** 443–6.

Treatment of Adverse Effects

Contaminated skin should be washed with soap and water. After ingestion water, milk, charcoal, and/or demulcents should be given; emesis should be avoided. Assisted ventilation may be required and shock should be alleviated appropriately. Convulsions should be controlled with diazepam and pain with morphine. Acidosis, resulting from metabolism of formaldehyde to formic acid, may require intravenous sodium bicarbonate or sodium lactate. The use of haemodialysis has been suggested.

Uses and Administration

Formaldehyde solution is a bactericidal disinfectant also effective against fungi and many viruses. It is slowly effective against bacterial spores but its sporicidal effect is greatly increased by increase in temperature.

Formaldehyde solution is usually used diluted and it is important to note that the strength of preparations is given in terms of the content of formaldehyde solution and not in terms of the final concentration of formaldehyde (see under Strength of Solutions, above).

Formaldehyde solution is used in the disinfection of blankets and bedding and in the disinfection of the membranes in dialysis equipment. It is important to ensure that there are no traces of formaldehyde on any equipment before it is used. Formaldehyde solution is also used with succinic dialdehyde for instrument disinfection.

When applied to the unbroken skin, formaldehyde solution hardens the epidermis, renders it tough and whitish, and produces a local anaesthetic effect. Formaldehyde solution 3% v/v has been used for the treatment of warts on the palms of the hands and soles of the feet. It is used similarly as a water-miscible gel containing formaldehyde 0.75% w/w. Sweating of the feet may be treated by the application of formaldehyde solution in glycerol or alcohol but such applications are liable to produce sensitisation reactions and other treatments are regarded as more effective (see Hyperhidrosis, p.1580).

After surgical removal of hydatid cysts, diluted formaldehyde solution has been used for irrigating the cavities to destroy scolices but other larvicides are preferred (see Echinococcosis, p.136). It is generally too irritant for use on mucous membranes but it has been used in mouthwashes and pastes as an antiseptic and hardening agent for the gums. In dentistry it has been used in endodontic treatment.

Formaldehyde solution in concentrations of up to 10% v/v in saline is used as a preservative for pathological specimens. It is not suitable for preserving urine for subsequent examination. Formaldehyde solution is used for the inactivation of viruses in vaccine production.

Formaldehyde gas has little penetrating power and readily polymerises and condenses on surfaces and its effectiveness depends on it dissolving in a film of moisture before acting on micro-organisms; in practice a relative humidity of 80 to 90% is necessary. Formaldehyde gas is used for the disinfection of rooms and cabinets. The gas may be produced from 500 mL of undiluted formaldehyde solution by boiling with 1 litre of water or by addition of potassium permanganate or by heating a formaldehyde-containing solid such as paraformaldehyde (p.1655). Formaldehyde gas is used with low-temperature steam for the sterilisation of heat-sensitive items.

Other compounds which are thought to act by releasing formaldehyde include noxytiolin (p.1654) and methenamine (p.298).

Haemorrhagic cystitis. Formaldehyde has been used for local therapy of haemorrhagic cystitis (p.2178), although there has been debate about the most appropriate regimen. The Fair regimen[1] for the intravesical use of formaldehyde solution in haemorrhagic cystitis involves passive irrigation of the bladder with 500 to 1000 mL of formaldehyde solution 1% v/v for a total of 10 minutes, the bladder subsequently being emptied and washed out with 1 litre of distilled water. Stronger concentrations of formaldehyde solution and other methods can be used if bleeding does not stop.[2] In a review of 118 patients treated with solutions of formaldehyde for intractable haematuria, the authors felt that this was probably the most effective treatment, but also probably the most dangerous.[3] More concentrated instillations, containing formaldehyde solution 5 to 10% seem to be generally viewed as unnecessary, and associated with an increased risk of complications which precludes their use.[4-7]

Glutaral *(USAN, rINN)*

Adehyd glutarowy; Glutaraldehid; Glutaraldehyde; Glutaralum; Glutaric Dialdehyde; Pentanedial. Pentane-1,5-dial.

Глутарал

$C_5H_8O_2$ = 100.1.

CAS — 111-30-8.

ATC — D08AX09.

Pharmacopoeias. Solutions of glutaral are included in *Br.*, *Chin.*, and *US.* A solution is also in *USNF.*

BP 2008: (Strong Glutaraldehyde Solution). It contains 47 to 53% w/w of glutaral. Store at a temperature not exceeding 15°.

USP 31 (Glutaral Concentrate). It contains 50 to 52% w/w of glutaral and has a pH between 3.7 and 4.5. Store at a temperature not exceeding 40° in airtight containers. Protect from light.

USNF 26 (Glutaral Disinfectant Solution). It has a pH between 2.7 and 3.7. Store at a temperature not exceeding 40° in airtight containers. Protect from light.

Adverse Effects

As for Formaldehyde Solution, p.1644.

Effects on the gastrointestinal tract. Insufficient rinsing of a glutaral 2% solution from flexible endoscopes after disinfection appears to be responsible for outbreaks of glutaral-induced colitis in patients undergoing colonoscopy and sigmoidoscopy.[1-4] Symptoms may occur within minutes or up to 48 hours after endoscopy and are usually abdominal pain, mucous diarrhoea, and rectal bleeding. Fever, nausea, vomiting and leucocytosis have also been reported. A case of glutaral-induced colitis has also been attributed to inadequate flushing and drying of the endoscope channels.[2]

4. Stein BL, *et al.* Glutaraldehyde-induced colitis. *Can J Surg* 2001; **44:** 113–16.

Occupational exposure. Reviews[1,2] of the occupational hazards of glutaral have noted that several studies showed adverse effects, including nausea, headache, airway obstruction, asthma, rhinitis, eye irritation, and dermatitis, occurring among medical personnel exposed to glutaral, generally at concentrations below the recommended limits. Skin reactions were due to hypersensitivity or a direct irritant effect. It was concluded that, when using glutaral, workers should take suitable precautions to protect the skin and eyes and should avoid inhaling the vapour. Appropriate procedures should also be followed for disposal and clean-up of spills.

The risk of occupational exposure to glutaral vapour may be higher in warm climates.[3]

There has also been a report of accidental ocular contact with glutaral due to leakage of glutaral solution retained in an anaesthesia mask; moderate chemical conjunctivitis ensued.[4]

1. Burge PS. Occupational risks of glutaraldehyde. *BMJ* 1989; **299:** 342.
2. Ballantyne B, Jordan SL. Toxicological, medical and industrial hygiene aspects of glutaraldehyde with particular reference to its biocidal use in cold sterilization procedures. *J Appl Toxicol* 2001; **21:** 131–51.
3. Mwaniki DL, Guthua SW. Occupational exposure to glutaraldehyde in tropical climates. *Lancet* 1992; **340:** 1476–7.
4. Murray WJ, Ruddy MP. Toxic eye injury during induction of anaesthesia. *South Med J* 1985; **78:** 1012–13.

Uses and Administration

Glutaral is a bactericidal disinfectant that is rapidly effective against Gram-positive and Gram-negative bacteria. It is also effective against *Mycobacterium tuberculosis*, some fungi, and viruses, including hepatitis B virus and HIV, and is slowly effective against bacterial spores. Aqueous solutions show optimum activity between pH 7.5 and 8.5; such solutions are chemically stable for about 14 days. Solutions at lower pH values are more stable.

A 2% aqueous solution buffered to a pH of about 8 (activated glutaral; alkaline glutaral) may be used for the sterilisation of endoscopic and dental instruments, rubber or plastic equipment, and for other equipment which cannot be sterilised by heat. Glutaral is non-corrosive towards most materials. Complete immersion in the solution for 10 to 20 minutes is sufficient for rapid disinfection of thoroughly cleansed instruments but exposure for up to 10 hours may be necessary for sterilisation. For further details, see Disinfection of Endoscopes, p.1623, and Disinfection in Hepatitis and HIV Infection, p.1623.

A 10% solution is applied twice daily for the treatment of warts (p.1584); a 5% solution and a 10% gel have also been used. Glutaral should not be used for facial or anogenital warts. Glutaral has also been used topically for treating hyperhidrosis of the palms and soles, although other agents are generally preferred (see p.1580).

Preparations

BP 2008: Glutaraldehyde Solution; Strong Glutaraldehyde Solution;
USNF 26: Glutaral Disinfectant Solution;
USP 31: Glutaral Concentrate.

Proprietary Preparations (details are given in Part 3)
Arg.: Asepto-Glutaral†; ***Austral.:*** Diswart; ***Fr.:*** Cidex†; Sekucid†; Steranios; ***Ger.:*** Cidex†; Korsolex-Endo-Disinfectant; Sekumatic FD†; ***India:*** Glutrex†; ***Irl.:*** Glutarol; ***Ital.:*** Citrosteril Sterilferri; Diba; Eso Cem; Eso H1, HP, and HP1; Esoxid; Ferriseptil; SaniSteril Sterilferri; Sporacid†; Sporex†; Sporicidin; T5†; ***S.Afr.:*** Virogerm; ***Thai.:*** Deconex 50FF†; ***UK:*** ASEP; Glutarol; ***USA:*** Cetylcide-G; Cidex.

Glyoxal

Biformilo; Ethanedial; Glioxal; Oxalaldehyde. 1,2-Ethanedione.

$C_2H_2O_2$ = 58.04.
CAS — 107-22-2.

Profile

Glyoxal is an aldehyde used for the disinfection of surfaces and of medical and surgical instruments.

Preparations

Proprietary Preparations (details are given in Part 3)
Thai.: Deconex 50FF†.

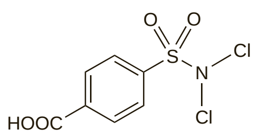
Multi-ingredient: ***Fr.:*** Aniospray 41; Bacterianos D†; Incidine†; ***Ger.:*** Buraton 10 F; Desoform†; Freka-Nol; Fugisept†; Incidin perfekt; Incidin Spezial; Incidur; Lysoformin 3000; Meliseptol; Melsept SF; Melsept†; Minutil†; Sekusept forte†; Ultrasol-F; ***Ital.:*** Incidin Spezial; Indulfan; Melsept; Melsept SF; Melsept Spray.

Halazone *(rINN)*

Halazona; Halazonum; Pantocide. 4-(Dichlorosulphamoyl)benzoic acid.

Галазон

$C_7H_5Cl_2NO_4S$ = 270.1.
CAS — 80-13-7.



Pharmacopoeias. In *US.*

USP 31 (Halazone). A white crystalline powder with a characteristic odour of chlorine. Soluble 1 in more than 1000 of water and of chloroform, 1 in 140 of alcohol, and 1 in more than 2000 of ether; soluble in glacial acetic acid. It dissolves in solutions of alkali hydroxides and carbonates with the formation of a salt. Store in airtight containers. Protect from light.

Profile

Halazone is a disinfectant with the general properties of chlorine (p.1638) in aqueous solution and is used for the disinfection of drinking water (p.1623). It contains about 52% of 'available chlorine' (see p.1638). One tablet containing 4 mg of halazone, stabilised with sodium carbonate and sodium chloride, may be sufficient to treat about 1 litre of water in about 30 minutes to 1 hour. The taste of residual chlorine may be removed by adding sodium thiosulfate.

Preparations

USP 31: Halazone Tablets for Solution.

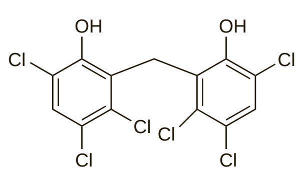
Proprietary Preparations (details are given in Part 3)
Ital.: Steridrolo a rapida idrolisi†; ***Port.:*** Speton†.

Hexachlorophene *(BAN, rINN)*

G-11; Heksaklorofeeni; Hexachlorofen; Hexachlorophane; Hexachlorophène; Hexachlorophenum; Hexaclorofeno; Hexaklorofen. 2,2′-Methylenebis(3,4,6-trichlorophenol).

Гексахлорофен

$C_{13}H_6Cl_6O_2$ = 406.9.
CAS — 70-30-4.
ATC — D08AE01.
ATC Vet — QD08AE01; QP52AG02.



Pharmacopoeias. In *Br.* and *US.*

BP 2008 (Hexachlorophene). A white or pale buff, odourless or almost odourless, crystalline powder. Practically insoluble in water; freely soluble in alcohol; very soluble in acetone and in ether. It dissolves in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Hexachlorophene). A white or light tan, crystalline powder which is odourless or has a slight phenolic odour. Insoluble in water; freely soluble in alcohol, in acetone, and in ether; soluble in chloroform and in dilute solutions of fixed alkali hydroxides. Store in airtight containers. Protect from light.

Incompatibility. The activity of hexachlorophene may be reduced in the presence of blood or other organic material. It retains some activity in the presence of soap.

The activity has been reported[1] to be reduced by alkaline media and by nonionic surfactants such as polysorbate 80. It is extremely sensitive to iron, and to avoid discoloration due to traces of this metal in hexachlorophene detergent solutions, it is advisable to incorporate a sequestrant such as disodium edetate.[2]

1. Walter G, Gump W. Effect of pH on hexachlorophene. *Soap Chem Spec* 1963; **39:** 55–6.
2. Bell M. Hexachlorophene-based skin cleansers. *Specialities* 1965; **1:** 16–18.

Adverse Effects and Treatment

After ingestion, anorexia, nausea, vomiting, diarrhoea, abdominal cramps, dehydration, shock, and confusion may occur. Convulsions and death may follow. CNS stimulation, convulsions, and death have also occurred after absorption of hexachlorophene from burns and damaged skin. There have been reports showing that hexachlorophene can be absorbed through the skin of infants in amounts sufficient to produce spongy lesions of the brain, sometimes fatal.

Photosensitivity and skin sensitisation have occasionally occurred after repeated use of hexachlorophene.

Treatment of adverse effects is as for Phenol, p.1656.

Effects on the respiratory system. Asthma developed in a 43-year-old nurse after long-term exposure to hexachlorophene powder.[1]

1. Nagy L, Orosz M. Occupational asthma due to hexachlorophene. *Thorax* 1984; **39:** 630–1.

Precautions

Hexachlorophene should not be applied to mucous membranes, large areas of skin, or to burnt, damaged, or denuded skin and should not be used vaginally, applied under occlusive dressings, or applied to areas affected by dermatoses. It should be used with caution on infants, especially premature and low birth-weight neonates. Its use is not advised in pregnancy.

Preparations of hexachlorophene are liable to contamination, especially with Gram-negative bacteria.

Breast feeding. The American Academy of Pediatrics[1] considers that, while no effects on the infant have been reported, there is a possibility of contamination of breast milk with hexachlorophene used by breast-feeding mothers for nipple washing.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 15/03/06)

Neonates. Spongiform encephalopathy has occurred in neonates who were treated topically with hexachlorophene.[1] Neonates with a birth-weight of 1.4 kg or less appeared to be most susceptible, whereas those weighing over 2 kg were not considered to be at risk.[1,2] Also most of the reports involved hexachlorophene applied in a concentration of 3%.

1. Anonymous. Hexachlorophene today. *Lancet* 1982; **i:** 87–8.
2. Plueckhahn VD, Collins RB. Hexachlorophene emulsions and antiseptic skin care of newborn infants. *Med J Aust* 1976; **1:** 815–19.

Pregnancy. Hexachlorophene is absorbed from the skin and crosses the placenta, but whether it has produced teratogenic effects is subject to debate.[1,2] However, it is considered best to avoid its use during pregnancy.

1. Halling H. Suspected link between exposure to hexachlorophene and malformed infants. *Ann N Y Acad Sci* 1979; **320:** 426–35.
2. Baltzar B, *et al.* Pregnancy outcome among women working in Swedish hospitals. *N Engl J Med* 1979; **300:** 627–8.

Pharmacokinetics

Hexachlorophene is absorbed from the gastrointestinal tract after accidental ingestion, and through intact and denuded skin. Percutaneous absorption may be significant in premature infants and through damaged skin. Hexachlorophene crosses the placenta.

Uses and Administration

Hexachlorophene is a chlorinated bisphenol antiseptic with a bacteriostatic action against Gram-positive organisms, but much less effective against Gram-negative organisms. It is most active at pH 5 to 6.

Hexachlorophene is mainly used in soaps and creams in a concentration of 0.23 to 3% and is an ingredient of various preparations used for skin disorders. After repeated use of these preparations for several days there is a marked diminution of the bacterial flora due to accumulation of hexachlorophene in the skin. This residual effect is rapidly lost after washing with unmedicated soap or alcohol.

A preparation containing 3% is used for the disinfection of the hands of surgeons and other health-care personnel. Thorough rinsing is recommended before drying. Hexachlorophene has been applied as a 0.33% dusting powder to the umbilical cord stump for the control of staphylococcal infection in the newborn. However, care is necessary when using hexachlorophene in neonates (see above).

Hexachlorophene sodium has also been used.

Disinfection. Eradication of an outbreak of infection with meticillin-resistant *Staphylococcus aureus* in a neonatal intensive care unit was achieved by use of hexachlorophene soap for hand washing. Previous infection-control measures including the use of chlorhexidine had failed.[1] For a discussion of staphylococcal infections and their treatment, see p.195.

1. Reboli AC, *et al.* Epidemic methicillin-gentamicin-resistant Staphylococcus aureus in a neonatal intensive care unit. *Am J Dis Child* 1989; **143:** 34–9.

(hexamidine)

NOTE. The name Hexamidinum has been used for primidone (p.503).

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Hexamidine Diisetionate; Hexamidine Isetionate BP 2008). A white or slightly yellow hygroscopic powder. Sparingly soluble in water; slightly soluble in alcohol; practically insoluble in dichloromethane. Store in airtight containers.

Profile

Hexamidine isetionate has antibacterial and antifungal properties and is available in preparations for the local treatment of minor infections.

Acanthamoeba keratitis. Hexamidine was suggested[1] as a possible alternative to propamidine for the treatment of *Acanthamoeba* keratitis (p.822) due to the poor cysticidal activity, chronic conjunctival infection, and resistance of some *Acanthamoeba* strains seen with propamidine.[1,2] Cures have been reported with 0.1% hexamidine used either as monotherapy[2,3] or with polihexanide.[2]

1. Perrine D, *et al.* Amoebicidal efficiencies of various diamidines against two strains of Acanthamoeba polyphaga. *Antimicrob Agents Chemother* 1995; **39:** 339–42.

Hexetidine *(BAN, rINN)*

Heksetidiini; Heksetidin; Heksetidinas; Hexetidin; Hexetidina; Hexétidine; Hexetidinum. 5-Amino-1,3-bis(2-ethylhexyl)hexahydro-5-methylpyrimidine.

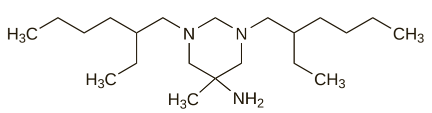
Гекcэтидин

$C_{21}H_{45}N_3$ = 339.6.

CAS — 141-94-6.

ATC — A01AB12.

ATC Vet — QA01AB12.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Hexetidine). An oily, colourless or slightly yellow liquid. Very slightly soluble in water; very soluble in alcohol, in acetone, and in dichloromethane. It dissolves in dilute mineral acids. Protect from light.

Adverse Effects

Allergic contact dermatitis, alterations in taste, and transient anaesthesia have occasionally been reported.

Uses and Administration

Hexetidine is a bactericidal and fungicidal antiseptic. It is used for minor infections of mucous membranes, and in particular as a 0.1% mouthwash for local infections and oral hygiene.

Oral hygiene. A mouthwash containing 0.1% hexetidine was no more effective than placebo in the management of patients with aphthous ulceration (see Mouth Ulceration, p.1700) and provided no additional benefits to oral hygiene or gingival health.[1] However, such a mouthwash does appear to be of benefit in reducing supragingival plaque and gingival inflammation.[2]

Hexylresorcinol *(BAN)*

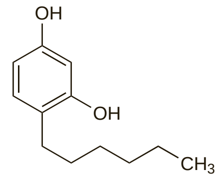
Esilresorcina; Heksilrezorcinolis; Heksyyliresorsinoli; Hexilresorcinol; Hexilrezorcin; Hexylresocinolum; Hexylresorc; Hexylrésorcinol; Hexylresorcinolum. 4-Hexylbenzene-1,3-diol.

$C_{12}H_{18}O_2$ = 194.3.

CAS — 136-77-6.

ATC — R02AA12.

ATC Vet — QR02AA12.



Pharmacopoeias. In *Eur.* (see p.vii) and *US*.

Ph. Eur. 6.2 (Hexylresorcinol). A colourless, yellowish or reddish crystalline powder or needles, turning brownish-pink on exposure to light or air. It exhibits polymorphism. M.p. 66° to 68°; melting may occur at about 60° followed by solidification and a second melting at 66° to 68°. Very slightly soluble in water; freely soluble in alcohol and in dichloromethane. Store in airtight containers. Protect from light.

USP 31 (Hexylresorcinol). M.p. 62° to 67°. Store in airtight containers. Protect from light.

Incompatibility. Hexylresorcinol is incompatible with alkalis and oxidising agents.

Profile

Hexylresorcinol is a phenolic antiseptic that is used topically for the treatment of minor infections of the skin and mucous membranes, and in the form of lozenges for the treatment of sore throat. It has also been used in vaginal spermicidal preparations.

High concentrations of hexylresorcinol are irritant and corrosive to skin and mucous membranes. Alcoholic solutions are vesicant.

It was formerly used as an anthelmintic.

Preparations

USP 31: Hexylresorcinol Lozenges.

Profile

Hydrargaphen is a mercurial antiseptic with antibacterial and antifungal properties. It has been used in the treatment of vaginitis, wounds, burns, and infections of the skin.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Hong Kong:*** Penotran†.

Hydrogen Peroxide

Hidrojen Peroksit; Hydrogène, peroxyde d'; Hydrogenii peroxidum; Peróxido de hidrógeno.

Перекись Водорода

H_2O_2 = 34.01.

CAS — 7722-84-1.

ATC — A01AB02; D08AX01; S02AA06.

ATC Vet — QA01AB02; QD08AX01; QS02AA06.

NOTE. The BP 2008 directs that when Hydrogen Peroxide is prescribed or demanded, Hydrogen Peroxide Solution (6 per cent) shall be dispensed or supplied.

Incompatibility. Hydrogen peroxide solutions are incompatible with reducing agents, including organic matter and oxidisable substances, and with some metals, metallic salts, alkalis, iodides, permanganates, and other stronger oxidising agents.

Stability. Aqueous solutions of hydrogen peroxide gradually decompose on standing and if allowed to become alkaline. Decomposition is increased by light, agitation, and heat. Incompatibility may also produce decomposition. Solutions are comparatively stable in the presence of a slight excess of acid. Strong solutions are considered to be more stable than weak solutions.

Storage. Solutions of hydrogen peroxide should be stored in airtight containers at 15° to 30° (but see Hydrogen Peroxide Solution (30 per cent), below). Solutions should not be stored for long periods. Those not containing a stabiliser should be stored at a temperature not exceeding 15°. Protect from light.

Hydrogen Peroxide Solution (3 per cent)

3 %-os hidrogén-peroxid-oldat; Dilute Hydrogen Peroxide Solution; Hydrogen Peroxide Solution (10-volume); Hydrogen Peroxide Topical Solution; Hydrogenii Peroxidum 3%; Hydrogenii Peroxidum 3 Per Centum; Oxydol; Peroxid vodíku 3%; Peróxido de hidrógeno, solución al 3%; Vandenilio peroksido 3% tirpalas; Väteperoxid 3%; Vetyperoksidi 3%; Wodoru nadtlenek 3%.

ATC — A01AB02; D08AX01; S02AA06.

ATC Vet — QA01AB02; QD08AX01; QS02AA06.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Hydrogen Peroxide Solution (3 per cent)). A clear colourless liquid containing 2.5 to 3.5% w/w of H_2O_2 corresponding to about 10 times its volume of oxygen. It decomposes in contact with oxidisable organic matter and with certain metals and if allowed to become alkali. It may contain a suitable stabilising agent. Solutions not containing a stabilising agent should be stored at a temperature below 15°. Protect from light.

The BP 2008 directs that when Hydrogen Peroxide is prescribed or demanded, Hydrogen Peroxide Solution (6 per cent) shall be dispensed or supplied.

USP 31 (Hydrogen Peroxide Topical Solution). It contains 2.5 to 3.5% w/v of H_2O_2. It may contain up to 0.05% of a suitable preservative or preservatives. Store in airtight containers at a temperature between 15° and 30°. Protect from light.

Hydrogen Peroxide Solution (6 per cent)

ATC — A01AB02; D08AX01; S02AA06.

ATC Vet — QA01AB02; QD08AX01; QS02AA06.

Pharmacopoeias. In *Br.*

BP 2008 (Hydrogen Peroxide Solution (6 per cent)). A clear colourless aqueous liquid containing 5.0 to 7.0% w/v of H_2O_2 corresponding to about 20 times its volume of available oxygen. It decomposes in contact with oxidisable organic matter and with certain metals and if allowed to become alkali. It may contain a suitable stabilising agent. It should not be stored for long periods. Solutions not containing a stabilising agent should be stored at a temperature below 15°. Protect from light.

The BP directs that when Hydrogen Peroxide is prescribed or demanded, Hydrogen Peroxide Solution (6 per cent) shall be dispensed or supplied.

Hydrogen Peroxide Solution (27 per cent)

Hydrogenii Peroxidum; Perossido D'Idrogeno Soluzione; Peróxido de hidrógeno, solución al 27%; Solutio Hydrogenii Peroxydati; Strong Hydrog. Perox. Soln; Strong Hydrogen Peroxide Solution.

ATC — A01AB02; D08AX01; S02AA06.

ATC Vet — QA01AB02; QD08AX01; QS02AA06.

Description. Hydrogen peroxide solution (27 per cent) is a clear, colourless aqueous solution containing 26 to 28% w/w of H_2O_2, corresponding to about 100 times its volume of available oxygen. It may contain a suitable stabilising agent.

The symbol † denotes a preparation no longer actively marketed

The BP 2008 directs that when Hydrogen Peroxide is prescribed or demanded, Hydrogen Peroxide Solution (6 per cent) shall be dispensed or supplied.

Hydrogen Peroxide Solution (30 per cent)

30 %-os hidrogén-peroxid-oldat; Hydrogen Peroxide Concentrate; Hydrogen Peroxide Solution (100-volume); Hydrogenii Peroxidum 30%; Hydrogenii Peroxidum 30 Per Centum; Peroxid vodíku 30%; Peróxido de hidrógeno, solución al 30%; Vandenilio peroksido 30% tirpalas; Väteperoxid 30%; Vetyperoksidi 30%; Wodoru nadtlenek 30%.

ATC — A01AB02; D08AX01; S02AA06.
ATC Vet — QA01AB02; QD08AX01; QS02AA06.

Pharmacopoeias. In *Eur.* (see p.vii).
Chin. specifies 26 to 28%.
US and *Viet.* specify 29 to 32%.
Ph. Eur. 6.2 (Hydrogen Peroxide Solution (30 per cent)). A clear colourless liquid containing 29.0 to 31.0% w/w of H_2O_2 corresponding to about 110 times its volume of available oxygen. It decomposes in contact with oxidisable organic matter and with certain metals and if allowed to become alkali. It may contain a suitable stabilising agent. Solutions not containing a stabilising agent should be stored at a temperature below 15°. Protect from light.
The BP 2008 directs that when Hydrogen Peroxide is prescribed or demanded, Hydrogen Peroxide Solution (6 per cent) shall be dispensed or supplied.
USP 31 (Hydrogen Peroxide Concentrate). A clear, colourless liquid containing 29 to 32% w/w of H_2O_2. It may contain up to 0.05% of a suitable preservative or preservatives. It is acid to litmus. It slowly decomposes and is affected by light. Store in partially-filled containers having a small vent in the closure, at a temperature of 8° to 15°.

Adverse Effects and Precautions

Strong solutions of hydrogen peroxide produce irritating 'burns' on the skin and mucous membranes with a white eschar, but the pain disappears in about an hour. Continued use of hydrogen peroxide as a mouthwash may cause reversible hypertrophy of the papillae of the tongue.

It is dangerous to inject or instil hydrogen peroxide into closed body cavities from which the released oxygen has no free exit. Colonic lavage with solutions of hydrogen peroxide has been followed by gas embolism, rupture of the colon, proctitis, ulcerative colitis, and gangrene of the intestine.

Closed body cavities. Liberation of oxygen during the use of hydrogen peroxide in surgical procedures has resulted in oxygen embolism and local emphysema.[1-3] Gas embolism has also been reported after accidental ingestion of hydrogen peroxide solution.[4] Local damage to the colonic and rectal mucosa has followed the use of hydrogen peroxide 3% as an enema[5,6] and from residual hydrogen peroxide after disinfection of endoscopes.[7]

Effects on the mouth. Use of hydrogen peroxide 3% as a mouthwash has been reported to cause mouth ulceration. A review[1] on the safety of hydrogen peroxide in dentistry concluded that low concentrations of hydrogen peroxide (1.5 to 3%) used long-term in mouthwashes and dentifrices, resulted in no adverse changes to the hard or soft tissues in the mouth. However, irritation may occur with low concentrations in patients with a thin or ulcerated oral mucosa. Short-term exposure to higher concentrations (30 to 35%), such as those used in teeth bleaching products and procedures, have resulted in mucosal erythema and sloughing, while long-term exposure may cause inflammation or hyperplasia.

Intravascular administration. Intravenous injection of hydrogen peroxide solutions as unconventional therapy for AIDS or cancer has resulted in severe acute haemolysis.[1,2] Haemolysis and methaemoglobinaemia have been reported due to contamination of haemodialysis fluid with hydrogen peroxide.[3,4]
