Carcinogenicity. Follow-up data from a large study of folate supplementation suggested a greater risk of death due to breast cancer in those women randomised to high doses; the association was not statistically significant and further studies were considered necessary.[1] In contrast, other studies suggest a reduced risk of some cancers with folate supplementation, see Prophylaxis of Malignant Neoplasms, p.1927. A large study found that folic acid supplementation did not reduce colorectal adenoma risk; evidence for an increased risk of adenomas with supplementation was equivocal.[2] *Animal* studies suggest that folic acid may have dual modulatory effects on carcinogenesis, depending on dose and timing of supplementation. Folate deficiency may inhibit, whereas supplementation may promote, the progression of established neoplasms. In normal tissue, however, folate deficiency can predispose towards neoplastic transformation and modest amounts of folate may suppress tumour development; supraphysiological doses may enhance tumour progression.[3,4] Thus, use of folate before the existence of preneoplastic lesions may prevent tumour development, whereas use once early lesions are established appears to increase tumorigenesis.[5] However, determining the presence of preneoplastic foci in the general population is almost impossible.[4] Given the tendency for cancer patients to consume more supplements than healthy subjects, the possibility of adverse effects of folic acid on cancer progression, recurrence, and metastasis should be borne in mind, and research on folate supplementation among patients with cancer is needed.[5] Careful monitoring of the long-term effects of folic acid food fortification is also advised,[3,4] and some have advocated against mandatory fortification on this basis.[6]

Vitamin B_{12} deficiency. The issue of fortification of food with folic acid to reduce the number of infants born with neural tube defects (see below) has created debate[1-7] on the amount of fortification and on the risks of masking vitamin B_{12} deficiency, particularly in the elderly. As mentioned in Precautions, above, it is accepted that folic acid should not be used in megaloblastic anaemia due to vitamin B_{12} deficiency, because it will not prevent the neurological manifestations of this deficiency, and may delay the diagnosis. Masking of vitamin B_{12} deficiency has been noted with daily doses of folic acid of 5 mg, and it is generally considered that very low doses do not have this effect. It has also been stated that folic acid may precipitate the neurological manifestations of vitamin B_{12} deficiency; however, a review of the evidence suggests this is unlikely.[8]

Nevertheless, concerns regarding neurological effects of vitamin B_{12} deficiency in the elderly have led to adoption of a level of folic acid fortification in the USA that is accepted will not provide optimum protection against neural tube defects, but that is hoped will minimise any risks.[9] It has been suggested that fortification with vitamin B_{12} as well might also be a solution.[10-12] While some studies of food fortification show no evidence of a deterioration in vitamin B_{12} status in elderly patients,[13,14] there is concern[12,15] that individuals may be consuming folic acid in excess of the upper limit of 1 mg daily (see under Human Requirements, below). Because several countries in the Americas fortify flour, but at varying levels, a technical consultation was convened by the Pan American Health Organization, the March of Dimes, and the CDC, in order to develop guidelines on fortification.[15] It was recommended[16] that all women of reproductive age consume 400 micrograms daily of synthetic folic acid in addition to dietary intake; a minimum additional intake of 200 micrograms daily of folic acid from fortified foods was proposed. A target mean intake of 1 microgram daily of vitamin B_{12} from food fortification was recommended in countries where data are consistent with vitamin B_{12} deficiency; this amount was considered sufficient since, unlike dietary sources of vitamin B_{12}, synthetic vitamin B_{12} is highly bioavailable.

Interactions

Folate deficiency states may be produced by drugs such as antiepileptics, oral contraceptives, antituberculous drugs, alcohol, and folic acid antagonists such as methotrexate, pyrimethamine, triamterene, trimethoprim, and sulfonamides. In some instances, such as during methotrexate or antiepileptic therapy, replacement therapy with folinic acid or folic acid may become necessary in order to prevent megaloblastic anaemia developing; folate supplementation has reportedly decreased serum-phenytoin concentrations in a few cases (see Vitamins, p.500) and there is a possibility that such an effect could also occur with barbiturate antiepileptics.

Antiepileptic-associated folate deficiency is discussed further under Effects on the Blood in Phenytoin, p.495.

Pharmacokinetics

Folic acid is rapidly absorbed from the gastrointestinal tract, mainly from the duodenum and jejunum. Dietary folates are stated to have about half the bioavailability of crystalline folic acid. The naturally occurring folate polyglutamates are largely deconjugated, and then reduced by dihydrofolate reductase in the intestines to form 5-methyltetrahydrofolate, which appears in the portal circulation, where it is extensively bound to plasma proteins. Folic acid given therapeutically enters the portal circulation largely unchanged, since it is a poor substrate for reduction by dihydrofolate reductase. It is converted to the metabolically active form 5-methyltetrahydrofolate in the plasma and liver.

The principal storage site of folate is the liver; it is also actively concentrated in the CSF.

Folate undergoes enterohepatic circulation. Folate metabolites are eliminated in the urine and folate in excess of body requirements is excreted unchanged in the urine. Folate is distributed into breast milk. Folic acid is removed by haemodialysis.

Human Requirements

Body stores of folate in healthy persons have been reported as being between 5 to 10 mg, but may be much higher. In the UK about 150 to 200 micrograms of folate daily is considered a suitable average intake for all healthy persons except women of child-bearing potential and pregnant women who require additional folic acid to protect against neural tube defects in their offspring (see below). In the US the recommended dietary allowance is 400 micrograms of dietary folate equivalents (see below) in both men and women. Folate is present, chiefly combined with several L(+)-glutamic acid moieties, in many foods, particularly liver, kidney, yeast, and leafy green vegetables. The vitamin is readily oxidised to unavailable forms and is easily destroyed during cooking.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) have been published for folate.[1] In the USA recommended dietary allowances (RDAs) had been set, and have recently been reviewed[2] under the programme to set Dietary Reference Intakes (see p.1925). Differing amounts are recommended for infants and children of varying ages, for adult males and females, and for pregnant and lactating women. In the UK the Reference Nutrient Intake (RNI) for adult males and females is 200 micrograms daily and the Estimated Average Requirement (EAR) is 150 micrograms daily. In the USA the RDA is expressed in terms of dietary folate equivalents (DFEs) where 1 microgram DFE is equivalent to 1 microgram folate from natural sources, 0.5 micrograms of a folic acid supplement taken on an empty stomach, or 0.6 micrograms of folic acid from fortified food or as a supplement taken with meals. An RDA of 400 micrograms DFE daily for adult men and women has been set; the EAR is 320 micrograms DFE daily and the tolerable upper intake level is 1 mg daily.

Folate requirements are increased during pregnancy; an RNI of 300 micrograms daily has been suggested for pregnant women in the UK and an RDA of 600 micrograms daily in the USA. In view of the value of folate in preventing neural tube defects, it is now recommended that women planning a pregnancy receive supplemental folic acid before conception and during the first trimester (see Neural Tube Defects, below). To increase the intake in women of child-bearing age, folic acid fortification of grain-based foods has been adopted in the USA, and advocated in other countries including the UK. However, there remains some debate over the appropriate level of fortification to optimise prevention of neural tube defects and to minimise the risks of masking underlying vitamin B_{12} deficiency in the elderly (see Vitamin B_{12} deficiency, above).

Uses and Administration

Folic acid is a member of the vitamin B group. Folic acid is reduced in the body to tetrahydrofolate, which is a coenzyme for various metabolic processes including the synthesis of purine and pyrimidine nucleotides, and hence in the synthesis of DNA; it is also involved in some amino-acid conversions, and in the formation and utilisation of formate. Deficiency, which can result in megaloblastic anaemia (p.1982), develops when the dietary intake is inadequate (as in malnutrition), when there is malabsorption (as in sprue), increased utilisation (as in pregnancy or conditions such as haemolytic anaemia), increased loss (as in haemodialysis), or as a result of the use of folate antagonists and other drugs that interfere with normal folate metabolism (see Interactions, above).

Folic acid is used in the treatment and prevention of the folate deficiency state. It does not correct folate deficiency due to dihydrofolate reductase inhibitors; calcium folinate (p.1944) is used for this purpose. Folic acid is also used in women of child-bearing potential and pregnant women to protect against neural tube defects in their offspring. This is discussed in more detail in Neural Tube Defects, below.

For the treatment of folate-deficient megaloblastic anaemia it is recommended in the UK that folic acid is given orally in doses of 5 mg daily for 4 months; up to 15 mg daily may be necessary in malabsorption states. Continued oral dosage with folic acid 5 mg every 1 to 7 days may be necessary in chronic haemolytic states such as thalassaemia major or sickle-cell anaemia, depending on the diet and rate of haemolysis; similar doses may be necessary in some patients receiving renal dialysis in order to prevent deficiency. The *BNFC* recommends an oral dose of 500 micrograms/kg once daily for folate-dependent megaloblastic anaemia in children up to the age of 1 year; older children may be given similar doses to those in adults. For prophylaxis of folate deficiency in children on dialysis it suggests 250 micrograms/kg once daily from 1 month to 12 years of age, and 5 to 10 mg daily in older children.

In the USA the usual recommended therapeutic dose for folate deficiency is lower; oral folic acid 0.25 to 1 mg daily is suggested until a haematopoietic response has been obtained, although some patients require higher doses, especially in malabsorption states. The usual maintenance dose is 400 micrograms daily.

In the prophylaxis of megaloblastic anaemia of pregnancy, the usual dose is 200 to 500 micrograms daily in the UK.

For women of child-bearing potential at high risk of having a pregnancy affected by neural tube defect, the dose of folic acid is 4 or 5 mg daily starting before pregnancy (in the USA the recommendation is 4 weeks before) and continued through the first trimester. For other women of child-bearing potential the dose is 400 micrograms daily.

Folic acid may also be given by intramuscular, intravenous, or subcutaneous injection as the sodium salt.

Cardiovascular disease. Epidemiological studies indicate that individuals with a low serum folate are at increased risk of fatal coronary heart disease,[1] and that those with a high intake of folate,[2] or folic acid and vitamin B_6,[3] from vitamin supplements or food, are at lower risk of ischaemic heart disease or stroke. Vitamin deficiency, especially folic acid deficiency, is a common cause of hyperhomocysteinaemia.[4,5] Elevated blood-homocysteine concentrations may be an independent risk factor for atherosclerosis, ischaemic heart disease (p.1159), venous thrombosis (p.1189), and stroke (p.1185).[4-8] Whether hyperhomocysteinaemia directly causes cardiovascular disease, as concluded by a meta-analysis,[9] or is a possible marker of increased vascular risk,[10] remains controversial.[11,12]

Folic acid reduces blood-homocysteine concentrations;[13-15] vitamin B_{12}, but not B_6, may have an additional effect.[14] The higher the baseline blood-homocysteine concentration, or the lower the baseline value of folate,[14] the greater the effect of folate supplements; reductions were similar with daily doses from 0.5 to 5 mg of folic acid,[14] although a randomised trial[15] found greater effects with a daily 2-mg dose compared with a dose of 0.2 mg. A recent meta-analysis concluded that a daily dose of 0.8 mg or more was needed to achieve maximum reductions in homocysteine concentrations.[16]

Results of studies assessing cardiovascular risk versus folate intake have been variable. Although some have found the risk of hypertension,[17] or stroke[18] to be lower in patients with higher folate intakes (dietary or via supplementation), and there are suggestions that endothelial function is improved by folate supplementation,[19,20] others have reported no association between intake and cardiovascular risk.[21,22] A large open-label study[23] found that, while folic acid supplementation significantly reduced plasma homocysteine concentrations, it did not reduce recurrence of cardiovascular events in patients with stable coronary artery disease. (Most patients had been treated with lipid-lowering therapy, and the authors stated that this might have overshadowed any potential beneficial effects of folic acid.) Similarly, a randomised controlled study, the Vitamin Intervention for Stroke Prevention (VISP) trial,[24] found that high daily doses of folic acid, vitamin B_6 and vitamin B_{12} modestly decreased total homocysteine concentrations compared with low daily doses, but had no treatment effect on recurrent stroke, myocardial infarction, or death. Two further large controlled studies (HOPE-2 and NORVIT) also found no significant beneficial effect of combined treatment with folic acid and vitamins B_6 and B_{12} on cardiovascular disease risk, despite adequate homocysteine-lowering effects;[25,26] such therapy was even suggested to be harmful.[25] While one meta-analysis[27] concluded that folic acid supplementation could effectively reduce the risk of stroke in patients without a history of stroke, another[28] found no reduction in risk of cardiovascular disease, stroke, or all-cause mortality in patients with pre-existing cardiovascular or renal disease. Exclusion of the VISP study from the latter meta-analysis led to a significant protective effect of folic acid supplementation on stroke.[28]

Results of other ongoing studies are considered necessary before definite conclusions can be drawn as to the so-called 'homocysteine hypothesis' of atherothrombotic vascular disease; while some recommend against routine treatment,[4,29,30] others consider homocysteine-lowering treatment in high-risk patients to be justified.[31,32] A meta-analysis[33] of observational studies indicated that the relationship between hyperhomocysteinaemia and ischaemic heart disease and stroke risk in healthy individuals might not be as strong as had previously been suggested, with stronger associations found in retrospective studies than in prospective studies. The American Heart Association has stated[7] that, until the results of more controlled studies become available, routine testing of plasma-homocysteine concentrations cannot be justified; all patients should, however, be encouraged to consume the recommended dietary allowance (RDA) of folate, vitamin B_6 and vitamin B_{12}.

Daily treatment with oral folic acid, vitamin B_6, and vitamin B_{12} significantly decreased restenosis and target-vessel revascularisation after percutaneous coronary angioplasty.[34] In contrast, in another study[35] folic acid, vitamin B_6, and vitamin B_{12}, increased restenosis and target-vessel revascularisation. The studies differed in dosage regimen, patient population, lesion length, and procedure used,[36,37] but the strong proliferative effect of folate on neointimal growth may exceed the positive effect of lowering homocysteine concentrations,[38] and it has been stated[36] that these vitamins should not be routinely used in patients receiving coronary stents.

Patients with renal impairment develop hyperhomocysteinaemia as a result of delayed elimination and altered metabolism; the prevalence of plasma homocysteine levels greater than 15 micromoles/L has been reported to be 80 to 90% in dialysis patients, compared with 5% in the general population. In haemodialysis patients with moderate to severe hyperhomocysteinaemia, intravenous folinic acid 10 mg three times weekly has been reported to dramatically decrease homocysteine concentrations, although normal levels of homocysteine were not attained.[39] In a small study in renal transplant recipients with hyperhomocysteinaemia, vitamin B_6 was effective in reducing post-methionine-loading plasma homocysteine concentrations, and folic acid plus vitamin B_{12} was effective in lowering fasting plasma-homocysteine concentrations. The authors concluded that all three of these B-group vitamins may have a role in reducing atherosclerotic outcomes in this patient group.[40]

Food fortification. Mandatory fortification of foods with folic acid has caused much controversy, with some advocating this measure as prevention against neural tube defects (below) and others concerned about folic acid supplementation masking vitamin B_{12} deficiency (above) or having possible carcinogenic effects (above).

Mental function. For a discussion of the effects of folate supplementation on cognitive function and depression, see Mental Function, p.1926.

Neural tube defects. Failure of the fetal neural tube to fuse normally during the first 4 weeks of pregnancy may result in one of several congenital defects. These include anencephaly (absence of the brain and cranial vault) and spina bifida (failure of the vertebrae to fuse).[1,2] The latter ranges from spina bifida occulta, where neurological abnormalities are rare, to meningocoele or meningomyelocoele, where the meninges, or meninges and spinal cord, herniate outwards through the vertebral defect and which may be associated with hydrocephalus and paralysis of the lower limbs and sphincters.

The reasons for this failure in normal development are not well understood and appear to include both environmental and genetic factors. The risk is increased in certain geographical areas, and in the offspring of parents with previous children who had neural tube defects, or of parents who themselves suffer from the condition.[1]

A defect in the methylenetetrahydrofolate reductase gene has been identified, which is estimated to occur in about 5 to 15% of white populations, and appears to result in an increased requirement for folates, and an increased risk of recurrent early pregnancy loss and neural tube defects.[3,4] Since the 1960s there has been some evidence that the mother's folate status was significant, and in the early 1980s two groups published evidence for claims that oral folic acid, with or without other vitamins, in the period around conception, reduced the incidence of neural tube defect in the offspring of mothers who had previously borne children with the defect.[5,6]

Although criticised on several grounds, the conclusions of these studies were borne out by a large multicentre study initiated by the UK Medical Research Council (MRC).[7] This study was terminated early because of overwhelming evidence that folic acid 4 mg daily taken from before conception until the twelfth week of gestation by women with a history of a previous pregnancy affected by a neural tube defect reduced the incidence of such defect by about two-thirds. Other studies and systematic reviews have since confirmed the benefits of supplementation.[8,9] Multivitamins alone (A, D, B_1, B_2, nicotinamide, B_6, and C) did not demonstrate a similar benefit.

Prevention of recurrence. In the light of the MRC study, it is recommended in the UK that in couples with spina bifida or a history of previous offspring with neural tube defect, all those women who may become pregnant should receive folic acid 5 mg daily (in the absence of a commercially-available 4-mg dosage form) until the twelfth week of pregnancy.[10] In the USA, recommendations are 4 mg of folic acid daily from at least 4 weeks before conception through the first 3 months of pregnancy.[11] It must be borne in mind that only about 60 to 70% of neural tube defects appear to be folate-sensitive, and parents should be counselled appropriately. Similar doses of folic acid have been recommended for women in intermediate- to high-risk categories for neural tube defects in Canada.[12]

The investigators in the MRC trial acknowledged that a 4-mg dose may not be optimal, and both early[5,6] and later[13] studies imply that much lower doses of folic acid may reduce the risk of recurrence, but this has yet to be clearly demonstrated. Furthermore, the optimum length of time that supplements should be given to these women before conception is unknown.

Prevention of occurrence. First occurrences of neural tube defects account for about 95% of cases, and there are obvious public health implications if the benefits of folate in mothers known to be at risk can be extended to the general population. A study in Hungary[14] indicated that folic acid 800 micrograms daily with multivitamins, taken for at least one month before conception and until the third month of gestation decreased the incidence of first occurrence of neural tube defects. A case control study in the USA[15] (where the normal incidence of neural tube defect is much lower than Hungary) suggested that a periconceptional folic acid intake of as little as 400 micrograms daily reduced the occurrence of the disorder by 60%.

With such results in mind the US Public Health Service has recommended that all women of child-bearing age who are capable of pregnancy should receive folic acid 400 micrograms daily although care should be taken to keep folate consumption below 1 mg daily except under medical supervision.[1,16] Such universal coverage would allow for the problem of unplanned pregnancies but would be difficult to achieve, other than by fortification of dietary staples with folate. Food fortification has therefore been adopted in the USA, at a level of 140 micrograms of folic acid per 100 g of cereal-grain product. While this amount will probably be insufficient to provide maximum reduction in the incidence of neural tube defects,[17,18] there is some evidence of benefit,[19] and it was chosen to minimise the risk of masking vitamin B_{12} deficiency in the elderly.[20] Efforts to increase the use of folic acid supplements in women of child-bearing potential are still advocated. In Canada, where food fortification has been associated with a significant reduction in neural tube defects,[21] similar recommendations have been made.[12]

In the UK, the current recommendation is that all women planning a pregnancy should take an extra 400 micrograms of folic acid daily before conception and during the first 12 weeks of pregnancy, bringing the average folate intake to about 600 micrograms daily.[10] In unplanned pregnancies, supplementation should begin as soon as pregnancy is suspected. Some, however, consider this amount to be too low.[22] As in the USA, food fortification has been considered, and the Committee on Medical Aspects of Food and Nutrition Policy (COMA) concluded that universal fortification of flour at 240 micrograms of folic acid per 100 g in food would significantly reduce the number of neural tube defects.[23] In May 2007, the UK Food Standards Agency agreed that mandatory fortification be introduced. However, there are concerns about possible carcinogenic effects (see Carcinogenicity, above) and results of further studies are awaited. Debate has continued as to the amount, if any, of fortification necessary.[22,24-29] The UK Scientific Advisory Committee on Nutrition reconfirmed[30] the COMA recommendation for fortification of flour but said that further consideration should be given to the amount and form of folate used and also called for better monitoring of vitamin B_{12} in those aged 65 and over. There has also been a renewed call for fortification of foods in Europe,[31-34] and Australia and New Zealand,[35,36] as issuing recommendations on folic acid use has not led to a substantial decrease in the incidence of neural tube defects, and efforts have not reached all the target population. Certainly, mandatory food fortification with folic acid has been shown to dramatically decrease the incidence of neural tube defects in Canada,[37] Chile,[38] and the USA.[39-41] Fears of masking vitamin B_{12} deficiency appear to have not been borne out (see Vitamin B_{12} Deficiency, above).

Patients receiving antiepileptic drugs are at increased risk of neural tube defect and it has been suggested that folic acid supplementation for such patients should be at the level used for prevention of recurrence,[42] i.e. 4 or 5 mg daily.

The mechanism by which folic acid protects against neural tube defects is unknown, but various theories have been postulated including a positive effect in promoting neural tube closure,[43] or a selective abortifacient effect on affected fetuses (terathanasia),[44] although the latter has been disputed.[45] There is some evidence that low maternal vitamin B_{12} concentrations are an independent risk factor for neural tube defects,[46,47] perhaps indicating a role for methionine synthase in their aetiology, and suggesting that additional supplementation with cobalamins may be warranted, or that methionine supplements could be investigated as an alternative to folic acid.[48,49] Some suggest that hyperhomocysteinaemia may be a cause of some neural tube defects and that they may be due to an inborn error of folate and/or homocysteine metabolism; furthermore, a dietary deficiency may trigger a genetic predisposition towards the development of neural tube defects.[2] Interestingly, the results from the Hungarian programme[50,51] and from other studies[52-54] suggest that multivitamin supplements (including folic acid) may also reduce the occurrence of other congenital abnormalities. Maternal folate deficiency has also been associated with an increased risk of adverse birth outcomes, apart from neural tube defects, such as preterm delivery, low infant birth-weight, and fetal growth retardation.[55]

Osteoporosis. Treatment with folate and vitamin B_{12} can reduce elevated plasma homocysteine concentrations and may subsequently decrease the risk of osteoporosis and hip fracture, see Osteoporosis, under Vitamin B_{12}, p.1983.

Prophylaxis of malignant neoplasms. For reference to suggestions that folate supplements may be associated with reduced risk of certain cancers, see p.1927. However, folic acid may have dual modulatory effects on carcinogenesis, see Carcinogenicity, above.

Preparations

BP 2008: Ferrous Fumarate and Folic Acid Tablets; Folic Acid Tablets;
USP 31: Folic Acid Injection; Folic Acid Tablets.

Proprietary Preparations (details are given in Part 3)

Arg.: Acifol; Anemidox Folico; Anfolic; Azolac Folico; Biolfolic; Coflic; Conacid; Dupofol; Edulsan Folic; Egestan; Folaport; Foliagen; Folimax; Folinemic; Galfol; Livifol; Medifol; Ronfolic; Sojar Folico; Suprafol; ***Austral.:*** Megafol; ***Austria:*** Folsan; ***Belg.:*** Folavit; ***Braz.:*** Acfol†; Afopic; Endofolin; Enfol; Folacin; Folin†; Folital; Materfolic; Neo Folico; ***Chile:*** Folacid; Folifemin; Folisanin; ***Denm.:*** Folimet; ***Fin.:*** Folvite; ***Fr.:*** Speciafoldine; ***Ger.:*** DreisaFol; Fol-Asmedic†; Folarell; Folcur; Folgamma Mono; Folsan; Folverlan; Gravi-Fol; Lafol; RubieFol†; ***Gr.:*** Filicine; ***Hung.:*** Feroglobin-B12; Folsav; Huma-Folacid; ***India:*** Folet; Folvite; Ingafol; Rubraplex; Vitafol; ***Indon.:*** Folac; Folacite; Folacom; Folas; Folavit; Folaxin; Nufolic; ***Irl.:*** Cardioguard†; Clonfolic; ***Ital.:*** Fertifol; Folidex; Folina; Folingrav; Serengrav; ***Mex.:*** AF; Folivital; Materfol; Prinac Ac; ***Philipp.:*** Enhansid; Purifol; ***Pol.:*** Acifolik; Folacid; Folifem; Folik; Folimin; Folovit; ***Port.:*** Acfol; Dozefol; Folicil; ***Rus.:*** Folacin (Фолацин); ***Spain:*** Acfol; Zolico; ***Swed.:*** Folacin; ***Switz.:*** Andreafol; Drossafol; Foli-Rivo†; Folvite; ***Thai.:*** Foliamin; Folicare; Folivit; ***Turk.:*** Folbiol; ***UAE:*** Folicum; ***UK:*** Folicare; Lexpec; Preconceive; ***USA:*** Folvite; ***Venez.:*** Afoklin; Folac.

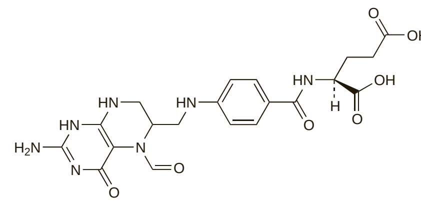
Folinic Acid *(BAN)*

Citrovorum Factor; Folínico, ácido; Leucovorin. 5-Formyltetrahydropteroylglutamic acid; *N*-[4-(2-Amino-5-formyl-5,6,7,8-tetrahydro-4-hydroxypteridin-6-ylmethylamino)benzoyl]-L(+)-glutamic acid.

Фолиновая Кислота

$C_{20}H_{23}N_7O_7$ = 473.4.

CAS — 58-05-9.



Calcium Folinate *(BANM, rINN)*

Calcii folinas; Calcii Folinas Hydricus; Calcium, folinate de; Calcium Folinate-SF; Calcium Leucovorin; Folinate de Calcium; Folinato cálcico; Kalcio folinatas; Kalciumfolinat; Kalcium-folinát; Kalcium-folinát hydrát; Kalsiumfolinaatti; Kalsiyum Folinat; Kalsiyum Lökovorin; Leucovorin Calcium; NSC-3590. The calcium salt of folinic acid (1:1).

Кальция Фолинат

$C_{20}H_{21}CaN_7O_7$ = 511.5.

CAS — 1492-18-8 (anhydrous calcium folinate); 41927-89-3 (calcium folinate pentahydrate); 6035-45-6 (calcium folinate pentahydrate).

ATC — V03AF03.

ATC Vet — QV03AF03.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *Jpn*, and *US*.

Chin. includes the pentahydrate ($C_{20}H_{21}CaN_7O_7,5H_2O$ = 601.6)
.

Ph. Eur. 6.2 (Calcium Folinate). A white or light yellow, amorphous or crystalline powder. Sparingly soluble in water; practically insoluble in alcohol and in acetone. A 2.5% solution in water has a pH of 6.8 to 8.0. Store in airtight containers. Protect from light.

USP 31 (Leucovorin Calcium). A yellowish-white or yellow, odourless, powder. Very soluble in water; practically insoluble in alcohol. Protect from light.

Incompatibility. Calcium folinate and fluorouracil, with or without 5% glucose, were incompatible when mixed in various ratios and stored in PVC containers at various temperatures.[1]

1. Trissel LA, *et al.* Incompatibility of fluorouracil with leucovorin calcium or levoleucovorin calcium. *Am J Health-Syst Pharm* 1995; **52:** 710–15.

Calcii Levofolinas; Calcii levofolinas pentahydricus; Kalcio levofolinatas; Kalciumlevofolinat; Kalcium-levofolinát pentahydrát; Kalcium-levofolinát-pentahidrát; Kalciumlevofolinatpentahydrat; Kalsiumlevofolinaatti; Kalsiumlevofolinaattipentahydraatti; Levofolinate; Lévofolinate calcique pentahydraté; Lévofolinate de Calcium; Levofolinato de calcio; Levoleucovorin Calcium *(USAN)*. The calcium salt of the isomer of *S*-folinic acid (1:1).

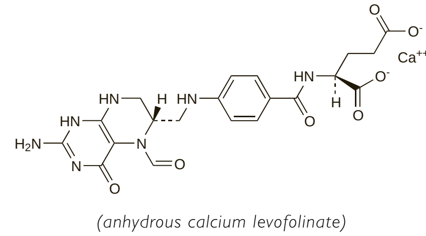
Кальция Левофолинат

$C_{20}H_{21}CaN_7O_7,5H_2O$ = 601.6.

CAS — 80433-71-2 (anhydrous calcium levofolinate).

ATC — V03AF04.

ATC Vet — QV03AF04.



(anhydrous calcium levofolinate)

Pharmacopoeias. In *Eur.* (see p.vii).
Ph. Eur. 6.2 (Calcium Levofolinate Pentahydrate). A white or light yellow, amorphous or crystalline, hygroscopic powder. Slightly soluble in water; practically insoluble in alcohol and in acetone. A 0.8% solution in water has a pH of 7.5 to 8.5. Store in airtight containers. Protect from light.

Sodium Folinate

Disodium folinate *(BANM)*.
Натрия Фолинат
$C_{20}H_{21}N_7O_7Na_2$ = 517.4.
CAS — 42476-21-1 (monosodium folinate).
ATC — V03AF06.
ATC Vet — QV03AF06.

Adverse Effects

Occasional hypersensitivity, including anaphylactic reactions, has been reported; pyrexia has occurred rarely after injections. Gastrointestinal disturbances, insomnia, agitation, and depression have been reported rarely, after high doses.

Precautions

As for Folic Acid, p.1940.

Interactions

As for Folic Acid, p.1940.

Folinic acid should not be used with a folic acid antagonist such as methotrexate as this may nullify the effect of the antagonist. Folinic acid enhances the toxicity, as well as the antineoplastic action, of fluorouracil, especially on the gastrointestinal tract.

Pharmacokinetics

Calcium folinate is well absorbed after oral and intramuscular doses and, unlike folic acid (p.1941), is rapidly converted to biologically active folates. Sodium folinate is considered to be bioequivalent to calcium folinate. Folate is concentrated in the liver and CSF although distribution occurs to all body tissues. Folates are mainly excreted in the urine, with small amounts in the faeces.

Uses and Administration

Folinic acid is the 5-formyl derivative of tetrahydrofolic acid, the active form of folic acid. Folinic acid is used principally as an antidote to folic acid antagonists, such as methotrexate (p.747), which block the conversion of folic acid to tetrahydrofolate by binding the enzyme dihydrofolate reductase. It does not block the antimicrobial action of folate antagonists such as trimethoprim or pyrimethamine, but may reduce their haematological toxicities. It is also used as an adjunct to fluorouracil in the treatment of colorectal cancer.

Folinic acid is given as calcium or sodium folinate, although doses are stated in terms of folinic acid. 1.08 mg of anhydrous calcium folinate, 1.27 mg of calcium folinate pentahydrate, or 1.09 mg of sodium folinate are each equivalent to about 1 mg of folinic acid. Calcium folinate can be given orally, by intramuscular injection, or by intravenous injection or infusion. It has been recommended that oral doses should not be greater than 50 mg, since absorption is saturable. Calcium levofolinate, the active laevo-isomer, is used similarly to calcium folinate; it is given in doses half those recommended for the racemic form. Sodium folinate is given by intravenous injection or infusion; sodium levofolinate is used similarly.

In cases of inadvertent **overdosage of a folic acid antagonist**, folinic acid should be given as soon as possible and preferably within the first hour. Doses equal to or greater than the dose of methotrexate have been recommended. Intravenous injections should be given over several minutes because of their calcium content; the maximum recommended rate is equivalent to folinic acid 160 mg/minute. Alternatively it has been stated that for large doses or overdoses of methotrexate, calcium folinate may be given by intravenous infusion in a dose equivalent to 75 mg of folinic acid within 12 hours, followed by 12 mg intramuscularly every 6 hours for 4 doses. Although vincristine is not a folic acid antagonist, folinic acid has also been proposed for some manifestations of vincristine toxicity overdosage—see p.787.

Folinic acid is used with high-dose methotrexate antineoplastic therapy to reduce the toxicity of the methotrexate ('**folinic acid rescue**'; 'calcium leucovorin rescue'). Calcium folinate rescue is necessary when methotrexate is given at doses exceeding 500 mg/m^2 and should be considered with methotrexate doses of 100 to 500 mg/m^2. It may sometimes be considered in patients who have received lower doses.

Dosage and duration of folinic acid rescue must be adapted according to the methotrexate regimen and the patient's ability to clear the antineoplastic; many antineoplastic regimens include appropriate rescue protocols. In general, UK licensed drug information recommends that the first dose of calcium folinate is the equivalent of 15 mg folinic acid (6 to 12 mg/m^2) to be given 12 to 24 hours (usually the latter) after the beginning of methotrexate infusion. The same dose is given every 6 hours for 24 hours, initially by intramuscular injection or intravenous injection or infusion, but switching to the oral form after one or more parenteral doses. At the end of this time (48 hours after the start of the original methotrexate infusion) the residual methotrexate concentration should be measured. If this is *less* than a threshold concentration of 0.5 micromoles/litre, the same dose is continued usually for a further 48 hours. If it is *greater* than this value, further calcium folinate dosages should be adapted according to methotrexate concentration as follows, and given every 6 hours for a further 48 hours or until the serum-methotrexate concentration falls below 0.05 micromoles/litre (i.e. one-tenth of the threshold concentration):

- serum methotrexate > 0.5 micromoles/litre: calcium folinate equivalent to 15 mg/m^2 folinic acid
- serum methotrexate > 1 micromole/litre: calcium folinate equivalent to 100 mg/m^2 folinic acid
- serum methotrexate > 2 micromoles/litre: calcium folinate equivalent to 200 mg/m^2 folinic acid

The dose of sodium folinate in rescue therapy is also based on serum-methotrexate concentrations (as measured 24 to 30 hours after beginning methotrexate):

- serum methotrexate 0.01 to 1.5 micromoles/litre: sodium folinate equivalent to 10 to 15 mg/m^2 folinic acid every 6 hours for 48 hours
- serum methotrexate 1.5 to 5 micromoles/litre: sodium folinate equivalent to 30 mg/m^2 folinic acid every 6 hours until methotrexate concentration is less than 0.05 micromoles/litre
- serum methotrexate > 5 micromoles/litre: sodium folinate equivalent to 60 to 100 mg/m^2 folinic acid every 6 hours until methotrexate concentration is less than 0.05 micromoles/litre

In patients who have received doses of methotrexate below 100 mg, and in whom rescue therapy is considered appropriate, doses of folinic acid 15 mg by mouth every 6 hours for 48 to 72 hours may suffice.

In addition, measures to ensure the prompt excretion of methotrexate (maintenance of high urine output and alkalinisation of urine) are integral parts of rescue treatment. Renal function should be monitored daily.

Folinic acid is also used **with fluorouracil** to enhance the cytotoxic effect in advanced colorectal cancer. Both high-dose regimens (typically doses of folinic acid 200 mg/m^2, followed by fluorouracil) and low-dose regimens (20 mg/m^2) have been used—for details, see Uses and Administration of Fluorouracil, p.723. Sodium folinate has been used in similar doses. It may also be given at a dose equivalent to folinic acid 500 mg/m^2 by intravenous infusion over 2 hours. An intravenous injection of fluorouracil 600 mg/m^2 is given one hour after the start of the folinate infusion. Alternatively, a continuous infusion of fluorouracil 2.6 g/m^2 is given for 24 hours after the sodium folinate dose. Treatment is given weekly for 6 weeks, and may then be repeated after a 2-week interval; the number of cycles depends on the response of the tumour.

Folinic acid, like folic acid, is effective in the treatment of folate-deficient **megaloblastic anaemia** (see p.1982). Doses of 15 mg daily by mouth have been suggested. If given intramuscularly a dose of up to 1 mg daily has been recommended on the grounds that higher doses have not been proven to be any more effective. It is unsuitable for megaloblastic anaemia secondary to vitamin-B_{12} deficiencies.

Cardiovascular disease. For a report of the use of intravenous folinic acid to reduce levels of homocysteine in haemodialysis patients, see Cardiovascular Disease, under Folic Acid, p.1941.

Deficiency states. Cerebral folate deficiency has been defined as any neurological syndrome associated with low CSF concentrations of 5-methyltetrahydrofolate, the active metabolite of folic acid.[1,2] Neurodevelopmental disorders have been associated with this deficiency, manifest as irritability, sleep disturbances, cerebellar ataxia, spastic paraplegia, dyskinesia, epileptic seizures, and speech difficulties. Dramatic improvements in some symptoms have been noted with oral folinic acid;[1-3] 0.5 to 1 mg/kg folinic acid daily has been used.[1] Analysis of CSF folate metabolites is recommended for patients presenting with movement disorders, mental retardation, or autism.[2,3]

3. Moretti P, *et al.* Cerebral folate deficiency with developmental delay, autism, and response to folinic acid. *Neurology* 2005; **64:** 1088–90.

HIV infection and AIDS. Calcium folinate has been used to reduce the toxicity of pyrimethamine and trimethoprim in patients with HIV infection. However, oral calcium folinate given to patients with AIDS receiving co-trimoxazole for the treatment of pneumocystis pneumonia was associated with a higher rate of therapeutic failure and a decrease in survival and did not reduce the frequency of dose-limiting co-trimoxazole toxicity.[1] Calcium folinate also did not reduce the toxicity of co-trimoxazole being used for the primary prophylaxis of PCP.[2] Vitamin B_{12} and folinic acid supplementation in patients with HIV infection did not prevent or reduce zidovudine-induced myelosuppression.[3]

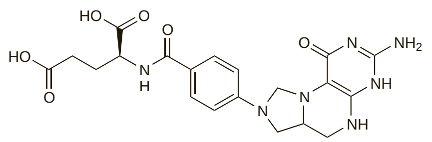
Folitixorin *(pINN)*

Folitixorina; Folitixorine; Folitixorinum; 5,10-Methylenetetrahydrofolate; 5,10-Methylenetetrahydrofolic acid; Tetrahydromethylenefolate. N-{4-[3-Amino-1,2,5,6,6a,7-hexhydro-1-oxoimidazo(1,5-f)pteridin-8(9H)-yl]benzoyl}-L-glutamic acid.

Фолитиксорин

$C_{20}H_{23}N_7O_6$ = 457.4.

CAS — 3432-99-3.



Profile

Folitixorin is an active metabolite of folinic acid. It is under investigation for use with fluorouracil in the treatment of pancreatic cancer and metastatic colorectal cancer.

Fructose

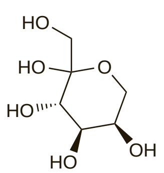
Fructosa; D-Fructose; Fructosum; Fruit Sugar; Fruktoosi; Fruktos; Fruktosa; Fruktóz; Fruktoza; Fruktozė; Laevulose; Laevulosum; Levulose. D-(−)-Fructopyranose.

$C_6H_{12}O_6$ = 180.2.

CAS — 57-48-7.

ATC — V06DC02.

ATC Vet — QV06DC02.



Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*
USNF includes High Fructose Corn Syrup.

Ph. Eur. 6.2 (Fructose). A white or almost white, crystalline powder with a very sweet taste. Very soluble in water; soluble in alcohol.

USP 31 (Fructose). Colourless crystals or a white crystalline powder. Is odourless and has a sweet taste. Freely soluble in water; soluble 1 in 15 of alcohol and 1 in 14 of methyl alcohol.

USNF 26 (High Fructose Corn Syrup). A sweet, nutritive saccharide mixture prepared as a clear, aqueous solution from high-glucose-equivalent corn starch hydrolysate by the partial enzymatic conversion of glucose to fructose, using an insoluble glucose isomerase enzyme preparation. It is available in two types, 42% and 55%, based on fructose content. Store in airtight containers.

Adverse Effects

Large doses of fructose given by mouth may cause flatulence, abdominal pain, and diarrhoea. Lactic acidosis and hyperuricaemia may follow intravenous infusions; fatalities have occurred.

Gout. Fructose may increase serum concentrations of uric acid, especially in those with existing hyperuricaemia or gout. A large cohort study found that consumption of fructose was associated with an increased risk of gout in men. Fructose-rich fruits or fruit juice may also increase the risk.[1] It has been pointed out that fructose intake has increased in the USA, where soft drinks are usually sweetened with high fructose corn syrup (also known as isoglucose), whereas elsewhere they tend to be sweetened with sucrose.[2]

1. Choi HK, Curhan G. Soft drinks, fructose consumption, and the risk of gout in men: prospective cohort study. *BMJ* 2008; **336:** 309–12.
2. Underwood M. Sugary drinks, fruit, and increased risk of gout. *BMJ* 2008; **336:** 285–6.

Hypersensitivity. Urticaria associated with the ingestion of certain foods by a patient was found to be caused by D-psicose, a minor constituent of high-fructose syrup, which is used as a sweetening agent.[1]

1. Nishioka K, *et al*. Urticaria induced by -psicose. *Lancet* 1983; **ii:** 1417–18.

Precautions

Fructose should not be given to patients with hereditary fructose intolerance.

It should be given with caution to patients with impaired kidney function or severe liver damage.

Intravenous administration. Reiterations of the view that the use of intravenous infusions containing fructose and sorbitol, which remained popular in some countries, should be abandoned.[1,2] Not only can they lead to life-threatening build-up of lactic acid, they have led to fatalities in patients with undiagnosed hereditary fructose intolerance.

1. Collins J. Time for fructose solutions to go. *Lancet* 1993; **341:** 600.
2. Committee on Safety of Medicines/Medicines Control Agency. Reminder: fructose and sorbitol containing parenteral solutions should not be used. *Current Problems* 2001; **27:** 13. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON007456&RevisionSelectionMethod=LatestReleased (accessed 21/07/08)

Pharmacokinetics

Fructose is absorbed from the gastrointestinal tract but more slowly than glucose. It is metabolised more rapidly than glucose, mainly in the liver where it is phosphorylated and a part is converted to glucose; other metabolites include lactic and pyruvic acid. Although the metabolism of fructose is not dependent on insulin, and insulin is not considered necessary for its removal from the blood, glucose is a metabolic product of fructose and requires the presence of insulin for its further metabolism.

Uses and Administration

Fructose is sweeter than sucrose or sorbitol. It is used as a sweetener in foods for diabetics (although it is not clear it offers any advantage over sucrose); in the UK it has been advised that the intake of fructose be limited to 25 g daily in persons with diabetes mellitus.

Fructose has been used as an alternative to glucose in parenteral nutrition but its use is not recommended because of the risk of lactic acidosis. Use by intravenous infusion in the treatment of severe alcohol poisoning is also no longer recommended.

Solutions of fructose with glucose have been used in the treatment of nausea and vomiting (p.1700) including vomiting of pregnancy. Fructose is also used as a dissolution enhancer and tablet diluent in pharmaceuticals.

Pain. Oral fructose solution was considered to be as effective as oral glucose solution (p.1946) in alleviating mild pain in neonates.[1]

1. Akçam M. Oral fructose solution as an analgesic in the newborn: a randomized, placebo-controlled and masked study. *Pediatr Int* 2004; **46:** 459–62.

Preparations

BP 2008: Fructose Intravenous Infusion;
USP 31: Fructose and Sodium Chloride Injection; Fructose Injection.

Proprietary Preparations (details are given in Part 3)
Hung.: Fructosol; ***Ital.:*** Fructal†; Fructan; Fructofin; Fructopiran†; Fructosil; Laevosan†; ***Spain:*** Levulosado†.

Gleptoferron *(BAN, USAN, rINN)*

Gleptoferrón; Gleptoferronum; Iron Heptonate.

Глептоферрон

$C_7H_{14}O_8.(C_6H_{10}O_5)_n$.FeOOH.

CAS — 57680-55-4.

ATC Vet — QB03AC91.

Profile

Gleptoferron is a macromolecular complex of ferric hydroxide and dextran-glucoheptonic acid. It has been used for iron-deficiency anaemia in veterinary medicine. It is given by intramuscular injection.

Glucose

Dekstoz Monohidrat; Glucosa; Glukoz; Glukoza; Gukoz.

ATC — B05CX01; V04CA02; V06DC01.

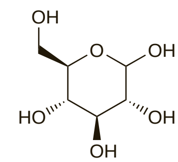
ATC Vet — QB05CX01; QV04CA02; QV06DC01.

Anhydrous Glucose

Anhydrous Dextrose; Anhydrous Glucose; Dextrosum Anhydricum; Gliukozė, bevandenė; Glucosa anhidra; D-Glucose; Glucose anhydre; Glucosum; Glucosum anhydricum; Glukoosi, vedetön; Glukos, vattenfri; Glukosa; Glukoza bezwodna; Vízmentes glükóz. D-(+)-Glucopyranose.

$C_6H_{12}O_6$ = 180.2.

CAS — 50-99-7.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,*and *Viet.*

Some pharmacopoeias include anhydrous glucose and/or glucose monohydrate as separate monographs whereas others permit the anhydrous and/or monohydrate under a single monograph.

Ph. Eur. 6.2 (Glucose, Anhydrous). A white or almost white, crystalline powder with a sweet taste. Freely soluble in water; sparingly soluble in alcohol.

The BP 2008 directs that when Glucose Intravenous Infusion is required as a diluent for official injections or intravenous infusions, Glucose Intravenous Infusion 5% should be used.

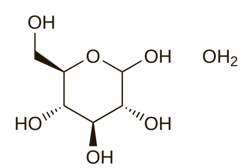
USP 31 (Dextrose). It contains one molecule of water of hydration or is anhydrous. Colourless crystals or white, crystalline or granular powder. It is odourless and has a sweet taste. Soluble 1 in 1 of water and 1 in 100 of alcohol; very soluble in boiling water; soluble in boiling alcohol.

Glucose Monohydrate

Dextrosum Monohydridicum; Gliukozė monohidratas; Glucosa monohidrato; Glucose monohydraté; D-Glucose Monohydrate; Glucosum monohydricum; Glukoosimonohydraatti; Glukosa monohydrát; Glukosmonohydrat; Glükóz-monohidrát; Glycosum; Grape Sugar. D-(+)-Glucopyranose monohydrate.

$C_6H_{12}O_6,H_2O$ = 198.2.

CAS — 5996-10-1.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., US,* and *Viet.*

Some pharmacopoeias include anhydrous glucose and/or glucose monohydrate as separate monographs whereas others permit the anhydrous and/or monohydrate under a single monograph.

Eur. includes Glucose, Liquid and Glucose, Liquid, Spray-dried. *USNF* includes Dextrose Excipient, Liquid Glucose, and Corn Syrup Solids.

Ph. Eur. 6.2 (Glucose Monohydrate; Glucose BP 2008). A white or almost white crystalline powder with a sweet taste. Freely soluble in water; sparingly soluble in alcohol.

Ph. Eur. 6.2 (Glucose, Liquid). A clear, colourless, or brown viscous liquid containing a mixture of glucose, oligosaccharides, and polysaccharides obtained by hydrolysis of starch, in aqueous solution. It contains not less than 70.0% of dry matter. Miscible with water. It may partly or totally solidify at room temperature, liquefying again on heating to 50°.

Ph. Eur. 6.2 (Glucose, Liquid, Spray-dried). A white or almost white, slightly hygroscopic powder or granules. Freely soluble in water.

USP 31 (Dextrose). It contains one molecule of water of hydration or is anhydrous. Colourless crystals or white, crystalline or granular powder. It is odourless and has a sweet taste. Soluble 1 in 1 of water and 1 in 100 of alcohol; very soluble in boiling water; soluble in boiling alcohol.

USNF 26 (Dextrose Excipient). A sugar usually obtained by hydrolysis of starch. It contains one molecule of water of hydration. Colourless crystals or white, crystalline or granular powder. Freely soluble in water; very soluble in boiling water; slightly soluble in alcohol; sparingly soluble in boiling alcohol.

USNF 26 (Liquid Glucose). It is obtained by incomplete hydrolysis of starch; it consists chiefly of glucose, dextrins, maltose, and water. It is a colourless or yellowish, thick, syrupy, odourless or nearly odourless liquid. Miscible with water; sparingly soluble in alcohol.

USNF 26 (Corn Syrup Solids; Dried Glucose Syrup). A dried mixture of saccharides obtained by partial hydrolysis of edible corn starch by food grade acids and/or enzymes. It contains not less than 20% reducing sugar content (dextrose equivalent) expressed as D-glucose, calculated on the dried basis. A sweet, white to light yellow powder or granules. Soluble in water. Store in airtight containers at a temperature of 8° to 15°.

Adverse Effects and Precautions

Intravenous glucose solutions (particularly hyperosmotic solutions, which also have a low pH) may cause local pain, vein irritation, and thrombophlebitis, and tissue necrosis if extravasation occurs. Some of these reactions may be due to degradation products present after autoclaving or to poor technique in giving the solution. Intravenous infusion can lead to fluid and electrolyte disturbances including hypokalaemia, hypomagnesaemia, and hypophosphataemia. Prolonged or rapid infusion of large volumes of iso-osmotic solutions may cause oedema or water intoxication; conversely, prolonged or rapid use of hyperosmotic solutions may result in dehydration as a consequence of the induced hyperglycaemia.

The use of hyperosmotic glucose solutions is contra-indicated in patients with anuria, intracranial or intraspinal haemorrhage, and in delirium tremens where there is dehydration. They should be used with caution in patients with diabetes mellitus, as rapid infusion can lead to hyperglycaemia, as well as in those with malnutrition, thiamine deficiency, carbohydrate intolerance, sepsis, shock, or trauma.

It has been suggested that glucose solutions should not be used after acute ischaemic strokes as hyperglycaemia has been implicated in increasing cerebral ischaemic brain damage and in impairing recovery.

Glucose solutions should not be given through the same infusion equipment as whole blood as haemolysis and clumping can occur.

Pregnancy. Glucose solutions are commonly used as hydrating fluids and as vehicles for other drugs. If given during labour it has been suggested that the glucose load on the mother may lead to fetal hyperglycaemia, hyperinsulinaemia, and acidosis, with subsequent neonatal hypoglycaemia and jaundice.[1,2] Others[3] have found no evidence of such an effect, especially if the fetus is well-oxygenated,[4] and note that the number of patients included in such reports is often small and the selection criteria not homogeneous.

A placebo-controlled study[5] in healthy women scheduled for termination of pregnancy at mid-gestation found that giving 100 g of oral glucose 1 hour before termination had no adverse effect on fetal acid–base levels. Fetuses with malformations had been excluded. However, the authors cautioned that, at higher maternal glucose concentrations (as may be found in pregnant diabetics), changes consistent with fetal metabolic acidosis might occur, and that the glucose tolerance test might also be hazardous to fetuses with growth retardation. Late reactions to the acute glucose load could not be studied.

Stroke. Hyperglycaemia may be caused by physiological stress during ischaemic stroke, and this worsens cerebral ischaemic damage and impairs recovery. During cerebral ischaemia, cellular hypoxia causes a shift from aerobic to anaerobic metabolism of glucose leading to intracellular lactic acidosis, which is toxic to the cell. Hyperglycaemia provides more glucose for anaerobic metabolism, further worsening intracellular acidosis. Blood-glucose concentrations should therefore be monitored and hyperglycaemia avoided or treated. Glucose infusions should not be used routinely after ischaemic stroke, unless specifically indicated. Hypoglycaemia must also be avoided and for patients who do require glucose, it should be given by continuous infusion, avoiding large infusions or boluses that can cause hyperglycaemia.[1]

1. Wass CT, Lanier WL. Glucose modulation of ischemic brain injury: review and clinical recommendations. *Mayo Clin Proc* 1996; **71:** 801–12.

Thiamine deficiency. Giving intravenous glucose to thiamine-deficient patients may precipitate Wernicke's encephalopathy (p.1977).[1,2]

1. Watson AJ, *et al.* Acute Wernickes encephalopathy precipitated by glucose loading. *Ir J Med Sci* 1981; **150:** 301–3.
2. Koguchi K, *et al.* Wernicke's encephalopathy after glucose infusion. *Neurology* 2004; **62:** 512.

Pharmacokinetics

Glucose is rapidly absorbed from the gastrointestinal tract. Peak plasma concentrations of glucose occur about 40 minutes after oral doses in hypoglycaemic patients. It is metabolised via pyruvic or lactic acid to carbon dioxide and water with the release of energy. All body cells are capable of oxidising glucose and it forms the principal source of energy in cellular metabolism.

Uses and Administration

Glucose, a monosaccharide, is given by mouth or by intravenous infusion in the treatment of carbohydrate and fluid depletion. It is the preferred source of carbohydrate in parenteral nutrition regimens (p.1923) and is used in oral rehydration solutions (p.1672) for the prevention and treatment of dehydration due to acute diarrhoeal diseases (p.1694).

Glucose is also used in the treatment of hypoglycaemia (see below) and is given orally in the glucose tolerance test as a diagnostic aid for diabetes mellitus (see p.431).

The way in which the strengths of glucose solutions for intravenous use are expressed varies in different countries. Both Glucose Intravenous Infusion (BP 2008) and Dextrose Injection (USP 31) may be prepared from either anhydrous glucose or glucose monohydrate. However, the potency of the BP 2008 preparation is expressed in terms of anhydrous glucose whereas that of the USP 31 is expressed in terms of glucose monohydrate. Anhydrous glucose 0.9 g is equivalent to about 1 g of glucose monohydrate. Thus, the term glucose 5% may represent, depending on origin, either 50 g/litre of anhydrous glucose (equivalent to about 55 g/litre of glucose monohydrate) or 50 g/litre of glucose monohydrate (equivalent to about 45 g/litre of anhydrous glucose). As the manner in which such preparations are referred to in the medical literature is sometimes ambiguous, it has not always been possible to state clearly in *Martindale* whether the strengths of glucose solutions mentioned relate to the anhydrous or hydrated form; however, in *Martindale*, unless otherwise specified, glucose injection is a 5% solution to distinguish it from more concentrated forms. For many practical purposes it is probably less important to know the exact way in which the strength of a given concentration is expressed than to avoid confusion between completely different strengths such as 5, 10, and 50% as the more concentrated forms are associated with particular adverse effects and precautions.

Solutions of glucose in water are iso-osmotic with blood at a concentration of anhydrous glucose 5.05% or glucose monohydrate 5.51%. Glucose solution 5% is therefore the strength often employed for fluid depletion; it may be given via a peripheral vein. Glucose solutions with a concentration greater than 5% are hyperosmotic and are generally used as a carbohydrate source; a 50% solution is often used in the treatment of severe hypoglycaemia (but see also Hypoglycaemia, below). Hyperosmotic solutions should generally be given via a central vein although the *American Hospital Formulary Service* suggests that concentrations up to 10% may be given via a large peripheral vein for short periods provided the site is alternated regularly. In the emergency treatment of hypoglycaemia it may be necessary to use a peripheral vein but the solution should be given slowly; a suggested rate for glucose 50% in such circumstances is 3 mL/minute.

The dose of glucose is variable and is dependent on individual patient requirements; serum-glucose concentrations may need to be carefully monitored. The maximum rate of glucose utilisation has been estimated to be about 500 to 800 mg/kg per hour.

Strongly hyperosmotic glucose solutions (25 to 50%) have also been given to reduce cerebrospinal pressure (p.1181) and cerebral oedema caused by delirium tremens or acute alcohol intoxication (see p.1626) although they do not appear to be widely used. Glucose solution (25 to 50%) has also been used as a sclerosing agent in the treatment of varicose veins (p.2347) and as an irritant to produce adhesive pleuritis in the management of pleural effusions and pneumothorax. Liquid glucose is used as a sweetener, binder, or granulating and coating agent in pharmaceuticals.

Ectopic pregnancy. Ectopic pregnancy is now recognised at earlier stages as a result of improved diagnostic techniques. Surgery remains the mainstay of treatment, but although conservative surgical techniques may be used in an attempt to preserve fertility, nonsurgical methods have been increasingly investigated. The best established therapy is with methotrexate (p.749), but hyperosmolar glucose solutions have also been used. Local instillation of 5 to 20 mL of glucose 50% into the gestational sac (salpingocentesis) has been described.[1] It was reported to be more effective than expectant management of early tubal pregnancy[2] but another study was stopped because of a higher failure rate with glucose than local methotrexate.[3]

3. Sadan O, *et al.* Methotrexate versus hyperosmolar glucose in the treatment of extrauterine pregnancy. *Arch Gynecol Obstet* 2001; **265:** 82–4.

Glycogen storage disease type I. Starch may be a more acceptable alternative to glucose in the control of the hypoglycaemia of type I glycogen storage disease, see p.1968.

Haemodialysis-induced cramp. Suggestions that haemodialysis-induced cramps (p.1671) are due to hypovolaemia are supported by the efficacy of volume expansion with hypertonic solutions in the management of such cramps. Intravenous infusion of 50 mL of glucose 50% solution has been used as an effective alternative to infusion of sodium chloride or mannitol.[1,2]

1. Milutinovich J, *et al.* Effect of hypertonic glucose on the muscular cramps of hemodialysis. *Ann Intern Med* 1979; **90:** 926–8.
2. Canzanello VJ, *et al.* Comparison of 50% dextrose water, 25% mannitol, and 23.5% saline for the treatment of hemodialysis-associated muscle cramps. *Trans Am Soc Artif Intern Organs* 1991; **37:** 649–52.

Hyperkalaemia. Insulin, together with glucose to prevent hypoglycaemia, is given to stimulate the cellular uptake of potassium in the emergency treatment of moderate to severe hyperkalaemia (p.1669). Usually, 50 mL of glucose 50% is given.

Hypoglycaemia. Glucose is used to correct insulin-induced hypoglycaemia, as discussed on p.447, either by mouth or by infusion of a hypertonic solution (20 or 50%). Glucose 5 or 10% may be used but larger volumes are required. Although 50% glucose solution has been generally used to correct hypoglycaemia in children, some consider that so concentrated a solution is associated with unacceptable morbidity and possible mortality, and that it should be replaced by the 10% solution for this purpose.[1] A 5 or 10% solution is used to prevent the hypoglycaemia associated with insulin infusion for the treatment of diabetic ketoacidosis, once blood-glucose concentrations have fallen below 12.5 mmol/litre (see under Diabetic Emergencies, p.435).

1. Winrow AP, *et al.* Paediatric resuscitation: don't use 50% dextrose. *BMJ* 1993; **306:** 1612.

Myocardial infarction. The value of a glucose, insulin, and potassium combination in patients with myocardial infarction has been investigated (see p.452).

Pain. Oral glucose solution or spray has been used similarly to sucrose solution (p.1970) to alleviate mild pain in neonates,[1-4] and there is some suggestion it may be more effective than topically applied local anaesthetic.[5]

Glucose solutions have been injected for prolotherapy (the local injection of irritant solutions to stimulate proliferation)[6,7] in the management of painful musculoskeletal conditions such as low back pain[7] and groin strain.[8] The value of such treatment has been disputed.

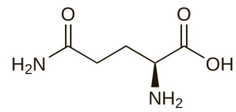
Левоглутамид

$C_5H_{10}N_2O_3$ = 146.1.
CAS — 56-85-9.
ATC — A16AA03.
ATC Vet — QA16AA03.



Pharmacopoeias. In *Ger.* and *US.*
USP 31 (Glutamine). White crystals or crystalline powder. Soluble in water; practically insoluble in alcohol and in ether. Store at a mean temperature not exceeding 25°.

Profile

Glutamic acid is a non-essential amino acid which is degraded readily in the body to form glutamine (levoglutamide). Glutamic acid and glutamine are used as dietary supplements. The dipeptides *N*(2)-L-alanyl-L-glutamine (Ala-Gln) and glycyl-L-glutamine (Gly-Gln) are used similarly.

Glutamic acid hydrochloride, which releases hydrochloric acid in the stomach, has been used in the symptomatic treatment of achlorhydria or hypochlorhydria in usual oral doses of 250 to 750 mg with meals.

A glutamine-based oral suspension is under investigation for the treatment of oral mucositis.

Antineoplastic toxicity. Vincristine neurotoxicity has been reduced by the use of oral glutamic acid (see Administration Error, p.787).

Oral supplementation with glutamine may also have a role in alleviating the diarrhoea associated with irinotecan (see Effects on the Gastrointestinal System, p.737).

A glutamine-based oral suspension is under investigation for the treatment of oral mucositis associated with cancer chemotherapy (p.640). In breast cancer patients with moderate to severe oral mucositis glutamine reduced both the incidence and severity of the mucositis.[1] A literature review[2] reported variable results with glutamine supplementation for chemotherapy-induced mucositis, but stated that higher doses may be beneficial.

Oral glutamine was found to be of no benefit in alleviating myalgias or arthralgias associated with paclitaxel therapy.[3]

Parenteral and enteral nutrition. Evidence that glutamine is involved in the regulation of muscle protein synthesis, maintenance of gut mucosal barrier function, and possibly enhanced immunological response has led to studies of supplementation with glutamine or more stable peptide derivatives in parenteral and enteral nutrition regimens for patients with injury and infection.[1] Although non-essential under normal circumstances, many consider glutamine to be a conditionally essential amino acid in patients with catabolic disease.[2,3]

Supplementation of parenteral nutrition regimens with glutamine has been shown to reduce clinical infection in patients who have undergone bone marrow transplantation[4] or who have suffered multiple trauma.[5] Improved survival has been reported among intensive-care patients given parenteral feeds supplemented with glutamine,[6,7] although a larger study found it difficult to demonstrate benefit.[8] A systematic review,[9] including these studies, inferred that seriously ill patients, with gastrointestinal failure and receiving parenteral nutrition, should receive glutamine supplements for at least 6 days and at a dose of greater than 200 mg/kg daily, in order to derive maximum benefit. Low plasma glutamine concentration upon admission to an intensive-care unit was considered to be an independent risk factor for mortality, and it has been suggested that plasma concentrations be used as an indicator for glutamine supplementation.[10]

In patients undergoing major uncomplicated surgery on the lower gastrointestinal tract, a significantly better postoperative nitrogen balance was achieved in those whose total parenteral nutrition regimen had been supplemented with about 20 g daily of glutamine coupled with alanine (L-alanyl-L-glutamine) (equivalent to about 12 g daily of glutamine) when compared with a control group.[11] Others[12] have shown that supplementation of total parenteral nutrition solutions with a glutamine dipeptide (glycyl-L-glutamine), in quantities equivalent to 230 mg/kg of glutamine daily, prevented the increased intestinal permeability and atrophic changes in the intestinal mucosa associated with unsupplemented solutions. Supplementation of total parenteral nutrition with α-ketoglutarate or a dipeptide, ornithine-α-ketoglutarate, reduced muscle protein depletion in one study,[13] suggesting that this may be a more physiological way of providing glutamine. Although recognising that clinical benefit in terms of infectious complications remained to be established, a review[14] of the use of ornithine-α-ketoglutarate stated that supplementation in the elderly improved clinical outcome in chronic malnutrition, by increasing appetite and body-weight gain and improving healing.

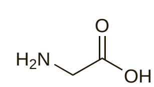
Glycine *(rINN)*

Acidum Aminoaceticum; Aminoacetic Acid; Aminoättiksyra; Aminoetikkahappo; E640 (glycine or glycine sodium); G; Glicin; Glicina; Glicinas; Glicyna; Gly; Glycin; Glycinum; Glycocoll; Glysiini; Sucre de Gélatine.

Глицин

$C_2H_5NO_2$ = 75.07.
CAS — 56-40-6.
ATC — B05CX03.
ATC Vet — QB05CX03.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US.*
Ph. Eur. 6.2 (Glycine). A white or almost white crystalline powder. It exhibits polymorphism. Freely soluble in water; very slightly soluble in alcohol. A 5% solution in water has a pH of 5.9 to 6.4.
USP 31 (Glycine). A white, odourless crystalline powder. Soluble 1 in 4 of water at 25°, 1 in 2.6 at 50°, 1 in 1.9 at 75°, and 1 in 1.5 at 100°; soluble 1 in 1254 of alcohol; very slightly soluble in ether. Its solutions are acid to litmus.

Adverse Effects and Precautions

Systemic absorption of glycine irrigation solutions can lead to disturbances of fluid and electrolyte balance and cardiovascular and pulmonary disorders (see below).

Glycine irrigation should be used cautiously in patients with hepatic impairment since any absorption and consequent metabolism may cause hyperammonaemia. The possible effects on fluid and electrolyte balance warrant cautious use in patients with cardiopulmonary or renal dysfunction; glycine irrigation is contraindicated in anuric patients.

Systemic absorption. Absorption of glycine irrigation solution during surgical procedures can cause disturbances of the circulatory and nervous systems.[1-3] Often seen after transurethral resection of the prostate, these symptoms and signs have been referred to as the transurethral resection syndrome,[1] although they have also been described after other urological or gynaecological surgical procedures.[4,5] Hyponatraemia and glycine toxicity are thought to be responsible for the clinical manifestations.[1,2,5]

Symptoms and signs include chest pains, hypertension, hypotension, bradycardia, anuria, dyspnoea, nausea, vomiting, restlessness, confusion, apprehension, irritability, headache, and seizures.[1,3-5] Chills, diarrhoea, and abdominal pain have also been reported,[1] as have visual disturbances and blindness.[3,6] Myocardial infarction,[7,8] coma, and death may occur.[5,7]

Absorption may occur rapidly, through the intravascular route, or, more rarely, slowly via extravascular absorption.[1,2,4] Extravasation should be suspected when abdominal pain and swelling are apparent.[4,9] Ethanol has been added to the irrigation fluid, and ethanol breath tests performed regularly during procedures in order to detect and monitor absorption.[1,2,4,9] However, the syndrome has still occurred despite monitoring;[9] awareness of the pattern of ethanol changes and clinical symptoms associated with extravascular as well as intravascular absorption are considered essential.[4,9]

Uses and Administration

Glycine is a non-essential aliphatic amino acid. It is used as a dietary supplement.

Glycine is sometimes used with antacids in the treatment of gastric hyperacidity. It is also used as an ingredient of some aspirin preparations with the object of reducing gastric irritation.

Sterile solutions of glycine 1.5% in water, which are hypotonic and non-conductive, are used as urogenital irrigation solutions during certain surgical procedures, particularly transurethral resection of the prostate.

Glycine hydrochloride has also been used.

Preparations

BP 2008: Glycine Irrigation Solution;
USP 31: Glycine Irrigation.

Proprietary Preparations (details are given in Part 3)

Halibut-liver Oil

Aceite de hígado de fletán; Aceite de Higado de Hipogloso; Heilbuttleberöl; Ol. Hippogloss.; Oleum Hippoglossi; Oleum Jecoris Hippoglossi.

Палтусовый Печёночный Жир

CAS — 8001-46-5.

Pharmacopoeias. In *Br.*

BP 2008 (Halibut-liver Oil). The fixed oil extracted from the fresh or suitably preserved liver of the halibut species belonging to the genus *Hippoglossus*. It contains not less than 30 000 units of vitamin A activity per g. Wt per mL 0.915 to 0.925 g. A pale to golden yellow liquid with a fishy, but not rancid, odour and taste. Practically insoluble in alcohol; miscible with chloroform, with ether and with petroleum spirit. Store in well-filled containers. Protect from light.

Profile

Halibut-liver oil is used as a means of giving vitamins A (p.1971) and D (p.1986); the proportion of vitamin A to vitamin D is usually greater in halibut-liver oil than in cod-liver oil (p.1935). It is usually given in capsules.

Preparations

BP 2008: Halibut-liver Oil Capsules.

Proprietary Preparations (details are given in Part 3)
Arg.: Pancutan Base; ***Canad.:*** Nutrol A; ***Switz.:*** Halibut.

Hetaflur *(BAN, USAN, rINN)*

Cetylamine Hydrofluoride; GA-242; Hétaflur; Hetaflurum; SKF-2208. Hexadecylamine hydrofluoride.

Гетафлур

$C_{16}H_{35}N,HF = 261.5.$

CAS — 3151-59-5.

Profile

Hetaflur is used as a source of fluoride (see Sodium Fluoride, p.1962) in the prevention of dental caries.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: *Israel:* Elmex†.

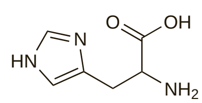
Histidine *(USAN, rINN)*

H; His; Histidiini; Histidin; Histidina; Histidinas; L-Histidine; Histidinum; Hisztidin; NSC-137773. L-2-Amino-3-(1*H*-imidazol-4-yl)propionic acid.

Гистидин

$C_6H_9N_3O_2 = 155.2.$

CAS — 71-00-1.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Histidine). Colourless crystals or a white or almost white crystalline powder. Soluble in water; very slightly soluble in alcohol. Protect from light.

USP 31 (Histidine). White, odourless crystals. Soluble in water; very slightly soluble in alcohol; insoluble in ether. pH of a 2% solution in water is between 7.0 and 8.5.

Histidine Hydrochloride

Histidiinihydrokloridimonohydraatti; Histidina, hidrocloruro; Histidine (chlorhydrate d') monohydraté; Histidine Monohydrochloride; Histidin-hydrochlorid monohydrát; Histidinhydrokloridmonohydrat; Histidini hydrochloridum monohydricum; Histidinium Chloride; Histidino hidrochloridas monohidratas; Histydyny monochlorowodorek; Hisztidin-hidroklorid-monohidrát. L-Histidine hydrochloride monohydrate.

$C_6H_9N_3O_2,HCl,H_2O = 209.6.$

CAS — 645-35-2 (anhydrous histidine hydrochloride).

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).

Ph. Eur. 6.2 (Histidine Hydrochloride Monohydrate). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; slightly soluble in alcohol. A 5% solution in water has a pH of 3.0 to 5.0. Protect from light.

Profile

Histidine is a basic amino acid that is essential for infant growth and which may be essential for some other groups, such as patients with uraemia. Histidine and histidine hydrochloride are used as dietary supplements.

Honey

Clarified Honey; Gereinigter Honig; Honung; Hunaja; Madu; Med; Medus; Mel; Mel Depuratum; Mel Despumatum; Miel; Miel Blanc; Miel purificada; Purified Honey; Strained Honey.

Мёд

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Honey; Mel). It is produced by bees (*Apis mellifera*) from the nectar of plants or from secretions of living parts of plants, which the bees collect, transform by combining with specific substances of their own, deposit, dehydrate, store, and leave in the honey comb to ripen and mature. If the bee has been exposed to treatment to prevent or cure diseases or to any substance intended for preventing, destroying, or controlling any pest, unwanted species of plants or animals, appropriate steps are taken to ensure that the levels of residues are as low as possible. It is an almost white to dark brown, viscous liquid which may be partly crystalline.

USNF 26 (Purified Honey). It is obtained by purification of honey from the comb of the bee, *A. mellifera* and all subspecies of *A. mellifera*. The honey is extracted by centrifugation, pressure, or other suitable procedures. Specific gravity 1.400 and 1.435 at 20°. Store in airtight containers. It is not intended for infants under one year of age unless it is free from *Clostridium* spp.

Profile

Honey, which contains about 70 to 80% of glucose and fructose, is used as a demulcent and sweetening agent, especially in linctuses and cough mixtures (p.1547). Preparations containing honey are used in the management of skin ulcers, wounds, and burns.

Contamination. Honey has been identified as a source of *Clostridium botulinum* spores and thus recommendations have been made that honey should not be given to infants under 1 year because of the risk of causing infant botulism.[1,2]

Honey produced from certain species of *Rhododendron* plants has been found to contain grayanotoxins. Grayanotoxin I is responsible for honey poisoning, manifest as bradycardia, cardiac arrhythmias, hypotension, gastrointestinal disturbances, dizziness, loss of consciousness, blurred vision, chills, cyanosis, sweating, and salivation.[3,4] Convulsions have also been reported.[4]

4. Dilber E, *et al.* A case of mad honey poisoning presenting with convulsion: intoxication instead of alternative therapy. *Turk J Med Sci* 2002; **32:** 361–2.

Wounds. Anecdotal reports and traditional usage dating back to ancient Egypt suggest that honey may be of some value as a wound dressing (p.1585). Its antibacterial properties are attributed both to high osmolality and the liberation of hydrogen peroxide, but may vary with the source:[1-4] in Europe, some of the best activity has been seen with lime-flower honey.[2] Sterilised manuka honey (p.2337) was reported to heal a leg ulcer infected with meticillin-resistant *Staphylococcus aureus*,[5] although a randomised open-label study found no evidence that dressings impregnated with manuka honey improved the healing of venous leg ulcers at 12 weeks compared with usual care.[6] In a preliminary study, honey obtained from the tea plant (see Xanthine-containing Beverages, p.2415) significantly reduced the incidence of grade 3 and 4 radiation-induced oral mucositis.[7]

A group from India[8] has reported that the properties of honey offer a potentially simple and cheap means of preserving skin grafts in developing countries, with 100% uptake of reconstituted grafts stored for up to 6 weeks and 80% uptake of those stored for 7 to 12 weeks. In comparison with sulfadiazine silver, occlusive honey dressings were also found to be more effective for the treatment of superficial partial thickness thermal burns.[9]

However, concern has been expressed since honey may contain not only chemical contaminants but clostridial spores (see also above), and it has been suggested[2] that to be medically acceptable, honey must be sterile, residue-free, and of measured antibacterial activity.

Sugar has been used similarly to honey in treating wounds (see p.1970).

Invert Sugar

Azúcar invertido.

CAS — 8013-17-0.

ATC — C05BB03.

ATC Vet — QC05BB03.

Pharmacopoeias. *Br.* and *US* include preparations of invert sugar.

Profile

Invert sugar is an equimolecular mixture of glucose and fructose which may be prepared by the hydrolysis of sucrose with a suitable mineral acid such as hydrochloric acid. Invert sugar has similar actions and uses to those of glucose (p.1945) and fructose (p.1945). It has been used as a 10% solution as an alternative to glucose in parenteral nutrition but, as with fructose, such use cannot be recommended.

A syrup of invert sugar is used as a stabilising agent; when mixed with suitable proportions of sucrose-based syrup it will help to prevent crystallisation of the sucrose.

Preparations

BP 2008: Invert Syrup;
USP 31: Invert Sugar Injection; Multiple Electrolytes and Invert Sugar Injection Type 1; Multiple Electrolytes and Invert Sugar Injection Type 2; Multiple Electrolytes and Invert Sugar Injection Type 3.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***S.Afr.:*** Emex; ***USA:*** Travert.

Iron

Eisen; Fer; Ferro; Ferrum; Hierro; Ijzer; Järn; Rauta; Żelazo; Železo.

Fe = 55.845.

CAS — 7439-89-6.

Pharmacopoeias. *Eur.* (see p.vii) includes a form for homoeopathic preparations.

Ph. Eur. 6.2 (Iron for Homoeopathic Preparations; Ferrum ad Praeparationes Homoeopathicae). A fine, blackish-grey powder, without metallic lustre, obtained by reduction or sublimation. Practically insoluble in water and in alcohol; it dissolves with heating in dilute mineral acids.

Adverse Effects

The astringent action of **oral** iron preparations sometimes produces gastrointestinal irritation and abdominal pain with nausea and vomiting. These irritant adverse effects are usually related to the amount of elemental iron taken rather than the type of preparation. Other gastrointestinal effects may include either diarrhoea or constipation. Adverse effects can be reduced by giving it with or after food (rather than on an empty stomach) or by beginning therapy with a small dose and increasing gradually. Modified-release products are claimed to produce fewer adverse effects but this may only reflect the lower availability of iron from these preparations. Oral liquid preparations containing iron salts may blacken the teeth and should be drunk through a straw. The faeces of patients taking iron salts may be coloured black.

The adverse effects associated with iron given **parenterally** are described under iron dextran (see p.1951).

Since absorbed iron is conserved by the body, **iron overload**, with increased storage of iron in various tissues (haemosiderosis), may occur as a result of excessive or mistaken therapy, especially parenteral therapy. Patients with pre-existing iron storage or absorption diseases are also at risk.

Acute iron **overdosage** can be divided into four stages.

- In the first phase, which occurs up to 6 hours after oral ingestion, gastrointestinal toxicity, notably vomiting and diarrhoea, predominates. Other effects may include cardiovascular disorders such as hypotension, metabolic changes including acidosis and hyperglycaemia, and CNS depression ranging from lethargy to coma. Patients with only mild to moderate poisoning do not generally progress past this first phase.
- The second phase, which is not always seen, may occur at 6 to 24 hours after ingestion and is characterised by a temporary remission or clinical stabilisation.
- In the third phase, 12 to 48 hours after ingestion, gastrointestinal toxicity recurs together with shock, metabolic acidosis, severe lethargy or coma, hepatic necrosis and jaundice, hypoglycaemia, coagulation disorders, oliguria or renal failure, and possible myocardial dysfunction.
- The fourth phase may occur several weeks after ingestion and is characterised by gastrointestinal obstruction and possibly late hepatic damage.

Relatively small amounts of iron may produce symptoms of toxicity. It has been stated that more than the equivalent of 20 mg/kg of iron could lead to some symptoms of toxicity and that in a young child the equivalent of about 60 mg/kg of iron should be regarded as extremely dangerous. Estimates of acute lethal dosages have ranged from the equivalent of 150 mg/kg of iron upwards. Serum-iron concentrations have also been used as an indication of the severity of overdosage: a peak concentration of 5 micrograms/mL or more is reportedly associated with severe poisoning in many patients.

Effects on the cardiovascular system. For a suggestion that iron overload may contribute to ischaemic heart disease, see Effects in Non-deficient Subjects, below.

Effects on growth. Iron supplementation in iron-replete children has been reported to adversely affect their growth—see Effects in Non-deficient Subjects, below.

Iron overload. Because the body lacks a mechanism for the excretion of excess iron, abnormally high absorption or repeated blood transfusion will result in iron overload (p.1442), leading eventually to haemochromatosis. The consequences of haemochromatosis include pigment deposition in skin and other organs, mild liver dysfunction, endocrine dysfunction (failure of the adolescent growth spurt, hypogonadism, sometimes diabetes and hypothyroidism), and heart disease (pericarditis, heart failure, and arrhythmias). If unchecked, the iron build-up can lead to death, mainly through heart failure or arrhythmia. Where iron overload is due to increased absorption, phlebotomy is the treatment of choice; however, if phlebotomy is not tolerated or in patients who are transfusion-dependent (as in β-thalassaemia—see p.1045) treatment with iron chelators such as desferrioxamine is used to retard accumulation.

Treatment of Adverse Effects

In treating acute iron poisoning, speed is essential to reduce absorption of iron from the gastrointestinal tract. Activated charcoal is ineffective, but gastric lavage should be considered in those who have ingested the equivalent of more than 60 mg/kg of elemental iron within 1 hour of presentation. Serum-iron concentrations may be an aid to estimating the severity of poisoning. Although these do not correlate well with symptoms, the UK Poisons Information Service considers that concentrations taken about 4 hours after ingestion generally indicate the severity of poisoning as follows:

- less than 3 micrograms/mL, mild poisoning
- 3 to 5 micrograms/mL, moderate poisoning
- 5 micrograms/mL or more, severe poisoning

In patients with moderate poisoning, or severe asymptomatic poisoning, the measurement should be repeated after a further 2 hours, and chelation therapy with desferrioxamine (p.1441) should be considered if the concentration is rising. In patients with severe symptomatic poisoning, chelation therapy should be considered straight away.

Other measures include the symptomatic management and therapy of metabolic and cardiovascular disorders.

Overdosage in pregnancy. Limited data on the treatment of iron overdose in pregnancy from the UK National Teratology Information Service, suggested that treatment with desferrioxamine should not be withheld if clinically indicated.[1-3] Most pregnancies had a normal outcome. A literature review[4] of iron overdose in pregnant women found that women with peak serum-iron concentrations greater than or equal to 4 micrograms/mL were more frequently symptomatic, but that there was no relationship between peak iron level and frequency of spontaneous abortion, preterm delivery, congenital anomalies, or perinatal or maternal death. However, women with stage 3 iron toxicity, defined as those manifesting with hepatic, renal, or cardiac failure, were more likely to spontaneously abort, deliver preterm, or die.

Precautions

Iron compounds should not be given to patients receiving repeated blood transfusions or to patients with anaemias not produced by iron deficiency unless iron deficiency is also present. Oral and parenteral iron therapy should not be used together. Care should be taken in patients with iron-storage or iron-absorption diseases such as haemochromatosis, haemoglobinopathies, or existing gastrointestinal diseases such as inflammatory bowel disease, intestinal strictures and diverticulae.

Liquid preparations containing iron salts should be well diluted with water and swallowed through a straw to prevent discoloration of the teeth.

Effects in non-deficient subjects. There has been concern about the potential consequences of iron supplementation in individuals and groups who are not actually iron-deficient. Apart from the suggestion that certain populations may be at somewhat increased risk of microbial *infection* after supplementation (see Infections, below), there is some evidence that supplementation in children without iron deficiency may *retard their growth*.[1,2] It has also been proposed that iron may be associated with *ischaemic heart disease*, by modifying low-density lipoprotein in ways which increase its atherogenic potential and by sensitising the myocardium to ischaemic injury.[3,4] However, conclusions of a cohort study[5] and a systematic review[6] did not support any correlation between iron status and coronary heart disease. There is some suggestion that an excess of iron may be *carcinogenic*;[7,8] conclusive studies are lacking.

INFECTIONS. Iron is not only an essential element for humans but is also essential for many micro-organisms. Thus, it has been suggested that persons with either adequate iron stores or iron overload may provide optimum conditions for microbial growth and therefore be susceptible to an increased incidence and severity of infection; conversely, iron-deficiency anaemia may offer some protection against infections. The topic has been reviewed[1,2] and although there is no evidence that small amounts of iron supplements or iron-fortified food in normal people will render them more prone to infection[3] there is some evidence that in populations with a high prevalence of endemic infectious disease such as malaria, iron therapy may be followed by a higher incidence of infectious complications or by a flare-up of existing low-grade disease. Therefore, the routine use of iron supplements in such communities has been questioned,[4,5] although an increasing number of studies failed to demonstrate a detrimental effect.[6-10] A subsequent systematic review[11] concluded that, while iron supplementation slightly increases the risk of developing diarrhoea, it has no apparent harmful effect on the overall incidence of infectious illnesses in children. More recently, a controlled study found that supplementation with iron and folic acid increased the risk of severe illness and death in pre-school children in a population with high rates of malaria. The authors concluded that, while iron-deficient children can benefit from supplementation in the presence of active prophylaxis and treatment of malaria, supplementation in non-deficient subjects might be harmful.[12] Data conflict on the association between parenteral iron and infection in dialysis patients; some consider that treatment with parenteral iron should be avoided during active infection.[13,14]

Interference with diagnostic tests. Although studies *in vitro* found that iron (ferrous sulfate) caused a false-positive result in the Hemoccult test for blood in faeces, this did not occur *in vivo* in persons receiving oral iron therapy.[1-3] An explanation for the difference in these findings was that hydrogen peroxide in the Hemoccult developer converted ferrous ions in solution to ferric ions, which caused oxidation in the test, whereas *in vivo* the iron was probably eliminated in the faeces in the form of non-reactive insoluble iron precipitates.[2]

Porphyria. Erythropoietic protoporphyria was exacerbated by oral iron therapy in 4 patients;[1] a further patient had a variable reaction to iron, being able to tolerate it on some occasions but suffering from exacerbation of porphyria on others.[2] Intravenous iron precipitated porphyria cutanea tarda in one patient on haemodialysis.[3]

Interactions

Iron salts are not well absorbed by mouth, and food may further impair their absorption.

Compounds containing calcium and magnesium, including antacids and mineral supplements, and bicarbonates, carbonates, oxalates, or phosphates, may impair the absorption of iron by the formation of insoluble complexes. Zinc salts may also decrease the absorption of iron. The absorption of both iron salts and tetracyclines is diminished when taken together orally. If treatment with both drugs is required, a time interval of about 2 to 3 hours should be allowed between them. A suitable interval is also advised if an iron supplement is needed in patients given trientine. Iron is chelated by acetohydroxamic acid, reducing the absorption of both. Iron should not be given with dimercaprol as toxic complexes may form.

The response to iron may be delayed in patients receiving systemic chloramphenicol.

Some agents, such as ascorbic acid and citric acid, may actually increase the absorption of iron.

In addition to those already mentioned, iron salts can also decrease the absorption of other drugs and thus reduce their bioavailability and clinical effect. Drugs so affected include cefdinir, bisphosphonates, entacapone, fluoroquinolones, levodopa, methyldopa, mycophenolate mofetil, and penicillamine. Iron salts may reduce the efficacy of levothyroxine (p.2173).

Interactions with parenteral iron are mentioned under Iron Dextran, p.1952.

Pharmacokinetics

Iron is irregularly and incompletely absorbed from the gastrointestinal tract, the main sites of absorption being the duodenum and jejunum. Absorption is aided by the acid secretion of the stomach and by some dietary acids (such as ascorbic acid) and occurs more readily when the iron is in the ferrous state or is part of the haem complex (haem-iron). Absorption is also increased in conditions of iron deficiency or in the fasting state but is decreased if the body stores are overloaded. Normally only about 5 to 15% of the iron ingested in food is absorbed.

Most absorbed iron is bound to transferrin and transported to the bone marrow where it is incorporated into haemoglobin; the remainder is contained within the storage forms, ferritin (p.1938) or haemosiderin, or as myoglobin, with smaller amounts occurring in haem-containing enzymes or in plasma bound to transferrin.

Only very small amounts of iron are excreted as the majority released after the destruction of the haemoglobin molecule is re-used. This conservation of body iron, and lack of an excretory mechanism for excess iron, is the reason for the development of iron overload with excessive iron therapy or repeated transfusions.

Human Requirements

The body contains about 4 g of iron most of which is present as haemoglobin.

Apart from haemorrhage, iron is mainly lost from the body in the faeces, urine, from skin, and sweat, but the total loss is very small. Iron is also lost in small amounts in breast milk and in menstrual blood. In healthy men and postmenopausal women the loss is replaced by the absorption of about 1 mg of iron daily; about 1.5 to 2 mg needs to be absorbed daily by premenopausal women. In childhood and adolescence, the need is proportionately greater because of growth. Iron absorption is variable but is usually between 5 and 15% and therefore a dietary allowance containing the equivalent of about 10 mg of iron daily is usually sufficient for men and postmenopausal women; up to 15 mg daily may be necessary for premenopausal women with normal menstrual blood losses; some authorities recommend higher amounts or supplements during pregnancy. For further details concerning dietary requirements, see below and for a discussion of prophylactic iron given during pregnancy, see Iron-deficiency Anaemia, under Uses and Administration, below.

Good dietary sources of haem-iron are animal products such as meat and fish; non-haem-iron is also found in animal products and in vegetable products such as legumes and some leafy vegetables, but some vegetable products with a high iron content also contain phosphates or phytates which inhibit absorption by the formation of unabsorbable complexes.

UK and US recommended dietary intake. In the UK, dietary reference values (DRV)[1] and in the USA, recommended dietary allowances (RDA)[2] have been published for iron.

In the UK the estimated average requirement (EAR) for adult males and postmenopausal females is 6.7 mg daily and the reference nutrient intake (RNI) is 8.7 mg daily; for premenopausal females, but without heavy menstrual blood losses, the EAR and RNI are 11.4 and 14.8 mg daily respectively. Amounts for infants, children, and adolescents, which are proportionately higher than those for adults, are also given. No increase is considered necessary during pregnancy or lactation.[1]

In the USA the RDA for adult males and postmenopausal females is 8 mg daily and that for premenopausal women is 18 mg. The tolerable upper intake level is 45 mg daily. Amounts for infants, children, and adolescents, again proportionately higher than for adults, are also provided. The RDA for pregnant women is 27 mg daily. An RDA of 9 mg for lactating adult women has been estimated from the EAR of non-menstruating women plus the average iron content of human milk.[2]

The Food and Agriculture Organization of the United Nations and the WHO have together published guidelines concerning iron requirements and these take into account many factors including bioavailability of iron in the diet.[3]

For the definitions of DRV, EAR, RNI, and RDA, see under Vitamins, p.1925.

Uses and Administration

Iron is an essential constituent of the body, being necessary for haemoglobin formation and for the oxidative processes of living tissues. Iron deficiency results in defective erythropoiesis and anaemia. Iron and iron salts should only be given for the treatment or prophylaxis of iron-deficiency anaemias (see below). They should not be given for the treatment of other types of anaemia except where iron deficiency is also present. Iron-deficiency anaemias respond readily to iron therapy but the underlying cause of the anaemia should be determined and treated.

The preferred route for giving iron is oral, usually as soluble ferrous salts which are better absorbed than ferric salts. The usual adult dose for the treatment of iron-deficiency anaemia is 100 to 200 mg of iron daily in divided doses. The usual adult prophylactic dose is about 60 to 120 mg of iron daily. There are various recommendations for children's doses and up to 2 mg/kg of iron three times daily for treatment, and 1 to 2 mg/kg daily for prophylaxis of iron-deficiency anaemia (usually to a maximum of 30 mg) has been used. Therapy is generally continued until haemoglobin concentrations reach normal values, which may take some weeks, and then for a further 3 months or more to restore body-iron stores.

Further information concerning the dosage of iron salts and compounds used is provided in the individual monographs; this information, however, tends to reflect the amounts of iron contained in different salts or available commercial preparations and therefore, in some instances, may not be within the general range of iron dosages as quoted above.

The iron content of various iron salts is tabulated in Table 1, below.

Modified-release dosage forms of iron are claimed to result in reduced gastrointestinal adverse effects and have the advantage of once-daily dosage. The preparations are designed to release the iron gradually along the gut but in some instances the iron may not be released until the preparation reaches a part of the gut where absorption is poor thus resulting in sub-optimal dosing.

Iron can also be given parenterally in circumstances where oral therapy cannot be undertaken and such use is typified by iron dextran (see p.1951).

Administration in the elderly. Patients over 80 years of age with iron-deficiency anaemia (below) were randomised to elemental iron therapy in daily doses of 15 mg, 50 mg (as liquid ferrous gluconate), or 150 mg (as tablets of calcium ferrous citrate) and treated for 2 months.[1] Serum haemoglobin and ferritin concentrations increased significantly in all patients, without significant differences between the 3 doses. The authors concluded that, while these results may not apply to patients with iron deficiency due to malabsorption, chronic disease, or untreated *Helicobacter pylori* infection, low-dose therapy is an effective option for elderly patients with iron-deficiency anaemia, in whom the adverse effects of iron could cause considerable morbidity and impaired compliance. Younger patients could also probably be treated effectively with low-dose iron therapy.

1. Rimon E, *et al.* Are we giving too much iron? Low-dose iron therapy is effective in octogenarians. *Am J Med* 2005; **118:** 1142–7.

Anoxic seizures. Reductions in the frequency of breath-holding episodes in children treated with iron,[1] and especially in those with iron-deficiency anaemia,[2,3] suggest that there might be a relationship between anoxic seizures (p.1221) and iron deficiency.[4]

4. Hannon DW. Breath-holding spells: waiting to inhale, waiting for systole, or waiting for iron therapy? *J Pediatr* 1997; **130:** 510–12.

Cough. In a small study[1] of 19 patients, iron supplementation with ferrous sulfate successfully reduced the cough associated with ACE inhibitors (see p.1194). The authors hypothesised that this effect was due to the inhibition by iron of nitric oxide synthase. However, there are some concerns[2] about the effect of giving a nitric oxide synthase inhibitor to hypertensive patients, as it has been found to increase blood pressure in *animal* studies.

Iron-deficiency anaemia. The iron content of the body is normally kept constant by regulation of the amount absorbed to balance the amount lost. If loss is increased, and/or intake inadequate, a negative iron-balance may lead by degrees to depletion of body iron stores, iron deficiency, and eventually to anaemia. Iron requirements are increased during infancy, puberty, pregnancy, and during menstruation, and iron-deficiency anaemias are most common in women and children; the most common cause in adult males and postmenopausal women is blood loss, usually from the gastrointestinal tract.

Iron deficiency usually results in a microcytic, hypochromic anaemia, but the diagnosis of iron deficiency should be confirmed, if there is any doubt, by measurement of serum ferritin, erythrocyte protoporphyrin, or total iron binding capacity (transferrin). Iron therapy can begin once deficiency is confirmed, but the underlying cause of the deficiency should still be sought and treated.

Treatment. The prevention and control of iron-deficiency anaemias has been reviewed.[1-4] Almost all iron-deficiency anaemias respond readily to treatment with iron. The treatment of choice is an oral ferrous salt (ferrous iron is better absorbed than ferric iron).[1] Many iron compounds have been used for this purpose, but do not offer any real advantage over the simple ferrous fumarate, gluconate, or sulfate salts. The usual adult dose is sufficient of these salts to supply about 100 to 200 mg of elemental iron daily (for the elemental iron content of various iron salts, see above), with the aim of increasing haemoglobin concentrations by about 1 g/litre daily or about 20 g/litre every 3 weeks.[1] Haemoglobin response is greatest in the first few weeks of therapy and is proportional to the severity of the original anaemia. Once haemoglobin concentrations have risen to the normal range, iron therapy should be continued for a further 3 months to aid replenishment of iron stores.[1,3] For the view that low-dose iron therapy may be as effective as higher doses, see Administration in the Elderly, above.

Oral iron has been given with agents such as ascorbic acid to enhance iron absorption, and modified-release preparations have been used in patients intolerant of ordinary formulations of iron but the *BNF* considers them to have no therapeutic advantage.

Failure to respond to oral iron after about 3 weeks of therapy may be indicative of non-compliance, continued blood loss with inadequate replacement of iron, malabsorption, wrong diagnosis, or other complicating factors, and the treatment should be reassessed.

Parenteral iron therapy is rarely indicated, may produce severe adverse effects, and should be reserved for patients who are genuinely intolerant of oral iron, persistently non-compliant,[3] who have gastrointestinal disorders exacerbated by oral iron therapy, continuing blood loss too severe for oral treatment to provide sufficient iron, or for those unable to absorb iron adequately from the gastrointestinal tract. Patients with chronic renal failure on haemodialysis (and some on peritoneal dialysis) require regular iron. US guidelines[5] suggest that intravenous use is preferred in haemodialysis patients, but that iron may be given either intravenously or orally in predialysis and peritoneal dialysis patients. The most common parenteral forms are iron dextran, iron sorbitol, iron sucrose, and sodium ferric gluconate complex.

Exceptionally, in patients with profound anaemia, blood transfusion may be necessary to restore dangerously low concentrations of haemoglobin. This may be the case, for example, in cases of worsening angina or severe coexisting pulmonary disease.[1] However, transfusion should always be avoided if possible.

Prophylaxis. Prophylaxis may be desirable in some groups at risk of iron deficiency and consequent anaemia, and may include therapy with oral iron supplements, measures to improve dietary iron intake, fortification of food staples, or control of infection. For the possible problems associated with iron supplementation in those who are not deficient, see Effects in Non-deficient Subjects, under Precautions, above.

WHO[2] recommends that universal supplementation of iron and folic acid should be implemented for pregnant women, starting as soon as possible after gestation starts and continuing for the rest of the pregnancy. WHO also recommends that where anaemia prevalence is above 40%, women of child-bearing age and lactating women should be given 3 months of iron and folic acid supplementation. However, the US Preventive Services Task Force has reviewed the subject of iron supplementation during pregnancy,[6] and concluded that there was insufficient evidence for or against routine supplementation.[7]

Iron supplementation is accepted in menorrhagia, after gastrectomy, and in the management of low birth-weight infants such as the premature. Iron deficiency in infants and children may result in developmental delay or impairment of cognitive function.[2] Breast feeding should be encouraged during the first year of life.[1] WHO has suggested[2] that low birth-weight infants be given universal supplementation. Where the diet does not include foods fortified with iron or where anaemia prevalence is above 40%, iron supplementation should be given to all children between 6 and 23 months of age; for children aged 24 months and above, a 3-month course of iron supplementation should be given where the anaemia prevalence is above 40%.

The usual prophylactic dose in adults suggested by WHO is about 60 mg of elemental iron daily. Doses of about 2 mg/kg of elemental iron daily (up to 30 mg) have been suggested for prophylaxis in children (see also Uses and Administration, above).

Dietary measures, such as addition of vitamin-C-rich foods, or other enhancers of iron absorption including iron in the form of haem (found in meat or fish) to the diet, control of parasitic infections such as hookworm (which are responsible for considerable occult blood loss), and malaria prophylaxis are particularly important for the general community in developing countries. Fortification of food staples poses technical problems as iron salts react with food components and may produce rancidity or other undesirable changes on storage. Nonetheless, wheat or maize flour, rice, and milk products have been fortified in some countries, and consideration has also been given to fortification of salt or sugar.

Restless legs syndrome. Iron deficiency is present in about a quarter of people with restless legs syndrome (see Sleep-associated Movement Disorders, p.958), particularly older people, and serum ferritin concentrations are inversely correlated with the severity of symptoms. Iron may have a role in the pathophysiology of the disorder, and treatment of iron deficiency may reduce symptoms.[1]

Iron Dextran

Demir Dekstran; Hierro dextrano; Iron-Dextran Complex.
CAS — 9004-66-4.
ATC Vet — QB03AB90; QB03AC90.

Pharmacopoeias. *Br., Chin.,* and *US* include injections.
BP 2008 (Iron Dextran Injection). A sterile colloidal solution containing a complex of ferric hydroxide and dextrans of weight average molecular weight between 5000 and 7000. It contains 4.75 to 5.25% of iron and 17.0 to 23.0% of dextrans. pH 5.2 to 6.5.
USP 31 (Iron Dextran Injection). A sterile colloidal solution of ferric hydroxide in complex with partially hydrolysed dextran of low molecular weight. It may contain not more than 0.5% of phenol as a preservative. pH 5.2 to 6.5.

Adverse Effects and Treatment

Severe anaphylactoid reactions may occur with iron dextran and fatalities have been reported. It is therefore recommended that it be given where there are facilities for the emergency treatment of such reactions, that certain precautions be observed, and that test doses be used (see Precautions, below).

Rapid intravenous use may be associated with vascular flushing and hypotension. Thrombophlebitis may occur at the site of injection, although the incidence can be reduced by giving iron dextran in sodium chloride 0.9% rather than glucose 5%. Intramuscular injection is associated with local reactions, pain, and staining at the site of injection; leakage along the injection track may occur unless the proper technique is used (see Uses and Administration, below). Cardiovascular effects such as chest pain or tightness, shock, myocardial infarction, hypertension, tachycardia, bradycardia, and arrhythmias may occur with either route. Rashes, urticaria, purpura, and pruritus have been reported. Other reactions include gastrointestinal disturbances, haematuria, dyspnoea, and taste disturbance.

Patients may also experience delayed reactions 1 to 2 days after injection of iron dextran, such as backache, arthralgia, myalgia, lymphadenopathy, chills, fever, paraesthesia, dizziness, malaise, headache, nausea, and vomiting.

Overdose of parenteral iron is unlikely to be associated with any acute manifestations. Unwarranted parenteral iron therapy will result in iron overload and excess storage of iron (haemochromatosis) in the long term. The consequences of this include liver and endocrine dysfunction and heart disease (see Iron Overload, p.1949), and possibly an increased risk of infection (see Infections, under Precautions for Iron, p.1950). Iron overload may require chelation therapy with desferrioxamine (p.1441).

Intramuscular injection of iron complexes such as iron dextran has resulted in sarcomas at the injection site in *animals*. There is some evidence that this may occur in humans.

Effects on the blood. A 1-year-old girl with Down's syndrome and iron-deficiency anaemia was given three intramuscular injections of iron dextran over 6 days (to a total of 30 mg/kg). Pancytopenia developed subsequently, which reappeared when challenged with iron dextran. Tests indicated an allergic pathogenesis for the pancytopenia.[1] For further discussion of hypersensitivity reactions to iron dextran, see under Hypersensitivity, below.

Thrombocytopenia has also been reported after iron dextran[2] and iron sucrose[3] therapy.

1. Hurvitz H, *et al.* Pancytopenia caused by iron-dextran. *Arch Dis Child* 1986; **61:** 194–6.
2. Go RS, *et al.* Thrombocytopenia after iron dextran administration in a patient with severe iron deficiency anemia. *Ann Intern Med* 2000; **132:** 925.
3. Taskapan H, *et al.* Transient severe thrombocytopenia in a patient on CAPD after intravenous iron administration. *Perit Dial Int* 2003; **23:** 408–9.

Hypersensitivity. The Boston Collaborative Drug Surveillance Program monitored consecutively 32 812 medical inpatients. Drug-induced anaphylaxis occurred in 1 of 169 patients given iron dextran (route not stated).[1] An investigation of 481 persons given a total of 2099 intravenous injections of iron dextran found 3 life-threatening immediate anaphylactoid reactions; 8 severe delayed reactions were also observed, and many reactions of a less serious nature.[2] In a more recent series,[3] 10 of 573 patients had anaphylactoid reactions after intravenous iron dextran. Other serious reactions included 1 case of cardiac arrest, and 3 cases of dyspnoea, hypertension, or chest pain.

Test doses are recommended before giving a full therapeutic dose (see Uses and Administration, below) and emergency measures for the treatment of allergic reactions should be available. A desensitisation protocol has been used successfully in a patient who reacted to the test dose[4] and in a patient with a previous life-threatening reaction to iron infusion;[5] methylprednisolone 50 mg was given intravenously at 13 hours, 7 hours, and 1 hour before iron dextran, and diphenhydramine 50 mg and ephedrine 25 mg were given intramuscularly 1 hour before infusion. Dextran 1 (p.1058) was given just before the iron dextran infusion. Approximately 2 g of iron was then given over a period of about 4 days.

It is not clear whether hypersensitivity to iron dextran is due to the dextran or the iron component.[6-8] When compared with lower molecular-weight iron dextran, a higher molecular-weight iron dextran was reported to be associated with significantly higher rates of adverse reactions,[7,9,10] including fatalities and anaphylactoid reactions;[9] some have called for the use of high-molecular-weight iron dextran to be abandoned.[11] Reviews[6,8,12] suggest that parenteral dextran-free iron compounds such as iron sucrose or sodium ferric gluconate complex may be safer alternatives to iron dextran. Iron sucrose has been reported to be well tolerated in patients previously intolerant to iron dextran, sodium ferric gluconate complex, or both.[13] However, adverse reactions have still been reported in patients treated with dextran-free preparations,[8,14] and some have challenged the view that they are safer than iron dextran.[15,16]

In a report of a lupus-like disorder associated with use of iron dextran,[17] the illness resolved with appropriate treatment but recurred on rechallenge.

For discussion of pancytopenia believed to have an underlying allergic pathogenesis, see Effects on the Blood, above.

Overdosage. A 29-year-old woman was given 32 mL iron dextran (*Imferon*) intravenously. Twenty-four hours later she developed muscle cramps, bilateral frontal headaches, with subsequent neck stiffness, and marked opisthotonia with photophobia.[1] The haemoglobin concentration did not rise after the infusion of iron which indicated there had been no iron deficiency. Thus, abnormally high concentrations of free iron had followed the iron therapy and this free iron was able to cross into the CSF and was responsible for the meningitic symptoms.

1. Shuttleworth D, *et al.* Meningism due to intravenous iron dextran. *Lancet* 1983; **ii:** 453.

Precautions

Iron dextran is contra-indicated in patients with severe liver damage or acute kidney infection. It is also contra-indicated in persons with a history of hypersensitivity to the preparation. Teratogenicity has been demonstrated in non-anaemic *animals* given the equivalent of about three times the maximum human dose and its use should be avoided in pregnancy if possible.

Additionally, iron dextran should be given with caution to patients with a history of allergic disorders or asthma and in these patients the intramuscular, and not the intravenous, route should be used. Patients with rheumatoid arthritis may develop worsening of symptoms when given iron dextran intravenously. Patients with other inflammatory disorders may be at increased risk of delayed reactions. Large doses of iron dextran by infusion may lead to serum discoloration; this should not be mistaken as evidence of haemolysis. Oral iron salts should be stopped before giving parenteral iron.

A test dose should be given before a full therapeutic dose is given (see Uses and Administration, below) and emergency measures for the treatment of allergic reactions should be available (see Anaphylaxis and Anaphylactic Shock, p.1205). Patients should be kept under observation for at least 1 hour after a test dose or after intravenous doses.

Iron dextran formulated with phenol as a preservative is intended to be given by the intramuscular route only.

Interactions

As for Iron, p.1950.

Enalapril. Enalapril may possibly potentiate the adverse systemic reactions seen with intravenous iron therapy.[1]

1. Rolla G, *et al.* Systemic reactions to intravenous iron therapy in patients receiving angiotensin-converting enzyme inhibitor. *J Allergy Clin Immunol* 1994; **93:** 1074–5.

Pharmacokinetics

After intramuscular injection iron dextran is absorbed primarily through the lymphatic system: most is absorbed after 3 days and the remainder over 3 to 4 weeks. A variable portion may become fixed in the muscle for several weeks or months. After intravenous infusion, iron dextran is taken up by the cells of the reticuloendothelial cells, particularly in the liver and spleen. The reticuloendothelial cells gradually separate iron from the iron-dextran complex; the distribution and elimination of iron is described on p.1950.

Uses and Administration

Iron dextran is given by injection, and should be used only in the treatment of proven iron-deficiency anaemia (p.1951) where oral therapy is ineffective or impracticable.

For iron-deficiency anaemia, total dosage is **calculated** according to the haemoglobin concentration and body-weight of the patient; allowance is also made for additional iron to replenish iron stores. Iron dextran injection is usually supplied with a table from which the recommended dose can be obtained for patients of different weights and haemoglobin (Hb) status. There may be variations between countries in the doses obtained from such tables. Doses can also be calculated from various formulae. A typical formula used for a preparation containing the equivalent of 50 mg/mL of iron is:

$$\text{Dose in mL} = \{0.0442 \times \text{body-weight (kg)} \times [\text{desired Hb level (g/100 mL)} - \text{measured Hb level}]\} + (0.26 \times \text{body-weight})$$

In adults, the calculated lean body-weight should normally be used in this formula rather than the actual body-weight. Note that doses obtained from tables or the above formulae are for iron-deficiency anaemia, and are not suitable for iron replacement for simple blood loss.

Before starting therapy, all patients should receive a **test** dose via the intended route, and should be observed for adverse reactions (see Precautions, above).

The total dose requirement may be given as a series of **intramuscular** injections daily or once or twice weekly. It is given by deep intramuscular injection into the upper outer quadrant of the buttock; to prevent leakage along the injection track, the subcutaneous tissue is drawn to one side before the needle is inserted. Before the first therapeutic dose, a test dose should be given and the patient observed for at least 1 hour: a dose of 0.2 mL (10 mg) has been suggested for children weighing less than 10 kg, 0.3 mL (15 mg) for those weighing 10 to 20 kg, and 0.5 mL (25 mg) for adults. A suggested daily maximum dosage for children is: less than 5 kg, up to 0.5 mL (25 mg); 5 to 9 kg, up to 1 mL (50 mg). Larger children and adults normally receive 2 mL (100 mg).

Iron dextran is also given **intravenously** either by total-dose infusion (TDI) or as divided injections. A test dose of 25 mg is given before the first therapeutic dose and the patient is observed for at least 1 hour; if no adverse reactions occur within that time, the remainder of the initial dose may be given. For subsequent doses, the first portion of the dose is given more slowly than the remainder of the dose, during which time the patient is observed for adverse reactions; recommendations for the rate at which this is done may vary in different countries.

In total-dose infusion, the total dose calculated according to the haemoglobin concentration (as outlined above) is given by slow intravenous infusion in about 500 mL of sodium chloride 0.9% or glucose 5%; sodium chloride may be preferable because of the reduced incidence of thrombophlebitis. The first 25 mg of iron should be infused over 15 minutes, and if no adverse reaction has occurred during this time the rate of infusion may be increased progressively to 45 to 60 drops/minute; the infusion usually takes 4 to 6 hours.

For divided intravenous use, the total dose is also calculated according to the haemoglobin concentration. In the UK, the usual recommended dosage schedule is 100 to 200 mg of iron given 2 to 3 times weekly until the total dose has been given. It may be given diluted in 10 to 20 mL of sodium chloride 0.9% or glucose 5%; the first 25 mg of iron is given slowly over 1 to 2 minutes. If no adverse reactions occur within 15 minutes, the remaining portion of the dose is given. Alternatively, 100 to 200 mg may be diluted in 100 mL of sodium chloride 0.9% or glucose 5%; the first 25 mg of iron is given over 15 minutes and if no adverse reactions occur during this time, the remaining portion of the infusion is given at a rate of not more than 100 mL in 30 minutes. In the USA, the injection may be given undiluted at a rate not exceeding 50 mg iron (1 mL) per minute; maximum daily doses are similar to those given for intramuscular injection.

Iron Polymaltose

Demir III Hidroksit Polimaltoz; Ferromaltose; Ferrum Polyisomaltose; Hierro polimaltosa.

Profile

Iron polymaltose is a complex of ferric hydroxide and isomaltose. It is used as a source of iron (p.1949) for iron-deficiency anaemia (p.1951). It is given orally in usual doses containing the equivalent of 100 mg of iron daily although up to 300 mg daily has been given in some countries. It is also given parenterally, the total dose being calculated and given by intravenous infusion or, preferably, as a series of intramuscular injections containing the equivalent of up to 200 mg of iron in a single day; injections are usually given only every few days. For further information relating to the parenteral use of iron, see Iron Dextran, p.1951.

Preparations

Proprietary Preparations (details are given in Part 3)

Iron Sorbitol

Astra-1572; Demir Sorbitol; Hierro sorbitol; Iron Sorbitex *(USAN)*; Iron-Sorbitol-Citric Acid Complex.

CAS — 1338-16-5.
ATC Vet — QB03AC03.

Pharmacopoeias. *US* includes an injection.

USP 31 (Iron Sorbitex Injection). A sterile solution of a complex of iron, sorbitol, and citric acid that is stabilised with the aid of dextrin and an excess of sorbitol. pH 7.2 to 7.9.

Adverse Effects, Treatment, and Precautions

As for Iron Dextran, p.1951.

There may be severe systemic reactions; cardiac complications, such as complete AV block, ventricular tachycardia, and atrial or ventricular fibrillation, may be fatal. The urine of patients treated with iron sorbitol may become dark on standing.

Iron sorbitol should not be given intravenously. It should preferably be avoided in patients with pre-existing cardiac abnormalities.

Effects on the heart. A description of adverse events in 3 patients with the malabsorption syndrome treated with intramuscular injections of iron sorbitol.[1] Two patients died; in one, findings were consistent with anaphylaxis but in the other cardiac toxicity was considered to be due to a direct effect. In the third patient direct cardiac toxicity was also implicated. In another report,[2] a patient developed cardiac arrhythmia after his seventh injection of iron sorbitol. He was found to have a low serum concentration of alpha-tocopherol, supposed by the authors to be caused by the patient's malabsorption syndrome. This had apparently predisposed the patient to arrhythmia by contributing to myocardial cell sensitivity to lipid peroxidation, which is catalysed by ferrous ions. Insufficient alpha-tocopherol to scavenge the free radicals generated by the iron could also have led to loss of myocardial fatty acids, thereby disturbing membrane function. It was suggested that iron sorbitol was a less stable form of iron than iron dextran, and should be given with extreme caution to patients with malabsorption and low levels of alpha-tocopherol.

2. Lindvall S, *et al.* Alpha-tocopherol and cardiac toxicity of iron. *Scand J Haematol* 1980; **25:** 331–8.

Interactions

As for Iron Dextran, p.1952.

Pharmacokinetics

About 66% of iron sorbitol is absorbed within 3 hours of intramuscular injection, most of it directly into the blood circulation, and some via the lymphatic system. Almost all is absorbed within about 10 days. Clearance of iron sorbitol from the plasma is rapid, and is mainly via the reticuloendothelial system, as described for Iron Dextran, p.1952.

Uses and Administration

Iron sorbitol should be used only in the treatment of proven iron-deficiency anaemia (p.1951) where oral therapy is ineffective or impracticable.

It is given by deep intramuscular injection into the upper outer quadrant of the buttock; to prevent leakage along the injection track, the subcutaneous tissue is drawn to one side before the needle is inserted.

Total dosage is calculated according to body-weight and the haemoglobin concentration of the blood, and tables are usually provided with iron sorbitol injections for this purpose. The recommended single dose is the equivalent of 1.5 mg/kg of iron up to a maximum of 100 mg daily; these doses are then given daily or every other day until the required haemoglobin concentration has been achieved. Iron sorbitol is not recommended in children weighing under 3 kg.

Iron sorbitol should not be given intravenously.

Preparations

USP 31: Iron Sorbitex Injection.

Proprietary Preparations (details are given in Part 3)

Iron Sucrose *(BAN, USAN)*

Demir Sükroz; Eisenzucker; Ferri oxidum saccharatum; Ferric Hydroxide Sucrose; Ferric Oxide, Saccharated; Ferrique (oxyde) sucré; Ferrum Oxydatum Saccharatum; Hierro sacarosa; Iron (III) hydroxide-sucrose complex; Iron Saccharate; Oxyde de Fer Sucré; Saccharated ferric oxide; Saccharated Iron Oxide; XI-921.

CAS — 8047-67-4.
ATC — B03AB02; B03AC02.
ATC Vet — QB03AB02; QB03AC02.

Pharmacopoeias. In *Swiss.*
US includes an injection.

USP 31 (Iron Sucrose Injection). A sterile, colloidal solution of ferric hydroxide in complex with sucrose in water for injection. Sodium hydroxide may be added to adjust the pH. It contains no antimicrobial agent, chelating agent, dextran, gluconate, or other added substances. pH 10.5 to 11.1 at 20°. It is intended for intravenous use only. When given by intravenous infusion, it should be diluted with 0.9% sodium chloride injection to a concentration of 0.5 to 2.0 mg of elemental iron/mL. Do not allow to freeze.

Adverse Effects, Treatment, and Precautions

For parenteral iron, see Iron Dextran, p.1951. Iron sucrose injection is strongly alkaline and must not be given subcutaneously or intramuscularly. UK (but not US) licensed drug information contra-indicates its use in patients with a history of asthma, eczema, anaphylaxis, or other allergic disorders.

Effects on the blood. For a report of thrombocytopenia associated with iron sucrose, see under Iron Dextran, p.1952.

Hypersensitivity. For a discussion of whether iron sucrose may be a safer alternative to iron dextran, see p.1952.

Pharmacokinetics

Iron sucrose is rapidly cleared from the plasma after intravenous injection with a terminal half-life of about 6 hours. A competitive exchange of iron takes place from the iron sucrose complex to the iron-binding protein transferrin. About 5% of a dose is eliminated via the kidneys in the first 4 hours after a dose.

Uses and Administration

Iron sucrose is used as a source of iron (p.1949) for iron-deficiency anaemia (p.1951). It is given when oral iron therapy is ineffective or impractical, by slow intravenous injection, or intravenous infusion; when used in haemodialysis patients, it may be given into the venous limb of the dialyser. The dose is calculated according to body-weight and iron deficit. In the UK the cumulative dose is given in single doses of 100 mg of iron not more than three times weekly; if rapid delivery is required, the dose may be increased up to 200 mg not more than three times weekly. The dose may be given undiluted at a rate of 20 mg/minute, after a test dose of 20 mg of iron has been given over 1 to 2 minutes. Alternatively, 100 mg is diluted in a maximum of 100 mL of sodium chloride 0.9% and the first 25 mg given as a test dose over 15 minutes; the remaining portion is given at a rate not exceeding 50 mL per 15 minutes.

In the USA, a similar dose is given for haemodialysis patients receiving supplemental erythropoietin therapy, to a total cumulative dose of 1 g. For peritoneal dialysis patients on erythropoietin, two infusions of 300 mg over 1.5 hours are given 14 days apart, followed by an infusion of 400 mg over 2.5 hours 14 days later. The doses are diluted in a maximum of 250 mL of sodium chloride 0.9%. For patients not on dialysis, a total cumulative dose of 1 g is given over a 14-day period, as a 200 mg slow undiluted intravenous injection over 2 to 5 minutes on 5 separate occasions within this time. Iron sucrose has also been given orally.

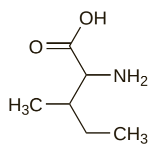
Isoleucine *(USAN, rINN)*

I; Ile; Isoleucin; Isoleucina; L-Isoleucine; Isoleucinum; Isoleusiini; Izoleucin; Izoleucinas. L-2-Amino-3-methylvaleric acid.

Изолейцин

$C_6H_{13}NO_2$ = 131.2.

CAS — 73-32-5.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Isoleucine). A white or almost white, crystalline powder or flakes. Sparingly soluble in water; slightly soluble in alcohol. It dissolves in dilute mineral acids and in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Isoleucine). White, practically odourless crystals. Soluble in water; slightly soluble in hot alcohol; insoluble in ether. pH of a 1% solution in water is between 5.5 and 7.0.

Profile

Isoleucine is a branched-chain aliphatic amino acid that is an essential constituent of the diet. It is used as a dietary supplement. It is also an ingredient of several preparations that have been promoted for disorders of the liver.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ger.:*** Bramin-hepa†; Falkamin; ***Ital.:*** Falkamin†; Isobranch; Isoram.

Isomalt *(BAN)*

Bay-i-3930; E953; Isomalta; Isomalti; Isomaltitol; Isomaltum; Izomalt; Izomaltas; Palatinit.

CAS — 64519-82-0.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Isomalt). A mixture of 6-*O*-α-D-glucopyranosyl-D-glucitol ($C_{12}H_{24}O_{11}$ = 344.3) and 1-*O*-α-D-glucopyranosyl-D-mannitol dihydrate ($C_{12}H_{24}O_{11},2H_2O$ = 380.3) and neither of the two components is less than 3%, calculated with reference to the anhydrous substance. A white or almost white powder or granules. Freely soluble in water; practically insoluble in dehydrated alcohol.

USNF 26 (Isomalt). 6-*O*-α-D-Glucopyranosyl-D-glucitol (1,6-GPS) and 1-*O*-α-D-glucopyranosyl-D-mannitol (1,1-GPM), and neither of the two components is less than 3.0% of the mixture, calculated on the anhydrous basis.

Profile

Isomalt is a sugar alcohol (polyol) used as a bulk sweetener in foods. The ingestion of large quantities may produce flatulence and have a laxative effect.

Metabolism. Isomalt is partly metabolised in the small intestine to glucose, mannitol, and sorbitol and the remaining isomalt is completely metabolised by the flora of the large intestine.[1] The Australian manufacturers have commented that the hydrolysis and absorption is minimal and does not significantly affect blood-sugar or insulin concentrations; they consider isomalt to be suitable for use by diabetic patients.[2]

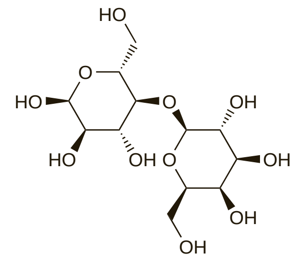
Lactose

Lactosa; Lactosum; Laktoosi; Laktos; Laktosa; Laktóz; Laktoza; Laktozė; Lattosio; Milk Sugar; Saccharum Lactis; Saccharum Lactis.

CAS — 63-42-3 (anhydrous lactose); 5989-81-1 (lactose monohydrate); 10039-26-6 (lactose monohydrate, cyclic); 64044-51-5 (lactose monohydrate, open form).



(anhydrous lactose)

Description. Lactose is a disaccharide obtained from the whey of milk. It may exist in a number of distinct forms depending upon the crystallisation and drying processes employed. The forms can vary in the contents of crystalline and amorphous lactose, the amounts of α-lactose (*O*-β-D-galactopyranosyl-(1→4)-α-D-glucopyranose) and β-lactose (*O*-β-D-galactopyranosyl-(1→4)-β-D-glucopyranose), and in their hydration states. The α-form of lactose exists in either the anhydrous ($C_{12}H_{22}O_{11}$ = 342.3) or monohydrate ($C_{12}H_{22}O_{11},H_2O$ = 360.3) state whereas the β-form exists only in the anhydrous state. Commercial lactose is mainly the α-monohydrate.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn*, and *Viet.* Also in *USNF.* Some pharmacopoeias include separate monographs for anhydrous lactose and lactose monohydrate.

Ph. Eur. 6.2 (Lactose, Anhydrous). It is β-lactose or a mixture of α-lactose and β-lactose. A white or almost white, crystalline powder. Freely but slowly soluble in water; practically insoluble in alcohol.

Ph. Eur. 6.2 (Lactose Monohydrate; Lactose BP 2008). It is the monohydrate of α-lactose. It may be modified as to its physical characteristics and may contain varying proportions of amorphous lactose. A white or almost white, crystalline powder. Freely but slowly soluble in water; practically insoluble in alcohol. Store in airtight containers.

USNF 26 (Anhydrous Lactose). It is β-lactose or a mixture of α- and β-lactose. It is a white or almost white powder. Freely soluble in water; practically insoluble in alcohol. Store in airtight containers.

USNF 26 (Lactose Monohydrate). It is a natural disaccharide, obtained from milk, which consists of one glucose and one galactose moiety. It may be modified as to its physical characteristics, and may contain varying proportions of amorphous lactose. It is a white, free-flowing powder. Freely, but slowly soluble in water; practically insoluble in alcohol. Store in airtight containers.

Adverse Effects and Precautions

Lactose intolerance occurs due to a deficiency of the intestinal enzyme lactase. Ingestion of lactose by patients with lactase deficiency leads to a clinical syndrome of abdominal pain, diarrhoea, distension, and flatulence; symptoms may also occur in persons without such a deficiency who have ingested excessive amounts of lactose.

Lactose is contra-indicated in patients with galactosaemia, the glucose-galactose malabsorption syndrome, or lactase deficiency.

Lactose intolerance. Reviews of lactose intolerance.[1-3] The capacity of the infant intestine to produce lactase, the enzyme responsible for digesting lactose, is retained into adulthood only by a minority of the world's population, mostly in those of north European descent; in Africa and Asia more than 90% of the population are lactase deficient. Because of the ubiquity of lactose in the diet and the consequent frequency of abdominal symptoms, attempts have been made to treat lactose intolerance by dietary exclusion (which need not be complete since lactase deficiency is rarely absolute). An alternative is enzyme replacement therapy with β-galactosidase from micro-organisms (see Tilactase, p.2402), but the role of such therapy has yet to be fully determined. The findings of one study[4] suggested that, in adults with lactose intolerance, the use of lactose-digestive aids is unnecessary if lactose intake is limited to the equivalent of 240 mL of milk or less daily.

There has been concern that lactose might be contaminated with protein from milk, and it has been recommended that children with cow's milk allergy avoid lactose-containing foods. However, a small study[5] found that children allergic to cow's milk could still tolerate lactose.

For the use of soya in infants intolerant to cow's milk, see Food Intolerance, p.1967.

5. Fiocchi A, *et al.* Clinical tolerance to lactose in children with cows' milk allergy. *Pediatrics* 2003; **112:** 359–62.

Pharmacokinetics

Lactose is hydrolysed by lactase in the small intestine to glucose and galactose, which are then absorbed.

Uses and Administration

Lactose, the carbohydrate component of milk, is less sweet than sucrose.

Lactose is widely used as an excipient in pharmaceutical manufacturing. In the production of capsules or tablets it may be used as a diluent, bulking agent, or filler, and in powders as a bulking agent. Lactose is also used as a carrier for drugs in dry powder inhalers. Characteristics such as particle size or flow characteristics make different grades of lactose suitable for different applications.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austria:*** Ichth-Oestren; ***Fr.:*** Tavag.

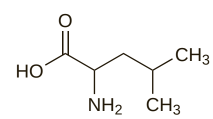
Leucine *(USAN, rINN)*

α-Aminoisocaproic Acid; L; Leu; Leucin; Leucina; Leucinas; L-Leucine; Leucinum; Leucyna; Leusiini. L-2-Amino-4-methylvaleric acid.

Лейцин

$C_6H_{13}NO_2$ = 131.2.

CAS — 61-90-5.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Leucine). A white or almost white, crystalline powder or shiny flakes. Sparingly soluble in water; practically insoluble in alcohol. It dissolves in dilute mineral acids and in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Leucine). White, practically odourless crystals. Sparingly soluble in water; insoluble in ether. pH of a 1% solution in water is between 5.5 and 7.0.

Profile

Leucine is a branched-chain aliphatic amino acid that is an essential constituent of the diet. It is used as a dietary supplement. It is also an ingredient of several preparations that have been promoted for disorders of the liver.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Fr.:*** Revitalose; ***Ger.:*** Bramin-hepa†; Falkamin; ***Ital.:*** Falkamin†; Isobranch; Isoram.

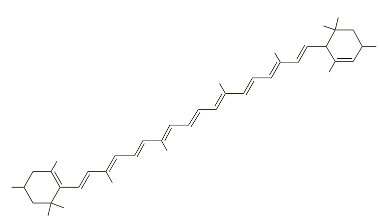
Lutein

E161(b); Xanthophyll. (3*R*,3′*R*,6′*R*)-β,ε-Carotene-3,3′-diol.

Лютеин

$C_{40}H_{56}O_2$ = 568.9.

CAS — 127-40-2.



Pharmacopoeias. In *US.*

US. also includes Lutein Preparation.

USP 31 (Lutein). A red crystalline powder. Soluble in dehydrated alcohol, in dichloromethane, and in ethyl acetate; partially soluble in hexane. Store at 8° to 15° in tightly-sealed, airtight containers. Protect from light and oxygen.

Profile

Lutein is a naturally occurring carotenoid that has been investigated for its supposed role in a number of conditions including age-related macular degeneration (p.785), cataracts, cardiovascular disease, and cancer.

Lutein is also used as a colouring agent.

Magnesium Fluoride

Фторид Магния

MgF_2 = 62.30.
CAS — 7783-40-6.

Profile

Magnesium fluoride is used as a fluoride supplement (see Sodium Fluoride, p.1962) for the prevention of dental caries. Magnesium fluoride is also used as a source of magnesium.

Homoeopathy. Magnesium fluoride has been used in homoeopathic medicines under the following names: Magnesia Fluorata; Magnesium Fluoratum; Magnesia Fluoricum.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Spain:*** Magnesium Pyre; Magnogene.

Maize Oil

Aceite de maíz; Corn Oil; Huile de Maïs; Kukoricamagolaj; Kukuřičný olej; Kukurūzų aliejus; Maïs, huile de; Maissiöljy; Majsolja; Maydis oleum; Ol. Mayd.; Olej kukurydziany; Oleum Maydis.

Pharmacopoeias. In *Chin., Eur* (see p.vii), and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Maize Oil, Refined; Maydis Oleum Raffinatum). The refined fatty oil obtained from the seeds of *Zea mays*. A clear, light yellow or yellow oil. Practically insoluble in water and in alcohol; miscible with dichloromethane and with petroleum spirit (b.p.: 40° to 60°). Store at a temperature not exceeding 25°. Protect from light.
USNF 26 (Corn Oil). The refined fixed oil obtained from the embryos of *Zea mays* (Gramineae). A clear, light yellow, oily liquid having a faint characteristic odour. Slightly soluble in alcohol; miscible with chloroform, with ether, with petroleum spirit, and with benzene. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

Profile

Maize oil is a fixed oil with a high content of unsaturated acids, and has been used to replace saturated acids in the diets of patients with familial hypercholesterolaemia. It is also used as an oily vehicle in pharmaceutical formulations.

Preparations

Proprietary Preparations (details are given in Part 3)
Pol.: Gal-Vit†.

Multi-ingredient: ***Fr.:*** Preservation; ***USA:*** Lipomul.

Malt Extract

Extractum Bynes; Malta, extracto de.

Profile

Malt extract contains 50% or more of maltose, with dextrin, glucose, and small amounts of other carbohydrates, and protein. It is prepared from malted grain of barley (*Hordeum distichon*, *H. vulgare*) or a mixture of this with not more than 33% of malted grain of wheat (*Triticum aestivum* or *T. turgidum*).

Malt extract has nutritive properties. It is chiefly used as a vehicle in preparations containing cod-liver oil (p.1935) and halibut-liver oil (p.1948). It is a useful flavouring agent for masking bitter tastes.

A product known as malt soup extract, obtained from barley grains, and containing 73% maltose with 12% other polymeric carbohydrates as well as small amounts of proteins, electrolytes, and vitamins, is sometimes used as a laxative.

Preparations

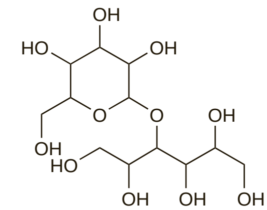
Proprietary Preparations (details are given in Part 3)
Chile: Maltin; ***USA:*** Maltsupex.

Multi-ingredient: ***Fr.:*** Galactogil; ***S.Afr.:*** Cough Elixir.

Maltitol *(BAN)*

E965; Hydrogenated Maltose; D-Maltitol; Maltitoli; Maltitolis; Maltitolum. α-D-Glucopyranosyl-1,4-D-glucitol.

$C_{12}H_{24}O_{11}$ = 344.3.
CAS — 585-88-6.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Maltitol). A white or almost white, crystalline powder. Very soluble in water; practically insoluble in dehydrated alcohol.
USNF 26 (Maltitol). A white, crystalline powder. Very soluble in water; practically insoluble in dehydrated alcohol.

Maltitol Syrup

E965; Hydrogenated Glucose Syrup; Hydrogenated High Maltose-glucose Syrup; Liquid Maltitol; Maltitol ciekły; Maltitol, flytande; Maltitol, jarabe de; Maltitol liquide; Maltitol roztok; Maltitol Solution; Maltitoli, nestemäinen; Maltitolum liquidum; Maltitszirup; Skystasis maltitolis.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Maltitol, Liquid). An aqueous solution of a hydrogenated, part hydrolysed starch, containing not less than 68.0% w/w and not more than 85.0% w/w of anhydrous substance composed of a mixture of mainly D-maltitol with D-sorbitol and hydrogenated oligo- and polysaccharides. It contains not less than 50.0% w/w of D-maltitol and not more than 8.0% w/w of D-sorbitol, both calculated with reference to the anhydrous substance. A clear, colourless, syrupy liquid. Miscible with water and with glycerol.
USNF 26 (Maltitol Solution). A water solution containing, on the anhydrous basis, not less than 50.0% of D-maltitol (w/w) and not more than 8.0% of D-sorbitol (w/w).

Nomenclature. Hydrogenated glucose syrup is a generic term encompassing products of widely varying composition and it was concluded that such products containing up to 90% of maltitol should more properly be called maltitol syrup.[1] This was subsequently amended to include products containing up to 98% maltitol.[2] Preparations containing a minimum of 98% of maltitol were assigned the title maltitol.

1. FAO/WHO. Evaluation of certain food additives and contaminants: thirty-third report of the joint FAO/WHO expert committee on food additives. *WHO Tech Rep Ser 776* 1989.
2. FAO/WHO. Evaluation of certain food additives and contaminants: forty-first report of the joint FAO/WHO expert committee on food additives. *WHO Tech Rep Ser 837* 1993.

Profile

Maltitol and maltitol syrup are bulk sweeteners used in foods and pharmaceuticals; they are considered to be less cariogenic than sucrose. The ingestion of large quantities may produce flatulence and diarrhoea.

Maltodextrin

Maltodekstriini; Maltodekstrinas; Maltodextrina; Maltodextrine; Maltodextrinum.
CAS — 9050-36-6.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Maltodextrin). A mixture of glucose, disaccharides, and polysaccharides, obtained by the partial hydrolysis of starch. The degree of hydrolysis, expressed as dextrose equivalent (DE) is not more than 20 (nominal value). A white or almost white, slightly hygroscopic powder or granules. Freely soluble in water.
USNF 26 (Maltodextrin). A nonsweet, nutritive saccharide mixture of polymers that consists of D-glucose units with a dextrose equivalent of less than 20. It is prepared by the partial hydrolysis of food grade starch with suitable acids and/or enzymes. White, hygroscopic powder or granules. Freely soluble or readily dispersible in water; slightly soluble to insoluble in dehydrated alcohol. pH of a 20% solution in water is between 4.0 and 7.0. Store in airtight containers at a temperature not exceeding 30° and a relative humidity not exceeding 50%.

Profile

Maltodextrin, a glucose polymer (malto-oligosaccharide), is a source of carbohydrate often used in oral dietary supplements and tube feeding. It rapidly releases glucose in the gastrointestinal tract but because of the high average molecular weight of maltodextrin, solutions have a lower osmolarity than isocaloric solutions of glucose. Additionally, preparations based on maltodextrin and intended for dietary supplementation usually have a low electrolyte content and are free of other sugars such as fructose, galactose, lactose, and sucrose. These properties make such preparations suitable for dietary supplementation in a variety of diseases including certain gastrointestinal disorders where malabsorption is a problem, in disaccharide intolerance (without isomaltose intolerance), and in acute and chronic hepatic and renal diseases where protein, mineral, and fluid restriction are often necessary.

Maltodextrin is also employed as a pharmaceutical excipient.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Carbohidrato 100; MC Modulo Calorico; ***Austral.:*** Maxijul; ***Braz.:*** Nidex; Oligossac†; ***Canad.:*** Moducal†; ***Chile:*** Modulo Calorico; ***Cz.:*** Fantomalt†; ***Fin.:*** Fantomalt; ***Hong Kong:*** Fiber Basics; ***Ital.:*** Energen; Fantomalt; Maltovis; Nidex; ***NZ:*** Moducal; ***Port.:*** Fantomalt†; Moducal†; ***USA:*** Moducal; ***Venez.:*** Fantomalt.

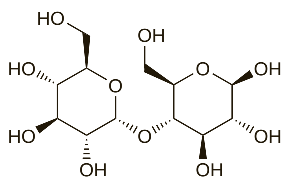
Multi-ingredient: *Chile:* Nutrasweet†; ***Fr.:*** Gumilk; ***Indon.:*** Fantomalt; ***Ital.:*** Giflorex; ***Pol.:*** Fantomalt; ***Venez.:*** Glutapak; Glutapak-R; Hermesetas Gold; Modulo Calorico; Multidex.

Maltose

D-maltose; Maltobiose; Maltosa. 4-*O*-α-D-Glucopyranosyl-β-D-glucopyranose.

$C_{12}H_{22}O_{11}$ = 342.3.

CAS — 69-79-4 (anhydrous maltose); 6363-53-7 (maltose monohydrate).



(anhydrous maltose)

Pharmacopoeias. *Jpn* includes the monohydrate. *USNF* permits the anhydrous and monohydrate forms.

USNF 26 (Maltose). It contains one molecule of water of hydration or is anhydrous. A white, odourless, crystalline powder that has a sweet taste. Freely soluble in water; very soluble in dehydrated alcohol; practically insoluble in ether; slightly soluble in methyl alcohol. pH of a 10% solution in water is between 3.7 and 4.7 (anhydrous form) and between 4.0 and 5.5 (monohydrate form).

Profile

Maltose, a disaccharide composed of two glucose molecules, is less sweet than sucrose. It is obtained from starch by hydrolysis with amylase. Maltose is often present with other sugars in mixtures used as carbohydrate sources. It is also used as a pharmaceutical excipient.

Adverse effects. Hyponatraemia developed after intravenous infusion of normal immunoglobulin in 10% maltose in a patient with acute renal failure after liver transplantation.[1] The effect, which recurred on each of four successive infusions, resembled that of hyperglycaemia and was thought to be due to accumulation of maltose and other osmotically active metabolites in the extracellular fluid.

1. Palevsky PM, *et al.* Maltose-induced hyponatremia. *Ann Intern Med* 1993; **118:** 526–8.

Precautions. Preparations that contain, or are metabolised to, maltose may interfere with the results from glucose tests (p.2314). Overestimation of glucose results may mask hypoglycaemia, resulting in the inappropriate use of insulin.[1,2] The problem may also occur with icodextrin, which produces maltose as a metabolite (see Dialysis, p.1937).

Manganese

Mangan; Manganèse; Manganeso; Manganum.

Mn = 54.938045.

CAS — 7439-96-5.

Manganese Chloride

Manganeso, cloruro de.

$MnCl_2.4H_2O$ = 197.9.

CAS — 7773-01-5 (anhydrous manganese chloride); 13446-34-9 (manganese chloride tetrahydrate).

Pharmacopoeias. In *US.*

USP 31 (Manganese Chloride). Large, irregular, pink, odourless, translucent crystals. Soluble in water and in alcohol; insoluble in ether. Store in airtight containers. pH of a 5% solution in water is between 3.5 and 6.0.

Manganese Gluconate

Manganèse, gluconate de; Manganeso, gluconato de; Mangani gluconas. Bis(D-gluconato-O^1,O^2) manganese; Manganese D-gluconate.

$C_{12}H_{22}MnO_{14}$ = 445.2.

Pharmacopoeias. In *Eur.* (see p.vii), which allows either anhydrous or hydrated forms, and in *US*, which allows either anhydrous or the dihydrate.

Ph. Eur. 6.2 (Manganese Gluconate). A white or pale pink, slightly hygroscopic, crystalline powder. Soluble in water; practically insoluble in anhydrous ethanol; insoluble in dichloromethane. Store in non-metallic, airtight containers.

USP 31 (Manganese Gluconate).

Manganese Sulfate

Mangaanisulfaattimonohydraatti; Manganèse (sulfate de) monohydraté; Manganese Sulphate; Manganeso, sulfato de; Mangani Sulfas; Mangani sulfas monohydricum; Mangán(II)-szulfát-monohidrát; Mangano sulfatas; Mangansulfatmonohydrat; Manganu siarczan; Síran manganatý. Manganese (II) sulphate monohydrate.

$MnSO_4,H_2O$ = 169.0.

CAS — 7785-87-7 (anhydrous manganese sulfate); 10034-96-5 (manganese sulfate monohydrate); 10101-68-5 (manganese sulfate tetrahydrate).

Pharmacopoeias. In *Eur.* (see p.vii) and *US. Br.* and *Fr.* also include the tetrahydrate.

BP 2008 (Manganese Sulphate). The tetrahydrate occurs as pale pink, odourless or almost odourless, crystals or crystalline powder. Freely soluble in water; practically insoluble in alcohol.

Ph. Eur. 6.2 (Manganese Sulphate Monohydrate). It occurs as a pale pink, slightly hygroscopic, crystalline powder. Freely soluble in water; practically insoluble in alcohol.

USP 31 (Manganese Sulfate). The monohydrate occurs as pale red, slightly efflorescent crystals, or as a purple, odourless powder. Soluble in water; insoluble in alcohol. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°.

Adverse Effects and Precautions

Acute poisoning due to ingestion of manganese or manganese salts is rare. The main symptoms of chronic poisoning, either from injection or usually inhalation of manganese dust or fumes in air, include extrapyramidal effects which may be followed by progressive deterioration in the CNS. Parenteral manganese should be used cautiously in patients with reduced biliary excretion, especially in cholestatic liver disease. When the duration of total parenteral nutrition is likely to exceed 1 month, serum-manganese concentration and liver function should be checked before starting treatment and regularly during treatment; additives containing manganese should be stopped if serum-manganese concentrations are raised or cholestasis develops.

Accumulation. There are reports of cholestatic liver disease, and possibly changes in the basal ganglia, associated with hypermanganesaemia in children given long-term parenteral nutrition;[1,2] manganese accumulation may be secondary to impaired biliary excretion.[3] Manganese supplementation in such patients requires re-appraisal and whole blood manganese concentrations should be monitored regularly. A low-dose regimen of not more than 1 microgram/kg (0.018 micromoles/kg) daily has been suggested,[2,3] a dose that was also recommended by the American Society for Parenteral and Enteral Nutrition.[4] Hypermanganesaemia and basal ganglia manganese deposition resolved over time in 2 children when the manganese dose in their parenteral nutrition was reduced.[5] Manganese accumulation in the basal ganglia has been seen in patients with liver cirrhosis,[6,7] and may be associated with parkinsonism[7,8] (for reference to the use of aminosalicylic acid in the treatment of manganese-induced parkinsonism, see p.202). Concern has been expressed[9] at the high levels of manganese contained in infant formulas.

9. Hozyasz KK, Ruszczynska A. High manganese levels in milk-based infant formulas. *Neurotoxicology* 2004; **25:** 733.

Pharmacokinetics

Absorption of manganese from the gastrointestinal tract is variable, ranging from 3 to 50%. There is some evidence that the amount absorbed decreases as intake increases, suggesting a homoeostatic response. In the circulation, manganese is bound to transmanganin, a beta-1-globulin. Manganese is stored in the brain, kidneys, pancreas, and liver. It is excreted in bile, and undergoes enterohepatic circulation.

Uses and Administration

Manganese is an essential trace element and small amounts of a salt such as the chloride or sulfate are sometimes added to solutions for total parenteral nutrition. Suggested doses are 275 micrograms (5 micromoles) elemental manganese daily for adults and children over 40 kg, and 1 microgram/kg (0.0182 micromol/kg) daily for infants and children to a maximum of 15 micrograms (see also Accumulation, above).

Manganese compounds or salts that have been used in therapeutics in addition to those mentioned above include manganese amino acid chelate, manganese dioxide, manganese gluconate, and manganese hydrogen citrate.

Human requirements. In the UK neither a reference nutrient intake (RNI) nor an estimated average requirement (EAR) (see p.1925) has been set for manganese although a safe intake for adults was believed to lie above 1.4 mg (26 micromoles) daily.[1] Similarly, in the USA a recommended dietary allowance has not been published, although an adequate intake has been estimated to be 2.3 mg daily for men and 1.8 mg daily for women.[2] A tolerable upper intake level of 11 mg has also been set.[2] WHO has not proposed a safe range of mean population intakes for manganese since neither intakes resulting in deficiency nor threshold toxicity levels have been established.[3] Diets high in unrefined cereals, nuts, leafy vegetables, and tea will be high in manganese.

Medium-chain Triglycerides

Keskipitkäketjuiset tyydyttyneet triglyseridit; Triacylglyceroly střední nasycené; Trigliceridai, vidutinės grandinės; Trigliceridek, közepes szénláncú zsírsavaké; Triglicéridos de cadena media; Triglycerida saturata media; Triglycerider, medellångkedjiga; Triglycérides à chaîne moyenne.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Triglycerides, Medium-chain). They are obtained from the oil extracted from the hard, dried fraction of the endosperm of *Cocos nucifera* or from the dried endosperm of *Elaeis guineensis.* They consist of a mixture of triglycerides of saturated fatty acids, mainly of octanoic acid and of capric acid ($C_{10}H_{20}O_2$ = 172.3). They contain not less than 95% of saturated fatty acids with 8 and 10 carbon atoms. A colourless or slightly yellowish, oily liquid. Practically insoluble in water; miscible with alcohol, with dichloromethane, with petroleum spirit, and with fatty oils. Store in well-filled containers. Protect from light.

USNF 26 (Medium-Chain Triglycerides). They are obtained from the oil extracted from the hard, dried fraction of the endosperm of *Cocos nucifera* or from the dried endosperm of *Elaeis guineensis.* They consist of a mixture of triglycerides of saturated fatty acids, mainly of octanoic acid and of capric acid ($C_{10}H_{20}O_2$ = 172.3). They contain not less than 95% of saturated fatty acids with 8 and 10 carbon atoms. A colourless or slightly yellowish, oily liquid. Practically insoluble in water; miscible with alcohol, with dichloromethane, with petroleum spirit, and with fatty oils. Store in airtight containers at a temperature not exceeding 25°. Protect from light.

Profile

Medium-chain triglycerides are used for enteral and parenteral nutrition (p.1923) in conditions associated with malabsorption of fat, such as cystic fibrosis, enteritis, and steatorrhoea, and after intestinal resection. Medium-chain triglycerides are more readily hydrolysed than long-chain triglycerides and are not dependent upon biliary or pancreatic secretions for absorption from the gastrointestinal tract. They provide 35 kJ (8.3 kcal) per g. They do not provide essential fatty acids.

Medium-chain triglycerides have also been used as bases for pharmaceutical preparations.

Preparations

Proprietary Preparations (details are given in Part 3)

Arg.: Teceeme; ***Austral.:*** Liquigen; MCT Oil; ***Canad.:*** MCT Oil†; ***Fin.:*** Liquigen; MCT Oljy; ***Fr.:*** Liquigen; ***Gr.:*** MCT Oil; ***Hung.:*** Structolipid; ***Israel:*** MCT; ***Ital.:*** MCT; Mytic 810; ***Malaysia:*** MCT Oil†; ***NZ:*** Liquigen; MCT Oil; ***Port.:*** MCT Oil; ***Singapore:*** MCT†; ***UK:*** Alembicol D; MCT Oil; ***USA:*** MCT.

Molybdenum

Molibdeno; Molybdän; Molybdène.

Mo = 95.96.

Ammonium Molybdate

Amonowy molibdenian; Molibdato de amonio. Hexaammonium molybdate tetrahydrate.

$(NH_4)_6Mo_7O_{24},4H_2O$ = 1236.0.

CAS — 12054-85-2.

Pharmacopoeias. In *US.*

USP 31 (Ammonium Molybdate). Colourless or slightly greenish or yellowish crystals. Soluble in water; practically insoluble in alcohol. Store in airtight containers.

Sodium Molybdate

Molibdato de sodio; Molybdenan sodný dihydrát; Natrii molybdas dihydricus; Natrio molibdatas dihidratas; Nátrium-molibdenát-dihidrát; Natriummolybdaattidihydraatti; Natriummolybdatdihydrat; Sodium (molybdate de) dihydraté; Sodu molibdenian.

$Na_2MoO_4,2H_2O$ = 242.0.

Pharmacopoeias. In *Eur.* (see p.vii). *Ger.* also includes a monograph for the anhydrous substance.

Ph. Eur. 6.2 (Sodium Molybdate Dihydrate). A white or almost white powder or colourless crystals. Freely soluble in water.

Adverse Effects

Very high intakes of molybdenum, and associated increases in xanthine oxidase activity, may result in hyperuricaemia, and possibly gout. Molybdenum intoxication may impair the utilisation of copper.

Uses and Administration

Molybdenum is an essential trace element and small amounts, in the form of ammonium molybdate or sodium molybdate, are sometimes added to solutions for total parenteral nutrition. A suggested dose is about 20 to 120 micrograms (0.2 to 1.2 micromoles) elemental molybdenum daily.

Ammonium molybdate is used in veterinary medicine to treat copper poisoning in sheep.

Human requirements. In the UK neither a reference nutrient intake (RNI) nor an estimated average requirement (EAR) (see p.1925) has been set for molybdenum although a safe intake was believed to be between 50 and 400 micrograms (0.5 and 4 micromoles) daily for adults.[1] In the USA, the recommended dietary allowance is 45 micrograms daily for adults.[2] The tolerable upper intake level is 2 mg daily.[2] WHO make the suggestion that the adult basal requirement for molybdenum could be about 25 micrograms daily,[3] corresponding to approximately 400 nanograms/kg.

Foods contributing to dietary molybdenum include milk, beans, breads, and cereals; however, extreme regional variations occur in molybdenum contents of food crops due to soil differences.

Preparations

USP 31: Ammonium Molybdate Injection.

Proprietary Preparations (details are given in Part 3)

Fr.: Molybdene Injectable; ***USA:*** Molypen.

Neohesperidin Dihydrochalcone

E959; Neohesperidiinidihydrokalkoni; Neohesperidin DC; Neohesperidin-dihidrochalkonas; Neohesperidin-dihydrochalconum; Neohesperidin-dihydrochalkon; Neohesperidindivätekalkon; Neohesperidine DC; Néohespéridine-dihydrochalcone; Neoheszperidin-dihidro-kalkon; NHDC. 3,5-Dihydroxy-4-[3-(3-hydroxy-4-methoxyphenyl)propionyl]phenyl 2-*O*-(6-deoxy-α-L-mannopyranosyl)-β-D-glucopyranoside.

$C_{28}H_{36}O_{15}$ = 612.6.

CAS — 13241-33-3 (neohesperidin); 20702-77-6 (neohesperidin dihydrochalcone); 18916-17-1 (naringin dihydrochalcone); 65520-51-6 (neoeriocitrin dihydrochalcone).

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Neohesperidin-dihydrochalcone). A white or yellowish-white powder. Practically insoluble in water and in dichloromethane; freely soluble in dimethyl sulfoxide; soluble in methyl alcohol. Protect from light.

Profile

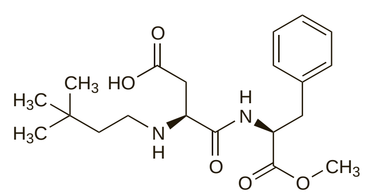
Neohesperidin dihydrochalcone is an intense sweetener derived from naringin, a flavonoid present in citrus peel. It is about 1000 to 1500 times as sweet as sucrose and is used in foods, beverages, and pharmaceuticals. It has a synergistic sweetening effect when used with other sweeteners.

Neotame

Neotamo. *N*-[*N*-(3,3-Dimethylbutyl)-L-α-aspartyl]-L-phenylalanine 1-methyl ester.

$C_{20}H_{30}N_2O_5$ = 378.5.

CAS — 165450-17-9.



Pharmacopoeias. In *USNF.*

USNF 26 (Neotame). Store in a dry place at a temperature not exceeding 40°.

Profile

Neotame is an intense sweetener used in foods and beverages. It has between 7000 and 13 000 times the sweetening power of sucrose and is stable to heat.

◊ References.

Nicotinamide Ascorbate *(rINNM)*

Ascorbato de nicotinamida; Niacinamide Ascorbate; Nicoscorbine; Nicotinamide, Ascorbate de; Nicotinamidi Ascorbas.

Никотинамида Аскорбат

$C_{12}H_{14}N_2O_7$ = 298.2.

CAS — 1987-71-9.

Profile

Nicotinamide ascorbate is a complex of nicotinamide (p.1957) with ascorbic acid (p.1983) that is used in multivitamin preparations. It has also been given with betaine glucuronate and diolamine glucuronate for liver disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Hong Kong:*** Jetepar; ***Ital.:*** Ietepar†; ***Malaysia:*** Jetepar; ***Philipp.:*** Jetepar; ***Singapore:*** Jetepar.

Nicotinic Acid *(rINN)*

375; Acide nicotinique; Ácido nicotínico; Acidum nicotinicum; Kwas nikotynowy; Kyselina nikotinová; Niacin; Nikotiinihappo; Nikotinik Asit; Nikotino rūgštis; Nikotinsäure; Nikotinsav; Nikotinsyra. Pyridine-3-carboxylic acid.

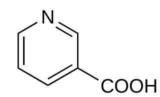
Никотиновая Кислота

$C_6H_5NO_2$ = 123.1.

CAS — 59-67-6.

ATC — C04AC01; C10AD02.

ATC Vet — QC04AC01; QC10AD02.



NOTE. Some published sources use the term niacin as a generic term to include both nicotinic acid and nicotinamide.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Nicotinic Acid). A white or almost white, crystalline powder. Sparingly soluble in water; soluble in boiling water and in boiling alcohol. It dissolves in dilute solutions of alkali hydroxides and carbonates. Protect from light.

USP 31 (Niacin). White crystals or crystalline powder, odourless or has a slight odour. Soluble 1 in 60 of water; freely soluble in boiling water, in boiling alcohol, and in solutions of alkali hydroxides and carbonates; practically insoluble in ether.

Nicotinamide *(rINN)*

Niacinamide; Nicotinamida; Nicotinamidum; Nicotinic Acid Amide; Nicotylamide; Nikotiiniamidi; Nikotinamid; Nikotinamidas; Nikotynamid; Vitamin B_3; Vitamin PP. Pyridine-3-carboxamide.

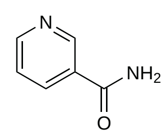
Никотинамид

$C_6H_6N_2O$ = 122.1.

CAS — 98-92-0.

ATC — A11HA01.

ATC Vet — QA11HA01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Nicotinamide). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water and in dehydrated alcohol. A 5% solution in water has a pH of 6.0 to 7.5.

USP 31 (Niacinamide). A white crystalline powder, odourless or practically so. Soluble 1 in 1.5 of water, 1 in 10 of boiling water, and 1 in 5.5 of alcohol; soluble in glycerol. Its solutions are neutral to litmus. Store in airtight containers.

Adverse Effects and Treatment

Nicotinic acid has a vasodilator action and when given by mouth or by injection in therapeutic doses it may cause flushing, a sensation of heat, faintness, and a pounding in the head. Flushing may be accompanied by dizziness, tachycardia, palpitations, dyspnoea, sweating, chills, or oedema. These symptoms are transient and various strategies have been proposed to reduce them (see Incidence of Adverse Effects, below). Nicotinamide does not have a vasodilator action.

Other adverse effects that have been reported, especially after high doses of nicotinic acid, include dryness of the skin, pruritus, hyperpigmentation, cramps, diarrhoea, nausea and vomiting, anorexia, activation of peptic ulcer, amblyopia, jaundice and impairment of liver function, decrease in glucose tolerance, hyperglycaemia, and hyperuricaemia. Most of these effects subside on withdrawal of the drug. Hypophosphataemia, a reduction in platelet counts, and prolongation of prothrombin time have also been reported. Insomnia, myalgia, hypotension, and rhinitis may occur rarely.

Topical nicotinamide may cause dryness of the skin and, less frequently, pruritus, erythema, burning sensation, and irritation. Frequency of application should be reduced if these effects occur.

Incidence of adverse effects. Nicotinic acid produces frequent adverse effects, but they are not usually serious, tend to decrease with time, and some can be minimised by following appropriate instructions for use.[1,2] Dermal and gastrointestinal reactions are most common. Truncal and facial flushing are reported in 90 to 100% of treated patients in large clinical trials; they appear to be prostaglandin-mediated and can be reduced with aspirin 75 mg or 325 mg given shortly before the nicotinic acid, or simply by giving nicotinic acid with food, and by starting therapy with a low dose and gradually increasing this. Flushing may be less common with modified-release formulations.[2]

2. American Society of Health-System Pharmacists. ASHP therapeutic position statement on the safe use of niacin in the management of dyslipidemias. *Am J Health-Syst Pharm* 1997; **54:** 2815–19.

Effects on the eyes. Retrospective survey of hyperlipidaemic patients suggested that dry eyes (sicca syndromes), blurred vision, and swollen eyelids might be associated with nicotinic acid therapy in some patients.[1] The effects appeared to be dose-related and reversible. In 2 patients treatment was stopped because of symptoms suggestive of cystoid macular oedema. Other cases of nicotinic acid maculopathy have been reported.[2,3]

Effects on glucose tolerance. Nicotinic acid can reduce glucose tolerance, and this may be problematic in patients with diabetes mellitus,[1,2] although it has been investigated in the prevention of diabetes mellitus (see below).

Effects on the liver. Hepatotoxicity may occur with nicotinic acid.[1-6] Significant elevations of liver enzymes are occasionally seen with nicotinic acid therapy. They are more common in patients given large dosage increases over short periods of time, and in patients treated with modified-release formulations. It has been suggested[7] that since effects on liver function may in some instances lead to hepatic failure and are more common with modified-release dosage forms the use of crystalline immediate-release preparations should be preferred, a view shared by other commentators.[8] However, although studies appear to confirm a more frequent association of hepatotoxicity with modified-release dosage forms[4,9,10] it should be borne in mind that these effects can also occur with the immediate-release preparations, especially at high doses. Some manufacturers of modified-release preparations have stated that cases of severe hepatotoxicity, including fulminant hepatic necrosis, have occurred when patients have substituted modified-release dosage forms for immediate-release crystalline preparations at equivalent doses. There is also a suggestion that not all modified-release preparations are alike in their effects.[11]

Effects on the muscles. Myopathy has been noted with nicotinic acid.[1,2] Rhabdomyolysis has occurred when nicotinic acid was given with lovastatin (see Lipid Regulating Drugs, under Interactions of Simvastatin, p.1393).

1. Litin SC, Anderson CF. Nicotinic-acid associated myopathy: a report of three cases. *Am J Med* 1989; **86:** 481–3.
2. Gharavi AG, *et al.* Niacin-induced myopathy. *Am J Cardiol* 1994; **74:** 841–2.

Hyperuricaemia. Nicotinic acid decreases urinary excretion of uric acid, which may result in elevation of serum uric acid and exacerbation of pre-existing gout.[1]

1. American Society of Health-System Pharmacists. ASHP therapeutic position statement on the safe use of niacin in the management of dyslipidemias. *Am J Health-Syst Pharm* 1997; **54:** 2815–19.

Precautions

Nicotinic acid should be given cautiously to patients with a history of peptic ulcer disease, and to those with diabetes mellitus, gout, or hepatic impairment. Modified-release preparations should not be substituted for equivalent doses of immediate-release crystalline nicotinic acid preparations, as cases of severe hepatotoxicity, including fulminant hepatic necrosis, have occurred. Liver function tests and plasma glucose should be frequently monitored.

Interactions

There may be an increased risk of myopathy or rhabdomyolysis when nicotinic acid is used with statins (see Lipid Regulating Drugs, under Interactions of Simvastatin, p.1393). Nicotinic acid may increase the requirements for insulin or oral hypoglycaemics. Aspirin may reduce the clearance of nicotinic acid. *In vitro* studies suggest that colestipol and colestyramine may reduce the availability of nicotinic acid, and some licensed product information recommends an interval of at least 4 to 6 hours between giving nicotinic acid and bile-acid binding resins.

Antiepileptics. For the effect of nicotinamide on *carbamazepine*, see Vitamins, p.475.

Nicotine. A patient started to have flushing and dizziness after her usual doses of nicotinic acid when transdermal nicotine patches were added to her therapy.[1] She had experienced such reactions 3 years previously on starting nicotinic acid therapy, but not since, and it was suggested that on this occasion an interaction might have been responsible.

1. Rockwell KA. Potential interaction between niacin and transdermal nicotine. *Ann Pharmacother* 1993; **27:** 1283–4.

Pharmacokinetics

Nicotinic acid and nicotinamide are readily absorbed from the gastrointestinal tract after oral doses and widely distributed in the body tissues. Nicotinic acid appears in breast milk. The main route of metabolism is their conversion to *N*-methylnicotinamide and the 2-pyridone and 4-pyridone derivatives; nicotinuric acid is also formed. Small amounts of nicotinic acid and nicotinamide are excreted unchanged in urine after therapeutic doses; however the amount excreted unchanged is increased with larger doses.

Human Requirements

The daily human requirement of nicotinic acid, though not definitely known, is probably about 15 to 20 mg. Yeast, meat, fish, potatoes, legumes, and wholemeal cereals are good sources of nicotinic acid and nicotinamide. However they may be present in a bound, unabsorbable form in cereals, especially maize. Nicotinic acid can also be obtained from the conversion of tryptophan in the body, 60 mg of dietary tryptophan being considered equivalent to 1 mg of dietary nicotinic acid, so requirements are influenced by dietary protein intake and if protein intake is adequate there is little need for any preformed vitamin in the diet. There is generally little loss of nicotinic acid from foods during cooking.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) have been published for nicotinic acid[1] and in the USA recommended dietary allowances (RDAs) have been set.[2] In the UK the reference nutrient intake (RNI) is 6.6 mg niacin equivalent per 1000 kcal daily and the estimated average requirement (EAR) is 5.5 mg niacin equivalent per 1000 kcal daily for adult males and females. One niacin equivalent is equal to 1 mg of dietary nicotinic acid or 60 mg of dietary tryptophan. In the US the RDAs are also expressed in niacin equivalents and are 16 mg daily for adult males and 14 mg daily for adult females; the EAR is 12 mg daily in males and 11 mg daily in females. The tolerable upper intake level for adults is 35 mg daily.[2]

Also available at: http://www.nap.edu/openbook.php?isbn=0309065542 (accessed 21/07/08)

Uses and Administration

Nicotinic acid and nicotinamide, the form that occurs naturally in the body, are water-soluble vitamin B substances that are converted to nicotinamide adenine dinucleotide (nadide, p.2350) and nicotinamide adenine dinucleotide phosphate (NADP). These coenzymes are involved in electron transfer reactions in the respiratory chain.

Nicotinic acid deficiency develops when the dietary intake is inadequate. Deficiency leads to the development of a syndrome known as pellagra, characterised by skin lesions, especially on areas exposed to sunlight, with hyperpigmentation and hyperkeratinisation. Other symptoms include diarrhoea, abdominal pain, glossitis, stomatitis, loss of appetite, headache, lethargy, and mental and neurological disturbances. Nicotinic acid deficiency may occur with other vitamin B-complex deficiency states, for example in alcoholism.

Nicotinic acid and nicotinamide are used in the treatment and prevention of **nicotinic acid deficiency**. Nicotinamide is preferred as it does not cause vasodilatation. They are usually given orally, the preferred route, but may also be given by the intramuscular route or by slow intravenous injection. Doses of up to 500 mg daily (of either compound) in divided doses have been recommended.

Nicotinic acid has been used for its **vasodilator** action in the treatment of a variety of disorders; its value is not considered to be established.

In high doses, nicotinic acid has beneficial effects on blood lipid profiles, and has been used, with dietary modification and often with other lipid regulating drugs, in **hyperlipidaemias** (see below). For the immediate-release preparations, up to 600 mg daily in 3 divided oral doses has been given initially, gradually increased over 2 to 4 weeks to doses of up to 6 g daily; adverse effects may be a limiting factor. Alternatively, initial doses of 375 or 500 mg at night have been given as a modified-release preparation and gradually increased according to response to a maintenance dose of 1 to 2 g at bedtime. The daily dose should not be increased by more than 500 mg in any 4-week period. A combination preparation containing nicotinic acid with laropiprant, a prostaglandin D_2 antagonist that inhibits nicotinic acid-induced flushing, may also be used.

Topical nicotinamide is used in the treatment of mild to moderate inflammatory **acne** (see below), typically as a 4% gel applied twice daily.

Nicotinamide has been shown to inhibit the destruction of pancreatic beta cells *in vitro* and is therefore being investigated in the prevention and treatment of type 1 **diabetes mellitus** (see below).

Acne. Topical nicotinamide may be used in the treatment of inflammatory acne (p.1577); nicotinamide 4% was as effective as clindamycin 1% when applied topically twice daily for 8 weeks.[1]

1. Shalita AR, *et al.* Topical nicotinamide compared with clindamycin gel in the treatment of inflammatory acne vulgaris. *Int J Dermatol* 1995; **34:** 434–7.

Diabetes mellitus. Nicotinic acid can affect glucose tolerance and should be used with care in established diabetes (see Effects on Glucose Tolerance, above). However, the drug has been used successfully in patients with diabetes. Nicotinamide has been reported to induce remission in patients with newly diagnosed type 1 diabetes mellitus (p.431), and may delay the onset of disease.[1,2]

However, a randomised trial found modified-release nicotinamide at 1.2 g/m^2 daily (to a maximum of 3 g daily) to be ineffective in preventing the onset of diabetes mellitus in first-degree relatives of patients with the disease.[3] Nicotinic acid can also raise high-density lipoprotein (HDL)-cholesterol concentrations (see below);[4,5] changes in glucose tolerance were mild enough for the drug to be considered as an alternative to statins and fibrates in diabetic patients.

Hyperlipidaemias. The first-line treatment for hyperlipidaemias remains dietary and lifestyle modification; where this fails, drug therapy may be considered (p.1169). Nicotinic acid is reported to have a favourable effect on blood-lipid profiles, raising high-density lipoprotein (HDL)-cholesterol and lowering low-density lipoprotein (LDL)-cholesterol.[1-3] Nicotinic acid is used particularly in familial hypertriglyceridaemia, or in familial combined hyperlipidaemia when both triglyceride and cholesterol concentrations are similarly elevated. Nicotinic acid was less effective than lovastatin at reducing LDL-cholesterol in patients with primary hypercholesterolaemia, but more effective at increasing HDL-cholesterol; lovastatin was better tolerated.[4] A combination of nicotinic acid with lovastatin was found to be comparable to atorvastatin and more effective than simvastatin in reducing LDL-cholesterol, and more effective than either atorvastatin or simvastatin in increasing HDL-cholesterol, in a study of patients with dyslipidaemia.[5] Some have recommended that nicotinic acid be substituted for a statin to lower LDL-cholesterol when patients cannot tolerate a statin.[2] Combination therapy is recommended when the reduction in LDL-cholesterol is insufficient with statin monotherapy,[2,6] or when raising HDL-cholesterol would be beneficial,[7-9] as in patients with type 2 diabetes mellitus, or the metabolic syndrome.[8] The risk of muscle toxicity with this combination is not considered to be significantly different to that with statin monotherapy.[7]

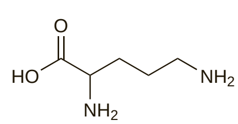
Ornithine *(rINN)*

α,δ-Diaminovaleric Acid; Orn; L-Ornithine; Ornithinum; Ornitina. L-2,5-Diaminovaleric acid.

Орнитин

$C_5H_{12}N_2O_2$ = 132.2.

CAS — 70-26-8.



Pharmacopoeias. *Ger.* includes Ornithine Aspartate and Ornithine Hydrochloride.

Profile

Ornithine is an aliphatic non-essential amino acid. It is used as a dietary supplement.

The aspartate, hydrochloride, and oxoglurate (ornithine ketoglutarate, see also Parenteral and Enteral Nutrition under Glutamic Acid, p.1947) have been used in various indications including the treatment of hyperammonaemia (p.1929) and hepatic encephalopathy (p.1697).

ATC Vet — QA11HA31; QD03AX04.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, *US*, and *Viet.*
US also has a monograph for Racemic Calcium Pantothenate.
Ger. also includes Sodium Pantothenate.

Ph. Eur. 6.2 (Calcium Pantothenate). A white or almost white, slightly hygroscopic powder. Freely soluble in water; slightly soluble in alcohol. A 5% solution has a pH of 6.8 to 8.0. Store in airtight containers.

USP 31 (Calcium Pantothenate). The calcium salt of the dextrorotatory isomer of pantothenic acid. A white, odourless, slightly hygroscopic powder. Soluble 1 in 3 of water; practically insoluble in alcohol, in chloroform, and in ether; soluble in glycerol. Store in airtight containers.

USP 31 (Racemic Calcium Pantothenate). A mixture of the calcium salts of the dextrorotatory and laevorotatory isomers of pantothenic acid. The physiological activity of Racemic Calcium Pantothenate is about one-half that of Calcium Pantothenate. A white, slightly hygroscopic powder, having a faint characteristic odour. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether; soluble in glycerol. Its solutions are neutral or alkaline to litmus. Store in airtight containers.

Adverse Effects

Pantothenic acid is reported to be generally non-toxic.

Eosinophilia. A report of life-threatening eosinophilic pleuropericarditis associated with the use of biotin and pantothenic acid.[1] Symptoms resolved on stopping the vitamins.

1. Debourdeau PM, *et al.* Life-threatening eosinophilic pleuropericardial effusion related to vitamins B and H. *Ann Pharmacother* 2001; **35:** 424–6.

Pharmacokinetics

Pantothenic acid is readily absorbed from the gastrointestinal tract after oral doses. It is widely distributed in the body tissues and appears in breast milk. About 70% of pantothenic acid is excreted unchanged in the urine and about 30% in the faeces.

Human Requirements

Pantothenic acid is widely distributed in foods. Meat, legumes, and whole grain cereals are particularly rich sources; other good sources include eggs, milk, vegetables, and fruits.

UK and US recommended dietary intake. In the UK neither a reference nutrient intake (RNI) nor an estimated average requirement (EAR) has been set (see p.1925) for pantothenic acid although an intake of 3 to 7 mg daily for adults was believed to be adequate.[1] Similarly, in the USA a recommended dietary allowance has not been published but an adequate intake for adults was believed to be 5 mg daily, increased to 6 mg in pregnancy and 7 mg during lactation.[2]

1. DoH. Dietary reference values for food energy and nutrients for the United Kingdom: report of the panel on dietary reference values of the committee on medical aspects of food policy. *Report on health and social subjects 41*. London: HMSO, 1991.
2. Standing Committee on the Scientific Evaluation of Dietary Reference Intakes of the Food and Nutrition Board. *Dietary Reference Intakes for thiamin, riboflavin, niacin, vitamin B , folate, vitamin B , pantothenic acid, biotin, and choline*. Washington, DC: National Academy Press, 2000. Also available at: http://www.nap.edu/openbook.php?isbn=0309065542 (accessed 21/07/08)

Uses and Administration

Pantothenic acid is traditionally considered to be a vitamin B substance. It is a component of coenzyme A which is essential in the metabolism of carbohydrate, fat, and protein.

Deficiency of pantothenic acid is unlikely in man because of its widespread distribution in food.

Pantothenic acid has no accepted therapeutic uses in human medicine, though it has been given by mouth as a nutritional supplement, often as the calcium salt and usually with other vitamins of the B group.

Preparations

USP 31: Calcium Pantothenate Tablets.

Proprietary Preparations (details are given in Part 3)
Arg.: Cidermex; ***Austral.:*** Pantonate; ***Ger.:*** Kerato Biciron; ***Mex.:*** Span Plex; ***Rus.:*** Zorex (Зорекс); ***Switz.:*** Pantothen.

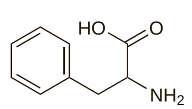
Phenylalanine *(USAN, rINN)*

α-Aminohydrocinnamic Acid; F; Fenilalanin; Fenilalanina; Fenilalaninas; Fenylalanin; Fenyloalanina; Fenyylialaniini; Phe; Phénylalanine; L-Phenylalanine; Phenylalaninum. L-2-Amino-3-phenylpropionic acid.

Фенилаланин

$C_9H_{11}NO_2$ = 165.2.

CAS — 63-91-2.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *US.*

Ph. Eur. 6.2 (Phenylalanine). A white or almost white, crystalline powder, or shiny, white flakes. Sparingly soluble in water; very slightly soluble in alcohol. It dissolves in dilute mineral acids and in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Phenylalanine). White, odourless crystals. Sparingly soluble in water; very slightly soluble in alcohol, in methyl alcohol, and in dilute mineral acids. pH of a 1% solution in water is between 5.4 and 6.0.

Profile

Phenylalanine is an aromatic amino acid that is an essential constituent of the diet. It is used as a dietary supplement.

Phenylalanine intake should be restricted in patients with phenylketonuria (see Amino Acid Metabolic Disorders, p.1922).

Vitiligo. There is no totally effective treatment for vitiligo (localised hypopigmentation, p.1582). Oral or topical photochemotherapy with psoralens is generally considered to be the best available treatment, but experimental therapy includes UVA phototherapy with phenylalanine. Use of phenylalanine in oral doses of up to 100 mg/kg with UVA/sunlight led to beneficial results in more than 90% of 200 patients with vitiligo.[1] Greatest benefit was noted in early disease, but prolonged use still induced repigmentation in long-standing cases. Repigmentation occurred mainly in areas rich in follicles. Such therapy is contra-indicated in phenylketonuria and in pregnancy.

Similarly a further open study reported responses in 94 of 149 patients receiving 50 to 100 mg/kg daily of phenylalanine plus twice weekly UVA treatment.[2] However, only 22% of responders had repigmentation in more than 60% of the affected area. Higher doses did not seem to be more effective than 50 mg/kg daily. Another group reported on 6 years of experience of treatment of vitiligo using 50 or 100 mg/kg daily of phenylalanine, with application of 10% phenylalanine gel and daily sun exposure.[3] Although not ideal, they considered the treatment useful, especially for its ability to rapidly repigment the face. The same group performed an open study, adding topical 0.025% clobetasol propionate, and ultraviolet exposure during autumn and winter; 65.5% of patients achieved 100% repigmentation on the face.[4]

Polysaccharide-Iron Complex

Polisacárido hierro, complejo.

Profile

Polysaccharide-iron complex is used as a source of iron (p.1949) for iron-deficiency anaemia (p.1951). It is given orally in doses containing the equivalent of up to 300 mg of iron daily.

Preparations

Proprietary Preparations (details are given in Part 3)
Belg.: Ferricure; ***Chile:*** Niferex†; ***Hong Kong:*** Niferex; ***Norw.:*** Niferex; ***Pol.:*** Venofer; ***UK:*** Niferex; ***USA:*** Fe-Tinic; Ferrex; Ferrex Plus; Hytinic†; Niferex; Nu-Iron†; Poly-Iron.

Multi-ingredient: ***USA:*** Fe-Tinic Forte; Ferrex Forte; Ferrex Forte Plus†; Ferrex PC; Hemocyte-F; Niferex Forte; Nu-Iron V; Poly-Iron Forte; Tandem.

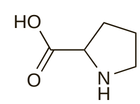
Proline *(USAN, rINN)*

P; Pro; Proliini; Prolin; Prolina; Prolinas; L-Proline; Prolinum. L-Pyrrolidine-2-carboxylic acid.

Пролин

$C_5H_9NO_2$ = 115.1.

CAS — 147-85-3.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Proline). A white or almost white, crystalline powder or colourless crystals. Very soluble in water; freely soluble in alcohol. Protect from light.

USP 31 (Proline). White, odourless crystals. Freely soluble in water and in dehydrated alcohol; insoluble in butyl alcohol, in ether, and in isopropyl alcohol.

Profile

Proline is a cyclic non-essential amino acid. It is used as a dietary supplement.

Preparations

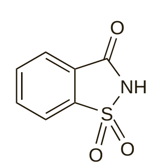
Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Port.:*** Creme Laser Hidrante.

Saccharin

Benzoic Acid Sulphimide; Benzoic Sulfimide; Benzosulphimide; E954; Gluside; Sacarina; Saccarina; Saccharine; Saccharinum; Sacharin; Sacharinas; Sacharyna; Sackarin; Sakkariini; *o*-Sulfobenzimide; Szacharin; Zaharina. 1,2-Benzisothiazolin-3-one 1,1-dioxide.

$C_7H_5NO_3S$ = 183.2.

CAS — 81-07-2.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn*. Also in *USNF.*

Ph. Eur. 6.2 (Saccharin). A white or almost white, crystalline powder or colourless crystals. Slightly soluble in cold water; sparingly soluble in boiling water and in alcohol. It dissolves in dilute solutions of alkali hydroxides and carbonates. A saturated solution, prepared without heating, is acid to litmus.

USNF 26 (Saccharin). White crystals or white, crystalline powder. Is odourless or has a faint, aromatic odour. In dilute solutions, it is intensely sweet. Soluble 1 in 290 of water, 1 in 25 of boiling water, and 1 in 31 of alcohol; slightly soluble in chloroform and in ether; is readily dissolved by dilute solutions of ammonia, by solutions of alkali hydroxides, and by solutions of alkali carbonates with the evolution of carbon dioxide. Its solutions are acid to litmus.

Saccharin Calcium

Calcium Benzosulphimide; Calcium Saccharin; E954; Sacarina cálcica; Saccharine calcique; Saccharinum calcicum.

$C_{14}H_8CaN_2O_6S_2,3\frac{1}{2}H_2O$ = 467.5.

CAS — 6485-34-3 (anhydrous saccharin calcium); 6381-91-5 (hydrated saccharin calcium).

Pharmacopoeias. In *US.*

USP 31 (Saccharin Calcium). White crystals or white, crystalline powder. Is odourless, or has a faint, aromatic odour, and has an intensely sweet taste, even in dilute solutions. Its dilute solution is about 300 times as sweet as sucrose. Soluble 1 in 2.6 of water and 1 in 4.7 of alcohol.

Saccharin Potassium

E954; Potassium Benzosulphimide; Potassium Saccharin.

$C_7H_5NO_3SK$ = 222.3.

CAS — 10332-51-1.

Saccharin Sodium

E954; Sacarina sódica; Saccharin Sod.; Saccharine sodique; Saccharinnatrium; Saccharinum natricum; Saccharoidum Natricum; Sacharin sodná sůl; Sacharino natrio druska; Sacharyna sodowa; Sackarinnatrium; Sakkariininatrium; Sodium Benzosulphimide; Sodium Saccharin; Soluble Gluside; Soluble Saccharin; Szacharin-nátrium.

$C_7H_4NNaO_3S$ = 205.2.

CAS — 128-44-9 (anhydrous saccharin sodium); 6155-57-3 (saccharin sodium dihydrate).

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.* Some pharmacopoeias specify the dihydrate but it may contain a variable quantity of water as a result of efflorescence.

Ph. Eur. 6.2 (Saccharin Sodium). A white or almost white, crystalline powder or colourless crystals. It may contain a variable quantity of water. Efflorescent in dry air. Freely soluble in water; sparingly soluble in alcohol. Store in airtight containers.

USP 31 (Saccharin Sodium). White crystals or white, crystalline powder. Is odourless, or has a faint, aromatic odour, and has an intensely sweet taste, even in dilute solutions. Its dilute solution is about 300 times as sweet as sucrose. When in powdered form, it usually contains about one-third the theoretical amount of water of hydration as a result of efflorescence. Soluble 1 in 1.5 of water and 1 in 50 of alcohol.

Adverse Effects

There have been rare reports of hypersensitivity and photosensitivity reactions with saccharin.

Saccharin-associated bladder tumours in *rats* given high doses have been the cause of much concern and investigation. However, it is now generally accepted that these findings are not relevant to the use of saccharin as a sweetener in man.

Effects on the liver. Elevated liver enzyme values in an elderly woman followed use of two different medications sweetened with saccharin sodium.[1] Findings resolved on stopping all preparations containing saccharin, and recurred on rechallenge with a small amount of saccharin sodium.

1. Negro F, *et al.* Hepatotoxicity of saccharin. *N Engl J Med* 1994; **331:** 134–5.

Pharmacokinetics

Saccharin is readily absorbed from the gastrointestinal tract. It is almost all excreted unchanged in the urine within 24 to 48 hours.

Uses and Administration

Saccharin and its salts are intense sweeteners, a dilute solution having about 300 times the sweetening power of sucrose. They are used in pharmaceuticals and in foods and beverages and are heat stable. They have no food value. The salts are more often used than saccharin itself as they are considered to be more palatable.

Preparations

USP 31: Saccharin Sodium Oral Solution; Saccharin Sodium Tablets.

Proprietary Preparations (details are given in Part 3)
Chile: Dul-Suc; Sukar-Sin; ***Fr.:*** Sucredulcor†; ***NZ:*** Sactabs; ***Turk.:*** Hermesetas; ***Venez.:*** Hermesetas.

Multi-ingredient: ***Arg.:*** Chuker; Rondo; Semble; Sucaryl; Suimel; ***Austral.:*** Sucaryl; ***Braz.:*** Finn Cristal; ***Chile:*** Sucaryl†; Sukar-Sin; ***Fr.:*** Sucaryl; ***Israel:*** Sucrin; ***Ital.:*** Diet Sucaryl; ***NZ:*** Sucaryl; ***Port.:*** Dulceril†; ***Rus.:*** Zuckli (Цюкли); ***Turk.:*** Dolce.

Safflower Oil

Aceite de alazor; Aceite de cártamo; Carthame (huile de) raffinée; Carthami oleum raffinatum; Dygminų aliejus, rafinuotas; Safflorolja, raffinerad; Saflorioljy, puhdistettu; Světlicový olej čištěný.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Chin., Eur. (see p.vii), and *Jpn* include Safflower, the flower of *Carthamus tinctorius.*

Ph. Eur. 6.2 (Safflower Flower; Carthami Flos). Dried flower of

Carthamus tinctorius. It contains not less than 1% of total flavonoids, expressed as hyperoside ($C_{21}H_{20}O_{12}$ = 464.4), calculated with reference to the dried drug. Protect from light.

Ph. Eur. 6.2 (Safflower Oil, Refined). The fatty oil obtained from seeds of *Carthamus tinctorius* (type I) or from seeds of hybrids of *C. tinctorius* (type II), by expression and/or extraction followed by refining. Type II refined safflower oil is rich in oleic acid. It may contain a suitable antioxidant. A clear, viscous, yellow to pale yellow liquid. Relative density about 0.922 (type I) and about 0.914 (type II). Practically insoluble in alcohol; miscible with petroleum spirit (b.p.: 40° to 60°). Store in well-filled airtight containers. Protect from light.

USP 31 (Safflower Oil). The refined fixed oil yielded from the seed of *Carthamus tinctorius* (Compositae). A light yellow oil. It thickens and becomes rancid on prolonged exposure to air. Insoluble in water; miscible with chloroform and with ether. Store in airtight containers. Protect from light.

Profile

Safflower oil is the refined fixed oil obtained from the seeds of the safflower, or false (bastard) saffron, *Carthamus tinctorius* (Compositae). It contains about 75% of linoleic acid as well as various saturated fatty acids.

Safflower oil has similar actions and uses to those of soya oil, p.1965. Emulsions containing a mixture of safflower oil 5% and soya oil 5%, or 10% and 10% respectively, are given as part of total parenteral nutrition regimens.

Adverse effects. For reference to the association of safflower oil-based emulsion, as part of a parenteral nutrition regimen, with the development of sinus bradycardia, see Effects on the Cardiovascular System, under Soya Oil, p.1966.

Preparations

Proprietary Preparations (details are given in Part 3)
Arg.: Lipidos†.

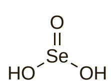
Selenium

Selen; Selenio; Sélénium.
Se = 78.96.

Selenious Acid

Kwas selenawy; Selenioso, ácido. Monohydrated selenium dioxide .
H_2SeO_3 = 129.0.
CAS — 7783-00-8.



Pharmacopoeias. In *US.*

USP 31 (Selenious Acid). Store in airtight containers.

Potassium Selenate

Selenato potásico.
K_2SeO_4 = 221.2.
CAS — 7790-59-2.

Pharmacopoeias. In *BP(Vet).*

BP(Vet) 2008 (Potassium Selenate). Colourless crystals or a white crystalline powder. Freely soluble in water.

Sodium Selenate

Disodium Selenate; Natriumseleniat; NSC-378348; Selenato sódico; Sodium Selenium Oxide.
Na_2SeO_4 = 188.9.
CAS — 13410-01-0.
ATC — A12CE01.
ATC Vet — QA12CE01.

Sodium Selenite

Natrii selenis pentahydricus; Natrio selenitas pentahidratas; Natriumseleniittipentahydraatti; Natriumselenitpentahydrat; Seleničitan sodný pentahydrát; Selenito sódico; Sodium (sélénite de) pentahydraté; Sodu selenin pięciowodny; Sodyum Selenit.
$Na_2SeO_3,5H_2O$ = 263.0.
CAS — 10102-18-8.
ATC — A12CE02.
ATC Vet — QA12CE02.

Pharmacopoeias. In *Eur.* (see p.vii). *BP(Vet)* includes anhydrous sodium selenite.

Ph. Eur. 6.2 (Sodium Selenite Pentahydrate). A white or almost white, hygroscopic, crystalline powder. Freely soluble in water; practically insoluble in alcohol. Store in airtight containers.

BP(Vet) 2008 (Sodium Selenite). A white to slightly greyish pink granular powder. Freely soluble in water; practically insoluble in alcohol and ether.

Adverse Effects

Overdosage of selenium has been associated with loss of hair, nail changes, diarrhoea, dermatitis, metallic taste, garlic odour of breath, irritability, fatigue, and peripheral neuropathy.

Effects on mortality. A systematic review[1] of the effect of antoxidant supplements on mortality in randomised primary and secondary prevention studies considered that selenium had no significant effect on mortality, either beneficial or harmful; however, it was recommended that future studies should be monitored closely for harm.

1. Bjelakovic G, *et al.* Antioxidant supplements for prevention of mortality in healthy participants and patients with various diseases. Available in The Cochrane Database of Systematic Reviews; Issue 2. Chichester: John Wiley; 2008 (accessed 18/06/08).

Toxicity. *Chronic* exposure to high amounts of selenium has been reported to cause toxic effects on endocrine function, hepatotoxicity, gastrointestinal disturbances, and dermatological effects such as nail and hair loss and dermatitis. There has been some suggestion also of neurotoxicity, and a possible increased risk of amyotrophic lateral sclerosis. Studies have had conflicting results, and different inorganic and organic forms may vary greatly in biological activity, toxicity, and nutritional importance.[1]

Acute toxicity has also been reported; characteristic symptoms of selenium toxicity are garlicky or sour breath odour, vomiting and gastrointestinal disturbances, restlessness, hypersalivation, muscle spasms, haemolysis, liver necrosis, cerebral and pulmonary oedema, coma, and death.[1-3] A man who had taken vitamin tablets containing between 500 and 1000 times the amount of selenium labelled on the bottle developed generalised alopecia, changes in nail colour, diarrhoea, worsening fatigue, and paraesthesias. Two weeks after stopping the vitamins, early regrowth of hair and yellowish-white and red transverse lines on his nails were noted.[2] In another case, an elderly man who was concerned that he might have prostate cancer ingested 10 g of sodium selenite. He developed significant abdominal pain, vomiting and diarrhoea, hypotension, and ventricular tachycardia. Blood tests showed acidosis, hypokalaemia and an excessive selenium concentration. Despite symptomatic therapy, he suffered a cardiac arrest and died.[3]

Pharmacokinetics

Selenium compounds are generally readily absorbed from the gastrointestinal tract. Selenium is stored in red blood cells, the liver, spleen, heart, and nails. It is converted in tissues to its metabolically active forms. Selenium is excreted in the urine, and to a lesser extent in the faeces.

Uses and Administration

Selenium is an essential trace element. It is an integral part of the enzyme system glutathione peroxidase, which protects intracellular structures against oxidative damage. Deficiency of selenium has been associated with an endemic form of cardiomyopathy, Keshan disease, seen in certain areas of China. It has also been associated with Kaschin-Beck disease, an endemic osteoarthropathy, which causes a severe deformity of the joints. Selenium is present in foods mainly as the amino acids selenomethionine and selenocysteine and derivatives.

Selenious acid and its sodium salt, sodium selenite, are used as a source of selenium, especially for patients with deficiency states after prolonged parenteral nutrition. Suggested doses for addition to total parenteral nutrition are 31.5 micrograms elemental selenium daily for adults and children greater than 40 kg, and 2 micrograms/kg daily for infants and children to a maximum of 30 micrograms daily. Sodium selenate has also been used.

For proven selenium deficiency that cannot be offset from food sources, selenium may be given orally, or by intramuscular or intravenous injection, usually in the form of sodium selenite pentahydrate, to provide doses of about 100 to 200 micrograms selenium daily; if necessary this can be increased to 500 micrograms daily.

Selenate and selenite salts are used for selenium deficiency states in veterinary medicine.

Action. References.

Administration in neonates. The low selenium plasma concentrations in preterm neonates have been suggested to be a potential risk factor for neonatal respiratory disorders and retinopathy of prematurity. A systematic review[1] found that supplementation with selenium did not reduce the incidence of these complications, nor is it associated with improved survival. However, it is associated with benefit in terms of reduction in the number of episodes of late-onset sepsis in very preterm infants. There was evidence that recommended doses in this group might be inadequate for some populations.

HIV infection and AIDS. A randomised controlled study found that oral supplementation with selenium 200 micrograms daily for 9 months suppressed the progression in HIV-1 viral load and provided indirect improvement of the CD4 count.[1] For a study reporting increased CD4 and CD8 counts, but increased genital HIV-1 shedding with multivitamin plus selenium supplementation, see HIV Infection and AIDS, p.1926.

Human requirements. In the UK dietary reference values (see p.1925)[1] and in the USA recommended dietary allowances (RDA)[2] have been published for selenium.

In the UK the reference nutrient intake for adults is 75 and 60 micrograms daily for men and women respectively; values are also given for infants and children of varying ages and for lactating women. The UK report also noted that there was no convincing evidence that high intakes protected against cancer or cardiovascular disease; indeed, there was even some evidence that high intakes disturbed selenium homoeostasis and it was recommended that the maximum safe intake from all sources should be set at 450 micrograms daily for adult males. The Expert Group on Vitamins and Minerals[3] have since established a safe upper level (SUL) for selenium of 450 micrograms daily.

In the USA, the RDA for adult males and females is 55 micrograms daily, and again values are also given for infants and children as well as pregnant and lactating women. The tolerable upper intake level is 400 micrograms daily.[2]

WHO have recommended a lower limit of the safe range of population mean intakes of dietary selenium of 40 micrograms daily for adult males and 30 micrograms daily for adult females.[4] A maximum daily safe dietary selenium intake of 400 micrograms was suggested for adults.

Prophylaxis of malignant neoplasms. Selenium supplementation did not protect against the development of new basal or squamous cell carcinomas of the skin in a study of patients with a history of these cancers.[1] Further follow-up data[2] showed a statistically significant increased risk of squamous cell carcinoma and of total non-melanoma skin cancer with selenium supplementation. However, analysis of secondary end-points at the first report indicated a reduced incidence of various other cancers in this study group.[1]

Subsequent study has suggested, in particular, an association between low selenium intake and the risk of prostate cancer; incidence was reduced by 63% in patients receiving the supplement.[3] Further follow-up confirmed this inverse association, but found that only men with low baseline selenium concentrations were likely to benefit.[4] Another group has also reported an inverse correlation between surrogate measurements of long-term selenium intake and the risk of advanced prostate cancer.[5] A case-control study[6] found an inverse association between pre-diagnostic plasma selenium concentrations and the subsequent risk of advanced prostate cancer, but not of localised prostate cancer. Higher pre-diagnostic selenium levels were associated with a lower risk of prostate cancer only for subjects with increased baseline prostate-specific antigen (PSA) concentrations (above 4 nanograms/mL). The authors hypothesised that selenium may influence tumour progression. Trials of selenium supplementation with prostate cancer detection as primary end-points are ongoing.

Similarly, an inverse association between selenium concentrations and the risk of bladder cancer has been reported, although results from case-control studies are inconsistent. Controlled studies investigating the effect of selenium on bladder cancer recurrence and prognosis are planned.[7]

For a finding that selenium supplementation had no beneficial effect on overall mortality, see Effects on Mortality, above.

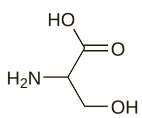
Serine *(USAN, rINN)*

β-Hydroxyalanine; S; Ser; Seriini; Serin; Serina; Serinas; Sérine; L-Serine; Serinum; Seryna; Szerin. L-2-Amino-3-hydroxypropionic acid.

Серин

$C_3H_7NO_3$ = 105.1.
CAS — 56-45-1 (serine); 302-84-1 (DL-serine).



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *US.*
Ph. Eur. 6.2 (Serine). White or almost white crystalline powder or colourless crystals. Freely soluble in water; practically insoluble in alcohol. Protect from light.
USP 31 (Serine). White, odourless crystals. Soluble in water; practically insoluble in dehydrated alcohol and in ether.

Profile

Serine is a non-essential amino acid. It is used as a dietary supplement.

The racemic form (DL-serine) has been included in iron supplements to increase iron absorption.

Preparations

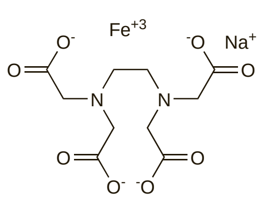
Proprietary Preparations (details are given in Part 3)
Used as an adjunct in: ***Austria:*** Aktiferrin; Aktiferrin Compositum; ***Cz.:*** Aktiferrin; Aktiferrin Compositum; ***Hung.:*** Aktiferrin; ***Israel:*** Aktiferrin-F; ***Malaysia:*** Aktiferrin-F; ***Rus.:*** Aktiferrin (Актиферрин); Aktiferrin Compositum (Актиферрин Композитум); ***Singapore:*** Aktiferrin-F; ***Switz.:*** Actiferrine; Actiferrine-F Nouvelle formule.

Sodium Feredetate *(BAN, rINN)*

Ferédétate de Sodium; Feredetato sódico; Natrii Feredetas; Sodium Ironedetate. The monohydrated iron chelate of the monosodium salt of ethylenediamine-*NNN′N′*-tetra-acetic acid; Iron (III) sodium ethylenediaminetetra-acetate monohydrate.

Натрия Фередетат

$C_{10}H_{12}FeN_2NaO_8,H_2O$ = 385.1.
CAS — 15708-41-5 (anhydrous sodium feredetate).
ATC — B03AB03.
ATC Vet — QB03AB03.



(anhydrous sodium feredetate)

Pharmacopoeias. In *Br.*
BP 2008 (Sodium Feredetate). A yellow or yellowish brown, hygroscopic, crystalline powder. A 1% solution in water has a pH of 4.0 to 6.5. Store in airtight containers.

Profile

Sodium feredetate is used as a source of iron (p.1949) for iron-deficiency anaemia (p.1951). It is given orally in doses of up to 1.42 g daily (equivalent to up to about 205 mg of iron daily).

Preparations

BP 2008: Sodium Feredetate Oral Solution.

Proprietary Preparations (details are given in Part 3)
Fr.: Ferrostrane; ***Philipp.:*** Ferrosmate; ***UK:*** Sytron.

Sodium Ferric Gluconate Complex *(USAN)*

Ferric Sodium Gluconate; D-Gluconic acid, iron (3+) sodium salt; Hierro gluconato sódico, complejo de; Iron Gluconate; Natrii ferrigluconas; Sodium Ferric Gluconate; Sodium ferrigluconate; Sodium-Iron(III) Gluconate Complex.

$[NaFe_2O_3(C_6H_{11}O_7)(C_{12}H_{22}O_{11})_5]_x$.
CAS — 34089-81-1.
ATC Vet — QB03AC07.

NOTE. Distinguish from Ferrous Gluconate.

Adverse Effects, Treatment, and Precautions

For parenteral iron, see Iron Dextran, p.1951.

Hypersensitivity. For a discussion as to whether sodium ferric gluconate complex may be a safer alternative to iron dextran, see p.1952.

Pharmacokinetics

Peak concentrations vary with the dose and rate at which sodium ferric gluconate complex is given. The volume of distribution does not appear to vary according to dose or rate. Elimination half-life varies by dose, and has been reported to be 0.85 hours for a dose of 62.5 mg and 1.45 hours for a dose of 125 mg; doses were given by slow intravenous injection.

Uses and Administration

Sodium ferric gluconate complex is used as a source of iron (p.1949) for iron-deficiency anaemia (p.1951). It is given as a solution containing the equivalent of 12.5 mg/mL of elemental iron. The recommended dose for haemodialysis patients who are receiving epoetin therapy is 125 mg iron (10 mL) diluted in 100 mL sodium chloride 0.9%, and given as an intravenous infusion over 1 hour; it may also be given undiluted as a slow intravenous injection (at a rate of 12.5 mg/minute) during dialysis. This dose is usually repeated over 8 dialysis sessions to achieve a favourable response. Children 6 years of age and older may be given 1.5 mg/kg of elemental iron (0.12 mL/kg), diluted in 25 mL sodium chloride 0.9% and infused over 1 hour, up to a maximum of 125 mg per dose.

Sodium Fluoride

Fluorid sodný; Fluoruro sódico; Natrii fluoridum; Natrio fluoridas; Natrium Fluoratum; Natriumfluorid; Nátrium-fluorid; Natriumfluoridi; Sodium, fluorure de; Sodu fluorek; Sodyum Fluorür.

NaF = 41.99.
CAS — 7681-49-4.
ATC — A01AA01; A12CD01.
ATC Vet — QA01AA01; QA12CD01.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *US.*
Ph. Eur. 6.2 (Sodium Fluoride). A white or almost white powder or colourless crystals. Soluble in water; practically insoluble in alcohol.
USP 31 (Sodium Fluoride). A white, odourless powder. Soluble 1 in 25 of water; insoluble in alcohol.

Adverse Effects and Treatment

In the controlled amounts recommended for fluoridation of drinking water and at the recommended doses used in dentistry for caries prophylaxis, sodium fluoride has not been shown to have significant adverse effects.

In **acute** poisoning, sodium fluoride taken by mouth is corrosive, forming hydrofluoric acid in the stomach. Adverse effects include a salty or soapy taste, increased salivation, gastrointestinal disturbances, abdominal pain, weakness, drowsiness, faintness, and shallow breathing; more serious effects include hypocalcaemia, hypomagnesaemia, hyperkalaemia, tremors, hyperreflexia, tetany, convulsions, cardiac arrhythmias, shock, respiratory arrest, and cardiac failure. Death may occur within 2 to 4 hours. Although there is much interindividual variation, a single oral dose of 5 to 10 g of sodium fluoride would be considered lethal in an untreated adult by most authorities. However, severe poisoning has been reported after oral doses of less than 1 g, and the minimum dose that can cause possibly fatal toxicity in children has been suggested to be 5 mg/kg of fluoride ion.

Treatment of acute poisoning involves gastric lavage with lime water or a weak solution of another calcium salt to precipitate fluoride, maintenance of high urine output, slow intravenous injections of calcium gluconate 10% for hypocalcaemia and tetany, and symptomatic and supportive measures. Magnesium sulfate may be given to correct hypomagnesaemia, and aluminium hydroxide may also reduce fluoride absorption. Haemodialysis may be considered.

Chronic fluoride poisoning may result in skeletal fluorosis, manifestations of which include increased density and coarsened trabeculation of bone and calcification in ligaments, tendons, and muscle insertions. Clinical signs are bone pain, stiffness, limited movement, and in severe cases, crippling deformities. Prolonged excessive intake by children during the period of tooth development before eruption can result in dental fluorosis characterised by mottled enamel. At fluoride concentrations in drinking water of 1 to 2 ppm (1 to 2 mg/litre) dental fluorosis is mild with white opaque flecks on the teeth. At higher concentrations, enamel defects become more severe with brown to black staining and the teeth have a pitted corroded appearance.

The **fluoridation** of water (below) has been a subject of considerable controversy. Suggestions that it increases the incidence of thyroid disorders, chromosome aberrations, and cancer have not been substantiated.

Carcinogenicity. Based on comparisons of cancer mortality rates for communities residing in fluoridated and non-fluoridated cities, it was alleged that artificial fluoridation of water might be associated with an increased risk of cancer.[1] Re-examination of these data by others did not confirm the relationship, nor did further studies in a number of countries.[2] In Great Britain, the Working Party on Fluoridation of Water and Cancer[3] found nothing that could lead them to conclude that either fluoride occurring naturally in water, or fluoride added to water supplies, was capable of inducing cancer, or of increasing the mortality from cancer. In this respect, fluoridation of drinking water was considered safe. Further study in *animal* models by the USA National Toxicology Programme[4] found no evidence of carcinogenicity in female *rats* or in *mice* of either sex. A small number of osteosarcomas was found in male *rats* in the medium- and high-dose groups, although the association between sodium fluoride and the tumour was uncertain. A review of epidemiological evidence of possible carcinogens in drinking water stated that additional data gathered since 1990 did not support an association between the risk of osteosarcoma, or any other cancer, and the fluoride in drinking water.[5]

A cohort study of workers exposed to high levels of fluoride dust reported excess incidences of primary lung cancer and bladder tumours.[6]

Effects on bones and joints. Exacerbation of **rheumatoid arthritis** in a 68-year-old woman was attributed to sodium fluoride given in a dose equivalent to 22 mg of fluorine daily for osteoporosis.[1]

An increased risk of **hip fracture** in the elderly has been suggested as being associated with fluoridated water;[2] another study[3] reported that this association was confined to fluoride concentrations of more than 110 micrograms/litre. However, a large case-control study[4] found no increase in the risk of hip fracture for people ingesting fluoridated water at concentrations of about 1 mg/litre (1 ppm). Similarly, a large prospective study[5] in older white women found no increase in the risk of fractures with long-term exposure to fluoridated drinking water, and even a suggestion of a reduction in the risk of fractures of the hip and vertebrae, due to increased bone mineral density of the femoral neck and lumbar spine, in those women continuously exposed to fluoridation. An epidemiological study in a large rural Chinese population determined that long-term fluoride exposure from drinking water containing 4.32 ppm or more increased the risk of overall fracture as well as hip fracture. Water containing 1 to 1.06 ppm decreased the risk of overall fractures relative to areas with negligible water fluoridation; a similar protective effect on the risk of hip fractures was not seen. Although the number of hip fractures were small, the authors suggested that this supported other findings that fluoride concentrations of about 1 ppm in drinking water do not increase the risk of hip fracture.[6] For comment on the influence of therapeutic doses of fluoride on the incidence of fractures, see below under Osteoporosis in Uses and Administration.

Use of fluoride, particularly in doses of 40 mg or more daily, may be associated with a **peripheral pain syndrome**, usually manifested as bone pain in the distal lower limbs, but sometimes involving the upper limbs and axial skeleton. The cause is uncertain: both stress fractures and increased bone growth at the site of pain have been proposed.[7]

Fluoride-related **bone disease** (skeletal fluorosis) manifesting as osteomalacia or osteosclerosis, has been reported after excessive consumption of tea (brewed, bottled, or iced).[8,9] Some bottled teas were found to have fluoride concentrations above the FDA's limit of 2.4 ppm for bottled beverages.[9]

Effects on the kidneys. Nephrotoxicity has been associated with high plasma concentrations of fluoride during anaesthesia with fluorine-containing anaesthetics such as methoxyflurane (p.1789). Elevated fluoride ion concentrations have also been noted in the plasma of patients receiving enflurane or isoflurane, although no clinical effect on renal function was found (see Effects on the Kidneys, p.1782 and Metabolism, p.1786).

Fluorosis. Discussions of chronic fluorosis.[1-5] In a 1994 report, WHO considered that in temperate climates, *teeth* seemed not to be affected if fluoride concentrations in drinking water were not greatly above 1 ppm; fluorosis affecting bone had not been detected at concentrations of 4 to 8 ppm in temperate regions, although it could occur at concentrations of more than 6 ppm in tropical areas.[6] However, a later systematic review[7] of the effects of water fluoridation, which included 214 studies worldwide, considered that at a concentration of 1 ppm, an estimated 12.5% of exposed people would develop sufficient fluorosis of their teeth to cause aesthetic concern. Swallowing of fluoridated toothpaste by young children has been implicated as a risk factor for fluorosis.[4,8] Higher concentrations of fluoride in toothpaste have been associated with less caries, but with higher levels of fluorosis,[9] and toothpastes with lower concentrations of fluoride have been recommended for use in children.[8,9] The use of infant formula feeds reconstituted with fluoridated water may result in ingestion of large amounts of fluoride[5] and subsequent fluorosis;[3] bottled water may also contain fluoride.[5]

Skeletal fluorosis associated with excess tea consumption has also been reported (see Effects on Bones and Joints, above).

Gum disease. In the Davangere district of India, the fluoride concentration in the drinking water ranges from 1.5 to 3 ppm; there is virtually no dental care. In a study of patients with dental fluorosis in this district, a strong association was found between the occurrence of periodontal disease and the severity of fluorosis; periodontitis was also high in subjects with poor oral hygiene. Gingivitis reduced as the degree of fluorosis increased. Fluoride may have a role in the etiology and pathogenesis of gum disease.[1]

1. Vandana KL, Reddy MS. Assessment of periodontal status in dental fluorosis subjects using community periodontal index of treatment needs. *Indian J Dent Res* 2007; **18:** 67–71.

Hypersensitivity. Dermatitis, urticaria, headaches, gastrointestinal reactions, stomatitis, and mouth ulcers have all been reported as hypersensitivity reactions after use of fluoride-containing toothpastes, tablets, drops or drinking water.[1] Topical treatment of the teeth with a sodium fluoride preparation has been reported to cause severe disseminated acute urticaria and facial angioedema, requiring hospitalisation.[2] However, 2 other cases of reaction to the same commercial preparation were considered to be due to colophony (p.2286) contained in the preparation.[3] It has been suggested that, in cases of probable toothpaste allergy, lack of response to patch tests on the skin may be because fluoride crosses the oral mucous membrane more easily than the skin.[4]

Stomatitis has also been reported after use of gels containing olaflur and dectaflur.[5]

Precautions

When considering fluoride supplementation, allowance should be made for fluorides ingested from other sources; fluoride supplements in children are not generally recommended when the fluoride content of drinking water is over 0.7 ppm (0.6 ppm in the USA) (see also Uses and Administration, below). Care should be taken to prevent children swallowing excessive fluoride after topical application to teeth.

Patients with impaired renal function may be particularly susceptible to fluorosis. Regular dialysis with fluoridated water may result in additional fluoride absorption; a maximum concentration of 0.2 ppm of fluoride in the dialysate has been recommended. Dialysis patients not using deionised water are at risk from changes in the fluoride content of the water supply.

Interactions

Aluminium, calcium, and magnesium salts may decrease the absorption of fluoride.

Pharmacokinetics

Sodium fluoride and other soluble fluorides are readily absorbed from the gastrointestinal tract. Inhaled fluorides (from industrial fumes and dusts) are absorbed through the lungs. Fluoride is deposited mainly in the bones and teeth. It is principally excreted in the urine but small amounts may also be excreted in faeces and sweat. It crosses the placenta and is present in saliva, nails, and hair. There is some evidence of distribution into breast milk.

Uses and Administration

Sodium fluoride is used to prevent dental caries and may be used to increase bone density in osteoporosis (see below). Sodium fluoride is used as a source of fluoride in total parenteral nutrition.

The content of sodium fluoride is usually expressed in terms of the fluoride; 2.2 mg of sodium fluoride is equivalent to about 1 mg of fluoride. Each g provides about 23.8 mmol of sodium and fluoride.

For **dental caries prophylaxis**, sodium fluoride is used as an adjunct to diet and oral hygiene. It may render the enamel of teeth more resistant to acid, promote remineralisation, or reduce microbial acid production. Fluoride can be given by *fluoridation* of the public water supply (below) to achieve a usual fluoride concentration of 1 ppm in temperate regions. The concentration may vary from 0.6 to 1.2 ppm depending on the climatic temperature with the lower concentrations being used in hotter regions where more water is likely to be consumed. Fluoridation of salt at a minimum concentration of 200 mg of fluoride per kg of salt is an alternative. Fluoridation of milk has been tried in some countries.

Alternatively, sodium fluoride may be given as an *oral supplement* to children considered to be at high risk of caries. The daily dosage should be adjusted for the fluoride content of the drinking water, for fluorides ingested from other sources such as the diet, and for the age of the child. Guidelines in the USA and the UK both suggest that, where the drinking water contains less than 0.3 ppm of fluoride, children may be given the following doses according to age:

- under 6 months, not recommended
- 6 months to 3 years, sodium fluoride 0.55 mg (equivalent to 0.25 mg of fluoride) daily
- 3 to 6 years, 1.1 mg (equivalent to 0.5 mg of fluoride) daily
- 6 years and over, 2.2 mg (equivalent to 1 mg of fluoride) daily.

When drinking water contains 0.3 to 0.7 ppm (0.3 to 0.6 ppm in the USA) of fluoride lower doses should be considered. Specifically, it is recommended that no additional fluoride should be given to children less than 3 years of age and for older children the above doses should be halved. If the water contains more than 0.7 ppm (0.6 ppm in the USA) of fluoride, supplementation is not recommended. Tablets should be sucked or chewed before swallowing since the topical action of fluoride on enamel and plaque is considered to be more important than the systemic effect. The value of giving fluoride during pregnancy, to benefit the child, is not established. Dental benefits from the use of dietary fluoride supplements by adults are unsubstantiated.

After tooth eruption, *local application* of fluoride is effective. Daily mouth-rinses of sodium fluoride 0.05% (about 225 ppm fluoride) or weekly mouth-rinses of sodium fluoride 0.2% (900 ppm) may be used, but are not recommended for children aged under 6 years because they are unable to effectively spit the rinse out after use. Sodium fluoride 2% (about 9090 ppm) solution is available for topical use, under professional supervision. Fluoridated toothpastes are now widely available and are a convenient source of fluoride. In the UK, the maximum permitted fluoride level in conventional toothpastes is sodium fluoride 0.32% (0.15% or 1500 ppm fluoride); higher concentrations of sodium fluoride 0.619% (2800 ppm fluoride) are available under professional supervision. Formulations for children under 7 years of age typically contain sodium fluoride 0.11% (500 ppm); higher concentrations may be used, but the amount applied should be supervised to avoid excessive use or ingestion. Sodium fluoride has also been applied topically as a varnish under professional supervision. Alternatively, sodium fluoride solutions or gels acidified with phosphoric acid (commonly known as acidulated phosphate fluoride preparations) may be used. These preparations are considered to increase the fluoride uptake by the enamel and protect the enamel from demineralisation. For maximum benefit, eating, drinking, or rinsing should be avoided for at least 15 to 30 minutes after topical fluoride application.

Other fluoride compounds used in oral hygiene products and toothpastes include aluminium fluoride, ammonium fluoride, calcium fluoride (p.1932), dectaflur (p.1937), magnesium fluoride (p.1955) nicomethanol hydrofluoride, olaflur (p.1959), potassium fluoride, sodium monofluorophosphate (p.1964), and stannous fluoride (p.1967). Other fluorides used in the fluoridation of water supplies include sodium silicofluoride (p.1965).

Sodium fluoride has also been used, like some other fluoride compounds, in **rodenticides** and **insecticides**.

Dental caries prophylaxis. There is strong and consistent evidence in favour of the effectiveness of fluoride in preventing or reducing the incidence of dental caries. However, there is no strong evidence that one form of topical fluoride is more effective than another.

Human requirements. In the USA dietary reference intakes have been set for fluoride. These propose an adequate intake (see p.1925) for dental caries prevention to be 4 mg daily in adult men and 3 mg in women;[1] lower values are suggested in children and adolescents, depending on age. The tolerable upper intake level is 10 mg daily in adults.[1]

Osteoporosis. Fluoride has been used in the treatment of osteoporosis (p.1084) to improve bone strength by inducing subclinical fluorosis. The main effect of fluoride on the skeleton is to stimulate osteoblasts and increase trabecular bone mass. Because antiresorptive drugs cannot restore lost bone mass, this is potentially valuable in the treatment of osteoporosis. However, too much fluoride can increase bone fragility, and the overall effect of sodium fluoride on the incidence of fracture has not been established.

A controlled study in patients with postmenopausal osteoporosis[1] found that sodium fluoride 75 mg daily with a calcium supplement increased trabecular bone mass of the spine but did not reduce the incidence of vertebral fractures. Patients given sodium fluoride also had a higher incidence of nonvertebral fractures. An extension and re-analysis of the study,[2] however, showed that gradual increases in bone mass observed in patients taking lower doses of sodium fluoride (down to about 40 mg daily) were associated with a decrease in the incidence of fractures. A previous study[3] had reported a beneficial effect in vertebral fracture rate in patients with primary osteoporosis and at least one vertebral crush fracture. In this study sodium fluoride was given in a daily dose of 50 mg; calcium and vitamin D were also given. Interim analysis of a subsequent study using a slow-release formulation of sodium fluoride 50 mg daily taken intermittently with a regular calcium supplement showed a decrease in vertebral fractures of 50% at 2.5 years.[4] At 4 years the beneficial effect was sustained, the main effect being seen in a reduced incidence of new vertebral fractures;[5] no reduction was seen in the incidence of recurrent fractures but this study found no evidence of an increase in nonvertebral fractures. Some consider that low-dose fluoride can be of benefit in established postmenopausal osteoporosis, but the therapeutic window is narrow, and calcium and vitamin D must also be given to meet the calcium demand and avoid resorption of established bone.[6] A further double-blind study failed to show a reduction in vertebral fracture rates in women with osteoporosis treated with fluoride, and calcium and vitamin D compared with women who received only calcium and vitamin D.[7] This was despite a significant increase in bone mass density of the spine in the fluoride-treated groups. Fluoride regimens consisted of 50 mg enteric-coated sodium fluoride daily, or 150 or 200 mg sodium monofluorophosphate daily. In contrast, a further 4-year study found a decrease in vertebral fracture rates in women with moderate osteoporosis treated with sodium monofluorophosphate 156 mg daily plus calcium compared with those receiving calcium alone.[8]

A systematic review of 11 studies concluded that fluoride can increase bone mineral density at the lumbar spine, but this does not reduce the rate of vertebral fractures.[9] The authors of this review considered that fluoride should not be used in the first-line therapy of postmenopausal osteoporosis.

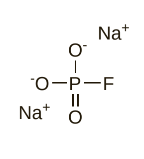
CAS — 10163-15-2.

ATC — A01AA02; A12CD02.

ATC Vet — QA01AA02; QA12CD02.



Pharmacopoeias. In *US.*

USP 31 (Sodium Monofluorophosphate). A white to slightly grey, odourless powder. Freely soluble in water. pH of a 2% solution in water is between 6.5 and 8.0.

Profile

Sodium monofluorophosphate is used as a source of fluoride (see Sodium Fluoride, p.1962) in toothpastes for the prevention of dental caries. It may also be given by mouth in the management of osteoporosis.

In the UK, the maximum permitted fluoride level in toothpastes is 1.14% of sodium monofluorophosphate (0.15% or 1500 ppm of fluoride). Formulations for children under 7 years of age typically contain sodium monofluorophosphate 0.38% (500 ppm fluoride); higher concentrations may be used, but the amount applied should be supervised to avoid excessive use or ingestion.

Other monofluorophosphate salts permitted for use in oral hygiene products and dentifrices include ammonium monofluorophosphate, calcium monofluorophosphate, and potassium monofluorophosphate. Glutamine monofluorophosphate has been used for osteoporosis.

Osteoporosis. For reference to the use of fluorides, including sodium monofluorophosphate, in the treatment of osteoporosis, see under Uses of Sodium Fluoride, p.1964.

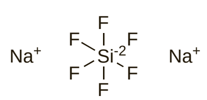
Sodium Silicofluoride

Fluosilicato sódico; Sodium Fluorosilicate; Sodium Fluosilicate; Sodium Hexafluorosilicate.

Na_2SiF_6 = 188.1.

CAS — 16893-85-9.



Profile

Sodium silicofluoride is used as a source of fluoride (see Sodium Fluoride, p.1962) for the fluoridation of drinking water. It has also been considered for inclusion in oral hygiene products.

Other silicofluoride (fluorosilicate) salts permitted for use in oral hygiene products include ammonium silicofluoride, magnesium silicofluoride, and potassium silicofluoride.

Sodium silicofluoride has also been used in insecticides.

Sorbitol

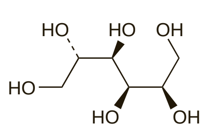
E420; D-Sorbitol; Sorbitoli; Sorbitolis; Sorbitolum; Szorbit. D-Glucitol.

$C_6H_{14}O_6$ = 182.2.

CAS — 50-70-4.

ATC — A06AD18; A06AG07; B05CX02; V04CC01.

ATC Vet — QA06AD18; QA06AG07; QB05CX02; QV04CC01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *Viet.* Also in *USNF.*

US includes only Sorbitol Solution.

Ph. Eur. 6.2 (Sorbitol). A white or almost white crystalline powder. It exhibits polymorphism. Very soluble in water; practically insoluble in alcohol.

USNF 26 (Sorbitol). White, odourless, hygroscopic powder, granules, or crystalline masses having a sweet taste with a cold sensation. Soluble 1 in 0.45 of water; sparingly soluble in alcohol; practically insoluble in solvent ether. pH of a 10% w/w solution in water is between 3.5 and 7.0.

Incompatibility. For reference to the incompatibility of sorbitol with hydroxybenzoates, see p.1649.

Adverse Effects and Precautions

As for Fructose, p.1945.

Effects on electrolyte balance. Sorbitol is used as a vehicle in some proprietary preparations of activated charcoal intended to reduce drug absorption after poisoning; the sorbitol increases the palatability of the preparation and also produces an osmotic diarrhoea that facilitates elimination of the activated charcoal and adsorbed drug. Repeated doses of such preparations are often advocated but there have been reports[1-3] of severe sorbitol-induced hypernatraemia in adults and children. In all cases, charcoal in a 70% sorbitol suspension had been given. It has been recommended that fluid and electrolyte balance be monitored closely, and that preparations with lower concentrations of sorbitol be used if possible.[2,3] For debate about such multiple dose therapy see Poisoning, under Activated Charcoal, p.1436.

3. Farley TA. Severe hypernatremic dehydration after use of an activated charcoal-sorbitol suspension. *J Pediatr* 1986; **109:** 719–22.

Effects on the gastrointestinal tract. Sorbitol is often used as a sweetener in sugar-free preparations and the risk of sorbitol-induced diarrhoea associated with such products has been highlighted.[1-4] Chronic sorbitol-induced diarrhoea with associated pneumatosis intestinalis has been reported in a child given 21.7 g sorbitol daily in liquid medications.[5] Colonic and upper gastrointestinal necrosis, including some fatalities, have been reported after use of sodium polystyrene sulfonate in sorbitol, and may have been associated with the sorbitol component, see p.1465.

It has also been suggested that sorbitol contributed to the morbidity in a patient who developed septicaemia as a complication of intestinal pseudo-obstruction, after the use of charcoal with sorbitol to treat self-poisoning with theophylline.[6] It was suggested that gaseous distension after bacterial metabolism of sorbitol had rendered the bowel wall ischaemic, facilitating passage of bacteria or of endotoxin into the systemic circulation.

6. Longdon P, Henderson A. Intestinal pseudo-obstruction following the use of enteral charcoal and sorbitol and mechanical ventilation with papaveretum sedation for theophylline poisoning. *Drug Safety* 1992; **7:** 74–7.

Pharmacokinetics

Sorbitol is poorly absorbed from the gastrointestinal tract after oral or rectal use. It is metabolised mainly in the liver, to fructose (see p.1945), a reaction catalysed by the enzyme sorbitol dehydrogenase. Some sorbitol may be converted directly to glucose by the enzyme aldose reductase.

Uses and Administration

Sorbitol is a polyhydric sugar alcohol (polyol) with half the sweetening power of sucrose. It occurs naturally in many fruits and vegetables and is prepared commercially by the reduction of glucose.

It has been given as a 30% solution as an alternative to glucose in parenteral nutrition (p.1923) but its use is not recommended because of the risk of lactic acidosis.

Sorbitol may be given orally or rectally as an osmotic laxative in the management of constipation (p.1693); doses of 20 to 50 g have been suggested.

Solutions containing about 3% of sorbitol are used as irrigating fluids in transurethral surgical procedures.

Sorbitol was formerly given intravenously as a 50% solution as an osmotic diuretic.

Sorbitol also acts as a bulk sweetening agent. It is used in limited quantities as a sweetener in energy-reduced diabetic food products. It is also used as an alternative to sucrose in many sugar-free oral liquid preparations and in sugar-free foods as it is less likely to cause dental caries.

Sorbitol also has humectant and stabilising properties and is used in various pharmaceutical and cosmetic products including toothpaste.

Preparations

Ph. Eur.: Sorbitol, Liquid (Crystallising); Sorbitol, Liquid (Non-crystallising); Sorbitol, Liquid, Partially Dehydrated;
USNF 26: Noncrystallizing Sorbitol Solution;
USP 31: Sorbitol Solution.

Soya Bean

Habas de soja; Soja Bean; Soyabean; Soybean.

Description. Soya bean is the seed of the soya plant *Glycine max* (*G. hispida*; *G. soja* (L.) Merr.). It is a source of soya oil and soya protein.*G.soja* Siebold & Zucc. is wild soybean.

Soya Oil

Aceite de soja; Soiae Oleum; Soijaöljy; Soja Bean Oil; Soja, huile de; Sojae oleum; Sojaolja; Sójový olej; Sojų aliejus; Soya Yağı; Soyabean Oil; Soya-bean Oil; Soybean Oil; Szójababolaj.

Pharmacopoeias. In *Chin., Jpn,* and *US.*

Eur. (see p.vii) includes both hydrogenated and refined oils. *Ger.* also includes a partially hydrogenated oil. *USNF* includes the hydrogenated oil.

Ph. Eur. 6.2 (Soya-bean Oil, Refined; Soiae Oleum Raffinatum). It is the fatty oil obtained from seeds of *Glycine soja* and *G. max* (*G. hispida*) by extraction and subsequent refining. It may contain a suitable antoxidant and is a clear, pale yellow liquid. Practically insoluble in alcohol; miscible with petroleum spirit. Store in well-filled containers at a temperature not exceeding 25°. Protect from light.

The BP 2008 directs that when Soya Oil, Soyabean Oil, or Soyabean Oil is demanded, Refined Soya Oil shall be supplied.

Ph. Eur. 6.2 (Soya-bean Oil, Hydrogenated; Soiae Oleum Hydrogenatum). It is obtained by refining, bleaching, hydrogenation, and deodorisation of soya oil. It consists mainly of triglycerides of palmitic and stearic acids and is a white or almost white mass or powder which melts to a clear, pale yellow liquid when heated. Practically insoluble in water; very slightly soluble in alcohol; freely soluble in dichloromethane, in petroleum spirit after heating, and in toluene. Protect from light.

USP 31: (Soybean Oil). The refined fixed oil obtained from the seeds of the soya plant *Glycine max* (Fabaceae). It may contain suitable antoxidants. A clear, pale yellow, oily liquid having a characteristic odour. Insoluble in water; miscible with chloroform and with ether. Store in airtight containers at a temperature not exceeding 40°. Protect from light.

USNF 26 (Hydrogenated Soybean Oil). The product obtained by refining, bleaching, hydrogenation, and deodorisation of oil obtained from seeds of the soya plant, *Glycine max* (Fabaceae). It consists mainly of triglycerides of palmitic and stearic acids. A white mass or powder that melts to a clear, pale yellow liquid when heated. M.p. between 66° and 72°. Practically insoluble in water; very slightly soluble in alcohol; freely soluble in dichloromethane, in petroleum spirit after heating, and in toluene. Store in airtight containers. Protect from light.

Incompatibility. For mention of the compatibility and stability of solutions and emulsions for parenteral nutrition see under Enteral and Parenteral Nutrition, p.1924.

Adverse Effects

Hypersensitivity reactions including fever and chills have been reported after the infusion of soya oil emulsion although they are considered to be fairly rare. Other rare immediate reactions include dyspnoea, cyanosis, hyperlipidaemia, hypercoagulability, nausea, vomiting, headache, and chest and back pain. Delayed reactions include hepatomegaly, splenomegaly, jaundice due to cholestasis, thrombocytopenia, leucopenia, and transient increases in liver function tests.

Prolonged or too rapid infusion of soya oil emulsion or its use in patients with impaired fat metabolism has been associated with the 'overload syndrome'. This is manifested by anaemia, leucocytopenia, thrombocytopenia, and impaired coagulation, hepatosplenomegaly, hyperlipidaemia, fever, focal seizures, shock, and coma. Metabolic acidosis has been associated with severe overdosage especially if carbohydrates are not also given. Pigmentation of tissues in the reticuloendothelial system after prolonged therapy with lipid emulsion infusions has also been reported.

Soya protein-based infant feeds can be antigenic and cause gastrointestinal adverse effects in sensitive individuals.

Bacteraemia. A strong association has been found between giving lipids through peripheral venous catheters made of Teflon and development of coagulase-negative staphylococcal bacteraemia in neonates.[1] It was suggested that investigation of catheters made of other materials, or other delivery systems, might reduce the opportunity for coagulase-negative staphylococci to adhere and come into contact with nutrient-rich growth media in the form of lipid emulsions. Others also took the view that this work should not lead to the abandonment of parenteral lipids in premature infants.[2]

2. Klein JO. From harmless commensal to invasive pathogen: coagulase-negative staphylococci. *N Engl J Med* 1990; **323:** 339–40.

Effects on the cardiovascular system. Sinus bradycardia has been reported in a patient receiving total parenteral nutrition that included soya oil-based emulsion via a central line.[1] The authors suggested that it might be wise to give fat emulsion only through a peripheral vein. However, sinus bradycardia has been reported after a safflower oil-based emulsion given via a peripheral vein as part of a TPN regimen.[2]

2. Traub SL, *et al.* Sinus bradycardia associated with peripheral lipids and total parenteral nutrition. *J Parenter Enteral Nutr* 1985; **9:** 358–60.

Effects on the endocrine system. Soya bean is a rich source of phytoestrogens including isoflavones, and it has been found that infants fed soya-based formula have high serum concentrations of these substances,[1] which has brought the safety of soya-based formulas into question. *Animal* and *in vitro* data suggest that isoflavones such as genistein have pharmacological effects on growth and development.[2] However, genistein and daidzein are less potent than endogenous oestrogens and have less binding affinity to oestrogen receptors.[3] It is not known to what extent infants are able to metabolise and deconjugate soya isoflavones.[4] A small retrospective study[5] observed no oestrogenic effects in children fed soya protein formula for at least 6 months. A larger retrospective cohort study[6] in adults observed no statistically significant differences between those who had been fed soya formula and those fed cow's milk formula as infants.

As yet, there is insufficient evidence of harm from soya-based formulas,[7] although further studies are deemed necessary to assess long-term effects.[2,4] The American Academy of Pediatrics[8] considers soya protein-based formulas to be safe and effective in healthy term infants, while providing no advantage over cow's milk protein-based formulas. However, soya-based formulas are not recommended for use in low birth-weight preterm infants because of concerns about poorer growth rates compared with infants given formulas based on cow's milk protein.

Before their supplementation with iodine, there had been reports of hypothyroidism associated with soya formula feeds. Abnormal thyroid function tests have since been reported in infants fed with soya formulas, and a retrospective analysis of infants with congenital hypothyroidism found those fed with soya took longer for their thyroid stimulating hormone levels to normalise.[9]

Effects on the nervous system. CNS disorders in 2 patients given infusions of fractionated soya emulsion included convulsions and coma; cortical blindness developed in one young woman.[1] A similar case was attributed to fat embolism,[2] but, occurring after what the manufacturers pointed out was a faster than recommended infusion,[3] may perhaps have represented a fat-overload syndrome. Neurological complications can be the presenting and principal signs of fat overload; focal and generalised seizures, weakness, and encephalopathy have been reported.[4]

Migraine with visual aura has also been reported in a 57-year old man taking soya beans, soya milk, and a soya protein supplement.[5]

Hypersensitivity. Urticaria has been reported in 2 patients after the intravenous use of soya oil emulsions.[1,2] In one case the patient had previously received the emulsion for 19 days without ill-effect.[1]

Anaphylactic reactions have been documented after the ingestion of several foods or foodstuffs containing, or prepared from, soya beans, although the exact allergen remains unknown. In one patient who suffered anaphylactic attacks after eating such products a specific IgE-antibody response to the allergen Kunitz soybean trypsin inhibitor was demonstrated.[3] This was not, however, the only allergen present in soya beans as other patients who had a negative response to this allergen had positive responses in whole soya bean tests. A type I reaction to soya bean protein has been described in patients given parenteral lipid emulsions containing soya bean lecithin as the emulsifier.[4] A patient who ingested a soya protein drink experienced exercise-induced anaphylaxis; skin prick tests were positive to soya, but specific IgE antibodies to soya were undetectable.[5]

IgE antibodies to soya bean antigens have also been found in workers who suffered from asthma after handling soya beans[6,7] leading to the suggestion that an allergic mechanism had been responsible; the asthma was believed to have been due to the dust released during the handling of the beans.

Pulmonary fat emboli. Pulmonary fat emboli or microemboli, sometimes fatal, have occurred in several infants who received infusions of fat emulsions based on soya oil.[1-3]

In one case[3] the patient's serum, which contained a high concentration of C-reactive protein, agglutinated the fat emulsion and this finding was considered to support the hypothesis that microemboli are formed by agglutination of fat emulsion in the blood by C-reactive protein. The authors of this report did not consider the precise pathogenesis to be clear, nor did they know whether the condition was preventable, but did suggest that it might be prudent either to ensure that the C-reactive protein concentration was normal (less than 10 mg/litre) or to perform a creaming test to determine which babies may embolise the infused fat emulsion. However, another study,[4] while not excluding a role of C-reactive protein in agglutination, failed to find any correlation between raised concentrations of this protein and the rate of agglutination. A review[5] classified fat embolism into those derived from direct entry of depot fat into the blood (e.g. after trauma), and those derived from agglutination of endogenous or exogenous fat. High concentrations of C-reactive protein were considered to be responsible for the agglutination of the liposomes of fat emulsions; chylomicrons and very low-density lipoproteins in the blood may also agglutinate, contributing to fat embolism.

Precautions

Intravenous soya oil emulsion should not be given to patients with severe liver disease, acute shock, or severe or pathological hyperlipidaemia, or when the ability to metabolise fat may otherwise be impaired. Caution has also been advised in patients with pulmonary disease, renal insufficiency, uncompensated diabetes mellitus, metabolic disorders, sepsis, anaemia, and some disorders of blood coagulation. If given to such patients, the elimination of fat should be monitored daily.

Intravenous soya oil emulsion may interfere with some laboratory tests if blood is taken before fat has adequately cleared; this may take 4 to 6 hours.

Egg-yolk phospholipids may be used as emulsifiers in some preparations, which should not be given to patients with severe egg allergy.

Fat emulsions may extract phthalate plasticisers from bags and giving sets and non-phthalate containing equipment should be used wherever possible.

Soya-based infant feeds should be avoided in infants with documented cow's milk protein-induced enteropathy or enterocolitis, as these infants are often also sensitive to soya protein.

Neonatal hyperbilirubinaemia. In neonates with hyperbilirubinaemia, intravenous lipid emulsions should be used with caution because of the risk of displacing bilirubin from albumin. The risk appears to be higher in preterm infants,[1] at higher doses,[1] and with intermittent rather than continuous dosing.[2]

1. Spear ML, *et al.* The effect of 15-hour fat infusions of varying dosage on bilirubin binding to albumin. *J Parenter Enteral Nutr* 1985; **9:** 144–7.
2. Brans YW, *et al.* Influence of intravenous fat emulsion on serum bilirubin in very low birthweight neonates. *Arch Dis Child* 1987; **62:** 156–60.

Uses and Administration

Emulsions of fractionated soya oil containing 10, 20, or 30% are given by slow intravenous infusion as part of total parenteral nutrition regimens (p.1923), usually with amino acid and carbohydrate solutions. The solutions and emulsions may be given at separate sites, at the same site through a Y-connector, or combined in one admixture. Fat emulsions provide a high energy intake in a relatively small volume. They may also be used to prevent or correct essential fatty acid deficiency. When used as a calorie source the dose of the emulsion is determined by the energy requirements and clinical status of the patient; the amount of total carbohydrate, generally, should not comprise more than 60% of patients' total calorie intake. For the prevention and correction of fatty acid deficiency about 5 to 10% of total calorific intake should be as an intravenous fat emulsion.

The composition and dosage recommendations of commercial preparations do differ slightly but they should be started slowly. Suggested initial rates for the 10% and 20% products are 1 mL/minute and 0.5 mL/minute respectively for 15 to 30 minutes. The rate may then be increased and up to about 500 mL (or 10 mL/kg) of 10% or 250 mL (or 5 mL/kg) of 20% emulsion may be given on the first day. The total daily dosage may then be increased gradually on subsequent days; suggested daily dose ranges are 500 to 1500 mL of a 10% or 500 to 1000 mL of a 20% emulsion and suggested rates of infusion are 500 mL of a 10% emulsion over a period of not less than 3 hours, and 500 mL of a 20% emulsion over not less than 5 hours. Where a 30% emulsion is used, a dose of 333 mL or about 4.75 mL/kg has been recommended, given over 5 hours or more; the first dose should not exceed 3 mL/kg.

Soya oil also has emollient properties and is used as a bath additive in the treatment of dry skin conditions.

Preparations made from whole soya beans, containing soya oil and soya protein, are used as the basis of lactose-free vegetable milks for infants and patients with lactose or similar disaccharide intolerance or with an allergy to cow's milk protein (see also below).

Administration. It has been suggested[1] that it is the concentration of phospholipid solubilisers, and particularly the excess present as free phospholipid liposomes, that determines the effect of lipid emulsions on plasma-lipid concentrations. In 20 premature infants requiring parenteral nutrition, infusion of up to 4 g/kg of fat daily as a 20% emulsion had less effect on plasma lipid concentrations than 2 g/kg daily as a 10% emulsion; the difference was thought to be due to the fact that the 20% emulsion was relatively liposome-poor, with a ratio of phospholipids to triglycerides of 0.06, whereas the liposome-rich 10% emulsion had a ratio of 0.12. The authors suggested that the 10% emulsion should not be used in preterm infants. Others noted similar results;[2] a 10% lipid emulsion with a reduced phospholipid content has, however, been reported to be relatively well tolerated in premature infants.[3]

For mention of the risk of kernicterus if lipid infusions are given to hyperbilirubinaemic neonates, see under Precautions, above.

Food intolerance. The American Academy of Pediatrics has recommended[1] that soya-based infant feeds are appropriate for use in galactosaemia and hereditary lactase deficiency, and documented allergy to cow's milk protein. However, infants with documented cow's milk protein enteropathy or enterocolitis should receive hydrolysed protein formula, as they are likely to be sensitive to soya protein. They concluded that soya-based infant feeds have no proven role in the prevention of atopic disease or in the management of infantile colic. In infants and children at high risk for developing food allergies or intolerance, a systematic review[2] found that there was no evidence that feeding with a soy formula compared to a cow's milk formula reduced the incidence of food allergies or intolerance.

The FDA has warned against the use of soya-based drinks intended for adults as the sole source for nutrition for infants.[3] It was stated that soya drinks can lead to severe protein and calorie malnutrition, multiple vitamin and mineral deficiency, and death in infants who receive no other source of nourishment, and should not be confused with soya-based infant formulas, which are specially formulated to meet the nutritional needs of infants.

For reference to the use of soya-based foods themselves causing allergic reactions, see under Hypersensitivity, above.

Hyperlipidaemias. Soya protein has been tried in the treatment of hyperlipidaemia (p.1169). Soya isoflavones such as genistein (p.2391) and daidzein (p.2391) can mimic oestrogen and should therefore have a beneficial effect on blood lipids.[1,2] Other constituents of soya protein, including fytic acid and saponins, may also contribute and thus intact soya protein may provide the maximum cholesterol-lowering effect.[2,3] A meta-analysis of controlled trials found that the substitution of soya protein for animal protein in the diet resulted in significant decreases in serum total cholesterol, low-density lipoprotein (LDL)-cholesterol, and triglyceride concentrations.[4] A subsequent systematic review of studies reached similar conclusions,[1] and the FDA considered that a low-fat diet including 25 g daily of soya protein might reduce the risk of ischaemic heart disease.[2] A later analysis by the American Heart Association[5] considered that cardiovascular benefit was very modest and appeared only when large amounts of animal protein were substituted with soya protein. The effect appeared to be more to do with a broader modification of diet than any effect of soya isoflavones. Soya protein does not appear to have a cholesterol-lowering effect in subjects with normal cholesterol concentrations,[2] although a small study found it to be beneficial in type 2 diabetes patients with near-normal lipid concentrations.[6]

Menopausal disorders. Soya contains phytoestrogens in the form of isoflavones, in particular genistein (p.2391) and daidzein (p.2391), which have been investigated for their oestrogen-modulating effects in the treatment of menopausal symptoms (p.2077).[1] It is thought that genistein may exert oestrogenic effects in the presence of low oestrogen concentrations, but that it may be anti-oestrogenic when concentrations of oestrogen are high.[2]

A small reduction in the incidence of hot flushes has been noted with soya isoflavone extract.[3] A systematic review,[4] however, concluded that phytoestrogens available as soya foods, soya extracts, or red clover extracts (p.2285) do not improve hot flushes or other menopausal symptoms.

Isoflavones may have a beneficial effect on cholesterol and lipid concentrations (see Hyperlipidaemias, above). Some epidemiological studies and *animal* data suggest that they may also provide protection against breast cancer.[1,2,5] However, phytoestrogens could also stimulate breast tumour growth due to oestrogenic activity.[6] These stimulating and inhibitory effects may be concentration-dependent; soya products contain only small amounts of phytoestrogens and it may be difficult to consume enough soy to have any beneficial effect on breast cancer growth.[7] A meta-analysis[8] concluded that soya intake may be associated with a small reduction in breast cancer risk, but that this result should be interpreted with caution due to confounding factors and a lack of dose response. Given the possibility of adverse effects, recommendations for high-dose soya isoflavone supplementation to prevent breast cancer or its recurrence are premature.

A few small studies have shown that soya isoflavones can decrease bone turnover, leading to speculation that they could be used to prevent osteoporosis (p.1084).[1] The effects of these isoflavones should be investigated in larger trials before they can be recommended as alternatives to conventional HRT.[5-7,9] (For the view that they may lack cardiovascular benefits see Hyperlipidaemias, above.) In a trial to investigate effects on cognitive function, bone mineral density, and plasma lipids in postmenopausal women, no differences were noted between soya protein containing isoflavones, and placebo.[10]

Stannous Fluoride

Fluoruro estañoso; Stannosi Fluoridum. Tin fluoride.

SnF_2 = 156.7.

CAS — 7783-47-3.

ATC — A01AA04.

ATC Vet — QA01AA04.

Pharmacopoeias. In *US.*

USP 31 (Stannous Fluoride). A white crystalline powder. Freely soluble in water; practically insoluble in alcohol, in chloroform, and in ether. pH of a freshly prepared 0.4% solution in water is between 2.8 and 3.5.

Stability. Aqueous solutions of stannous fluoride decompose within a few hours with the formation of a white precipitate; they slowly attack glass.

Profile

Stannous fluoride is used as a source of fluoride (see Sodium Fluoride, p.1962) for the prophylaxis of dental caries. Dental gels containing concentrations of stannous fluoride 0.4% are available for daily use. Higher concentrations have been applied under professional supervision. Stannous fluoride has also been used in dentifrices and mouth rinses.

Stannous fluoride has an unpleasant taste.

Preparations

USP 31: Stannous Fluoride Gel.

Proprietary Preparations (details are given in Part 3)

Fr.: Emoform; ***Ital.:*** Fluorigard Gel-Kam; Gel-Kam†; Oral-B Pasta Dentifricia Denti e Gengive; ***Switz.:*** Parocare†; ***UK:*** Fluorigard Gel-Kam; ***USA:*** Gel Kam; Gel-Kam; Gel-Tin; PerioMed; Stop.

Multi-ingredient: ***Fr.:*** Meridol†; ***Israel:*** Meridol; ***Ital.:*** Actifluor†.

Starch

Almidón; Amido; Amidon; Amidon de blé (wheat starch); Amidon de maïs (maize starch); Amidon de pomme de terre (potato starch); Amidon de riz (rice starch); Amidon prégélatinisé (pregelatinised starch); Amilo; Amylum; Amylum pregelificatum (pregelatinised starch); Bulvių krakmolas (potato starch); Burgonyakeményítő (potato starch); Búzakeményítő (wheat starch); Hidegenduzzadó keményítő (pregelatinised starch); Kukoricakeményítő (maize starch); Kukurūzų krakmolas (maize starch); Kviečių krakmolas (wheat starch); Maissitärkkelys (maize starch); Majsstärkelse (maize starch); Maydis amylum (maize starch); Oryzae amylum (rice starch); Perunatärkkelys (potato starch); Potatisstärkelse (potato starch); Pregelifikuotas krakmolas (pregelatinised starch); Pšeničný škrob (wheat starch); Riisitärkkelys (rice starch); Risstärkelse (rice starch); Rizskeményítő (rice starch); Ryžių krakmolas (rice starch); Škrob bramborový (potato starch); Škrob kukuřičný (maize starch); Škrob předbobtnalý (pregelatinised starch); Škrob rýžový (rice starch); Skrobia kukurydziana (maize starch); Skrobia pszeniczna (wheat starch); Skrobia ziemniaaczana (potato starch); Solani amylum (potato starch); Stärke; Tritici amylum (wheat starch); Vehnätärkkelys (wheat starch); Vetestärkelse (wheat starch).

CAS — 9005-25-8 (starch); 9005-82-7 (α-amylose); 9004-34-6 (β-amylose); 9037-22-3 (amylopectin).

Description. Starch consists of polysaccharide granules obtained from the caryopsis of maize, *Zea mays*, rice, *Oryza sativa*, wheat, *Triticum aestivum* (*T. vulgare*), from the tubers of potato, *Solanum tuberosum* or from the rhizomes of cassava, *Manihot utilissima*. Maize starch is also known as corn starch. Starch contains amylose and amylopectin, both polysaccharides based on α-glucose.

Pharmacopoeias. Some or all of the starches described are included in *Chin., Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*
Chin. and *Eur.* also include Pregelatinised Starch, *USNF* also includes Pregelatinized Starch, Modified Starch, and Pregelatinized Modified Starch. *US* includes Absorbable Dusting Powder and Topical Starch.

Ph. Eur. 6.2 (Maize Starch; Maydis Amylum). It is obtained from the caryopsis of *Zea mays*. It is a tasteless, matt, white to slightly yellowish, very fine powder that creaks when pressed between the fingers. The presence of granules with cracks or irregularities on the edge is exceptional. Practically insoluble in cold water and in alcohol. Store in airtight containers.

Ph. Eur. 6.2 (Potato Starch; Solani Amylum). It is obtained from the tuber of *Solanum tuberosum*. It is a very fine, white or almost white powder which creaks when pressed between the fingers. It does not contain starch grains of any other origin but may contain a minute quantity, if any, of fragments of the tissue of the original plant. Practically insoluble in cold water and in alcohol. The pH of a 20% mixture in water after 15 minutes is 5.0 to 8.0. Store in airtight containers.

Ph. Eur. 6.2 (Rice Starch; Oryzae Amylum). It is obtained from the caryopsis of *Oryza sativa*. It is a tasteless, very fine, white or almost white powder which creaks when pressed between the fingers. The presence of granules with cracks or irregularities on the edge is exceptional. Practically insoluble in cold water and in alcohol. Store in airtight containers.

Ph. Eur. 6.2 (Wheat Starch; Tritici Amylum). It is obtained from the caryopsis of *Triticum aestivum* (*T. vulgare*). It is a very fine, white or almost white powder which creaks when pressed between the fingers. It does not contain starch grains of any other origin but may contain a minute quantity, if any, of fragments of the tissue of the original plant. Practically insoluble in cold water and in alcohol. The pH of a 20% mixture in water after 15 minutes is 4.5 to 7.0. Store in airtight containers.

Ph. Eur. 6.2 (Pregelatinised Starch; Amylum Pregelificatum). It is prepared from maize starch, potato starch, or rice starch by mechanical processing in the presence of water, with or without heat, to rupture all or part of the starch granules, and subsequent drying. It contains no added substances but it may be modified to render it compressible and to improve its flow characteristics. It is a white or yellowish white powder that swells in cold water.

BP 2008 (Tapioca Starch). It is obtained from the rhizomes of *Manihot utilissima*. It is a very fine powder which creaks when pressed between the fingers. Practically insoluble in cold water and in alcohol. Store in airtight containers.

The BP 2008 gives Cassava Starch as an approved synonym.

The BP 2008 directs that when starch is specified and the type is not indicated, Maize Starch, Potato Starch, Rice Starch, Wheat Starch, or in tropical countries where these are not available, Tapioca Starch may be supplied or used.

USNF 26 (Corn Starch). It consists of the starch granules separated from the mature grain of corn, *Zea mays* (Gramineae). Irregular, angular, white masses or fine powder. Is odourless, and has a slight, characteristic taste. Insoluble in cold water and in alcohol. A 20% slurry in water, allowed to stand for 15 minutes after 1 minute of moderate agitation, has a pH of 4.0 to 7.0.

USNF 26 (Potato Starch). It is obtained from the tuber of *Solanum tuberosum*. Irregular, angular, white masses or fine powder. Is odourless, and has a slight, characteristic taste. Insoluble in cold water and in alcohol. A 20% slurry in water, allowed to stand for 15 minutes after 1 minute of moderate agitation, has a pH of 5.0 to 8.0.

USNF 26 (Tapioca Starch). Granules separated from the tubers of tapioca (cassava), *Manihot utilissima* (Euphorbiaceae). Irregular, angular, white to pale yellow masses or fine powder. Insoluble in cold water and in alcohol. A 20% slurry in water after 5 minutes of continuous agitation has a pH of 4.5 to 7.0.

USNF 26 (Wheat Starch). It is obtained from the caryopsis of *Triticum aestivum* (*T. vulgare*). Irregular, angular, white masses or fine powder. Is odourless and has a slight, characteristic taste. Insoluble in cold water and in alcohol. A 20% slurry in water, allowed to stand for 15 minutes after 1 minute of moderate agitation, has a pH of 4.5 to 7.0.

USNF 26 (Pregelatinized Starch). It is starch that has been chemically and/or mechanically processed to rupture all or part of the granules in the presence of water and subsequently dried. It may be modified to render it compressible and flowable.

USNF 26 (Modified Starch). It is starch modified by chemical means. Food starch may be acid-modified, bleached, oxidised, esterified, etherified, or treated enzymatically to change its functional properties. A 20% slurry in water, after 5 minutes stirring at a moderate rate, has a pH of 3.0 to 9.0.

USNF 26 (Pregelatinized Modified Starch). It is Modified Starch that has been chemically or mechanically processed, or both, to rupture all or part of the granules to produce a product that swells in cold water. Moderately coarse to fine, white to off-white powder. It is odourless and has a slight, characteristic taste. Slightly soluble to soluble in cold water; insoluble in alcohol.

Adverse Effects

Effects of cassava. In 1985 WHO added *malnutrition-related diabetes* (which included the type previously known as tropical diabetes) to its classification of diabetes mellitus.[1] Epidemiological evidence had suggested an association between fibrocalculous pancreatic diabetes (a subclass of malnutrition-related diabetes) and the consumption of cassava root (tapioca, manioc), which for many people living in tropical developing countries, where protein intake was low, was the main source of food energy.

Cassava root contains several cyanogenic substances and although food preparation and processing could reduce the cyanide content, there was the possibility that in persons with an inadequate protein intake, particularly if deficient in sulfur-containing amino acids which are involved in detoxification pathways, accumulation of cyanides might occur. WHO, however, did consider that further research was necessary to firmly establish any relation between this type of diabetes and high levels of cassava consumption. In a review that appeared in the following year[2] the cassava/malnutrition hypothesis was thought to be attractive, but unproven; also there was strong evidence against it being the only cause.

WHO deleted malnutrition-related diabetes from its most recent report on the classification of diabetes.[3] Fibrocalculous pancreatic diabetes is now fibrocalculous pancreatopathy, a disease which may cause diabetic mellitus but is not considered a form of diabetes.

Konzo, an upper motor neurone disease characterised by spastic paraparesis,[4] and commonly associated with optic neuropathy,[5] has been reported to be caused by dietary exposure to cyanide after ingestion of cassava root. *Growth retardation* has also been associated with consumption of inadequately processed cassava.[6]

Glove powder. The use of starch glove powders by surgeons has resulted in contamination of surgical wounds by starch and in the development of complications such as inflammation, adhesions, and granulomatous lesions. In addition, glove starch powder may be a risk factor in the development of latex allergy, and may act as a vector for bacterial pathogens. Because of these risks, it has been proposed that the use of powder in latex gloves be banned.[1-4]

Uses and Administration

Starch is absorbent and is widely used in dusting powders, either alone or mixed with zinc oxide or other similar substances. Starch is used as a surgical glove powder, but such use has been discouraged (see above). It is incorporated in many tablets as a binder, diluent, or disintegrating agent. Pregelatinised starch is used similarly as a tablet binder.

Starch mucilage is given by mouth in the treatment of iodine poisoning; it has been used topically as a skin emollient.

Rice-based solutions may be used in the prevention and treatment of dehydration due to acute diarrhoeal diseases (p.1694).

Glycogen storage disease type I. Type I glycogen storage disease is an autosomal recessive metabolic disorder in which glucose-6-phosphatase is not expressed, resulting in hypoglycaemia due to lack of glucose production. Accumulation of glycogen and other metabolic derangements can lead to complications including renal impairment, hepatomegaly and hepatic adenoma, hyperuricaemia, hyperlipidaemias, and lactic acidosis. The condition has been successfully managed by continuous nocturnal nasogastric infusion of glucose and frequent daytime feedings. However, such a regimen requires good patient compliance and monitoring of the night-time infusions.[1] As an alternative, a more standard diet together with uncooked corn starch suspensions prepared with tap water at room temperature and taken every 6 hours in doses of 1.75 to 2.5 g/kg have been reported[2] to be very satisfactory in maintaining normoglycaemia. In one infant, in whom starch was unsatisfactory, the lack of response was considered to be due to inadequate pancreatic amylase activity and although it was subsequently reported[3] that addition of a pancreatic enzyme concentrate had produced some improvement, the response was still inadequate to maintain normoglycaemia for more than 2 hours. It was considered that other amylase preparations should be identified for possible use in such patients. A small study of 7 young adults with glycogen storage disease type I found that a single dose of uncooked corn starch maintained plasma glucose concentrations for 7 hours in 5 of the patients.[4] A long-term study of the effects of corn starch therapy found that complications were less among patients with near normal metabolic control and in those having started therapy at a younger age, but other factors appeared to be involved in the pathogenesis.[5] Corn starch therapy has nonetheless been reported to have caused the amelioration of proximal renal tubular dysfunction in 3 patients who had previously only received frequent daytime feeding as therapy. In 16 other patients who had previously received treatment with corn starch or glucose infusions such renal dysfunction was not identified and it was considered that the rapid response to therapy may explain why renal tubular dysfunction is not found more frequently in these patients.[6]

Because optimal metabolic control reduces the risk of developing long-term complications, an attempt has been made to define guidelines for long-term management of the disease.[7] Continuous nocturnal nasogastric feeding with a glucose or glucose polymer or a sucrose-free maltodextrin formula low in lactose may be introduced in very young infants. Uncooked corn starch should not be started in patients under 1 year of age as pancreatic amylase activity may be immature. Thereafter, since no significant differences in growth or biochemical parameters have been found between the use of nocturnal nasogastric infusions and uncooked corn starch overnight, corn starch may be started at a dose of 250 mg/kg and increased slowly to prevent adverse effects. It is recommended that the corn starch be mixed with water in a ratio of 1:2 and that an uncooked corn starch tolerance test be performed to establish the duration of the fasting period. The total dietary plan should aim to provide 60 to 65% of the total energy intake from carbohydrates, 10 to 15% from protein, and the remainder from fat, preferably vegetable oils with a high linoleic acid content. Lactose, fructose, and sucrose should be restricted. Drug therapy for metabolic complications may be necessary, such as allopurinol for hyperuricaemia, and bicarbonate for correction of lactic acidosis.[7]

For mention of the possible role of starch in glycogen storage disease type V, see under Sucrose, p.1970.

For a brief description of glycogen storage disease type II, see under Acid Alpha Glucosidase, p.2245.

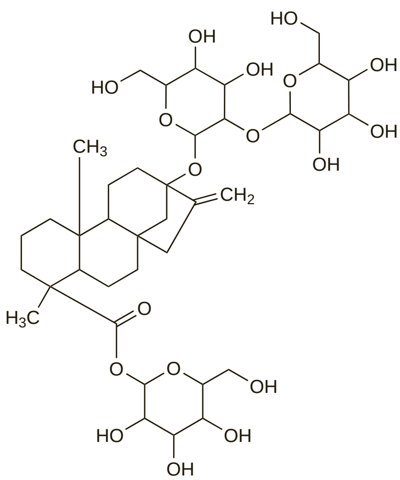
Stevioside

Esteviósido; Eupatorin; Rebaudin; Stevin; Steviosin.
$C_{38}H_{60}O_{18}$ = 804.9.
CAS — 57817-89-7.



Pharmacopoeias. In *Chin.*

Profile

Stevioside is a glycoside extracted from the leaves of yerba dulce, *Stevia rebaudiana* (Compositae). It has about 300 times the sweetness of sucrose and has been used as a sweetening agent in foods. Both the related glycoside rebaudioside A (rebiana), and an extract of the leaves of *Stevia rebaudiana* which contains these and other glycosides, have been used similarly. The use of stevioside or stevia leaves as a sweetener has been banned in some countries due to concerns about genotoxicity and possible effects on fertility.

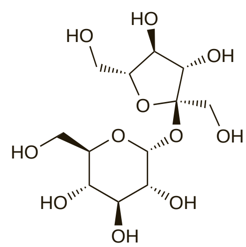
Sucrose

Azúcar; Cane Sugar; Refined Sugar; Sacarosa; Saccharose; Saccharosum; Saccharum; Sacharosa; Sacharoza; Sacharozė; Sackaros; Sakkaroosi; Sucre; Sucrosum; Szacharóz; Zucker. β-D-Fructofuranosyl-α-D-glucopyranoside.
$C_{12}H_{22}O_{11}$ = 342.3.
CAS — 57-50-1.



Description. Sucrose is obtained from sugar-cane, *Saccharum officinarum* (Gramineae), sugar-beet, *Beta vulgaris* (Chenopodiaceae), and other sources.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn,* and *Viet.* Also in *USNF.*
Br. also contains Compressible Sugar.
Eur. also includes Sugar Spheres.
USNF also includes Compressible Sugar, Confectioner's Sugar, and Sugar Spheres.

Ph. Eur. 6.2 (Sucrose). A white or almost white, crystalline powder or shiny, colourless or white or almost white crystals. Very soluble in water; slightly soluble in alcohol; practically insoluble in dehydrated alcohol.

USNF 26 (Sucrose). A sugar obtained from *Saccharum officinarum* (Gramineae), *Beta vulgaris* (Chenopodiaceae), and other sources. White, crystalline powder or lustrous, dry, colourless or white crystals. Soluble 1 in 0.5 of water, 1 in 0.2 of boiling water, and 1 in 170 of alcohol; practically insoluble in dehydrated alcohol.

Incompatibility. Sucrose may be contaminated by traces of heavy metals or sulfites and this can lead to incompatibility with other ingredients when it is used as a pharmaceutical excipient. Syrup preserved with hydroxybenzoates has been reported to be incompatible with a range of compounds.

Adverse Effects and Precautions

Sucrose consumption increases the incidence of dental caries.

Sucrose use should be avoided in patients with the glucose-galactose malabsorption syndrome, fructose intolerance, or sucrase-isomaltase deficiency. The intake of sucrose from dietary and other sources must be controlled in patients with diabetes mellitus.

Dietary sugar. The Panel on Dietary Sugars reviewed the evidence relating to sugars in the diet and the health of the population in the UK.[1]

No evidence was found that the consumption of most sugars naturally incorporated into the cellular structure of foods (intrinsic sugars) represented a threat to health and consideration was therefore mainly directed towards the dietary use of sugars not so incorporated (extrinsic sugars), of which sucrose was the principal non-milk extrinsic sugar.

There was extensive evidence suggesting that sugars were the most important dietary factor in the cause of dental caries and it was recommended that consumption of non-milk extrinsic sugars should be decreased.

It was considered that dietary sugars may contribute to the development of obesity, a condition which plays an important part in the aetiology of a number of diseases. For the majority of the population, who had normal plasma lipids and normal glucose tolerance, the consumption of sugars within the present range carried no special metabolic risks but those persons consuming more than about 200 g daily should replace the excess with starch. It was, however, recommended that those with special medical problems such as diabetes or hypertriglyceridaemia should restrict non-milk extrinsic sugar to less than about 20 to 50 g daily unless otherwise instructed by their own physician or dietitian. It was also concluded that current consumption of sugars, particularly sucrose, played no direct causal role in the development of cardiovascular (atherosclerotic coronary, peripheral, or cerebral vascular) disease, essential hypertension, or diabetes mellitus, and also had no significant specific effects on behaviour or psychological function. Although links between sucrose intake and certain other diseases (such as colorectal cancer, renal and biliary calculi, and Crohn's disease) had been proposed it was not felt that the evidence was adequate to justify any general dietary recommendations.

The conclusions of a joint FAO/WHO consultation on carbohydrates in human nutrition[2] were broadly in agreement with the above. However, they noted that the terms intrinsic and extrinsic sugars had not gained wide acceptance, either in the UK or other countries in the world, and they recommended against the use of these terms.

Effects on the kidneys. Acute renal failure with severe hyponatraemia has followed the use of granulated sugar to treat an infected pneumonectomy wound cavity.[1] It was noted that intravenous sucrose had long been known to be nephrotoxic in both *animal* models and man and that mild renal insufficiency before sucrose intoxication might have contributed to the nephrosis. Others, however, considered that the nephrotoxicity might have been caused by gentamicin, a solution of which had been used to irrigate the cavity before packing the wound.[2] Intravenous immunoglobulin preparations containing sucrose (as a stabilising agent) have also caused acute renal failure.[3,4]

Pharmacokinetics

Sucrose is hydrolysed in the small intestine by the enzyme sucrase to glucose and fructose, which are then absorbed. Sucrose is excreted unchanged in the urine when given intravenously.

Uses and Administration

Sucrose, a disaccharide, is used as a sweetening agent. It is commonly used as household sugar. If the sweetness of sucrose is taken as 100, fructose has a value of about 173, glucose 74, maltose 32, galactose 32, and lactose 16.

Sucrose is used as a tablet excipient and lozenge basis, and as a suspending and viscosity-increasing agent. Syrups prepared from concentrated solutions of sucrose form the basis of many linctuses. Treacle (molasses), a byproduct of sugar production that contains sucrose and minerals, has also been used.

Sucrose 30% eye drops have been used as a hypertonic agent for clearing corneal oedema.

Cough. Sucrose syrups are used as demulcents in linctuses used for treating cough (p.1547).

Diagnostic test for gastrointestinal damage. Sucrose is not absorbed from the healthy gastrointestinal tract. It has been proposed that the absorption of sucrose could be used as a diagnostic test of gastric damage.[1-3]

Gastrointestinal spasm. For mention of a beneficial effect of sucrose solution in infant colic, see p.1696.

Glycogen storage disease type V. Glycogen storage disease type V (McArdle's disease) is a rare autosomal recessive disorder characterised by mutations in the gene for myophosphorylase, an enzyme essential for glycogenolysis.[1,2] Patients present with exercise-induced pain, cramps, fatigue, and myoglobinuria which, if severe, can cause acute renal failure.[2] Low-dose creatine supplementation (60 mg/kg daily) produced modest benefits during ischaemic exercise testing, but higher doses (150 mg/kg daily) worsened symptoms.[2] Sucrose 75 g by mouth improved exercise tolerance in 12 patients in a randomised crossover study.[1] Uncooked corn starch, either alone or with sucrose, has been suggested as an alternative in order to avoid any pronounced increase in serum insulin,[3] but this has been rejected on the basis that the necessary rapid increase in blood glucose will not be produced.[4]

Hiccup. Giving a teaspoon of dry granulated sugar resulted in the immediate cessation of hiccup in 19 of 20 patients;[1] 12 of the patients had suffered from hiccup for less than 6 hours but in the remaining 8 persistent hiccup had been present for 24 hours to 6 weeks. The effect may be due to stimulation of the pharynx. An early protocol for the treatment of intractable hiccup (p.976) suggests that swallowing dry granulated sugar is one of the first treatments that should be tried.

1. Engleman EG, *et al.* Granulated sugar as treatment for hiccups in conscious patients. *N Engl J Med* 1971; **285:** 1489.

Pain. A systematic review[1] concluded that sucrose solutions could reduce physiological and behavioural indicators of stress and pain in neonates undergoing painful procedures although there had been some doubt expressed[2] over whether this indicated effective analgesia. The review[1] was unable to determine an optimal dose, but 1 mL of a 25% solution or 2 mL of a 50% solution has been reported to reduce crying time in premature[3] and full-term[4] infants, respectively, when given 2 minutes before heel-prick sampling. Similarly, 2 mL of a 75% sucrose solution by mouth reduced crying time in infants given intramuscular vaccines,[5] and 2 mL of oral sucrose 24% reduced pain scores in premature infants undergoing eye examinations for retinopathy of prematurity.[6] One literature review[7] suggested that a dose of 500 mg sucrose provided effective analgesia for neonates. However, a randomised study found pacifiers (dummies) to have a better analgesic effect than 2 mL of a 30% sucrose solution; a synergistic effect was found with a combination of sucrose and pacifiers.[8] Another review[9] recommended that, along with a pacifier, 0.1 to 0.4 mL of a 24% sucrose solution be given to premature infants, and up to 2 mL be given to term infants. Others have recommended the use of 0.5 mL/kg of a 33% sucrose solution (about 170 mg/kg), stating that more dilute solutions carry a risk of bacterial contamination.[10] The route by which sucrose solution is given may also be important: a reduced pain response was only noted after intraoral doses; giving it via a nasogastric tube was ineffective.[11]

A study in preterm infants found that, while there were no differences on neurobehavioural developmental outcomes between infants given repeated sucrose analgesia or placebo, higher number of doses of sucrose predicted lower scores in motor development, vigour, alertness and orientation. The authors postulated that repeated stimulation by sucrose may interfere with normal functioning and maturation of the preterm infant's endogenous opiate system, and cautioned against the routine use of sucrose analgesia in this population.[12] For choice of analgesic in children, see p.3.

Wound healing. Sugar, either in the form of granulated sugar[1-5] or pastes composed of caster sugar and icing sugar,[6,7] has been used successfully in the treatment of wounds (p.1585) including mediastinitis after cardiac surgery,[1,3] large abscesses and bed sores,[6,7] diabetic ulcers,[2,4] and recurrent bone infections after surgical debridement in patients with leprosy.[5] Debridement of the wound is believed to be due partly to the osmotic effect of sugar and partly to the mechanical cleansing action but it is not known how sugar stimulates granulation tissue to form.[6,7] Once granulation tissue is well established and the wound is shrinking, an alternative wound preparation, such as an alginate, hydrocolloid, or hydrogel, should be used as sugar pastes cause bleeding.[8] Sugar is also effective at deodorising malodorous wounds. The use of the combined caster and icing sugar pastes, of which details of the formulas used are provided in the original publications,[6,7] has been advocated as a way to overcome the problems of possible non-sterility and contamination of commercial granulated sugar.[6,7]

Sucrose Polyesters

Sacarosa, poliésteres de la.

Profile

A sucrose polyester that is a mixture of hexa-, hepta-, and octa-fatty acid esters of sucrose is used as a nondigestible fat substitute by the food industry. Fat substitutes have been promoted as part of a strategy to reduce fat and calories in the diet to aid body-weight control.

Possible adverse effects of sucrose polyesters are flatulence, anal leakage, abdominal cramps, and loose bowel movements. They may also reduce the absorption of fat-soluble vitamins.

Sunflower Oil

Aceite de girasol; Auringonkukkaöljy; Helianthi annui oleum; Helianthi Oleum; Huile de Tournesol; Napraforgóolaj; Olej słonecznikowy; Oleum Helianthi; Saulėgrąžų aliejus; Slunečnicový olej; Solrosolja; Sonnenblumenöl; Sunflowerseed Oil; Tournesol, huile de.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Sunflower Oil, Refined; Helianthi Annui Oleum Raffinatum). The fatty oil obtained from the seeds of *Helianthus annuus* by mechanical expression or by extraction and then refined. A suitable antioxidant may be added. A clear, light yellow liquid. Practically insoluble in water and in alcohol; miscible with petroleum spirit (b.p.: 40° to 60°). Store in well-filled airtight containers. Protect from light.

USNF 26 (Sunflower Oil). A refined fixed oil obtained from the seeds of the sunflower plant *Helianthus annuus* (Asteraceae alt. Compositae). Specific gravity between 0.914 and 0.924 at 20°. Store in airtight containers. Protect from light.

Profile

Sunflower oil is the fixed oil expressed from the fruits of *Helianthus annuus*. It is used as a salad oil and in pharmaceutical preparations. It is rich in linoleic acid (p.2308).

Multiple sclerosis. As discussed on p.892, the role of dietary lipids in multiple sclerosis remains to be proven,[1] although many patients modify their diets and take supplements of sunflower and other oils. One study showed a reduction in severity and duration of relapse in patients taking linoleic acid supplements (as sunflower oil).[2] Another[3] reported benefit in patients who limited their intake of dietary saturated fatty acids and supplemented their diet with polyunsaturated fatty acids. A systematic review[4] of the relationship between dietary interventions (including linoleic acid given as sunflower oils) and multiple sclerosis concluded that there was insufficient evidence to determine their benefits or risks.

Tagatose

D-*lyxo*-hexulose; D-Tagatose; Tagatosum; Tagatoza.

$C_6H_{12}O_6$ = 180.2.

CAS — 87-81-0 (tagatose); 17598-81-1 (DL-tagatose).

Pharmacopoeias. In *USNF.*

USNF 26 (Tagatose). Tagatose is a ketohexose, an epimer of fructose inverted at C-4. It is obtained from galactose by isomerisation under alkaline conditions in the presence of calcium. White or almost white crystals, having a sweet taste. Very soluble in water; very slightly soluble in alcohol.

Profile

Tagatose is a naturally occurring monosaccharide, produced commercially from lactose. It is 92% as sweet as sucrose, but contains fewer calories. It may be used as a sweetener in foods, beverages, toothpaste, mouthwashes, and medicines.

Thaumatin *(BAN)*

E957; Katemfe; Taumatina.

CAS — 53850-34-3.

Profile

Thaumatin is a protein extracted from the fruit of *Thaumatococcus daniellii* (Marantaceae); it is a mixture of polypeptides thaumatin I and thaumatin II, each consisting of 207 amino acid residues and having a molecular weight of about 22 000. The amino-acid range excludes histidine. Thaumatin is an odourless, cream-coloured powder with an intensely sweet taste. The sweetness builds up gradually but persists for up to an hour, and is considered to be by far the sweetest of such compounds in use, having 2000 to 3000 times the sweetness of sucrose. It is approved as a sweetener and flavour modifier in foods, beverages, and pharmaceuticals.

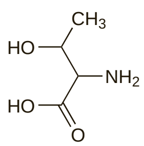
Threonine *(USAN, rINN)*

β-Methylserine; T; Thr; Threonin; Thréonine; L-Threonine; Threoninum; Treoniini; Treonin; Treonina; Treoninas. L-2-Amino-3-hydroxybutyric acid.

Треонин

$C_4H_9NO_3$ = 119.1.

CAS — 72-19-5.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Threonine). A white or almost white, crystalline powder or colourless crystals. Soluble in water; practically insoluble in alcohol. A 2.5% solution in water has a pH of 5.0 to 6.5. Protect from light.

USP 31 (Threonine). White, odourless crystals. Freely soluble in water; insoluble in dehydrated alcohol, in chloroform, and in ether. pH of a 5% solution in water is between 5.0 and 6.5.

Profile

Threonine is an amino acid that is an essential constituent of the diet. It is used as a dietary supplement.

Threonine has been investigated for the treatment of various spastic disorders.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Ital.:*** Stimolfit.

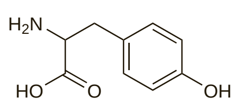
Tyrosine *(USAN, rINN)*

Tirosina; Tirozin; Tirozinas; Tyr; Tyrosiini; Tyrosin; L-Tyrosine; Tyrosinum; Tyrozyna; Y. L-2-Amino-3-(4-hydroxyphenyl)propionic acid.

Тирозин

$C_9H_{11}NO_3$ = 181.2.

CAS — 60-18-4.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), and *US*.

Ph. Eur. 6.2 (Tyrosine). A white or almost white, crystalline powder or colourless crystals. Very slightly soluble in water; practically insoluble in alcohol. It dissolves in dilute mineral acids and in dilute solutions of alkali hydroxides. Protect from light.

USP 31 (Tyrosine). White, odourless crystals or crystalline powder. Very slightly soluble in water; insoluble in alcohol and in ether.

Profile

Tyrosine is an aromatic non-essential amino acid. It is used as a dietary supplement.

Phenylketonuria. Tyrosine was not an effective alternative to a diet low in phenylalanine in patients with phenylketonuria, see under Amino Acid Metabolic Disorders, p.1922.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Austral.:*** Aussie Tan Pre-Tan; Bioglan Zellulean with Escin; Tyroseng†; ***India:*** Placentrex; ***Port.:*** Rilastil Dermo Solar.

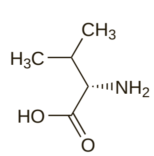
Valine *(USAN, rINN)*

α-Aminoisovaleric Acid; V; Val; Valiini; Valin; Valina; Valinas; L-Valine; Valinum. (*S*)-2-Amino-3-methylbutanoic acid.

Валин

$C_5H_{11}NO_2$ = 117.1.

CAS — 72-18-4.



Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Valine). A white or almost white, crystalline powder or colourless crystals. Soluble in water; very slightly soluble in alcohol. Protect from light.

USP 31 (Valine). White, odourless crystals. Soluble in water; practically insoluble in alcohol, in acetone, and in ether. pH of a 5% solution in water is between 5.5 and 7.0.

Profile

Valine is a branched-chain aliphatic amino acid that is an essential constituent of the diet. It is used as a dietary supplement. It is also an ingredient of several preparations that have been promoted for disorders of the liver.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Fr.:*** Revitalose; ***Ger.:*** Bramin-hepa†; Falkamin; ***Ital.:*** Falkamin†; Isobranch; Isoram.

Vitamin A *(USAN)*

Retinol *(BAN, rINN)*; Antixerophthalmic Vitamin; A-vitamiini; A-vitamin; Axerophtholum; Oleovitamin A; Rétinol; Retinolum; Vitamin A Alcohol; Vitaminas A; Vitamine A; Vitaminum A; Witamina A. 15-Apo-β-caroten-15-ol; 3,7-Dimethyl-9-(2,6,6-trimethylcyclohex-1-enyl)nona-2,4,6,8-tetraen-1-ol.

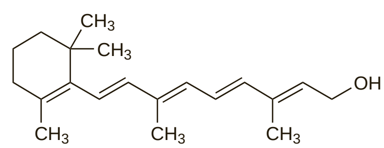
Ретинол

$C_{20}H_{30}O$ = 286.5.

CAS — 68-26-8.

ATC — A11CA01; D10AD02; R01AX02; S01XA02.

ATC Vet — QA11CA01; QD10AD02; QR01AX02; QS01XA02.



Description. Vitamin A is generally used in the form of esters, such as the acetate, palmitate, and propionate.

Vitamin A Acetate. Retinol Acetate; Retinyl Acetate; $C_{22}H_{32}O_2$ = 328.5; CAS — 127-47-9

Vitamin A Palmitate. Retinol Palmitate; Retinyl Palmitate; $C_{36}H_{60}O_2$ = 524.9; CAS — 79-81-2

Vitamin A Propionate. Retinol Propionate; Retinyl Propionate; $C_{23}H_{34}O_2$ = 342.5; CAS — 7069-42-3.

Pharmacopoeias. In *Eur.* (see p.vii), *US*, and *Viet.*, which permit retinol or its esters.

Chin. includes a monograph for the acetate. *Jpn* includes monographs for the acetate and the palmitate.

Br. includes a monograph for a natural ester concentrate.

Eur. also includes monographs for synthetic concentrates in an oily form, a powder form, and a solubilisate/emulsion.

Int. includes an oily concentrated form.

The BP 2008 states that the term 'Retinol' is used within BP titles for preparations containing synthetic ester(s) and the term 'Vitamin A' within the BP title for the preparation containing material of natural origin.

Ph. Eur. 6.2 (Vitamin A). Under the name Vitamin A are included a number of substances of very similar structure (including (*Z*)-isomers) found in animal tissues and possessing similar activity. The principal and biologically most active substance is all-(*E*) retinol.

Vitamin A is generally used in the form of esters such as the acetate, propionate, and palmitate. Synthetic retinol ester refers to an ester (acetate, propionate, or palmitate) or a mixture of synthetic retinol esters.

Retinol acetate occurs as pale yellow crystals. M.p. about 60°; once melted it tends to yield a supercooled melt. Retinol propionate occurs as a reddish-brown oily liquid. Retinol palmitate occurs as a fat-like, light yellow solid, or as a yellow oily liquid, if melted. M.p. about 26°. All retinol esters are practically insoluble in water; soluble or partly soluble in dehydrated alcohol; miscible with organic solvents.

Store in airtight containers. Protect from light. Once the container has been opened, its contents should be used as soon as possible and any part of the contents not used should be protected by an atmosphere of inert gas.

Ph. Eur. 6.2 (Vitamin A Concentrate (Oily Form), Synthetic; Vitaminum A Densatum Oleosum; Synthetic Retinol Concentrate (Oily Form) BP 2008). It is prepared from synthetic retinol ester as is or by dilution with a suitable vegetable oil. It contains not less than 500 000 units of vitamin A per g. It is a yellow or brownish-yellow, oily liquid; practically insoluble in water; soluble or partly soluble in dehydrated alcohol; miscible with organic solvents. Partial crystallisation may occur in highly concentrated solutions.

Store in airtight containers. Protect from light. Once the container has been opened, its contents should be used as soon as possible and any part of the contents not used at once should be protected by an atmosphere of inert gas.

Ph. Eur. 6.2 (Vitamin A Concentrate (Powder Form), Synthetic; Vitaminum A Pulvis; Synthetic Retinol Concentrate (Powder Form) BP 2008). It is obtained by dispersing a synthetic retinol ester in a matrix of gelatin or acacia or other suitable material. It contains not less than 250 000 units of vitamin A per g. It is a yellowish powder usually in the form of particles of almost uniform size. Practically insoluble in water or may swell or form an emulsion, depending on formulation.

Store in airtight containers. Protect from light. Once the container has been opened, its contents should be used as soon as possible and any part of the contents not used at once should be protected by an atmosphere of inert gas.

Ph. Eur. 6.2 (Vitamin A Concentrate (Solubilisate/Emulsion), Synthetic; Vitaminum A in Aqua Dispergibile; Synthetic Retinol Concentrate, Solubilisate/Emulsion BP 2008). It is a liquid form (water is generally used as solvent) of synthetic retinol ester and a suitable solubiliser. It contains not less than 100 000 units of vitamin A per g. It is a yellow or yellowish liquid of variable opalescence and viscosity. Highly concentrated solutions may become cloudy at low temperatures or take the form of a gel. A mixture of 1 g with 10 mL of water previously warmed to 50° gives after cooling to 20°, a uniform, slightly opalescent and slightly yellow dispersion.

Store in airtight containers. Protect from light. Once the container has been opened, its contents should be used as soon as possible and any part of the contents not used at once should be protected by an atmosphere of inert gas.

BP 2008 (Natural Vitamin A Ester Concentrate). It consists of a natural ester or a mixture of natural esters of retinol or of a solution of the ester or mixture of esters in arachis oil or other suitable vegetable oil. It contains not less than 485 000 units of vitamin A per g. It is a yellow oil or a mixture of oil and crystalline material, with a faint odour. Practically insoluble in water; soluble or partly soluble in alcohol; miscible with chloroform, with ether, and with petroleum spirit. Store in airtight containers at 8° to 15°. Protect from light.

USP 31 (Vitamin A). It may consist of retinol or its esters formed from edible fatty acids, principally acetic and palmitic acids. In liquid form, it is a light yellow to red oil that may solidify upon refrigeration. In solid form, has the appearance of any diluent that has been added. It may be practically odourless or may have a mild fishy odour but no rancid odour or taste. It is unstable in air and light. In liquid form, it is insoluble in water and in glycerol; soluble in dehydrated alcohol and in vegetable oils; very soluble in chloroform and in ether. In solid form, may be dispersible in water. Store in airtight containers, preferably under an atmosphere of inert gas. Protect from light.

Units

The International Standards for vitamin A and for provitamin A were discontinued in 1954 and 1956 respectively but the International units for these substances have continued to be widely used. In 1960–1, the WHO Expert Committee on Biological Standardization stated that the International unit for vitamin A is equivalent to the activity of 0.000344 mg of pure all-*trans* vitamin A acetate and the International unit for provitamin A is equivalent to the activity of 0.0006 mg of pure all-*trans* β-carotene.

The activity of one International unit is contained in 0.0003 mg of all-*trans* retinol, in 0.00055 mg of all-*trans* retinol palmitate, and in 0.000359 mg of all-*trans* retinol propionate.

The USP 31 defines 1 USP unit as equal to the biological activity of 0.0003 mg of the all-*trans* isomer of retinol, and is equivalent to the International unit.

Vitamin A activity in foods is currently expressed in terms of retinol equivalents: 1 retinol equivalent is defined as 1 microgram of all-*trans* retinol, 6 micrograms of all-*trans* beta carotene, or 12 micrograms of other provitamin A carotenoids.

Adverse Effects and Precautions

The use of excessive amounts of vitamin A substances over long periods can lead to toxicity. Rarely, acute toxicity may also occur with very high doses.

- Hypervitaminosis A (chronic toxicity) is characterised by fatigue, irritability, anorexia and loss of weight, vomiting and other gastrointestinal disturbances, low-grade fever, hepatomegaly, skin changes (yellowing, dryness, sensitivity to sunlight), pruritus, alopecia, dry hair, cracking and bleeding lips, anaemia, headache, hypercalcaemia, subcutaneous swelling, nocturia, and pains in bones and joints. Symptoms of chronic toxicity may also include raised intracranial pressure and papilloedema mimicking brain tumours, and visual disturbances which may be severe. Symptoms usually clear on withdrawal of vitamin A, but in children premature closure of the epiphyses of the long bones may result in arrested bone growth.

- Acute vitamin A intoxication is characterised by sedation, dizziness, confusion, diarrhoea and vomiting, sore mouth, bleeding gums, desquamation, and increased intracranial pressure (resulting in bulging fontanelle in infants or severe headache in adults). Hepatomegaly and visual disturbances may occur; irritability may be severe.

Hypervitaminosis A does not appear to be a problem with large doses of carotenoids (see Pharmacokinetics under Betacarotene, p.1931).

Enhanced susceptibility to the effects of vitamin A may be seen in children and in patients with liver disease.

Excessive doses of vitamin A should be avoided in pregnancy because of potential teratogenic effects; for further details see Pregnancy, below.

Gastrointestinal absorption of vitamin A may be impaired in cholestatic jaundice and fat-malabsorption conditions.

Benign intracranial hypertension. High doses of vitamin A cause increased intracranial pressure, and, in infants, this is manifested as bulging of the fontanelle. In one study,[1] 11.5% of infants receiving 3 doses of 50 000 units of vitamin A at monthly intervals had bulging fontanelle, compared with 1% of infants receiving placebo. The bulging lasted between 24 and 72 hours and subsided without treatment,[1] and did not appear to be associated with any physical or developmental abnormalities on long-term follow-up.[2] In another study in neonates, bulging fontanelle occurred in 4.6% of recipients of vitamin A 50 000 units and 2.7% of placebo recipients 24 hours after the dose.[3] In contrast, less than 1% of infants given 3 doses of 25 000 units of vitamin A at monthly intervals had bulging fontanelle in a further study.[4]

3. Agoestina T, *et al.* Safety of one 52 micromol (50 000 IU) oral dose of vitamin A administered to neonates. *Bull WHO* 1994; **72:** 859–68.
4. WHO/CHD Immunisation-Linked Vitamin A Supplementation Study Group. Randomised trial to assess benefits and safety of vitamin A supplementation linked to immunisation in early infancy. *Lancet* 1998; **352:** 1257–63. Correction. *ibid.* 1999; **353:** 154.

Carcinogenicity. For mention of the *increased* risk of lung cancer in high-risk individuals receiving betacarotene and vitamin A, when compared with placebo, in a study investigating vitamins in lung cancer prevention, see Prophylaxis of Malignant Neoplasms, p.1927.

Effects on the blood. Normochromic macrocytic anaemia developed in a patient who had been receiving vitamin A 150 000 units daily by mouth for several months.[1] The patient's haemoglobin returned to normal when vitamin A was stopped, and the accompanying symptoms of perioral dermatitis and glossitis also disappeared. Similarly, normochromic normocytic anaemia and thrombocytopenia in an infant given 62 000 units daily for 80 days, resolved on stopping vitamin A.[2] In contrast, vitamin A has been reported to have a beneficial effect on anaemia, see under Deficiency states, below.

2. Perrotta S, *et al.* Infant hypervitaminosis A causes severe anemia and thrombocytopenia: evidence of a retinol-dependent bone marrow cell growth inhibition. *Blood* 2002; **99:** 2017–22.

Effects on bone. Excessive dietary intake of vitamin A may be associated with osteoporosis. In an epidemiological study,[1] a dietary intake of retinol greater than 1500 micrograms daily (5000 units) doubled the risk of hip fracture compared with an intake of less than 500 micrograms daily (about 1670 units) in women (odds ratio, 2.1; 95% confidence interval 1.1 to 4.0). These data were confirmed by the Nurses' Health Study,[2] which found that postmenopausal women with the highest vitamin A and retinol intakes were at increased risk for hip fracture, irrespective of whether the intakes were from food plus supplements, or food alone. Women with daily retinol intakes of more than 1500 micrograms had a relative risk for hip fracture of 1.64 compared with those consuming less than 500 micrograms daily. Betacarotene intake, however, did not correlate significantly with an increased risk of fracture. A large cohort study[3] of men found that the overall risk of any fracture, including hip fractures, was substantially increased among men with the highest concentrations of serum retinol; there was no association between serum betacarotene levels and the risk of fracture. Subsequently, routine supplementation and the fortification of food with vitamin A in western countries has been questioned.[4] A report[5] from the UK Government's Scientific Advisory Committee on Nutrition cautions against the intake of more than 1.5 mg of vitamin A daily in those at increased risk of osteoporosis, such as postmenopausal women and the elderly. However, results from a cohort study in the elderly[6] suggest a U-shaped dose relationship, in that both high and low intakes of vitamin A were associated with reduced bone mineral density, and another study[7] in women aged between 50 and 74 years, found both high and low serum vitamin A concentrations to be associated with an increased risk of hip fracture.

Effects on the immune system. Vitamin A deficiency is generally associated with impaired immunity, and treatment of deficiency results in reductions in morbidity and mortality from a number of infectious diseases (see under Deficiency States, below). However, a few studies have shown increased prevalence of diarrhoea and/or respiratory-tract infections with high doses of vitamin A. There is a possibility that high single doses of vitamin A may temporarily attenuate the immune response in non-deficient children.[1] For the effect of high-dose vitamin A supplements on the response to measles vaccine in some studies, see p.2222.

1. Anonymous. Childhood morbidity, immunity and micronutrients. *WHO Drug Inf* 1996; **10:** 12–16.

Effects on the liver. Vitamin A is stored in the Dissë space of liver cells and excessive dosage can lead to fibrosis and obstruction of sinusoidal blood flow, causing non-cirrhotic portal hypertension and hepatocellular dysfunction.[1] Although hepatotoxicity has typically been reported with habitual ingestion of doses of vitamin A greater than 50 000 units daily, a case of severe hepatic fibrosis, with jaundice and hepatomegaly, has been reported in a patient who had been taking 25 000 units daily for at least 6 years in a multivitamin supplement.[2]

1. Sherlock S. The spectrum of hepatotoxicity due to drugs. *Lancet* 1986; **ii:** 440–4.
2. Kowalski TE, *et al.* Vitamin A hepatotoxicity: a cautionary note regarding 25,000 IU supplements. *Am J Med* 1994; **97:** 523–8.

Effects on mortality. Vitamin A supplementation has been reported to have beneficial effects on childhood mortality, especially in developing countries, see Deficiency States, below *et seq.* However, a systematic review of antoxidant supplementation in adults concluded that vitamin A either singly or with other antioxidants increased mortality.[1]

1. Bjelakovic G, *et al.* Antioxidant supplements for prevention of mortality in healthy participants and patients with various diseases. Available in The Cochrane Database of Systematic Reviews; Issue 2. Chichester: John Wiley; 2008 (accessed 18/06/08).

Hypersensitivity. Local inflammatory reactions and severe anaphylactoid reactions have occurred in patients receiving vitamin A injections, and are usually attributed to solubilisers such as polyoxyl castor oils (p.1918), and, less commonly, polysorbates (p.1919).

A case of cutaneous hypersensitivity to retinol palmitate itself has been described.[1]

1. Shelley WB, *et al.* Hypersensitivity to retinol palmitate injection. *BMJ* 1995; **311:** 232.

Overdosage. Although no clinical manifestations of toxicity were seen in 3 boys who ingested large amounts of vitamin A, their serum retinol concentrations continued to rise over about 3 weeks, and took several months to normalise; the authors cautioned that the use of chewable vitamins resembling confectionery may increase the risk of overdose in children.[1]

1. Lam HS, *et al.* Risk of vitamin A toxicity from candy-like chewable vitamin supplements for children. *Pediatrics* 2006; **118:** 820–4.

Pregnancy. The fact that synthetic vitamin A derivatives such as isotretinoin are teratogenic (p.1601) has prompted concern about the potential teratogenicity of high doses of vitamin A.

A prospective cohort study found that a total daily intake of vitamin A from all sources of greater than 15 000 units during early pregnancy was associated with a significantly increased risk of birth defects of structures arising from the cranial neural crest.[1] When vitamin A intake from supplements was analysed separately, an apparent vitamin A threshold dose for the development of birth defects of 10 000 units daily was suggested. However, this study has been criticised[2,3] and some suggest the data allows for a higher threshold dose.[3] A further study found no significant difference in birth defect rates between women consuming greater than 8000 or 10 000 units of vitamin A daily in the period around conception (as supplements and fortified cereals) and those consuming less than 5000 units daily.[4]

After earlier case reports in the USA suggesting that large doses of vitamin A (equivalent to about ten times the daily recommended dietary allowance of 2250 units) taken in early pregnancy may cause birth defects, the UK Chief Medical Officer cautioned women against the use of vitamin A supplements except under medical supervision.[5] Additionally, advice was given that liver or liver products should not be eaten because high concentrations of vitamin A had been detected in some samples of animal liver. However, others thought that the avoidance of liver or liver products might result in inadequate nutrition in some and that a less alarmist view might have been to suggest a limitation on intake rather than total prohibition.[6,7]

The American College of Obstetricians and Gynecologists has recommended that women who are pregnant or planning pregnancy should ensure that any vitamin supplements they take contain a daily dose of vitamin A of no more than 5000 units.[8] The Australian Adverse Drug Reactions Advisory Committee has advised women in this category to avoid vitamin A supplements and to not exceed the recommended daily allowance of 2500 units from all sources.[9]

Interactions

Absorption of vitamin A from the gastrointestinal tract may be reduced by the presence of neomycin, colestyramine, or liquid paraffin.

There is an increased risk of hypervitaminosis A if vitamin A is given with synthetic retinoids such as acitretin, isotretinoin, and tretinoin.

There is conflicting evidence regarding the effect of vitamin A on the response to measles vaccine (see p.2222).

Pharmacokinetics

Vitamin A substances are readily absorbed from the gastrointestinal tract but absorption may be reduced in the presence of fat malabsorption, low protein intake, or impaired liver or pancreatic function. Vitamin A esters are hydrolysed by pancreatic enzymes to retinol, which is then absorbed and re-esterified. Some retinol is stored in the liver. It is released from the liver bound to a specific α_1-globulin (retinol-binding protein) in the blood. The retinol not stored in the liver undergoes glucuronide conjugation and subsequent oxidation to retinal and retinoic acid; these and other metabolites are excreted in urine and faeces. Vitamin A does not readily diffuse across the placenta (but see Pregnancy, above), but is present in breast milk.

Human Requirements

Dietary vitamin A is derived from 2 sources, *preformed retinoids* from animal sources such as liver, kidney, dairy produce, and eggs (fish-liver oils are the most concentrated natural source), and *provitamin carotenoids* which can be obtained from many plants; the latter are converted to retinol in the body but are less effectively utilised. Carotenes (α, β, and γ) are major sources and of these, β-carotene (betacarotene—see p.1930) has the highest vitamin A activity and is the most plentiful in food. Variable amounts of β-carotenes are found in carrots and dark green or yellow vegetables. Red palm oil is a good source of α- and β-carotenes.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) have been published[1] for vitamin A and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] Differing amounts are recommended for infants and children of varying ages, for adult males and females, and for pregnant and lactating women (but see Pregnancy, above). In the UK the reference nutrient intake (RNI) for adult males and females is 700 and 600 micrograms retinol equivalents (about 2330 and 2000 units) daily, respectively and the estimated average requirement (EAR) is 500 and 400 micrograms retinol equivalents (about 1660 and 1330 units) daily, respectively. This UK report[1] also highlighted the toxicity associated with large doses of vitamin A and recommended that regular intakes should not exceed 9000 micrograms (30 000 units) daily in adult men and 7500 micrograms (25 000 units) daily in adult women. (A later report[3] was unable to establish a safe upper level for vitamin A intake, but considered that total intakes above 1500 micrograms retinol equivalents daily might be inappropriate.) Figures were also given in the earlier report for infants and children who were said to be more sensitive to the effects of vitamin A. These limits did not apply to therapeutic doses of vitamin A used under medical supervision.[1] In pregnancy the RNI is 700 micrograms retinol equivalents (2330 units) daily and in nursing mothers 950 micrograms (3160 units) daily. In the USA the RDA for adults is 900 micrograms daily for men and 700 micrograms daily for women.[2] The tolerable upper intake level is 3000 micrograms daily.

Uses and Administration

Vitamin A, a fat-soluble vitamin, is essential for growth, for the development and maintenance of epithelial tissue, and for vision, particularly in dim light. Vitamin A deficiency develops when the dietary intake is inadequate and is seen more frequently in young children than in adults. It is rare in developed countries but remains a major problem in many developing countries. Prolonged deficiency leads to xerophthalmia or 'dry eye', the initial symptom of which is night blindness which may progress to severe eye lesions and blindness. Other symptoms include changes in the skin and mucous membranes.

Vitamin A is used in the treatment and prevention of vitamin A deficiency. It may be given orally in an oil- or water-based form, the oil-based generally being the preferred type. It can also be given by intramuscular injection of a water-miscible form; oil-miscible preparations of vitamin A are poorly absorbed from injection sites after intramuscular injection and are not usually given by this route. For further details concerning vitamin A supplementation, including doses for the treatment and prophylaxis of xerophthalmia, see below.

Vitamin A supplements are often given to patients with primary biliary cirrhosis or chronic cholestatic liver disease as deficiencies are common in these disorders. An intramuscular dose of 100 000 units every 2 to 4 months has been suggested.

Vitamins A and D have been used together in creams or ointments in the treatment of minor skin disorders including abrasions. Vitamin A has also been used alone to treat various skin disorders including acne and psoriasis. It has been tried in patients with retinitis pigmentosa to retard the decline in retinal function.

Deficiency states. Vitamin A deficiency is relatively rare in developed countries and is usually only seen in certain medical conditions such as biliary cirrhosis or cholestatic jaundice. However, it is a continuing problem in many developing countries and children appear to be particularly vulnerable.

In **developing countries** where dietary intake is often less than desirable, infections such as measles, acute respiratory diseases, and diarrhoea can be major precipitating factors of vitamin A deficiency. Thus WHO have targeted elimination of vitamin A deficiency as an important strategy in child health,[1,2] and as part of the Expanded Programme on Immunization. They recommend the use of vitamin A supplements in the treatment of vitamin A deficiency and to prevent vitamin A deficiency where the periodic use of supplements is determined to be the most feasible and effective method of improving vitamin A status.

- In *universal distribution programmes*,[2,3] supplemental doses are given to all children up to the age of 5 at a dose of 200 000 units every 4 to 6 months, with infants between the ages of 6 and 12 months receiving half this dose. Infants aged less than 6 months may receive 50 000 units if they are not breast fed or if they are breast fed and their mothers have not received supplemental vitamin A. If clinical signs of vitamin A deficiency are evident at the time of routine supplementation, treatment should be given as described under Xerophthalmia, below. Mothers should receive 200 000 units within 6 weeks of delivery of a child.
- *Targeted distribution programmes* involve vitamin A supplementation to children and pregnant women in specific high-risk areas.[2] Doses used in children are similar to those used in universal programmes, but doses used in pregnant women should not exceed 10 000 units daily, or 25 000 units weekly.[2]

A number of studies have indicated that general supplementation with vitamin A decreases both mortality rates and morbidity among children in developing countries with a high prevalence of vitamin A deficiency.[4-7] Although not all studies have confirmed these findings,[8,9] two meta-analyses concur that the effect is likely to be genuine especially as regards measles infection,[10,11] (see Measles, below) and researchers and commentators have agreed that overall improvement of vitamin A status is worthwhile and necessary.[12-14] A study in children given half the dose of vitamin A recommended by WHO found that it provided equally good or better protection against mortality, but not against morbidity.[15] Supplementation with vitamin A 23 300 units weekly, or the equivalent amount of betacarotene, in women of child-bearing age reduced pregnancy-related mortality.[16] Some studies have evaluated mortality specifically in infants less than 6 months of age. In one study there was no overall benefit on early infant mortality with a tendency for the relative risk of mortality to increase with improved nutritional status,[17] whereas others reported decreases in mortality at 6 months[18] and 1 year[19] of age. A further study found no sustained benefit of vitamin A supplements on vitamin A status or morbidity beyond the age of 6 months, in infants receiving supplements with immunisation at 6, 10, and 14 weeks.[20] A study in vitamin-A-deficient children has demonstrated abnormalities in T-cell subsets which are corrected by vitamin A supplementation,[21] and it has been proposed that the apparent effects of vitamin A on morbidity and mortality may be due to modulation of immune function (see also Effects on the Immune System, above).

In **other countries** in which vitamin A deficiency is not widespread some form of supplementation may still be considered. Preterm infants have low vitamin A status at birth, which may increase their risk of developing chronic lung disease.[22] A meta-analysis of studies in low birth-weight infants found that vitamin A supplementation was associated with a reduced requirement for oxygen at 36 weeks postmenstrual age.[22] While studies of vitamin A supplementation to prevent chronic lung disease in very low birth-weight infants have had conflicting results,[23,24] some have commented that differences in patient population, postnatal therapies, and dosage of vitamin A could explain these discrepancies, and consider optimal supplementation necessary.[25] Others have called for further studies in preterm infants to define optimal dosage and mode of delivery of vitamin A; research should include quantification of hepatic stores, assessment of retinal function, and long-term clinical outcome.[26]

ANAEMIA. A study among pregnant Indonesian women with nutritional anaemia (see Iron-Deficiency Anaemia, p.1951) found a beneficial effect for vitamin A on haemoglobin when given with iron supplementation.[1] Similarly, in anaemic children given iron,[2] or adolescents given iron plus folic acid,[3] greater improvements in haemoglobin concentrations were seen with addition of vitamin A to supplementation. Vitamin A is considered essential for haematopoiesis; it has been suggested that vitamin A is required for the mobilisation and utilisation of iron for haemoglobin synthesis.[4] However, there are reports of anaemia caused by vitamin A supplementation, see Effects on the Blood, above.

DIARRHOEA. Although oral rehydration therapy remains the mainstay of the management of diarrhoea (p.1694) once it develops, it has been suggested that vitamin A supplementation may be of use in reducing the incidence and mortality of diarrhoea during childhood. Several large mortality studies reported that vitamin A supplementation was associated with reduced mortality attributed to diarrhoea,[1-3] although another did not.[4] The effect on morbidity from diarrhoea is even less clear. A reduction in the severity, but not the incidence, of diarrhoea has been noted in two studies.[5,6] However, in one study in children with subclinical vitamin A deficiency, there was an increased prevalence of diarrhoea for 2 weeks after vitamin A supplementation,[7] and in another study, vitamin A increased the incidence of diarrhoea in children aged less than 30 months.[8] A meta-analysis[9] concluded that vitamin A supplementation has no consistent overall protective effect on the incidence of diarrhoea. While severity was not examined, they noted that the decrease in diarrhoea mortality rates but not incidence can be reconciled if vitamin A reduces diarrhoea severity and not susceptibility to infection. This is possibly supported by a study that found that a single high-dose vitamin A supplement, given with standard antibacterial treatment, reduced the severity of acute shigellosis in children in Bangladesh.[10] One group[11] proposed that the inconsistent findings on morbidity of vitamin A supplementation may be due to co-existing micronutrient deficiencies, such as zinc deficiency, that affect the bioavailability of vitamin A. They found combined zinc and vitamin A supplementation to be more effective in reducing persistent diarrhoea and dysentery than either zinc or vitamin A alone (see Vitamin A Deficiency, under Zinc, p.2001).

HIV INFECTION AND AIDS. A study in Malawi found that the rates of vertical transmission of HIV infection (birth of seropositive infants to seropositive mothers) were inversely related to maternal vitamin A status;[1] vitamin A deficiency during pregnancy was associated with a threefold to fourfold increased risk of mother-to-child transmission of HIV. This was not incompatible with the role of vitamin A in immunity and maintenance of mucosal surfaces, and since both HIV infection and pregnancy are risk factors for vitamin A deficiency, it was suggested that nutritional intervention to reduce vitamin A deficiency might help combat mother-to-child transmission. A South African study[2] found, in contrast, that supplementing HIV-infected pregnant women with vitamin A and betacarotene did not reduce the overall risk of vertical transmission to neonates. Supplementation did reduce the incidence of preterm births, and among these neonates, risk of perinatal HIV transmission was lower in those whose mothers had been supplemented. Vitamin A supplementation actually increased the risk of HIV transmission through breast feeding, with no effect on mortality at 24 months, in a Tanzanian trial.[3] Yet another study,[4] again in Tanzania, for which vertical transmission data were not available, found no evidence of an effect of vitamin A on birth outcomes in HIV-infected women and the authors pointed out that serum concentrations of vitamin A might be a marker of the stage of HIV disease rather than being causally related to outcome. The study did however find that multivitamin supplements reduced the risk of low birth-weight and size for age, and of premature birth, in the offspring of these women.[4] Interestingly, another trial in Tanzania found little difference between vitamin A supplementation and placebo on the progression of HIV disease and mortality. Multivitamin (excluding vitamin A) supplementation delayed disease progression and was associated with decreased mortality; addition of vitamin A to the multivitamin regimen reduced this benefit.[5] This is in contrast to 2 studies in Tanzania[6] and Uganda,[7] which found that vitamin A supplementation decreased mortality in children infected with HIV; however these results were not considered generalisable to communities with access to better healthcare and nutrition.

A systematic review and meta-analysis,[8] which included some of these conflicting trials, did not support the use of vitamin A supplementation to reduce the risk of vertical transmission and concluded that it may in fact increase the risk. Maternal vitamin A supplementation was not considered to decrease childhood mortality at 1 year. In addition, multivitamin supplementation was considered to have no effect on reduction of childhood mortality at 1 year, nor on prevention of preterm delivery.

Means of reducing the risk of HIV infection in neonates are discussed under HIV Infection Prophylaxis, p.858.

MEASLES. Vitamin A supplementation has an important role in the prevention of complications from measles.[1,2] Two studies specifically addressing vitamin A status and measles have found that complications such as pneumonia and diarrhoea were less common in children who had received supplements at the time of diagnosis than in those given a placebo.[3,4] WHO has recommended treating children in populations where vitamin A deficiency is common with high-dose vitamin A supplements during episodes of measles as follows:[5]

- all children over 12 months of age—200 000 units
- those between 6 and 12 months of age—100 000 units
- infants less than 6 months of age—50 000 units

Doses are given on 2 consecutive days and followed by a third dose at least 2 weeks later.

Studies in the USA have indicated that even among well-nourished children from a developed country, vitamin A deficiency in measles patients is not uncommon,[6,7] and vitamin A supplementation needs to be considered in children at risk.[8]

PREMATURITY. The fetus accumulates vitamin A in the third trimester, and most premature infants have low plasma vitamin A concentrations. Inadequate vitamin A supplementation after birth may exacerbate the problem, and contribute to an increased risk of developing chronic lung disease. A systematic review found that supplementing very low birth-weight infants with vitamin A was associated with a reduction in death or oxygen requirement at 1 month of age.[1]

1. Darlow BA, Graham PJ. Vitamin A supplementation to prevent mortality and short and long-term morbidity in very low birth-weight infants. Available in The Cochrane Database of Systematic Reviews; Issue 4. Chichester: John Wiley; 2007 (accessed 12/03/08).

RESPIRATORY-TRACT INFECTIONS. Mortality studies did not show a consistent impact for vitamin A supplementation on death from non-measles-related respiratory infections.[1-3] Similarly, other studies have found no benefit of vitamin A on subsequent respiratory morbidity.[4-6] A meta-analysis of studies reporting pneumonia morbidity and mortality found no overall benefit or harm from vitamin A supplementation.[7] However, an increased prevalence of symptoms of respiratory infections associated with vitamin A supplementation has been noted in two studies,[8,9] particularly in children with adequate nutritional status. A meta-analysis of the effect of vitamin A supplementation on childhood morbidity found an increased incidence of respiratory-tract infections; since most trials had excluded children with overt vitamin A deficiency, the authors speculated that high-dose vitamin A given to children with adequate vitamin A stores might cause a temporary decline in immune status, increasing their susceptibility to infection.[10] A systematic review concluded that vitamin A should not be given to all children for *prevention* of acute lower respiratory-tract infections, but noted that children with vitamin A deficiency or poor nutritional status might benefit from supplementation in this respect.[11]

Vitamin A was not effective for the *treatment* of childhood non-measles-related lower respiratory-tract infections[12] or pneumonia.[13] Similarly, there was no benefit from vitamin A in the treatment of RSV infection in children in 2 studies.[14,15] In one of these studies there was a tendency for vitamin A to improve outcomes in the subgroup of severely ill children,[14] and in the other there was a slight increase in duration of hospitalisation in low-risk children receiving vitamin A.[15] A meta-analysis found no evidence that adjunctive treatment with high-dose vitamin A alters the course of pneumonia in children.[16]

XEROPHTHALMIA. Vitamin A deficiency is responsible in many developing countries for visual problems that may culminate in xerophthalmia and blindness.[1] Supplementation with vitamin A as recommended by WHO and discussed under Deficiency states, above, will raise the vitamin A status of the individual and act prophylactically against the development of xerophthalmia. For the treatment of xerophthalmia (which includes night blindness, conjunctival xerosis with Bitot's spots, corneal xerosis, corneal ulceration, and keratomalacia) WHO have stated[2] that oral doses of vitamin A, preferably in an oil-based preparation, are the treatment of choice and should be given immediately the disorder is recognised in the following doses:

- patients over 1 year of age (with the exception of women of reproductive age)—200 000 units
- infants aged 6 to 12 months—100 000 units
- those aged less than 6 months—50 000 units

Doses should be repeated the next day, and again at least 2 weeks later.

In *women of reproductive age* there is a need to balance the possible teratogenic effects of vitamin A should they be pregnant (see Pregnancy, above) with the serious consequences of xerophthalmia. WHO recommend that when there are severe signs of active xerophthalmia (i.e. acute corneal lesions) high-dose vitamin A treatment should be given as described above for those aged over 1 year. When only less severe signs are present (night blindness, Bitot's spots), women of reproductive age should receive a daily oral dose of 5000 to 10 000 units for at least 4 weeks. Alternatively, a weekly dose of not more than 25 000 units may be substituted.

Although xerophthalmia is far less common in developed countries, vitamin A deficiency should be considered in all patients with recurrent conjunctival or corneal disorders associated with gastrointestinal or liver disease.[3]

Malignant neoplasms. Epidemiological studies suggest that antoxidant vitamins such as the vitamin A substances may play a role in preventing the development of malignancy but there is currently little evidence from prospective studies that supplementation is helpful, and even some evidence of harm (see p.1927). Conversely, synthetic retinoids such as tretinoin (all-*trans*-retinoic acid) have an established role in treating some cancers (see p.1619).

Retinitis pigmentosa. Retinitis pigmentosa is the name applied to a group of slowly progressive hereditary degenerative diseases of the retina[1] that often result in blindness in adulthood. The rod and cone photoreceptors in the retina are primarily affected and initial symptoms include night blindness and intolerance to light. Later signs include infiltration of pigment from the retinal pigmentary epithelium into the retinal layers. Various treatments have been tried but none appear to have any proven benefit. Results of one large double-blind study[2] suggest that whereas treatment with vitamin A might slow the decline in visual acuity treatment with vitamin E appears to have a deleterious effect on the rate of decline. Vitamin E did appear to delay the rate of vision decline in 3 patients with retinitis pigmentosa and a defect in α-tocopherol-transfer protein associated with vitamin E deficiency.[3] Supplementation with 15 000 units of vitamin A daily for up to 12 years was considered to be safe in a study in adults with retinitis pigmentosa; no clinical manifestations of hepatotoxicity were apparent.[4] Docosahexaenoic acid has also been investigated, with variable results; some consider that vitamin A and oily fish in the diet could be beneficial in terms of visual preservation.[1] Transplantation of the retina is being investigated as a treatment for retinitis pigmentosa.[1,5] Devices to electrically stimulate the retina, optic nerve, or visual cortex are being developed.[1]

Retinopathy of prematurity. There is some suggestion that vitamin A supplementation may reduce the incidence of retinopathy of prematurity (p.1994).

Vitamin B Substances

Vitamina B, grupo de la.

The B vitamin group includes the B$_1$ substances (thiamine and its derivatives), B$_2$ (riboflavin), B$_6$ (pyridoxine and derivatives), and B$_{12}$ (the cobalamins). In addition, nicotinic acid and its derivatives (p.1957) and folic acid (p.1940) are held to be part of the group, as is pantothenic acid (p.1959), but these latter substances are not generally referred to by their traditional B nomenclature.

Vitamin B$_1$ Substances

Vitamina B$_1$.

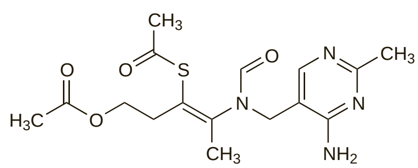
Acetiamine Hydrochloride *(rINNM)*

Acethiamine Hydrochloride; Acétiamine, Chlorhydrate d'; Acetiamini Hydrochloridum; Diacethiamine Hydrochloride; Hidrocloruro de acetiamina. *N*-(5-Acetoxy-3-acetylthiopent-2-en-2-yl)-*N*-(4-amino-2-methylpyrimidin-5-ylmethyl)formamide hydrochloride monohydrate.

Ацетиамина Гидрохлорид

$C_{16}H_{22}N_4O_4S,HCl,H_2O = 420.9.$

CAS — 299-89-8 (acetiamine).



(acetiamine)

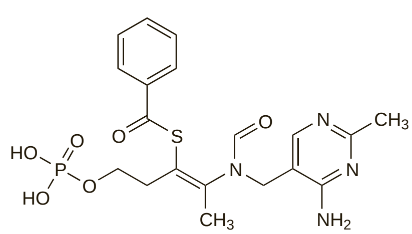
Benfotiamine *(rINN)*

Benfotiamina; Benfotiaminum; *S*-Benzoylthiamine *O*-Monophosphate. *N*-(4-Amino-2-methylpyrimidin-5-ylmethyl)-*N*-(2-benzoylthio-4-dihydroxyphosphinyloxy-1-methylbut-1-enyl)formamide.

Бенфотиамин

$C_{19}H_{23}N_4O_6PS = 466.4.$

CAS — 22457-89-2.
ATC — A11DA03.
ATC Vet — QA11DA03.



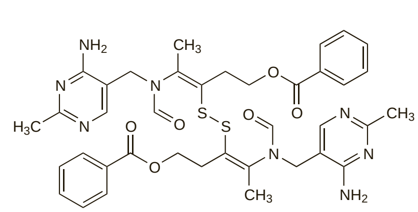
Bisbentiamine *(rINN)*

O-Benzoylthiamine Disulphide; Bisbentiamina; Bisbentiaminum. *NN'*-{Dithiobis[2-(2-benzoyloxyethyl)-1-methylvinylene]}bis[*N*-(4-amino-2-methylpyrimidin-5-ylmethyl)formamide].

Бисбентиамин

$C_{38}H_{42}N_8O_6S_2 = 770.9.$

CAS — 2667-89-2.



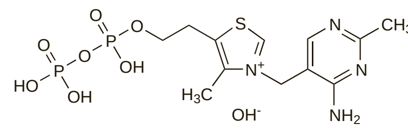
Cocarboxylase *(BAN, rINN)*

Cocarboxilasa; Co-carboxylase; Cocarboxylasum; Diphosphothiamine; Pyruvodehydrase; Thiamine Pyrophosphate. 3-(4-Amino-2-methylpyrimidin-5-ylmethyl)-5-{2-[dihydroxyphosphinyloxy-(hydroxy)phosphinyloxy]ethyl}-4-methylthiazolium hydroxide.

Кокарбоксилаза

$C_{12}H_{20}N_4O_8P_2S$ (hydroxide form) = 442.3.

CAS — 154-87-0 (cocarboxylase chloride).



Pharmacopoeias. *Pol.* includes the chloride.

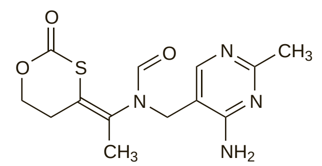
Cycotiamine *(rINN)*

CCT; Cicotiamina; Cyclocarbothiamine; Cycotiaminum. *N*-(4-Amino-2-methylpyrimidin-5-ylmethyl)-*N*-[1-(2-oxo-1,3-oxathian-4-ylidene)ethyl]formamide.

Цикотиамин

$C_{13}H_{16}N_4O_3S = 308.4.$

CAS — 6092-18-8.



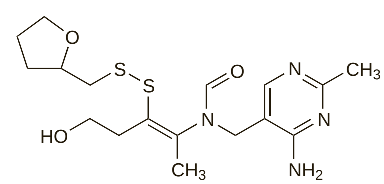
Fursultiamine *(rINN)*

Fursultiamina; Fursultiaminum; Thiamine Tetrahydrofurfuryl Disulphide; TTFD. *N*-(4-Amino-2-methylpyrimidin-5-ylmethyl)-*N*-[4-hydroxy-1-methyl-2-(tetrahydrofurfuryldithio)but-1-enyl]formamide.

Фурсультиамин

$C_{17}H_{26}N_4O_3S_2 = 398.5.$

CAS — 804-30-8.



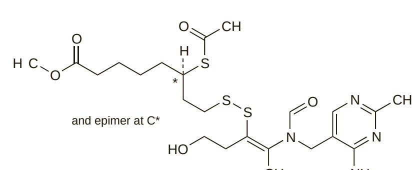
Octotiamine *(rINN)*

Octotiamina; Octotiaminum; Oktotiamiini; Oktotiamin; TATD; Thioctothiamine. *N*-[2-(3-Acetylthio-7-methoxycarbonylheptyldithio)-4-hydroxy-1-methylbut-1-enyl]-*N*-(4-amino-2-methylpyrimidin-5-ylmethyl)formamide.

Октотиамин

$C_{23}H_{36}N_4O_5S_3 = 544.8.$

CAS — 137-86-0.



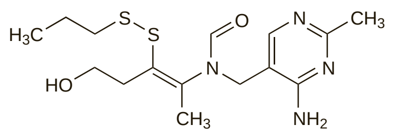
Prosultiamine *(rINN)*

DTPT; Prosultiamina; Prosultiamine; Prosultiaminum; Thiamine Propyl Disulphide. *N*-(4-Amino-2-methylpyrimidin-5-ylmethyl)-*N*-(4-hydroxy-1-methyl-2-propyldithiobut-1-enyl)formamide.

Просультиамин

$C_{15}H_{24}N_4O_2S_2$ = 356.5.

CAS — 59-58-5.



Sulbutiamine *(rINN)*

Bisibutiamine; *O*-Isobutyrylthiamine Disulphide; Sulbutiamina; Sulbutiaminum. *NN'*-{Dithiobis[2-(2-isobutyryloxyethyl)-1-methylvinylene]}bis[*N*-(4-amino-2-methylpyrimidin-5-ylmethyl)-formamide].

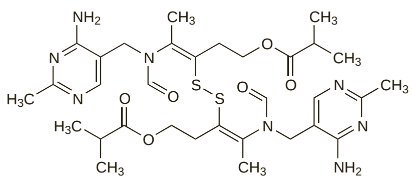
Сульбутиамин

$C_{32}H_{46}N_8O_6S_2$ = 702.9.

CAS — 3286-46-2.

ATC — A11DA02.

ATC Vet — QA11DA02.



Thiamine Hydrochloride *(BANM, rINNM)*

Aneurine Hydrochloride; Hidrocloruro de tiamina; Thiamin Hydrochloride; Thiamine, chlorhydrate de; Thiamine Chloride; Thiamin-hydrochlorid; Thiamini hydrochloridum; Thiaminii Chloridum; Tiamiinihydrokloridi; Tiamin-hidroklorid; Tiaminhydroklorid; Tiamino hidrochloridas; Tiaminy chlorowodorek; Vitamin B_1. 3-(4-Amino-2-methylpyrimidin-5-ylmethyl)-5-(2-hydroxyethyl)-4-methylthiazolium chloride hydrochloride.

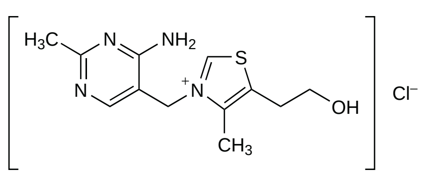
Тиамина Гидрохлорид

$C_{12}H_{17}ClN_4OS,HCl$ = 337.3.

CAS — 59-43-8 (thiamine); 67-03-8 (thiamine hydrochloride).

ATC — A11DA01.

ATC Vet — QA11DA01.



(thiamine)

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Thiamine hydrobromide is included in *Int.*

Ph. Eur. 6.2 (Thiamine Hydrochloride). A white or almost white, crystalline powder or colourless crystals. Freely soluble in water; slightly soluble in alcohol; soluble in glycerol. A 2.5% solution in water has a pH of 2.7 to 3.3. Store in nonmetallic containers. Protect from light.

USP 31 (Thiamine Hydrochloride). White crystals or crystalline powder, usually having a slight, characteristic odour. When exposed to air, the anhydrous product rapidly absorbs about 4% of water. Soluble 1 in 1 of water and 1 in 170 of alcohol; insoluble in ether and in benzene; soluble in glycerol. pH of a 1% solution in water is between 2.7 and 3.4. Store in airtight containers. Protect from light.

Stability. Sterile thiamine hydrochloride solutions of pH 4 or less lose activity only very slowly but neutral or alkaline solutions deteriorate rapidly, especially in contact with air.

Thiamine Nitrate *(BANM, rINNM)*

Aneurine Mononitrate; Nitrato de tiamina; Thiamine Mononitrate; Thiamine, nitrate de; Thiamini nitras; Thiamin-nitrát; Tiamiininitraatti; Tiaminnitrat; Tiamin-nitrát; Tiamino nitratas; Tiaminy azotan; Vitamin B_1 Mononitrate. 3-(4-Amino-2-methylpyrimidin-5-ylmethyl)-5-(2-hydroxyethyl)-4-methylthiazolium nitrate.

Тиамина Нитрат

$C_{12}H_{17}N_5O_4S$ = 327.4.

CAS — 532-43-4.

ATC — A11DA01.

ATC Vet — QA11DA01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Thiamine Nitrate). A white or almost white, crystalline powder or small, colourless crystals. Sparingly soluble in water; freely soluble in boiling water; slightly soluble in alcohol and in methyl alcohol. A 2% solution in water has a pH of 6.8 to 7.6. Store in nonmetallic containers. Protect from light.

USP 31 (Thiamine Mononitrate). White crystals or crystalline powder, usually having a slight characteristic odour. Soluble 1 in 44 of water; slightly soluble in alcohol; very slightly soluble in chloroform. pH of a 2% solution in water is between 6.0 and 7.5. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Adverse effects with thiamine are rare, but hypersensitivity reactions have occurred, mainly after parenteral doses. These reactions have ranged in severity from very mild to, very rarely, fatal anaphylactic shock (see below).

Breast feeding. Supplementation did not significantly affect thiamine concentration in breast milk of healthy, well-nourished women when compared with those not given thiamine; the authors supposed that absorptive capacity of the mammary gland may be saturable.[1] Based on this, the American Academy of Pediatrics considers its use to be usually compatible with breast feeding.[2]

Hypersensitivity. The UK CSM had received, between 1970 and July 1988, 90 reports of adverse reactions associated with the use of an injection containing high doses of vitamins B and C. The most frequent reactions were anaphylaxis (41 cases, including 2 fatalities), dyspnoea or bronchospasm (13 cases), and rash or flushing (22 cases); 78 of the reactions occurred during, or shortly after, intravenous injection and the other 12 after intramuscular injection.[1] They recommended that parenteral treatment be used only when essential, and that, when given, facilities for treating anaphylaxis should be available. They also recommended that, when the intravenous route was used, the injection be given slowly (over 10 minutes). Various authors[2,3] have noted that parenteral treatment is *essential* for the prophylaxis and treatment of Wernicke's encephalopathy (see below). However, further reports of anaphylaxis to parenteral thiamine have since been described,[4-6] including one with a fatal outcome.[4]

Pharmacokinetics

Small amounts of thiamine are well absorbed from the gastrointestinal tract after oral doses, but the absorption of doses larger than about 5 mg is limited. It is also rapidly absorbed on intramuscular injection. It is widely distributed to most body tissues, and appears in breast milk. Within the cell, thiamine is mostly present as the diphosphate. Thiamine is not stored to any appreciable extent in the body and amounts in excess of the body's requirements are excreted in the urine unchanged or as metabolites.

Human Requirements

Thiamine requirements are directly related to the carbohydrate intake and the metabolic rate. A daily dietary intake of about 0.9 to 1.5 mg of thiamine is recommended for healthy men and about 0.8 to 1.1 mg for healthy women. Cereals, nuts, peas, beans, yeast, and pork are rich sources of thiamine. Some other meats especially liver or kidneys, and also fish, contain significant amounts. Flour and bakery products are often enriched with thiamine. Considerable losses of thiamine may result from cooking processes.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) have been published for thiamine[1] and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] In the UK for adult males and females the reference nutrient intake (RNI) is 0.4 mg per 1000 kcal daily and the estimated average requirement (EAR) is 0.3 mg per 1000 kcal daily. In the USA an RDA of 1.2 mg daily in adult males and 1.1 mg daily in females is recommended.

Uses and Administration

Thiamine is a water-soluble vitamin, although some of its derivatives have greater lipophilicity. It is an essential coenzyme for carbohydrate metabolism in the form of the diphosphate (thiamine pyrophosphate, cocarboxylase). Thiamine deficiency develops when the dietary intake is inadequate; severe deficiency leads to the development of a syndrome known as beri-beri. Chronic 'dry' beri-beri is characterised by peripheral neuropathy, muscle wasting and muscle weakness, and paralysis. Acute 'wet' beri-beri is characterised by cardiac failure and oedema. Wernicke-Korsakoff syndrome (demyelination of the CNS) may develop in severe cases of thiamine deficiency notably in association with chronic alcoholism. Severe thiamine deficiency, characterised by lactic acidosis and neurological deterioration, has been reported within a relatively short time of starting thiamine-free total parenteral nutrition; some deaths have occurred.

Thiamine is used in the treatment and prevention of thiamine deficiency. It is given orally, the preferred route, or if necessary by the intramuscular or intravenous routes (but see Hypersensitivity, above); intravenous injections should be given slowly over 30 minutes. In the treatment of mild chronic thiamine deficiency usual oral doses of 10 to 25 mg daily, in single or divided doses, have been recommended. In severe thiamine deficiency doses of up to 300 mg daily are given, and even higher daily doses may be used in Wernicke-Korsakoff syndrome by the intravenous route.

Thiamine is usually given as either the hydrochloride or nitrate salts although other salts such as the dicamsylate, disulfide, monophosphate (monophosphothiamine) or pyrophosphate (cocarboxylase) may be used.

Other compounds that possess vitamin B_1 activity and may be given as alternatives to thiamine include benfotiamine, cycotiamine, octotiamine, prosultiamine, and sulbutiamine. Acetiamine, bisbentiamine, and fursultiamine have also been used.

Diabetes mellitus. Low plasma thiamine concentrations have been found[1] in patients with type 1 and type 2 diabetes mellitus (p.431). In a small placebo-controlled study, benfotiamine

100 mg given four times daily by mouth significantly improved neuropathic pain in patients with diabetic polyneuropathy (see p.6).[2]

2. Haupt E, *et al.* Benfotiamine in the treatment of diabetic polyneuropathy—a three-week randomized, controlled pilot study (BEDIP Study). *Int J Clin Pharmacol Ther* 2005; **43:** 71–7.

Wernicke-Korsakoff syndrome. The Wernicke-Korsakoff syndrome is a manifestation of thiamine deficiency seen particularly in alcoholics, but which may accompany other conditions including starvation or prolonged fasting, or persistent vomiting. It was originally classified as two separate disorders, Wernicke's encephalopathy and Korsakoff's syndrome, but these are now thought to represent aspects of a single pathological process.[1,2]

Classical Wernicke's symptoms comprise confusion, ataxia, ophthalmoplegia, and nystagmus. Ophthalmoplegia and ataxia may precede the mental symptoms by some days. Hypothermia may be seen, and collapse and sudden death may occur in some patients. The manifestations of Korsakoff's syndrome are short-term memory loss, learning deficits, and confabulation. The conditions are associated with demyelination and glial proliferation, as well as haemorrhagic lesions, mainly in the periventricular regions of the brain; characteristic biochemical abnormalities include raised serum-pyruvate concentration, which has been postulated as a cause of encephalopathy.[3]

Early recognition and treatment is important, both because of the risk of collapse and sudden death,[4] and to prevent irreversible damage to the CNS. Korsakoff symptoms respond less well to treatment than those associated with Wernicke's encephalopathy,[5] and may indeed only become evident on treatment.

Treatment is with parenteral thiamine, preferably intravenously, to ensure adequate absorption; any risks of parenteral treatment are considered justifiable.[1,2,6,7] Although as little as 2 or 3 mg may be enough to reverse the ocular symptoms, which generally begin to improve in 1 to 6 hours, doses of at least 100 mg should be given initially. (In practice a typical dose is 500 mg given intravenously with other vitamins every 8 hours, for 2 days if symptoms persist, and followed by 100 mg twice daily orally, or 250 mg daily intravenously until the patient can take oral thiamine.[6,8]) The ataxia and acute confusional state may also resolve dramatically although improvement may not be noted for days or months. Even several months after the onset of symptoms, treatment with high doses of thiamine has occasionally resulted in recovery.[9] The effects of the syndrome on memory are much harder to reverse. Some 25% of patients make a full, and 50% a partial, recovery.[5]

Vitamin B_2 Substances

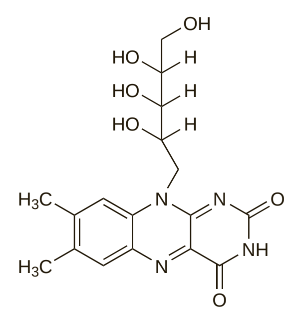
Vitamina B_2.

Riboflavin *(BAN, rINN)*

E101; Lactoflavin; Riboflaviini; Riboflavina; Riboflavinas; Riboflavine; Riboflavinum; Ryboflawina; Vitamin B_2; Vitamin G. 7,8-Dimethyl-10-(1′-D-ribityl)isoalloxazine; 3,10-Dihydro-7,8-dimethyl-10-(D-*ribo*-2,3,4,5-tetrahydroxypentyl)benzopteridine-2,4-dione.

Рибофлавин

$C_{17}H_{20}N_4O_6$ = 376.4.
CAS — 83-88-5.
ATC — A11HA04.
ATC Vet — QA11HA04.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Riboflavin). A yellow or orange-yellow crystalline powder. It exhibits polymorphism. Very slightly soluble in water; practically insoluble in alcohol. Store in airtight containers. Protect from light. Solutions deteriorate on exposure to light, especially in the presence of alkali.

USP 31 (Riboflavin). A yellow to orange-yellow crystalline powder, having a slight odour. When dry, it is not appreciably affected by diffused light, but in solution light induces quite rapid deterioration, especially in the presence of alkalis. Very slightly soluble in water, in alcohol, and in isotonic sodium chloride solution; insoluble in chloroform and in ether; soluble in dilute solutions of alkalis. Its saturated solution in water is neutral to litmus. Store in airtight containers. Protect from light.

Riboflavin Sodium Phosphate *(BANM, rINNM)*

Fosfato sódico de riboflavina; Natrii Riboflavini Phosphas; Riboflaviininatriumfosfaatti; Riboflavin fosfát sodná sůl; Riboflavin 5′-Phosphate Sodium; Riboflavine, phosphate sodique de; Riboflavine Phosphate (Sodium Salt); Riboflavine Sodium Phosphate; Riboflavin-foszfát-nátrium; Riboflavini natrii phosphas; Riboflavinnatriumfosfat; Riboflavino natrio fosfatas; Vitamin B_2 Phosphate.

The sodium salt of riboflavin 5′-phosphate.

Натрия Рибофлавина Фосфат

$C_{17}H_{20}N_4NaO_9P$ = 478.3.
CAS — 130-40-5.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.*
Chin. and *US* specify the dihydrate salt.

Ph. Eur. 6.2 (Riboflavin Sodium Phosphate). A yellow or orange-yellow, hygroscopic, crystalline powder. Soluble in water; very slightly soluble in alcohol. A 1% solution in water has a pH of 5.0 to 6.5. Store in airtight containers. Protect from light.

USP 31 (Riboflavin 5′-Phosphate Sodium). A fine, orange-yellow, hygroscopic, crystalline powder, having a slight odour. When dry, it is not affected by diffused light, but when in solution light induces rapid deterioration. Sparingly soluble in water. pH of a 1% solution in water is between 5.0 and 6.5. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Large doses of riboflavin result in a bright yellow discoloration of the urine that may interfere with certain laboratory tests.

Breast feeding. Supplementation significantly increased riboflavin concentration in the breast milk of women compared with those not given riboflavin. Significant differences between the two groups decreased over the period from 1 to 6 weeks postpartum; both groups of women had breast milk concentrations above previously reported normal values, and the authors concluded that supplementation was not necessary in healthy, well-nourished women.[1] The American Academy of Pediatrics considers the use of riboflavin to be usually compatible with breast feeding.[2]

Pharmacokinetics

Riboflavin is readily absorbed from the gastrointestinal tract. Although riboflavin is widely distributed to body tissues little is stored in the body.

Riboflavin is converted in the body to the coenzyme flavine mononucleotide (FMN; riboflavin 5′-phosphate) and then to another coenzyme flavine adenine dinucleotide (FAD). About 60% of FMN and FAD are bound to plasma proteins. Riboflavin is excreted in urine, partly as metabolites. As the dose increases, larger amounts are excreted unchanged. Riboflavin crosses the placenta and is distributed into breast milk.

Human Requirements

The riboflavin requirement is often related to the energy intake but it appears to be more closely related to resting metabolic requirements. A daily dietary intake of about 1.1 to 1.8 mg of riboflavin is recommended. Liver, kidney, fish, eggs, milk, cheese, yeast, and some green vegetables such as broccoli and spinach are the richest sources of riboflavin. In general, little loss of riboflavin occurs during cooking, but considerable losses may occur if foods, especially milk, are exposed to sunlight.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) have been published for riboflavin[1] and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] Differing amounts are recommended for infants and children of varying ages, for adult males and females of varying ages, and for pregnant and lactating women; the differences between age groups are intended to reflect the changes in caloric intakes at these ages. In the UK the reference nutrient intake (RNI) is 1.3 mg daily and 1.1 mg daily for adult males and females respectively; the estimated average requirement (EAR) is 1.0 mg daily and 0.9 mg daily respectively. In the USA the RDAs for adult males and females are 1.3 and 1.1 mg daily respectively.

Uses and Administration

Riboflavin, a water-soluble vitamin, is essential for the utilisation of energy from food. The active, phosphorylated forms, flavine mononucleotide (FMN) and flavine adenine dinucleotide (FAD), are involved as coenzymes in oxidative/reductive metabolic reactions. Riboflavin is also necessary for the functioning of pyridoxine and nicotinic acid.

Riboflavin deficiency develops when the dietary intake is inadequate. Deficiency leads to the development of a well-defined syndrome known as ariboflavinosis, characterised by cheilosis, angular stomatitis, glossitis, keratitis, surface lesions of the genitalia, and seborrhoeic dermatitis. There may also be normocytic anaemia and ocular symptoms including itching and burning of the eyes, and corneal vascularisation. Some of these symptoms may, in fact, be due to other vitamins such as pyridoxine or nicotinic acid which do not function correctly in the absence of riboflavin. Riboflavin deficiency may also occur with other vitamin B-complex deficiency states such as pellagra.

Riboflavin is used in the treatment and prevention of riboflavin deficiency. It is usually given in oral doses of 1 or 2 mg for prophylaxis; up to 30 mg daily in divided doses is used for treatment. Riboflavin, as the sodium phosphate, is also a component of intramuscular or intravenous vitamins B and C injections; riboflavin sodium phosphate 1.27 g is equivalent to about 1 g of riboflavin.

Riboflavin tetrabutyrate has also been used.

Riboflavin is also used as a colouring agent for food.

Glutaric aciduria. Milder forms of glutaric aciduria type II (p.1451) may respond to riboflavin.[1] Treatment with riboflavin 50 mg daily resulted in progressive improvement in a 4-year-old boy, with full recovery after 1 year. His brother, who had sustained permanent brain damage after epileptic seizures, showed moderate clinical improvement with riboflavin therapy.[2] In an adult patient with a history of recurrent pancreatitis and exercise intolerance, treatment with riboflavin 120 mg daily and levocarnitine resulted in no further episodes, although abnormal concentrations of amino acids were still apparent in her urine.[3]

3. Liang W-C, *et al*. Riboflavin-responsive glutaric aciduria type II with recurrent pancreatitis. *Pediatr Neurol* 2004; **31:** 218–21.

Migraine. Results from open studies[1,2] and a placebo-controlled trial[3] have suggested that riboflavin in high doses (400 mg daily) might be of some benefit in the prophylaxis of migraine attacks (p.616).

Vitamin B_6 Substances

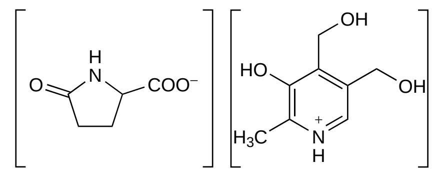
Vitamina B_6.

Vitamin B_6 is usually available as pyridoxine but the term is also used to refer to the related compounds, pyridoxal and pyridoxamine.

Metadoxine

Metadoxina; Pyridoxine Pidolate. Pyridoxine *l*-5-oxopyrrolidine-2-carboxylate.

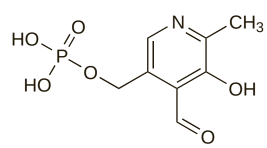
$C_8H_{11}NO_3,C_5H_7NO_3$ = 298.3.
CAS — 74536-44-0.



Pyridoxal Phosphate

Codecarboxylase; MC-I; Piridoxal, fosfato de; Pyridoxal 5-Phosphate. 3-Hydroxy-5-hydroxymethyl-2-methylpyridine-4-carboxaldehyde 5′-phosphate.

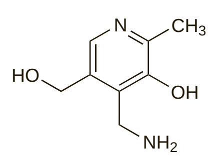
$C_8H_{10}NO_6P$ = 247.1.
CAS — 54-47-7.
ATC — A11HA06.
ATC Vet — QA11HA06.



Pyridoxamine Hydrochloride

Piridoxamina, hidrocloruro de; Pyridoxamine Dihydrochloride. 4-Aminomethyl-5-hydroxy-6-methyl-3-pyridinemethanol hydrochloride.

$C_8H_{12}N_2O_2,2HCl$ = 241.1.
CAS — 524-36-7.



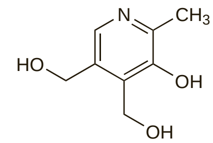
(pyridoxamine)

Pyridoxine Hydrochloride *(BANM, rINNM)*

Adermine Hydrochloride; Hidrocloruro de piridoxina; Piridoksin Hidroklorür; Piridoksino hidrochloridas; Piridossina Cloridrato; Piridoxin-hidroklorid; Pirydoksyny chlorowodorek; Pyridoksiinihydrokloridi; Pyridoxine, chlorhydrate de; Pyridoxin-hydrochlorid; Pyridoxinhydroklorid; Pyridoxini hydrochloridum; Pyridoxinii Chloridum; Pyridoxinium Chloride; Pyridoxol Hydrochloride; Vitamin B_6. 3-Hydroxy-4,5-bis(hydroxymethyl)-2-picoline hydrochloride.

Пиридоксина Гидрохлорид

$C_8H_{11}NO_3,HCl$ = 205.6.
CAS — 65-23-6 (pyridoxine); 58-56-0 (pyridoxine hydrochloride).
ATC — A11HA02.
ATC Vet — QA11HA02.



(pyridoxine)

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Pyridoxine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water; slightly soluble in alcohol. A 5% solution in water has a pH of 2.4 to 3.0. Protect from light.

USP 31 (Pyridoxine Hydrochloride). White or practically white crystals or crystalline powder. Soluble 1 in 5 of water and 1 in 115 of alcohol; insoluble in ether. Its solutions in water have a pH of about 3. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Long-term use of large doses of pyridoxine is associated with the development of severe peripheral neuropathies; the dose at which these occur is controversial (see below).

Breast feeding. Vitamin B_6 is excreted into breast milk.[1,2] While some have expressed concern over the inhibition of breast milk secretion by pyridoxine,[3] others have cautioned that pyridoxine deficiency may cause seizures in the neonate.[4] The American Academy of Pediatrics considers the use of pyridoxine to be usually compatible with breast feeding.[5]

Effects on the nervous system. Severe sensory neuropathy has been described in patients receiving large doses of pyridoxine (2 to 6 g daily) for periods of 2 to 40 months.[1] There has, however, been debate as to whether smaller doses can produce such effects. Some contend that amounts of pyridoxine below this level are unlikely to produce toxic effects.[2,3] However, there have been some case reports[4,5] with amounts up to about 500 mg daily and prolonged use of even lower doses (about 200 mg daily or less) may also cause sensory peripheral neuropathy.[6] After a review of the possible toxicity associated with lower doses of pyridoxine, proposals were put forward in the UK to limit the dose freely available in dietary supplements to 10 mg daily; products supplying up to 50 mg daily would continue to be available from pharmacies and higher doses would only be available on prescription.[7] These proposals were heavily contested.[7,8] An upper limit of 100 mg daily has been suggested in the USA.[8]

8. Anonymous. Still time for rational debate about vitamin B . *Lancet* 1998; **351:** 1523.

Interactions

Pyridoxine reduces the effects of levodopa (see p.808), but this does not occur if a dopa decarboxylase inhibitor is also given. Pyridoxine reduces the activity of altretamine. It has also been reported to decrease serum concentrations of phenobarbital (p.494) and phenytoin (p.500). Many drugs may increase the requirements for pyridoxine; such drugs include hydralazine, isoniazid, penicillamine, and oral contraceptives.

Pharmacokinetics

Pyridoxine, pyridoxal, and pyridoxamine are readily absorbed from the gastrointestinal tract after oral doses and are converted to the active forms pyridoxal phosphate and pyridoxamine phosphate. They are stored mainly in the liver where there is oxidation to 4-pyridoxic acid and other inactive metabolites which are excreted in the urine. As the dose increases, proportionally greater amounts are excreted unchanged in the urine. Pyridoxal crosses the placenta and is distributed into breast milk.

Human Requirements

For adults, the daily requirement of pyridoxine is probably about 1.5 to 2 mg and this amount is present in most normal diets. The requirement tends to increase as protein intake increases due to the role of the vitamin in amino acid metabolism. Meats, especially chicken, kidney, and liver, cereals, eggs, fish, and certain vegetables and fruits are good sources of pyridoxine.

UK and US recommended dietary intake. In the UK[1] dietary reference values (see p.1925) have been published for vitamin B_6 and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] Differing amounts are recommended for infants and children of varying ages, for adult males and females, and during pregnancy and lactation. In the UK the reference nutrient intake (RNI) is 15 micrograms per g of protein daily for adult males and females and the estimated average requirement (EAR) is 13 micrograms per g of protein daily for the same group. In the USA the RDA for adult men ranges from 1.3 to 1.7 mg daily and that for adult women ranges from 1.3 to 1.5 mg daily.[2] The tolerable upper intake level is 100 mg daily.[2] The Expert Group on Vitamins and Minerals[3] have established a safe upper level (SUL) for vitamin B_6 of 170 micrograms/kg daily.

Uses and Administration

Pyridoxine, a water-soluble vitamin, is involved mainly in amino acid metabolism, but is also involved in carbohydrate and fat metabolism. It is also required for the formation of haemoglobin.

Deficiency of pyridoxine is rare in humans because of its widespread distribution in foods. Pyridoxine deficiency may however be drug-induced and can occur, for instance, during isoniazid therapy. Inadequate utilisation of pyridoxine may result from certain inborn errors of metabolism. Pyridoxine deficiency may lead to anaemia, dermatitis, cheilosis, and neurological symptoms such as peripheral neuritis, and convulsions.

Pyridoxine is used in the treatment and prevention of pyridoxine deficiency states. It is usually given orally, the preferred route, but may also be given by the subcutaneous, intramuscular, or intravenous routes. Doses of pyridoxine hydrochloride up to 150 mg daily are used in general deficiency states; higher doses of up to 400 mg daily are used in the treatment of sideroblastic anaemias (see below); and similar high doses have been used to treat certain metabolic disorders such as homocystinuria (see Amino Acid Metabolic Disorders, below) or primary hyperoxaluria (below). Pyridoxine has also been used to treat seizures due to hereditary syndromes of pyridoxine deficiency or dependency in infants.

Pyridoxine has also been tried in the treatment of many other disorders, including depression and other symptoms associated with the premenstrual syndrome (see below) and the use of oral contraceptives, although its efficacy has been questioned.

Pyridoxine is usually given as the hydrochloride although other salts such as the citrate, oxoglurate, phosphate, and phosphoserinate, have also been used. Metadoxine, the pidolate, has been investigated in alcoholism (see below).

For the use of pyridoxine in the prophylaxis of isoniazid-induced peripheral neuritis and for the treatment of acute isoniazid toxicity, see Treatment of Adverse Effects, under Isoniazid, p.289.

Pyridoxal phosphate may be used to treat vitamin B_6 deficiency. Pyridoxamine has also been given.

Alcoholism and alcohol poisoning. Pyridoxine and its pidolate, known as metadoxine, have been tried in the treatment of alcohol poisoning and alcoholism.[1] One study showed pyridoxine to be ineffective in acute alcohol poisoning[2] but another[3] suggested that the pidolate might be of benefit as an adjunct in the management of alcohol withdrawal (p.1626). In patients treated for alcoholic fatty liver, liver function returned to normal more quickly with metadoxine, even in patients who did not completely abstain from alcohol.[4]

Amino acid metabolic disorders. Pyridoxine has been used in various inborn errors of amino acid metabolism, such as homocystinuria (p.1922), with or without cobalamins and folate. Relatively high doses may need to be given (see above). For children with metabolic disorders such as homocystinuria and cystathioninuria, the *BNFC* suggests pyridoxine in an oral dose of 50 to 100 mg once or twice daily for neonates, and 50 to 250 mg once or twice daily in patients aged 1 month to 18 years. For the use of pyridoxine in primary hyperoxaluria, another inherited metabolic disorder, see below.

Anaemias. Some patients with acquired or hereditary sideroblastic anaemia (p.1044) that is severe enough to require treatment will respond to high doses (up to 400 mg daily) of pyridoxine, and a trial is considered worthwhile in all patients.

Cardiovascular disease. For mention of the possible link between vitamin B_6, hyperhomocysteinaemia, and cardiovascular disease, see under Folic Acid, p.1941. Pyridoxal phosphate is thought to prevent cellular calcium overload in ischaemia-reperfusion injury, but a large multicentre study[1] investigating doses of 250 mg daily orally given 3 to 10 hours before coronary artery bypass graft surgery in intermediate- to high-risk patients, and for a further 30 days after the procedure, found it did not reduce the incidence of cardiovascular death or non-fatal myocardial infarction.

1. Alexander JH, *et al.* MEND-CABG II Investigators. Efficacy and safety of pyridoxal 5′-phosphate (MC-1) in high-risk patients undergoing coronary artery bypass graft surgery: the MEND-CABG II randomized clinical trial. *JAMA* 2008; **299:** 1777–87.

Carpal tunnel syndrome. Pyridoxine has been advocated by some[1] for patients with carpal tunnel syndrome (see Soft-tissue Rheumatism, p.13), but evidence of efficacy is considered to be limited.[2] In most studies reporting improvement with pyridoxine, doses have ranged from 50 to 300 mg daily for 12 weeks; a review concluded that treatment should be stopped if there is no apparent response after this period.[3]

Epilepsy. Pyridoxine-dependent epilepsy is an autosomal recessive disorder associated with decreased central γ-aminobutyric acid (GABA) concentrations and elevated cerebral glutamate concentrations. Untreated patients suffer from progressive encephalopathy, mental retardation, and intractable epilepsy; lifelong supplementation with pyridoxine can control epileptic symptoms but mental retardation may still develop. An epidemiological study[1] defined cases as those children with recurrent seizures that ceased within 7 days of oral pyridoxine at a usual dose of 30 mg/kg daily (minimum dose 15 mg/kg daily; maximum dose 1000 mg/kg daily), or within 30 minutes of intravenous pyridoxine (usual dose 100 mg; minimum dose 50 mg), that recurred when supplementation was withdrawn, and ceased again upon dosage as before. The study found that, despite their rarity, pyridoxine-dependent seizures frequently present atypically, and the author suggested that pyridoxine be given to all children with intractable seizures beginning before 3 years of age, including neonates with suspected hypoxic-ischaemic encephalopathy.

Test doses of pyridoxine intravenously, repeated at intervals of 10 minutes up to a total of 500 mg if necessary, have been suggested in the diagnosis of pyridoxine-dependent epilepsy; if the patient responds then a daily oral dose of 5 mg/kg is suggested although there is no real consensus on the appropriate dosage.[2] The *BNFC* suggests an intravenous test dose of 50 to 100 mg; in those who respond, oral doses of 50 to 100 mg once daily in neonates or 20 to 50 mg once or twice daily in older children, are suggested, adjusted as required. Alternatively, in patients with recurrent seizures refractory to conventional anticonvulsant therapy, oral pyridoxine supplementation of 15 mg/kg daily should lead to resolution of clinical seizures within a week in those with the condition; however, in some patients the daily dose required may be lower.[3]

A study in one patient[4] found that although pyridoxine 5 mg/kg reduced glutamate concentrations in CSF from the untreated value of 200 times normal limits, it did so only to 10 times the normal value, despite remission of symptoms. Doses of 10 mg/kg daily were required to normalise CSF glutamate, and it was suggested that this was a more appropriate target for therapy. In some children, pyridoxal phosphate has been suggested to be more effective than pyridoxine in controlling seizures.[5]

Palmar-plantar erythrodysesthesia syndrome. Pyridoxine, in doses of 100 to 300 mg daily, has been used successfully[1] for treating and preventing palmar-plantar erythrodysesthesia syndrome associated with antineoplastic therapy (see p.639).

1. Nagore E, *et al.* Antineoplastic therapy-induced palmar plantar erythrodysesthesia ('hand-foot') syndrome: incidence, recognition and management. *Am J Clin Dermatol* 2000; **1:** 225–34.

Premenstrual syndrome. Pyridoxine has been widely used in the premenstrual syndrome (p.2099) despite controversy over its effectiveness. Some consider that depressive symptoms may be provoked by pyridoxine deficiency because of its role as a coenzyme in the production of certain neurotransmitters, but it is difficult to attribute any of the other symptoms of the premenstrual syndrome to pyridoxine deficiency and doses of 50 mg are no more effective than a placebo.[1] A systematic review found that although treatment with pyridoxine was more effective than placebo, there was insufficient high-quality evidence to recommend its routine use in premenstrual syndrome.[2] If pyridoxine is used, the dosage should be restricted (see Effects on the Nervous System, above) because of concerns about neurotoxicity.[3]

Primary hyperoxaluria. Primary hyperoxaluria (as distinct from the various forms secondary to other disorders) is a genetic disorder characterised by excessive synthesis and urinary excretion of oxalic acid. Two forms are known, type I (hyperglycolic aciduria) and type II (L-glyceric aciduria), associated with different enzyme defects. They are marked by recurrent calcium oxalate kidney stones, or nephrocalcinosis, leading to renal failure, together with extrarenal deposition of calcium oxalate and frequently severe peripheral vascular insufficiency. Treatment with high doses of pyridoxine may help decrease oxalate excretion particularly in type I disease,[1,2] although response is variable.[3] A few patients may respond to lower (physiological) doses.[4] Such treatment can be used with an oral orthophosphate supplement, which helps reduce renal deposition of calcium oxalate, and the combination appears to preserve renal function.[5] Therapy with magnesium salts, potassium citrate, and thiazide diuretics has also been suggested.[2] In patients in whom renal failure develops, the results of kidney transplantation have been disappointing, due to deposition of calcium oxalate in the new kidney, although transplanting the liver as well can correct the enzyme defect.[1,6] Pre-emptive liver transplantation, performed before renal failure or systemic oxalosis has occurred, may be an option.[2]

Vitamin B_{12} Substances

Vitamina B_{12}.

Vitamin B_{12} is the name generally used for a group of related cobalt-containing compounds, also known as cobalamins, of which cyanocobalamin and hydroxocobalamin are the principal forms in clinical use.

Cobamamide *(pINN)*

Adenosylcobalamin; Cobamamida; Cobamamidum; Coenzyme B_{12}; Dibencozide; Dibenzcozamide; Dimebenzcozamide; Kobamamid. Inner salt of the *Co*-(5′-deoxyadenosine-5′) derivative of the 3′-ester of cinobinamide phosphate with 5,6-dimethyl-1-α-D-ribofuranosylbenzimidazole.

Кобамамид

$C_{72}H_{100}CoN_{18}O_{17}P$ = 1579.6.
CAS — 13870-90-1.
ATC — B03BA04.
ATC Vet — QB03BA04.

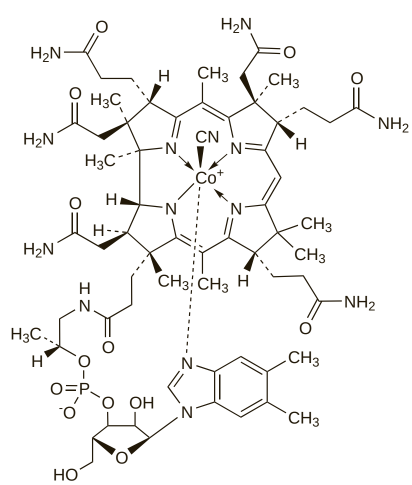
Pharmacopoeias. In *Chin.*

Cyanocobalamin *(BAN, rINN)*

Cianocobalamina; Cianokobalamin; Cianokobalaminas; Cobamin; Cyanocobalamine; Cyanocobalaminum; Cyanokobalamin; Cycobemin; Cyjanokobalamina; Kyanokobalamin; Siyanokobalamin; Syanokobalamiini. *Co*α-[α-(5,6-Dimethylbenzimidazolyl)]-*Co*β-cyanocobamide.

Цианокобаламин

$C_{63}H_{88}CoN_{14}O_{14}P$ = 1355.4.
CAS — 68-19-9.
ATC — B03BA01.
ATC Vet — QB03BA01.



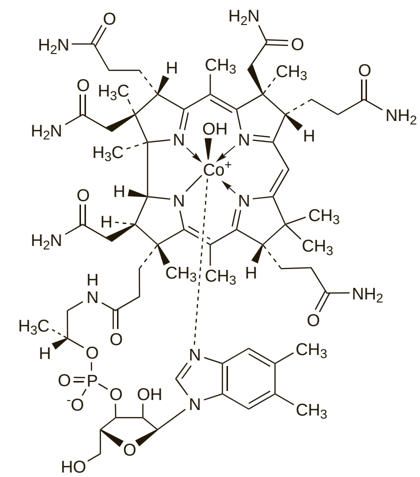
Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*
Ph. Eur. 6.2 (Cyanocobalamin). A dark red, crystalline powder or dark red crystals. The anhydrous substance is very hygroscopic. Sparingly soluble in water and in alcohol; practically insoluble in acetone. Store in airtight containers. Protect from light.
USP 31 (Cyanocobalamin). Dark red crystals or amorphous or crystalline red powder. In the anhydrous form it is very hygroscopic and when exposed to air it may absorb about 12% of water. Soluble 1 in 80 of water; soluble in alcohol; insoluble in acetone, in chloroform, and in ether. Store in airtight containers. Protect from light.

Hydroxocobalamin *(BAN, USAN, rINN)*

Hidroksokobalaminas; Hidroxocobalamina; Hydroksikobalamiini; Hydroxikobalamin; Hydroxocobalamine; Hydroxocobalaminum; Hydroxycobalaminum; Idrossocobalamina. *Co*α-[α-(5,6-Dimethylbenzimidazolyl)]-*Co*β-hydroxocobamide.

Гидроксокобаламин

$C_{62}H_{89}CoN_{13}O_{15}P$ = 1346.4.
CAS — 13422-51-0.
ATC — B03BA03; V03AB33.
ATC Vet — QB03BA03; QV03AB33.



NOTE. The hydrated form of hydroxocobalamin has been referred to as aquocobalamin.

Pharmacopoeias. In *Int.* and *US.*
USP 31 (Hydroxocobalamin). Dark red crystals or red crystalline powder. Is odourless or has not more than a slight acetone odour. The anhydrous form is very hygroscopic. Soluble 1 in 50 of water and 1 in 100 of alcohol; practically insoluble in acetone, in chloroform, in ether, and in benzene; sparingly soluble in methyl alcohol. pH of a 2% solution in water is between 8.0 and 10.0. Store in airtight containers at a temperature of 8° to 15°. Protect from light.

Hydroxocobalamin Acetate *(BANM, rINNM)*

Acetato de hidroxocobalamina; Acetatocobalamin; Hidroksokobalamino acetatas; Hidroxokobalamin-acetát; Hydroksokobalamiiniasetaatti; Hydroxocobalamine, acétate d'; Hydroxocobalamini acetas; Hydroxokobalamin acetát; Hydroxokobalamina-cetat.

Гидроксокобаламина Ацетат

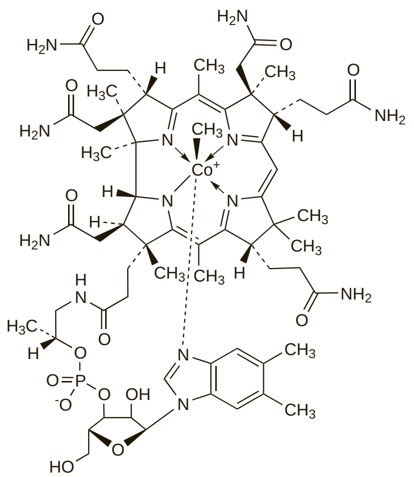
ATC Vet — QB03BA05.



Pharmacopoeias. In *Jpn.*

Adverse Effects and Precautions

Allergic hypersensitivity reactions have occurred rarely after parenteral doses of the vitamin B_{12} compounds cyanocobalamin and hydroxocobalamin. Antibodies to hydroxocobalamin-transcobalamin II complex have developed during hydroxocobalamin therapy.

Arrhythmias secondary to hypokalaemia have occurred at the beginning of parenteral treatment with hydroxocobalamin.

Intranasal cyanocobalamin may cause rhinitis, nausea, and headache.

Cyanocobalamin or hydroxocobalamin should, if possible, not be given to patients with suspected vitamin B_{12} deficiency without first confirming the diagnosis. Regular monitoring of the blood is advisable. Use of doses greater than 10 micrograms daily may produce a haematological response in patients with folate deficiency; indiscriminate use may mask the precise diagnosis. Conversely, folate may mask vitamin B_{12} deficiency (see p.1940).

Cyanocobalamin should not be used for Leber's disease or tobacco amblyopia since these optic neuropathies may degenerate further.

Breast feeding. Vitamin B_{12} is distributed into breast milk.[1] The American Academy of Pediatrics considers its use to be usually compatible with breast feeding.[2]

1. Samson RR, McClelland DBL. Vitamin B in human colostrum and milk. *Acta Paediatr Scand* 1980; **69:** 93–9.
2. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 09/01/06)

Hypersensitivity. Analysis, by the Boston Collaborative Drug Surveillance Program, of data on 15 438 patients hospitalised between 1975 and 1982 detected 3 allergic skin reactions attributed to cyanocobalamin among 168 recipients of the drug.[1] For the purposes of the study, reactions were defined as being generalised morbilliform exanthems, urticaria, or generalised pruritus only.

In a patient with a generalised pruritic reaction to hydroxocobalamin (with subsequent urticaria, bronchospasm, and oropharyngeal angioedema), cyanocobalamin was relatively well-tolerated, with only one episode of delayed urticaria.[2]

1. Bigby M, *et al*. Drug-induced cutaneous reactions: a report from the Boston Collaborative Drug Surveillance Program on 15 438 consecutive inpatients, 1975 to 1982. *JAMA* 1986; **256:** 3358–63.
2. Heyworth-Smith D, Hogan PG. Allergy to hydroxycobalamin, with tolerance of cyanocobalamin. *Med J Aust* 2002; **177:** 162–3.

Local reactions. After 3 years of monthly intramuscular vitamin B_{12} injections, a patient presented with a sclerotic plaque at the injection site, which was successfully treated by excision and local fat transfer. It was unclear as to whether the patient had reacted to the vehicle, the preservative, or to the cyanocobalamin.[1] Fascial haematoma after vitamin B_{12} injection leading to local compression (posterior arm compartment syndrome) has also been reported.[2]

2. Knapke D, Truumees E. Posterior arm and deltoid compartment syndrome after vitamin B12 injection. *Orthopedics* 2004; **27:** 520–1.

Interactions

Absorption of vitamin B_{12} from the gastrointestinal tract may be reduced by neomycin, aminosalicylic acid, histamine H_2-antagonists, omeprazole, and colchicine. Serum concentrations may be decreased by use of oral contraceptives. Many of these interactions are unlikely to be of clinical significance but should be taken into account when performing assays for blood concentrations. Parenteral chloramphenicol may attenuate the effect of vitamin B_{12} in anaemia.

Pharmacokinetics

Vitamin B_{12} substances bind to intrinsic factor, a glycoprotein secreted by the gastric mucosa, and are then actively absorbed from the gastrointestinal tract. Absorption is impaired in patients with an absence of intrinsic factor, with a malabsorption syndrome or with disease or abnormality of the gut, or after gastrectomy. Absorption from the gastrointestinal tract can also occur by passive diffusion; little of the vitamin present in food is absorbed in this manner although the process becomes increasingly important with larger amounts such as those used therapeutically. After intranasal dosage, peak plasma concentrations of cyanocobalamin have been reached in 1 to 2 hours. The bioavailability of the intranasal preparation is about 7 to 11% of that by intramuscular injection.

Vitamin B_{12} is extensively bound to specific plasma proteins called transcobalamins; transcobalamin II appears to be involved in the rapid transport of the cobalamins to tissues. Vitamin B_{12} is stored in the liver, excreted in the bile, and undergoes extensive enterohepatic recycling; part of a dose is excreted in the urine, most of it in the first 8 hours; urinary excretion, however, accounts for only a small fraction in the reduction of total body stores acquired by dietary means. Vitamin B_{12} diffuses across the placenta and also appears in breast milk.

Retention in the body. After injection of cyanocobalamin a large proportion is excreted in the urine within 24 hours; the body retains only 55% of a 100-microgram dose and 15% of a 1000-microgram dose. Body stores of vitamin B_{12} amount to 2000 to 3000 micrograms which is believed to be enough for 3 to 4 years. If 1000 micrograms is injected monthly, the 150 micrograms retained lasts for about 1 month. Hydroxocobalamin is better retained than cyanocobalamin; 90% of a 100-microgram dose and 30% of a 1000-microgram dose are retained and that range is believed to be enough for 2 to 10 months.[1]

1. Anonymous. Time to drop cyanocobalamin? *Drug Ther Bull* 1984; **22:** 43.

Human Requirements

For adults, the daily requirement of vitamin B_{12} is probably about 1 to 2 micrograms and this amount is present in most normal diets. Vitamin B_{12} occurs only in animal products; it does not occur in vegetables, therefore strict vegetarian (vegan) diets that exclude dairy products may provide an inadequate amount although it has been said that many years of vegetarianism are necessary before a deficiency is produced, if at all. Meats, especially liver and kidney, milk, eggs, and other dairy products, and fish are good sources of vitamin B_{12}.

UK and US recommended dietary intake. In the UK[1] dietary reference values (see p.1925) have been published for vitamin B_{12} and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] Differing amounts are recommended for infants and children of varying ages, adults and pregnant and lactating women. In the UK the reference nutrient intake (RNI) is 1.5 micrograms daily for adult males and females and the estimated average requirement (EAR) is 1.25 micrograms daily. In the USA the RDA for adults is 2.4 micrograms daily.

Uses and Administration

Vitamin B_{12}, a water-soluble vitamin, occurs in the body mainly as methylcobalamin (mecobalamin) and as adenosylcobalamin (cobamamide) and hydroxocobalamin. Mecobalamin and cobamamide act as coenzymes in nucleic acid synthesis. Mecobalamin is also closely involved with folic acid in several important metabolic pathways.

Vitamin B_{12} deficiency can occur in strict vegetarians with an inadequate dietary intake, although it may take many years before a deficiency is produced. Deficiency is more likely in patients with malabsorption syndromes or metabolic disorders, nitrous oxide-induced megaloblastosis, or after gastrectomy or extensive ileal resection. Deficiency leads to the development of megaloblastic anaemias and demyelination and other neurological damage. A specific anaemia known as pernicious anaemia develops in patients with an absence of the intrinsic factor necessary for good absorption of the vitamin from dietary sources.

Vitamin B_{12} preparations are used in the treatment and prevention of vitamin B_{12} deficiency. It is essential to identify the exact cause of deficiency, preferably before starting therapy. Hydroxocobalamin is generally preferred to cyanocobalamin; it binds more firmly to plasma proteins and is retained in the body longer (see under Pharmacokinetics, above). Cyanocobalamin and hydroxocobalamin are generally given by the intramuscular route, although cyanocobalamin may be given orally or subcutaneously, or intranasally (see also under Administration, below). Oral cyanocobalamin may be used in treating or preventing vitamin B_{12} deficiency of dietary origin.

In the UK, recommended doses for **pernicious anaemia** and other macrocytic anaemias *without neurological involvement* are hydroxocobalamin (or cyanocobalamin) 250 to 1000 micrograms intramuscularly on alternate days for 1 to 2 weeks, then 250 micrograms weekly until the blood count returns to normal. Maintenance doses of 1000 micrograms of hydroxocobalamin are given every 2 to 3 months (or monthly for cyanocobalamin). If there is *neurological involvement*, hydroxocobalamin or cyanocobalamin may be given in doses of 1000 micrograms on alternate days and continued for as long as improvement occurs. For the *prophylaxis* of anaemia associated with vitamin B_{12} deficiency resulting from gastrectomy or malabsorption syndromes hydroxocobalamin may be given in doses of 1000 micrograms intramuscularly every 2 or 3 months or cyanocobalamin in doses of 250 to 1000 micrograms intramuscularly each month. For vitamin B_{12} deficiency of *dietary* origin, oral cyanocobalamin 50 to 150 micrograms may be taken daily between meals.

Lower doses of both cyanocobalamin and hydroxocobalamin are recommended in the USA. For the *treatment* of deficiency, the usual intramuscular or subcutaneous dose of cyanocobalamin is 100 micrograms daily for 7 days, then on alternate days for 7 further doses, then every 3 to 4 days for 2 to 3 weeks. For hydroxocobalamin the usual intramuscular dose is 30 micrograms daily for 5 to 10 days. For *maintenance*, both cyanocobalamin and hydroxocobalamin are given at a dose of 100 to 200 micrograms monthly, based on haematological monitoring. Intranasal preparations of cyanocobalamin are also available for maintenance therapy, the recommended dose being 500 micrograms once weekly. Oral doses of up to 1000 micrograms of cyanocobalamin have also been used. In patients with normal gastrointestinal absorption, doses of 1 to 25 micrograms daily are considered sufficient as a *dietary supplement.*

Treatment usually results in rapid haematological improvement and a striking clinical response. However, neurological symptoms respond more slowly and in some cases remission may not be complete.

Cobamamide and mecobalamin may also be used for vitamin B_{12} deficiency.

Hydroxocobalamin may also be given in the treatment of **tobacco amblyopia** and **Leber's optic atrophy**; initial doses are 1000 micrograms daily for 2 weeks intramuscularly followed by 1000 micrograms twice weekly for as long as improvement occurs. Thereafter, 1000 micrograms is given every 1 to 3 months.

Hydroxocobalamin is also used for the treatment of known or suspected **cyanide toxicity** (see below). Each 2.5 g vial of hydroxocobalamin is reconstituted with 100 mL of diluent, preferably sodium chloride 0.9%. The starting dose for adults is 5 g intravenously over 15 minutes. Depending on the severity of the toxicity and the clinical response, a second dose of 5 g may be infused over 15 minutes to 2 hours.

Cyanocobalamin and hydroxocobalamin are also used in the **Schilling test** to investigate vitamin B_{12} absorption and deficiency states. They are given in a non-radioactive form together with cyanocobalamin radioactively-labelled with cobalt-57 (p.2053) or cobalt-58 (p.2053) and the amount of radioactivity excreted in the urine can be used to assess absorption status. A differential Schilling test, in which the forms of cyanocobalamin are given under different conditions (such as with intrinsic factor, antibacterials, or pancreatic enzymes) can provide information concerning the cause of the malabsorption.

Administration. The small amounts of vitamin B_{12} present in the diet are absorbed from the gastrointestinal tract by an active process that involves binding with intrinsic factor. As intrinsic factor is absent in patients who have developed pernicious anaemia it has often been assumed that oral vitamin B_{12} preparations will therefore be ineffective. However, about 1% of an oral dose is absorbed by passive diffusion, and with large doses this amount may be sufficient for therapy. Thus attention has been given again to the use of oral cobalamins for the treatment of pernicious anaemia.[1-3] Oral cyanocobalamin 2000 micrograms daily was as effective as intramuscular therapy in patients with vitamin B_{12} deficiency in a comparative study.[4] Some now consider that oral doses of 1000 micrograms daily,[3,5] or every 2 weeks for children,[6] are a suitable alternative to injections given at monthly or so intervals; others still deem oral use to be unjustified on the grounds of negligible oral absorption.[7] A systematic review[8] of 2 studies found some evidence for a satisfactory haematological, biochemical, and clinical short-term response to oral replacement in some patients with conditions associated with malabsorption. Another review[9] concluded that, while there is substantial evidence to support the use of 1000 to 2000 micrograms daily of oral cobalamin as maintenance therapy, parenteral therapy is preferable for initial treatment of those with neurological symptoms. Cyanocobalamin is also effective when given intranasally,[10] with peak plasma concentrations greater than those achievable orally, and this may offer another alternative to injection. The intranasal absorption of hydroxocobalamin has been studied.[11,12] Cobalamin has also been given sublingually. Normalisation of serum cobalamin concentration has been reported in 18 patients given cyanocobalamin 2000 micrograms sublingually for 7 to 12 days;[13] 500 micrograms sublingually was found to be as effective as the same dose given orally in correcting cobalamin deficiency.[14]

Amino acid metabolic disorders. References to the use of hydroxocobalamin in the treatment of inborn errors of vitamin B_{12} metabolism.[1-3] Some patients with homocystinuria (p.1922) or methylmalonic aciduria have responded to cobalamins—the *BNFC* suggests an initial intramuscular dose of 1 mg daily, for 5 to 7 days, in patients from one month of age; this is reduced, according to response, to 1 mg once or twice weekly. Some children respond to maintenance with 5 to 10 mg once or twice weekly by mouth.

Cardiovascular disease. For mention of the possible link between vitamin B_{12}, hyperhomocysteinaemia, and cardiovascular disease, see under Folic Acid p.1941.

Cyanide toxicity. Hydroxocobalamin combines with cyanide to form cyanocobalamin, and thus may be used as an antidote to cyanide toxicity (p.2045). Hydroxocobalamin is reported to be effective in controlling cyanide toxicity due to nitroprusside infusion,[1] and after exposure to inhaled combustion products in residential fires.[2]

It has been hypothesised that the amount of cyanocobalamin formed is limited by the number of cyanide ions present and the amount of hydroxocobalamin given. For a given dose of hydroxocobalamin a maximum concentration of cyanocobalamin would be reached, allowing measurement of cyanocobalamin as a surrogate emergency marker for cyanide levels, which are difficult and time-consuming to measure. For a 5-g dose of hydroxocobalamin given intravenously over 30 minutes, the authors of one study considered a cyanocobalamin concentration of about 300 micromoles/litre a sign that all the hydroxocobalamin had been used, and more should be given.[2] They cautioned, however, that, unless antidote regimen and blood sampling were similar to that in their study, this concentration should not be extrapolated to other patient populations.

In another patient given hydroxocobalamin 5 g intravenously over 2 hours,[3] plasma concentrations of cyanide rose 1 hour after treatment with hydroxocobalamin. The authors attributed this to hydroxocobalamin extracting cyanide from red blood cells to form cyanocobalamin in plasma, which was then measured as cyanide.

Deficiency states. The emergence of newer metabolic assays for homocysteine and methylmalonic acid has led to the identification of subtle vitamin B_{12} deficiency[1-3] without the overt manifestations of megaloblastic anaemia (see below) or neurological disease; this condition appears to be particularly common in the elderly.[1,4-6] At present, there is no clear clinical rationale for treating subtle deficiency.[1,7] A study in elderly patients suggested that food-cobalamin malabsorption, a disorder characterised by the inability to release vitamin B_{12} from food or its binding protein, might be to blame for this subtle deficiency; these patients had some neurological or haematological abnormalities, and treatment with oral or parenteral vitamin B_{12} was found to be effective.[6] There have also been suggestions that deficiency may be linked to some immunological impairment, identified as impaired antibody responses to pneumococcal vaccine.[8] Moreover, raised homocysteine concentrations have been identified as a risk factor for atherosclerosis and ischaemic heart disease, and there is increasing interest in the potential of B vitamins, including B_{12}, to reduce homocysteine concentrations and therefore atherosclerotic outcomes (see Cardiovascular Disease, under Uses of Folic Acid, p.1941). Evidence that hyperhomocysteinaemia may be a risk factor for dementia is limited.[5] A systematic review concluded that evidence for efficacy of vitamin B_{12} in improving cognitive function of people with dementia (and low serum vitamin B_{12} concentrations) was lacking.[9]

Dietary vitamin B_{12} deficiency in infants may lead to developmental abnormalities.[10,11]

The issue of fortification of food with folic acid to reduce the number of infants born with neural tube defects has created debate on the risks of masking vitamin B_{12} deficiency, and fortification with vitamin B_{12} has also been recommended, see under Folic Acid, p.1940.

Megaloblastic anaemia. The megaloblastic anaemias are characterised by macrocytosis (an increased mean cell volume) and the production of distinctive morphological changes and abnormal maturation in developing haematopoietic cells in the bone marrow: white cell and platelet lines are affected as well as erythroid precursors, and in severe cases anaemia may be associated with leucopenia and thrombocytopenia. Megaloblastic anaemia is a consequence of impaired DNA biosynthesis in the bone marrow, usually due to a deficiency of vitamin B_{12} (cobalamins) or folate, both of which are essential for this process. Although the haematological symptoms of B_{12} deficiency and folate deficiency are similar it is important to distinguish between them since the use of folate alone in B_{12}-deficient megaloblastic anaemia can improve haematological symptoms without preventing aggravation of accompanying neurological symptoms, and may lead to severe nervous system sequelae such as subacute combined degeneration of the spinal cord. Where it is desirable to start therapy immediately, combined treatment for both deficiencies may be started once suitable samples have been taken to permit diagnosis of the deficiency, and the patient converted to the appropriate treatment once the cause of the anaemia is known.

Vitamin B_{12} deficiency anaemia. Vitamin B_{12} deficiency and its associated symptoms may be due to malabsorption (including following gastrectomy), dietary deficiency (mainly in strict vegetarians), competition with intestinal bacteria or parasites, or to the effect of drugs such as nitrous oxide. In populations of northern European origin, pernicious anaemia, in which atrophy of the gastric mucosa results in a lack of the intrinsic factor essential for B_{12} absorption, is the most frequent cause. As body stores of the vitamin are large, it may take several years for signs of deficiency to manifest once the defect in absorption occurs.

In addition to megaloblastic anaemia, vitamin B_{12} deficiency may result in neurological damage, including peripheral neuropathy and effects on mental function ranging from mild neurosis to dementia.

TREATMENT. The treatment is with vitamin B_{12}, almost always by the intramuscular or sometimes the deep subcutaneous route since in most patients absorption from the gastrointestinal tract is inadequate. Hydroxocobalamin is generally preferred to cyanocobalamin since it need be given less often. Regimens may vary, but hydroxocobalamin 1 mg every few days for 6 doses will restore normal body stores of the vitamin (see also Uses and Administration, above). Dosage has not been well established in children; the *BNFC* recommends similar doses to those licensed in adults. The haematological response to therapy is rapid, with improvement in most parameters and symptoms beginning within 48 hours. Neurological abnormalities may take much longer to respond, and may not do so completely.

PROPHYLAXIS. Where the defect in B_{12} handling is irreversible, as in pernicious anaemia, maintenance therapy must continue for life to prevent a recurrence of the deficiency. Therapy must also be given prophylactically after total gastrectomy or total ileal resection, or where gastrointestinal surgery is shown to have impaired absorption of the vitamin. Typically, injection of hydroxocobalamin 1 mg every 3 months is used. In patients whose diet supplies inadequate B_{12}, deficiency may be prevented, in the absence of other causes, by much lower oral doses given as a supplement; up to 150 micrograms of cyanocobalamin daily has been recommended.

Folate-deficiency anaemia. Deficiency of folate may be due to inadequate diet, or malabsorption syndromes (such as coeliac disease or sprue), to increased need (as in pregnancy, one of the most common causes of megaloblastic anaemia, or the increased haematopoiesis of haemolytic syndromes), to increased urinary loss or loss due to haemodialysis, or to an adverse effect of alcohol, antiepileptics, or other drugs.

The clinical features of folate-deficient megaloblastic anaemia are similar to those of disease due to vitamin-B_{12} deficiency except that the accompanying severe neuropathy does not occur, and deficiency may develop much more rapidly. Deficiency may also be associated with neural tube defects (p.1942) if it occurs in pregnancy.

TREATMENT. Once folate deficiency has been established the usual treatment in the UK is folic acid 5 mg by mouth daily. Lower doses of up to 1 mg are suggested in the USA. It is customary to continue therapy for at least 4 months, the time necessary for complete red cell replacement. In patients with malabsorption, therapy may require higher doses, up to 15 mg of folic acid daily. As in B_{12}-deficiency anaemia, the response to therapy is rapid.

PROPHYLAXIS. Long-term maintenance is rarely needed, except in a few patients in whom the underlying cause of folate deficiency cannot be treated (for example in some severe haemolytic syndromes). Doses of 5 mg daily or even weekly have been suggested for prophylaxis in patients undergoing dialysis or with chronic haemolytic states, depending on the diet and rate of haemolysis; a dose of 400 micrograms daily is recommended in the USA.

For primary prophylaxis of megaloblastic anaemia in pregnancy, folic acid is given in the UK in usual doses of 200 to 500 micrograms daily, often with a ferrous salt for prophylaxis of iron deficiency.

Drugs that act as inhibitors of dihydrofolate reductase, such as methotrexate, may produce severe megaloblastic anaemia which cannot be reversed by therapy with folic acid. The adverse effects of such drugs may be largely prevented or reversed by therapy with folinic acid, which can be incorporated into folate metabolism without the need for reduction by the inhibited enzyme. For details of such 'folinic acid rescue', see under Folinic Acid, p.1944.

Neural tube defects. There is abnormality in homocysteine metabolism in many women who give birth to children with neural tube defects (p.1942); the enzyme methionine synthase, which converts homocysteine to methionine, requires both folate and vitamin B_{12} as cofactors, and low maternal vitamin B_{12} concentrations may be an independent risk factor for neural tube defects.[1] A case-control study found elevated mid-trimester methylmalonic acid concentrations in women with pregnancies affected by neural tube defects, suggesting that abnormalities of cobalamin metabolism, and subsequent methylation, may be involved in the aetiology of neural tube defects.[2] Decreased vitamin B_{12} concentrations, but no folate deficiency, were found in 3 women with pregnancies affected by neural tube defects.[3] A review[4] of case-control studies found a moderate association between low maternal vitamin B_{12} status and the risk of fetal neural tube defects. If confirmed, this would suggest that additional supplementation with cobalamins may be warranted.[3-5]

Osteoporosis. An elevated serum homocysteine concentration appears to be a risk factor for osteoporotic fractures in older men and women.[1-3] Treatment with vitamin B_{12} and folate can reduce plasma homocysteine concentrations (see Cardiovascular Disease, under Folic Acid, p.1941). In a placebo-controlled study of patients with hemiplegia following stroke (and at increased risk of hip fracture),[4] those given folate and vitamin B_{12} were found to have a significantly reduced risk of hip fracture despite a lack of effect on bone mineral density. Vitamin B_{12} status has been associated with bone health in a number of studies,[3,5] and it was suggested that the observed effects on fracture might be due to increased concentrations of vitamin B_{12} rather than the lowering of plasma homocysteine.[3,6]

Vitamin C Substances

Vitamina C.

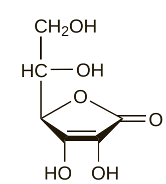
Several substances have vitamin C activity, notably ascorbic acid and its calcium and sodium salts. Natural products with a high vitamin C content include black currant (p.2267), lemon (p.2332), sweet orange (p.2357), and rose fruit (p.2381).

Ascorbic Acid *(BAN, rINN)*

Acide ascorbique; Ácido ascórbico; Acidum ascorbicum; L-Ascorbic Acid; Askorbiinihappo; Askorbik Asit; Askorbinsyra; Askorbo rūgštis; Aszkorbinsav; Cevitamic Acid; E300; Kwas askorbowy; Kyselina askorbová; Vitamin C. The enolic form of 3-oxo-L-gulofuranolactone; 2,3-Didehydro-L-*threo*-hexono-1,4-lactone.

Аскорбиновая кислота

$C_6H_8O_6$ = 176.1.
CAS — 50-81-7.
ATC — A11GA01; G01AD03; S01XA15.
ATC Vet — QA11GA01; QG01AD03; QS01XA15.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US*, and *Viet.*

Ph. Eur. 6.2 (Ascorbic Acid). A white or almost white crystalline powder or colourless crystals becoming discoloured on exposure to air and moisture. Freely soluble in water; soluble in alcohol. A 5% solution in water has a pH of 2.1 to 2.6. Store in nonmetallic containers. Protect from light.

USP 31 (Ascorbic Acid). White or slightly yellow crystals or powder. On exposure to light, it gradually darkens. In the dry state, is reasonably stable in air, but in solution rapidly oxidises. Soluble 1 in 3 of water and 1 in 40 of alcohol; insoluble in chloroform, in ether, and in benzene. Store in airtight containers. Protect from light.

Calcium Ascorbate *(BANM, rINNM)*

Ascorbate de Calcium; Ascorbato cálcico; Askorban vápenatý dihydrát; Calcii ascorbas; Calcii Ascorbas Dihydricus; Calcium, ascorbate de; E302; Kalcio askorbatas; Kalciumaskorbat; Kalcium-aszkorbát; Kalsiumaskorbaatti.

Кальций Аскорбат

$(C_6H_7O_6)_2Ca,2H_2O$ = 426.3.

CAS — 5743-27-1.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Calcium Ascorbate). A white or slightly yellowish crystalline powder. Freely soluble in water; practically insoluble in alcohol. A 10% solution in water has a pH between 6.8 and 7.4. Store in nonmetallic containers. Protect from light.

USP 31 (Calcium Ascorbate). A white to slightly yellow, practically odourless, powder. Freely soluble in water (about 1 in 2); slightly soluble in alcohol; insoluble in ether. pH of a 10% solution in water is between 6.8 and 7.4. Store in airtight containers. Protect from light.

Sodium Ascorbate *(BANM, rINN)*

Ascorbate de sodium; Ascorbate sodique; Ascorbato de sodio; Askorban sodný; E301; Monosodium L-Ascorbate; Natrii ascorbas; Natrio askorbatas; Natriumaskorbaatti; Natriumaskorbat; Nátrium-aszkorbát. 3-Oxo-L-gulofuranolactone sodium enolate.

Натрия Аскорбат

$C_6H_7NaO_6$ = 198.1.

CAS — 134-03-2.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *US.*

Ph. Eur. 6.2 (Sodium Ascorbate). A white or yellowish crystalline powder or crystals. Freely soluble in water; sparingly soluble in alcohol; practically insoluble in dichloromethane. A 10% solution in water has a pH of 7.0 to 8.0. Store in nonmetallic containers. Protect from light.

USP 31 (Sodium Ascorbate). White or very faintly yellow, odourless or practically odourless, crystals or crystalline powder. On exposure to light it gradually darkens. Soluble 1 in 1.3 of water; very slightly soluble in alcohol; insoluble in chloroform and in ether. pH of a 10% solution in water is between 7.0 and 8.0. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Ascorbic acid is usually well tolerated. Large doses are reported to cause diarrhoea and other gastrointestinal disturbances. It has also been stated that large doses may result in hyperoxaluria and the formation of renal calcium oxalate calculi and ascorbic acid should therefore be given with care to patients with hyperoxaluria (see Effects on the Kidneys, below). Tolerance may be induced with prolonged use of large doses, resulting in symptoms of deficiency when intake is reduced to normal. Prolonged or excessive use of chewable vitamin C preparations may cause erosion of tooth enamel.

Large doses of ascorbic acid have resulted in haemolysis in patients with G6PD deficiency (see Effects on the Blood, below).

Breast feeding. Vitamin C is excreted into breast milk and thus supplied to breast-feeding infants. Lactating women in developing countries have significantly lower concentrations of ascorbic acid in their breast milk compared with lactating women in developed countries,[1] and seasonal variation in consumption of foods rich in vitamin C leads to variable amounts of ascorbic acid in breast milk.[2] Supplementation with high-dose ascorbic acid (1 g daily for 10 days) led to significant increases in breast-milk concentrations in both European and African women;[1] however, the overall effect was modest in European women compared with a threefold increase observed in African women. Lower doses of 100 mg daily for 10 days approximately doubled the ascorbic acid breast milk content in the latter, as did supplementation with orange juice 3 or 5 times a week; a significant day-to-day effect was also noted, indicating that the ascorbic acid content of breast milk is regulated. In a small study[2] involving four different doses of ascorbic acid supplements, women in West Africa showed that increased intake caused an increase in the ascorbate concentration of breast milk, but concentrations approached a plateau at higher intakes; it was concluded that about 100 to 120 mg of vitamin C daily was needed to achieve acceptable plasma and breast-milk ascorbate concentrations in this population.

2. Bates CJ, *et al.* The effect of vitamin C supplementation on lactating women in Keneba, a West African rural community. *Int J Vitam Nutr Res* 1983; **53:** 68–76.

Effects on the blood. There are reports of haemolysis in patients with G6PD deficiency after large doses of ascorbic acid either intravenously[1,2] or in soft drinks.[3] There has also been a report[4] of a patient with paroxysmal nocturnal haemoglobinuria suffering haemolysis after taking large amounts of ascorbic acid in a soft drink. There is concern that the large quantities of vitamin C in feeds for premature neonates may have a pro-oxidant effect, and lead to haemolysis. However, a double-blind study found no increase in erythrocyte destruction or hyperbilirubinaemia in premature neonates receiving vitamin C.[5]

Effects on the kidneys. Although renal impairment associated with excessive oxalate excretion has been reported with large doses of ascorbic acid[1-3] it has been considered that healthy persons can ingest large amounts of ascorbic acid with relatively small increases in oxalate excretion[4-6] and without an increased risk of oxalate stone formation. A study of vitamin C supplementation with 1 or 2 g given daily for 3 days in calcium stone-forming patients, and 1 g given daily for 3 days in healthy subjects, found that urinary oxalate excretion and the risk of calcium oxalate crystallisation increased significantly in all groups.[7] A prospective cohort study found that increased vitamin C intake (over 1 g daily) was positively associated with the risk of stone formation; an increased risk was observed even at lower intakes of about 90 to 250 mg daily. The risk was raised for both dietary and supplemental vitamin C intake. However, the relation between vitamin C intake and stone formation had emerged only after the inclusion of dietary potassium in the analysis, with potassium intake positively associated with dietary vitamin C intake, but inversely associated with stone formation. This led the authors to conclude that, while limiting dietary vitamin C intake in men with calcium oxalate nephrolithiasis was unwarranted (because of the high potassium content of vitamin C-rich foods), supplemental vitamin C should be avoided.[8]

Effects on mortality. There is some suggestion that serum ascorbic acid concentrations are inversely related to all-cause mortality;[1-4] serum levels were also inversely related to cancer mortality in men but not in women.[1-3] However, a meta-analysis of 3 studies found vitamin C supplementation to have no benefit on mortality in elderly people.[5] A systematic review of antioxidant supplementation in adults also found no significant effect on mortality from studies in which vitamin C was used either singly or with other antioxidants;[6] small beneficial effects or large harmful effects could not be excluded, and since vitamin C can also act as a pro-oxidant, further studies should monitor closely for any harm.

Effects on the teeth. A report of dental enamel erosion attributed to the daily ingestion of chewable ascorbic acid tablets over a period of 3 years.[1] The tablets lowered the pH of the saliva to a level at which calcium was lost from the tooth enamel.

1. Giunta JL. Dental erosion resulting from chewable vitamin C tablets. *J Am Dent Assoc* 1983; **107:** 253–6.

Interference with laboratory tests. Ascorbic acid, a strong reducing agent, interferes with laboratory tests involving oxidation and reduction reactions. Falsely-elevated or false-negative test results may be obtained from plasma, faeces, or urine samples depending on such factors as the dose of ascorbic acid and specific method used.

Interactions

For the effect of ascorbic acid on various drugs see under desferrioxamine (p.1440), hormonal contraceptives (p.2068), HRT (p.2076), fluphenazine (under Chlorpromazine, p.975), and warfarin (p.1432). Ascorbic acid may increase the absorption of iron in iron-deficiency states. Omeprazole may affect the bioavailability of dietary vitamin C (see Malabsorption, under Omeprazole, p.1754).

Pharmacokinetics

Ascorbic acid is readily absorbed from the gastrointestinal tract and is widely distributed in the body tissues. Plasma concentrations of ascorbic acid rise as the dose ingested is increased until a plateau is reached with doses of about 90 to 150 mg daily. Body stores of ascorbic acid in health are about 1.5 g although more may be stored at intakes above 200 mg daily. The concentration is higher in leucocytes and platelets than in erythrocytes and plasma. In deficiency states the concentration in leucocytes declines later and at a slower rate, and has been considered to be a better criterion for the evaluation of deficiency than the concentration in plasma.

Ascorbic acid is reversibly oxidised to dehydroascorbic acid; some is metabolised to ascorbate-2-sulfate, which is inactive, and oxalic acid which are excreted in the urine. Ascorbic acid in excess of the body's needs is also rapidly eliminated unchanged in the urine; this generally occurs with intakes exceeding 100 mg daily. Ascorbic acid crosses the placenta and is distributed into breast milk. It is removed by haemodialysis.

Human Requirements

A daily dietary intake of about 30 to 100 mg of vitamin C has been recommended for adults. There is, however, wide variation in individual requirements. Humans are unable to form their own ascorbic acid and so a dietary source is necessary. Most dietary ascorbic acid is obtained from fruit and vegetable sources; only small amounts are present in milk and animal tissues. Relatively rich sources include rose hips (rose fruit), black currant, citrus fruits, leafy vegetables, tomatoes, potatoes, and green and red peppers.

Ascorbic acid is readily destroyed during cooking processes. Considerable losses may also occur during storage.

UK and US recommended dietary intake. In the UK[1] dietary reference values (see p.1925) have been published for vitamin C and similarly in the USA recommended dietary allowances (RDAs) have been set.[2] Differing amounts are recommended for infants and children of varying ages, for adult males and females, and for pregnant and lactating women. In the UK the reference nutrient intake (RNI) is 40 mg daily for adult males and females and the estimated average requirement (EAR) is 30 mg daily. In general the amount recommended in the USA for all ages and groups is higher than that set in the UK; the RDA is 90 mg daily for men and 75 mg daily for women.[2] The RDA is increased in smokers by 35 mg daily. The tolerable upper intake level is 2 g daily.[2] The EAR is 75 mg daily for men and 60 mg daily for women.

Uses and Administration

Vitamin C, a water-soluble vitamin, is essential for the synthesis of collagen and intercellular material. Vitamin C deficiency develops when the dietary intake is inadequate. It is rare in adults, but may occur in infants, alcoholics, or the elderly. Deficiency leads to the development of a well-defined syndrome known as scurvy. This is characterised by capillary fragility, bleeding (especially from small blood vessels and the gums), normocytic or macrocytic anaemia, cartilage and bone lesions, and slow healing of wounds.

Vitamin C is used in the treatment and prevention of deficiency. It completely reverses symptoms of deficiency. It is usually given orally, the preferred route, as ascorbic acid, and has been given to children in the form of a suitable fruit juice such as orange juice or as black currant or rose hip syrups. Ascorbic acid or sodium ascorbate may be given parenterally, preferably by the intramuscular route, but also by the intravenous or subcutaneous routes. Doses of 25 to 75 mg daily in the prevention of deficiency, and 250 mg or more daily in divided doses for the treatment of deficiency, have been recommended.

Ascorbic acid 100 to 200 mg daily may be given with desferrioxamine in the treatment of patients with thalassaemia, to improve the chelating action of desferrioxamine, thereby increasing the excretion of iron (see p.1441). In iron deficiency states ascorbic acid may increase gastrointestinal iron absorption and ascorbic acid or ascorbate salts are therefore included in some oral iron preparations. Ascorbic acid or sodium ascorbate have been used in treating methaemoglobinaemia. Ascorbic acid has been used to acidify urine. It has also been tried in the treatment of many other disorders (see below) but there is little evidence of beneficial effect.

Eye drops containing potassium ascorbate (ascorbic acid 10%) have been used for the treatment of chemical eye burns (p.1674); they may be used with sodium citrate eye drops (see Uses of Bicarbonate, p.1674).

Ascorbic acid and calcium and sodium ascorbates are used as antoxidants in pharmaceutical manufacturing and in the food industry.

Non-deficiency disorders. A beneficial effect of vitamin C therapy has been claimed for an extraordinary number of conditions, including age-related macular degeneration (under Betacarotene, p.1931) Alzheimer's disease (see Dementia, under Vitamin E, p.1994), atherosclerosis (see Prophylaxis of Ischaemic Heart Disease, p.1926), cancer (see Prophylaxis of Malignant Neoplasms, p.1927), the common cold (p.850), and idiopathic thrombocytopenic purpura (p.1505). Other conditions claimed to benefit include asthma, wound healing, psychiatric disorders, infections due to abnormal leucocyte function, infertility, osteogenesis imperfecta, pain in Paget's disease, and opioid withdrawal. Generally there are few properly controlled studies to substantiate these claims. Although preliminary evidence suggested a benefit in pre-eclampsia, this was not confirmed in later studies (see Hypertension, p.1171).

Preparations

BP 2008: Ascorbic Acid Injection; Ascorbic Acid Tablets; Paediatric Vitamins A, C and D Oral Drops; Vitamins B and C Injection;
USP 31: Ascorbic Acid Injection; Ascorbic Acid Oral Solution; Ascorbic Acid Tablets.

Vitamin D Substances

Vitamina D.

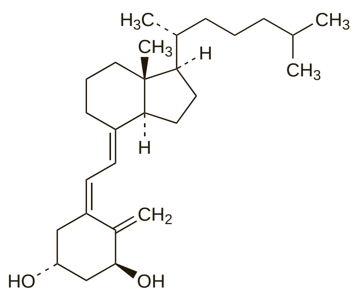
The term vitamin D is used for a range of closely related sterol compounds including alfacalcidol, calcifediol, calcitriol, colecalciferol, dihydrotachysterol, and ergocalciferol. Newer vitamin D analogues include doxercalciferol, falecalcitriol, maxacalcitol, and paricalcitol.

Alfacalcidol *(BAN, rINN)*

Alfacalcidolum; Alfakalcidol; Alfakalcidolis; Alfakalsidol; Alfakalsidoli; EB-644; 1α-Hydroxycholecalciferol; 1α-Hydroxyvitamin D_3; 1α-OHD_3. (5*Z*,7*E*)-9,10-Secocholesta-5,7,10(19)-triene-1α,3β-diol.

Альфакальцидол

$C_{27}H_{44}O_2$ = 400.6.
CAS — 41294-56-8.
ATC — A11CC03.
ATC Vet — QA11CC03.



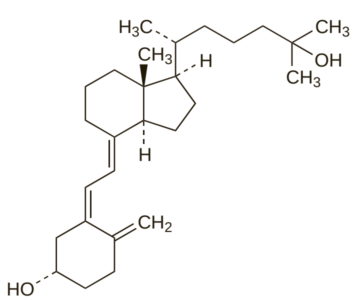
Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii).
Ph. Eur. 6.2 (Alfacalcidol). White or almost white crystals which are sensitive to air, heat, and light. Practically insoluble in water; freely soluble in alcohol; soluble in fatty oils. Reversible isomerisation to pre-alfacalcidol takes place in solution, depending on temperature and time. Activity is due to both compounds. Store at 2° to 8° under an atmosphere of nitrogen in airtight containers. The contents of an opened container should be used immediately. Protect from light.

Calcifediol *(BAN, USAN, rINN)*

Calcidiol; Calcifédiol; Calcifediolum; Calcifediolum Monohydricum; 25-Hydroxycholecalciferol; 25-Hydroxyvitamin D_3; Kalcifediol; Kalcifediol monohydrát; Kalcifediolis; Kalcyfediol; Kalsifedioli; 25-$(OH)D_3$; U-32070E. (5*Z*,7*E*)-9,10-Secocholesta-5,7,10(19)-triene-3β,25-diol monohydrate.

Кальцифедиол

$C_{27}H_{44}O_2,H_2O$ = 418.7.
CAS — 19356-17-3 (anhydrous calcifediol); 63283-36-3 (calcifediol monohydrate).
ATC — A11CC06.
ATC Vet — QA11CC06.



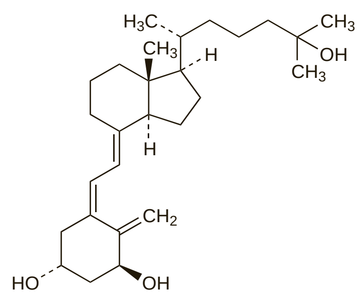
Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Calcifediol). White or almost white crystals which are sensitive to air, heat, and light. Practically insoluble in water; freely soluble in alcohol; soluble in fatty oils. Reversible isomerisation to pre-calcifediol takes place in solution, depending on temperature and time. The activity is due to both compounds. Store at 2° to 8° under an atmosphere of nitrogen in airtight containers. The contents of an opened container should be used immediately. Protect from light.
USP 31 (Calcifediol). Store in airtight containers. Protect from light.

Calcitriol *(BAN, USAN, rINN)*

Calcitriolum; 1,25-Dihydroxycholecalciferol; 1α,25-Dihydroxycholecalciferol; 1α,25-Dihydroxyvitamin D_3; Kalcitriol; Kalcitriolis; Kalsitriol; Kalsitrioli; 1α,25$(OH)_2D_3$; Ro-21-5535. (5*Z*,7*E*)-9,10-Secocholesta-5,7,10(19)-triene-1α,3β,25-triol.

Кальцитриол

$C_{27}H_{44}O_3$ = 416.6.
CAS — 32222-06-3 (anhydrous); 77326-95-5 (monohydrate).
ATC — A11CC04; D05AX03.
ATC Vet — QA11CC04; QD05AX03.



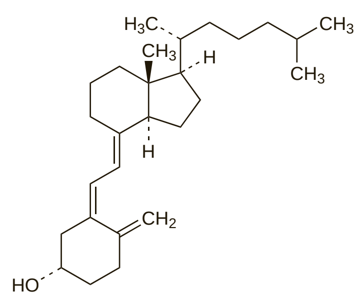
Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Calcitriol). White or almost white crystals. Practically insoluble in water; freely soluble in alcohol; soluble in fatty oils. It is sensitive to air, heat, and light. A reversible isomerisation to pre-calcitriol takes place in solution, depending on temperature and time. The activity is due to both compounds. Store at 2° to 8° under an atmosphere of nitrogen in airtight containers. The contents of an opened container should be used immediately. Protect from light.
USP 31 (Calcitriol). It may be anhydrous or contain one molecule of hydration. White or almost white crystals. Practically insoluble in water; freely soluble in alcohol; soluble in ether and in fatty oils. Store in airtight containers. Protect from light.

Colecalciferol *(BAN, rINN)*

Activated 7-Dehydrocholesterol; Cholécalciférol; Cholecalciferol; Cholecalciferolum; Cholekalciferol; Cholekalciferolis; Cholekalcyferol; Colécalciférol; Colecalciferolum; Kolekalciferol; Kolekalsiferol; Kolekalsiferoli; Vitamin D_3. (5*Z*,7*E*)-9,10-Secocholesta-5,7,10(19)-trien-3β-ol.

Колекальциферол

$C_{27}H_{44}O$ = 384.6.
CAS — 67-97-0.
ATC — A11CC05.
ATC Vet — QA11CC05.



Description. Colecalciferol is the naturally occurring form of vitamin D. It is produced from 7-dehydrocholesterol, a sterol present in mammalian skin, by ultraviolet irradiation.

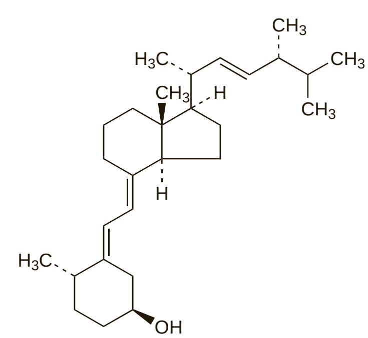
Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*
Eur. also includes monographs for concentrates in an oily form, a powder form, and a water-dispersible form. *US* also includes a solution.
Ph. Eur. 6.2 (Cholecalciferol; Colecalciferol BP 2008). White or almost white crystals which are sensitive to air, heat, and light. Practically insoluble in water; freely soluble in alcohol; soluble in trimethylpentane and in fatty oils. Solutions in solvents without an antioxidant are unstable and should be used immediately. A reversible isomerisation to pre-colecalciferol takes place in solution, depending on temperature and time. The activity is due to both compounds. Store under nitrogen in airtight containers at a temperature of 2° to 8°. The contents of an opened container should be used immediately. Protect from light.
The BP 2008 directs that when calciferol or vitamin D is prescribed or demanded, Colecalciferol or Ergocalciferol shall be dispensed or supplied.
Ph. Eur. 6.2 (Cholecalciferol Concentrate (Oily Form); Cholecalciferolum Densatum Oleosum; Colecalciferol Concentrate (Oily Form) BP 2008). A solution of colecalciferol in a suitable vegetable oil. It contains not less than 500 000 units/g. It may contain suitable stabilisers such as antoxidants. A clear, yellow liquid. Practically insoluble in water; slightly soluble in dehydrated alcohol; miscible with solvents of fats. Partial solidification may occur, depending on the temperature. Store in well-filled airtight containers. Protect from light. The contents of an opened container are to be used as soon as possible; any unused part is to be protected by an atmosphere of nitrogen.
Ph. Eur. 6.2 (Cholecalciferol Concentrate (Powder Form); Cholecalciferoli Pulvis; Colecalciferol Concentrate (Powder Form) BP 2008). It is obtained by dispersing an oily solution of colecalciferol in an appropriate matrix which is usually based on a combination of gelatin and carbohydrates of suitable quality. It contains not less than 100 000 units/g. It may contain suitable stabilisers such as antoxidants. White or yellowish-white, small particles. Depending on their formulation, it may be practically insoluble in water or may swell or form a dispersion. Store in well-filled airtight containers. Protect from light. The contents of an opened container are to be used as soon as possible; any unused part is to be protected by an atmosphere of nitrogen.
Ph. Eur. 6.2 (Cholecalciferol Concentrate (Water-dispersible Form); Cholecalciferolum in Aqua Dispergibile; Colecalciferol Concentrate (Water-dispersible Form) BP 2008). A solution of colecalciferol in a suitable vegetable oil to which suitable solubilisers have been added. It contains not less than 100 000 units/g. It may contain suitable stabilisers such as antoxidants. A slightly yellowish liquid of variable opalescence and viscosity. Highly concentrated solutions may become cloudy at low temperatures or form a gel at room temperature. Store in well-filled airtight containers. Protect from light. The contents of an opened container are to be used as soon as possible; any unused part is to be protected by an atmosphere of inert gas.
USP 31 (Cholecalciferol). White, odourless crystals. Insoluble in water; soluble in alcohol, in chloroform, and in fatty oils. M.p. about 85°. It is affected by air and light. Store under nitrogen in hermetically sealed containers at a temperature of 8° to 15°. Protect from light.
USP 31 (Cholecalciferol Solution). A solution of colecalciferol in an edible vegetable oil, in polysorbate 80, or in propylene glycol. Store in airtight containers. Protect from light.

Dihydrotachysterol *(BAN, rINN)*

Dichysterol; Dihidrotakisterol; Dihidrotaquisterol; Dihydrotachystérol; Dihydrotachysterolum; Dihydrotakisterol; Dihydrotakysterol; Dihydrotakysteroli. (5*E*,7*E*,22*E*)-10α-9,10-Secoergosta-5,7,22-trien-3β-ol.

Дигидротахистерол

$C_{28}H_{46}O$ = 398.7.
CAS — 67-96-9.
ATC — A11CC02.
ATC Vet — QA11CC02.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*
Ph. Eur. 6.2 (Dihydrotachysterol). Colourless crystals, or a white or almost white crystalline powder. It exhibits polymorphism. Practically insoluble in water; sparingly soluble in alcohol; freely soluble in acetone and in *n*-hexane. Store under an inert gas in airtight containers at 2° to 8°.
USP 31 (Dihydrotachysterol). Colourless or white, odourless crystals, or white, odourless, crystalline powder. Practically insoluble in water; soluble in alcohol; freely soluble in chloroform and in ether; sparingly soluble in vegetable oils. Store in hermetic glass containers from which the air has been displaced by an inert gas. Protect from light.

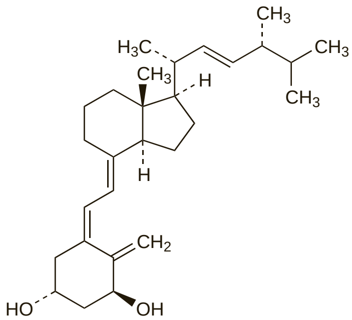
Doxercalciferol *(USAN, rINN)*

Doxercalciférol; Doxercalciferolum; 1α-Hydroxyergocalciferol; 1α-Hydroxyvitamin D_2; 1α-OH-D_2. (5*Z*,7*E*,22*E*)-9,10-Secoergosta-5,7,10(19),22-tetraene-1α,3β-diol.

Доксэркальциферол

$C_{28}H_{44}O_2$ = 412.6.

CAS — 54573-75-0.



Ergocalciferol *(BAN, rINN)*

Calciferol; Ergocalciférol; Ergocalciferolum; Ergokalciferol; Ergokalciferolis; Ergokalsiferol; Ergokalsiferoli; Irradiated Ergosterol; Viosterol; Vitamin D_2. (5*Z*,7*E*,22*E*)-9,10-Secoergosta-5,7,10(19),22-tetraen-3β-ol.

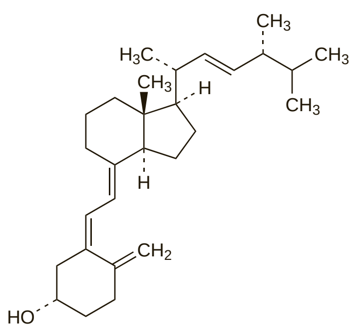
Эргокальциферол

$C_{28}H_{44}O$ = 396.6.

CAS — 50-14-6.

ATC — A11CC01.

ATC Vet — QA11CC01.



Description. Ergocalciferol is an antirachitic substance obtained from ergosterol, a sterol present in fungi and yeasts, by ultraviolet irradiation.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, *US*, and *Viet.*

Ph. Eur. 6.2 (Ergocalciferol). White or almost white, crystals or white or slightly yellowish crystalline powder. It is sensitive to air, heat, and light. Practically insoluble in water; freely soluble in alcohol; soluble in fatty oils. Solutions in volatile solvents are unstable and should be used immediately. A reversible isomerisation to pre-ergocalciferol takes place in solution, depending on temperature and time. The activity is due to both compounds. Store under nitrogen in airtight containers at a temperature of 2° to 8°. The contents of an opened container should be used immediately. Protect from light.

The BP 2008 directs that when calciferol or vitamin D is prescribed or demanded, Ergocalciferol or Colecalciferol shall be dispensed or supplied.

USP 31 (Ergocalciferol). White, odourless crystals. It is affected by air and light. Insoluble in water; soluble in alcohol, in chloroform, in ether, and in fatty oils. Store in hermetically sealed containers under nitrogen at a temperature of 8° to 15°. Protect from light.

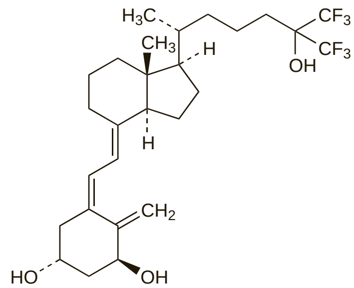
Falecalcitriol *(rINN)*

Falécalcitriol; Falecalcitriolum; Flocalcitriol; Hexafluorocalcitriol; Ro-23-4194; ST-630. (+)-(5*Z*,7*E*)-26,26,26,27,27,27-Hexafluoro-9,10-secocholesta-5,7,10(19)-triene-1α,3β,25-triol.

Фалекальцитриол

$C_{27}H_{38}F_6O_3$ = 524.6.

CAS — 83805-11-2.



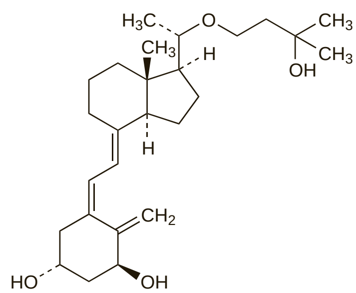
Maxacalcitol *(USAN, rINN)*

1α,25-Dihydroxy-22-oxavitamin D_3; Maxacalcitolum; OCT; 22-Oxacalcitriol; Sch-209579. (+)-(5*Z*,7*E*,20*S*)-20-(3-Hydroxy-3-methylbutoxy)-9,10-secopregna-5,7,10(19)-triene-1α,3β-diol.

Максакальцитол

$C_{26}H_{42}O_4$ = 418.6.

CAS — 103909-75-7.



Paricalcitol *(USAN, rINN)*

ABT-358; Compound 49510; Paracalcin; Paricalcitolum. (7*E*,22*E*)-19-Nor-9,10-secoergosta-5,7,22-triene-1α,3β,25-triol.

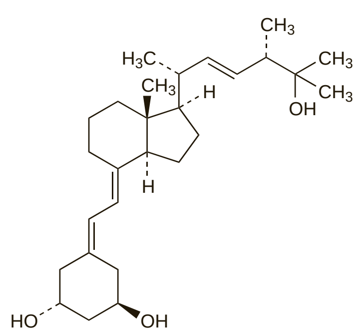
Парикальцитол

$C_{27}H_{44}O_3$ = 416.6.

CAS — 131918-61-1.

ATC — A11CC07.

ATC Vet — QA11CC07.



Pharmacopoeias. In *US.*

USP 31 (Paricalcitol). A white to almost white powder. Insoluble in water; soluble in alcohol. Store under argon in airtight containers at a temperature of −25° to −10°.

Units

The Second International Standard Preparation (1949) of vitamin D consisted of bottles containing about 6 g of a solution of colecalciferol in vegetable oil (1000 units/g). This standard has now been discontinued.

NOTE. Pharmacopoeias consider that one unit of vitamin D is contained in 25 nanograms of colecalciferol or ergocalciferol (i.e. 1 mg of colecalciferol or ergocalciferol is equivalent to 40 000 units of vitamin D as determined by bioassay in *rats*), but see below.

Equivalence. It has been proposed that units of vitamin D be defined in moles or molecules rather than weight terms; in which case, 1 unit of colecalciferol and ergocalciferol would be equivalent to 25 nanograms and 25.78 nanograms, respectively. This inequivalence in units might confound optimal vitamin D dosing recommendations.[1] For the view that colecalciferol is more potent than ergocalciferol, and should be preferred for vitamin D supplementation, see Administration, below.

1. Houghton LA, Vieth R. The case against ergocalciferol (vitamin D) as a vitamin supplement. *Am J Clin Nutr* 2006; **84:** 694–7.

Adverse Effects and Treatment

Excessive intake of vitamin D leads to the development of hyperphosphataemia or hypercalcaemia. Associated effects of hypercalcaemia include hypercalciuria, ectopic calcification, and renal and cardiovascular damage (for a discussion of vitamin-D mediated hypercalcaemia and its treatment, see p.1668). Symptoms of overdosage include anorexia, lassitude, nausea and vomiting, constipation or diarrhoea, polyuria, nocturia, sweating, headache, thirst, somnolence, and vertigo. Interindividual tolerance to vitamin D varies considerably; infants and children are generally more susceptible to its toxic effects. The vitamin should be withdrawn if toxicity occurs. It has been stated that vitamin D dietary supplementation may be detrimental in persons already receiving an adequate intake through diet and exposure to sunlight, since the difference between therapeutic and toxic concentrations is relatively small.

The most potent forms of vitamin D, such as alfacalcidol and calcitriol, might reasonably be expected to pose a greater risk of toxicity; however, their effects are reversed rapidly on withdrawal.

Hypersensitivity reactions have occurred. Skin irritation or contact dermatitis has been reported with topical preparations.

Hypercalcaemia. Vitamin D is the most likely of all vitamins to cause overt toxicity. Doses of 60 000 units daily can cause hypercalcaemia (p.1668), with muscle weakness, apathy, headache, anorexia, nausea and vomiting, bone pain, ectopic calcification, proteinuria, hypertension, and cardiac arrhythmias. Chronic hypercalcaemia can lead to generalised vascular calcification, nephrocalcinosis, and rapid deterioration of renal function.[1,2] A number of reports of accidental overdosage, leading to hypercalcaemia or nephrocalcinosis, occurred in the UK after introduction of a concentrated alfacalcidol oral solution that was 10 times stronger than the former presentation.[3]

Hypercalcaemia has been reported in a patient after brief industrial exposure to colecalciferol.[4]

A study in children treated for renal osteodystrophy has provided some evidence that hypercalcaemia may occur more frequently with calcitriol than with ergocalciferol.[5] Another such study has suggested that vitamin D has nephrotoxic properties independent of the degree of induced hypercalcaemia, and that the decline in renal function may be more marked with calcitriol.[6]

Topical calcitriol may affect calcium homoeostasis, and hypercalcaemia has been reported in some studies.[7] For reference to the effect of other vitamin D analogues used in psoriasis on calcium homoeostasis, see p.1591.

Precautions

Vitamin D should not be given to patients with hypercalcaemia. It should be used with caution in infants, who may have increased sensitivity to its effects, and patients with renal impairment or calculi, or heart disease, who might be at increased risk of organ damage if hypercalcaemia occurred. Plasma phosphate concentrations should be controlled during vitamin D therapy to reduce the risk of ectopic calcification.

It is advised that patients receiving pharmacological doses of vitamin D should have their plasma-calcium concentration monitored at regular intervals, especially initially or if symptoms suggest toxicity (see above). Similar monitoring is recommended in infants if they are breast fed by mothers receiving pharmacological doses of vitamin D (see below).

Breast feeding. Vitamin D is distributed into breast milk,[1] and its concentration appears to correlate with the amount of vitamin D in the serum of exclusively breast-fed infants.[2] The American Academy of Pediatrics considers the use of vitamin D to be usually compatible with breast feeding,[3] although they and others[4] recommend that the infant be closely monitored for hypercalcaemia or clinical manifestations of vitamin D toxicity if the mother is taking pharmacological doses of vitamin D.

4. Greer FR, *et al.* High concentrations of vitamin D in human milk associated with pharmacologic doses of vitamin D . *J Pediatr* 1984; **105:** 61–4.

Pregnancy. Hypercalcaemia during pregnancy may produce congenital disorders in the offspring, and neonatal hypoparathyroidism. However, the risks to the fetus of untreated maternal hypoparathyroidism are considered greater than the risks of hypercalcaemia due to vitamin D therapy. Indeed, one report noted increased requirements for vitamin D preparations during pregnancy for the treatment of hypoparathyroidism;[1] the dose needed tended to increase during the second half of pregnancy. In one woman in whom the dose of calcitriol remained raised after delivery (in an attempt to allow for the calcium loss involved in breast feeding) hypercalcaemia developed; this did not occur in 2 women who did not breast feed and in whom the dose of the vitamin D preparations was reduced soon after delivery.[1] For discussions regarding vitamin D requirements during pregnancy, see UK and US recommended dietary intake, p.1988, and Pregnancy and the Neonate, p.1991, below.

Interactions

There is an increased risk of hypercalcaemia if vitamin D is given with thiazide diuretics, calcium, or phosphate. Plasma-calcium concentrations should be monitored in such situations. Some antiepileptics may increase vitamin D requirements (e.g. carbamazepine, phenobarbital, phenytoin, and primidone). Rifampicin and isoniazid may reduce the effectiveness of vitamin D. Corticosteroids may counteract the effect of vitamin D. Ketoconazole may inhibit the metabolism of paricalcitol and these drugs should be used with caution together; care should be taken when using paricalcitol with other potent inhibitors of the cytochrome P450 isoenzyme CYP3A4.

Danazol. A report of hypercalcaemia associated with danazol in a patient maintained on alfacalcidol therapy for hypoparathyroidism.[1] Introduction of danazol appeared to reduce the maintenance requirement for alfacalcidol.

1. Hepburn NC, *et al.* Danazol-induced hypercalcaemia in alphacalcidol-treated hypoparathyroidism. *Postgrad Med J* 1989; **65:** 849–50.

Levothyroxine. Three patients taking dihydrotachysterol and calcium, for postoperative hypoparathyroidism after thyroidectomy, as well as levothyroxine, developed hypercalcaemia when the latter was stopped before a radio-iodine scan.[1] The dose of dihydrotachysterol should be reduced and serum-calcium concentrations should be monitored when thyroid treatment is interrupted, since elimination of dihydrotachysterol may be delayed in hypothyroidism.

1. Lamberg B-A, Tikkanen MJ. Hypercalcaemia due to dihydrotachysterol treatment in patients with hypothyroidism after thyroidectomy. *BMJ* 1981; **283:** 461–2.

Pharmacokinetics

Vitamin D substances are well absorbed from the gastrointestinal tract. The presence of bile is essential for adequate intestinal absorption; absorption may be decreased in patients with decreased fat absorption.

Vitamin D and its metabolites circulate in the blood bound to a specific α-globulin. Vitamin D can be stored in adipose and muscle tissue for long periods of time. It is slowly released from such storage sites and from the skin where it is formed in the presence of sunlight or ultraviolet light. Ergocalciferol and colecalciferol have a slow onset and a long duration of action; calcitriol and its analogue alfacalcidol, however, have a more rapid action and shorter half-lives.

Colecalciferol and ergocalciferol are hydroxylated in the liver by the enzyme vitamin D 25-hydroxylase to form 25-hydroxycholecalciferol (calcifediol) and 25-hydroxyergocalciferol respectively. These compounds undergo further hydroxylation in the kidneys by the enzyme vitamin D 1-hydroxylase to form the active metabolites 1,25-dihydroxycholecalciferol (calcitriol) and 1,25-dihydroxyergocalciferol respectively. Further metabolism also occurs in the kidneys, including the formation of the 1,24,25-trihydroxy derivatives. Of the synthetic analogues, alfacalcidol, dihydrotachysterol, and doxercalciferol are converted directly in the liver to their active metabolites (calcitriol, 25-hydroxydihydrotachysterol, and 1,25-dihydroxyergocalciferol respectively).

Vitamin D compounds and their metabolites are excreted mainly in the bile and faeces with only small amounts appearing in urine; there is some enterohepatic recycling but it is considered to have a negligible contribution to vitamin D status. Certain vitamin D substances may be distributed into breast milk.

Human Requirements

The daily requirements of vitamin D in adults are small and may be met mainly by exposure to sunlight and/or obtained from the diet. A daily dietary intake of about 200 to 400 units (5 to 10 micrograms of colecalciferol or ergocalciferol) of vitamin D is generally considered adequate for healthy adults. In comparison with older adults (in the age range of 25 years upwards) the requirements per kg body-weight are greater in infants, children, and young adults and during pregnancy and lactation. Requirements may also be higher in people who are not exposed to adequate sunlight such as the elderly or housebound.

Vitamin D is present in few foods. Fish-liver oils, especially cod-liver oil, are good sources of vitamin D. Other sources, which contain much smaller amounts, include butter, eggs, and liver. Some foods are fortified with vitamin D, and milk and margarine may therefore also supply the vitamin. Cooking processes do not appear to affect the activity of vitamin D.

UK and US recommended dietary intake. In the UK dietary reference values (see p.1925) for vitamin D have only been published for selected groups of the population.[1] In the USA recommended dietary allowances had been set, and were subsequently replaced by dietary reference intakes[2] (see p.1925). Differing amounts are recommended for infants and children of varying ages, for adults, and for pregnant and lactating women. In the UK a dietary intake was considered unnecessary for adults living a normal lifestyle who were being exposed to solar radiation; for those confined indoors a reference nutrient intake (RNI) of 10 micrograms (400 units) [as colecalciferol or ergocalciferol] daily was set. This RNI of 10 micrograms daily was also considered to be applicable to all persons aged 65 years or more and to pregnant and lactating women. RNIs were set for children up to the age of 3 years; dietary intake was considered unnecessary for older children. Mention was made that in order to achieve the above reference nutrient intakes, supplementation of the diet may actually be required and supplementation was also recommended for Asian [i.e. from the Indian subcontinent] women and children in the UK (see also Pregnancy and the Neonate, below). In the USA,[2] adequate intakes for vitamin D are: 5 micrograms (200 units) daily (as colecalciferol) for all persons from birth through to age 50 years, including pregnant or lactating women; 10 micrograms daily for adults aged 51 to 70 years; and 15 micrograms daily for those aged greater than 70 years. The tolerable upper intake level is 50 micrograms (2000 units) daily. The 2005 Dietary Guidelines for Americans (published jointly by the US Department of Health and Human Services, and the US Department of Agriculture) recommend that high-risk groups including the elderly, those with dark skin, and those exposed to insufficient UV radiation, consume daily intakes of 25 micrograms (1000 units) daily.[3] The definition of vitamin D deficiency and vitamin D insufficiency remains controversial in terms of serum vitamin D concentrations.[4,5] Because vitamin D insufficiency is considered to be common in northern latitudes,[5] and deficiency is increasing worldwide,[4] higher intakes than those mentioned above have been recommended. Some have called for the establishment of an estimated average requirement (EAR) in North America,[4] and estimate a recommended dietary allowance (RDA) of greater than 12.5 micrograms (500 units). Others[5] suggest that the adequate intake be increased to at least 20 to 25 micrograms (800 to 1000 units) daily. A risk assessment analysis concluded that the tolerable upper intake level of vitamin D could be increased to 250 micrograms (10 000 units) daily for the general healthy population.[6]

The consensus of over 300 scientists from 23 countries at a vitamin D workshop was that governmental guidelines, in all countries, with respect to daily vitamin D requirements (to maintain bone health and health in general) were too low and did not reflect advances in vitamin D research over the preceding decade. Eating vitamin D-rich foods does not solve vitamin D deficiency for most adults; fortification of food should be significantly improved and implemented. Recommendations were made that blood concentrations of vitamin D should be at least 20 nanograms/mL, and that the tolerable upper intake level of 50 micrograms (2000 units) be re-evaluated in light of new data.[7]

For the view that colecalciferol is more potent than ergocalciferol, and should be the preferred form of vitamin D supplementation, see Administration, below.

Uses and Administration

Vitamin D compounds are fat-soluble sterols, sometimes considered to be hormones or hormone precursors, which are essential for the proper regulation of calcium and phosphate homoeostasis and bone mineralisation.

Vitamin D deficiency develops when there is inadequate exposure to sunlight or a lack of the vitamin in the diet. Deficiency generally takes a long time to develop because of slow release of the vitamin from body stores. It may occur in some infants who are breast fed without supplemental vitamin D or exposure to sunlight, in the elderly whose mobility and thus exposure to light may be impaired, and in persons with fat malabsorption syndromes; certain disease states such as renal failure may also affect the metabolism of vitamin D substances to metabolically active forms and thus result in deficiency.

Deficiency leads to the development of a syndrome characterised by hypocalcaemia, hypophosphataemia, undermineralisation or demineralisation of bone, bone pain, bone fractures, and muscle weakness, known in adults as osteomalacia (see below). In children, in whom there may be growth retardation and skeletal deformity, especially of the long bones, it is known as rickets.

Vitamin D compounds are used in the treatment and prevention of vitamin D deficiency states and hypocalcaemia in disorders such as hypoparathyroidism and secondary hyperparathyroidism, as indicated by the cross-references given below.

Many forms and analogues of vitamin D are available, and the choice of agent depends on the cause of the condition to be treated and the relative properties of the available agents. Colecalciferol and ergocalciferol are traditionally considered equal in potency (but see Administration, below), and have a slow onset and relatively prolonged duration of action. Dihydrotachysterol has relatively weak antirachitic activity, but its actions are faster in onset and less persistent than those of the calciferols and it does not require renal hydroxylation. Calcifediol, an intermediate metabolite, has some action of its own but is also converted to the more potent 1,25-dihydroxycholecalciferol (calcitriol); calcitriol and its analogue alfacalcidol are the most potent and rapidly acting of the vitamin D substances.

- For the treatment of simple nutritional deficiencies **colecalciferol** or **ergocalciferol** are generally preferred. They are usually given orally, but may also be given by intramuscular injection. A dose of 10 micrograms (400 units) daily is generally sufficient in adults for the prevention of simple deficiency states; in the UK, 20 micrograms (800 units) daily is recommended in those whose exposure to sunlight is limited, in those whose diet is deficient in vitamin D, and in housebound or institutionalised elderly people. Deficiency due to malabsorption states or liver disease often requires higher doses for treatment, of up to 1 mg (40 000 units) daily. Doses of up to 5 mg (200 000 units) daily may be used in the treatment of hypocalcaemia due to hypoparathyroidism.
- Where large doses are required it may be preferable to use one of the more potent derivatives. In particular, when renal function is impaired as in secondary hyperparathyroidism associated with chronic renal failure, with consequent reduction in the conversion of calciferols to their active metabolites, then a drug such as alfacalcidol, calcitriol, doxercalciferol, maxacalcitol, or paricalcitol, which does not require renal hydroxylation, should be given.

  Calcitriol is given orally or by intravenous injection. Usual initial adult oral doses of 250 nanograms daily or on alternate days are given, increased if necessary, in steps of 250 nanograms at intervals of 2 to 4 weeks, to a usual dose of 0.5 to 1 microgram daily. Initial doses intravenously are usually 500 nanograms three times a week increased if necessary in steps of 250 to 500 nanograms at intervals of 2 to 4 weeks, to a usual dose of 0.5 to 3 micrograms three times a week. For moderate to severe secondary hyperparathyroidism in dialysis patients initial doses of 0.5 to 4 micrograms have been given three times a week, increased if necessary in steps of 250 nanograms to 1 microgram at intervals of 2 to 4 weeks to a maximum of 8 micrograms given three times a week.

  Alternatively, **alfacalcidol** is given in initial oral doses of 1 microgram daily, or 500 nanograms for elderly patients. Doses of 0.25 to 1 microgram daily may be given for maintenance. Suggested doses for children under 20 kg are 50 nanograms/kg daily and for premature infants and neonates a dose of 50 to 100 nanograms/kg daily. Doses of alfacalcidol may also be given by intravenous injection over 30 seconds.

  Doxercalciferol is given orally or by intravenous injection. The initial oral dose is 10 micrograms three times weekly at dialysis, increased by increments of 2.5 micrograms after 8 weeks if necessary. The maximum recommended oral dose is 20 micrograms three times weekly. The initial intravenous dose is 4 micrograms given three times weekly at dialysis, and increased after 8 weeks in increments of 1 to 2 micrograms if required. Doses are titrated according to parathyroid hormone concentrations.

  Maxacalcitol is given intravenously at a dose of 2.5 to 10 micrograms three times weekly; the dose may be gradually increased if necessary, to a maximum of 20 micrograms three times weekly.

  Paricalcitol is given intravenously in the USA at a dose of 40 to 100 nanograms/kg on alternate days or less frequently; in the UK the initial dose (in micrograms) is calculated by dividing the baseline intact parathyroid hormone concentration (in picograms/mL) by 80. The dose may be increased or decreased if necessary by 2 to 4 micrograms at intervals of 2 to 4 weeks, based on parathyroid hormone concentrations. Paricalcitol is also given orally either as a daily dose or three times weekly (no more frequently than every other day). Again, the initial dose is based on baseline intact parathyroid hormone concentrations. If these are 500 picograms/mL or less, paricalcitol is given at a dose of 1 microgram daily, or 2 micrograms three times weekly; if they are above 500 picograms/mL, paricalcitol 2 micrograms daily, or 4 micrograms three times weekly is suggested. Doses are titrated according to parathyroid hormone concentrations.
- Of the other available forms, **calcifediol**, the 25-hydroxylated metabolite of colecalciferol, has been given in usual adult oral doses of 50 to 100 micrograms daily or 100 to 200 micrograms on alternate days. For hypocalcaemic tetany due to hypoparathyroidism, **dihydrotachysterol** is given in initial adult oral doses of 250 to 2400 micrograms daily, depending on severity, for about three days. Maintenance doses have ranged from 250 micrograms weekly to 1000 micrograms daily.

When vitamin D substances are given in pharmacological doses, dosage must be individualised for each patient, and should be based on regular monitoring of plasma-calcium concentrations (initially once or twice weekly), to optimise clinical response and avoid hypercalcaemia.

Vitamin D, usually in the form of calcitriol, may be used in the treatment of osteoporosis (see below). In established postmenopausal osteoporosis, calcitriol 0.25 micrograms twice daily is recommended. Vitamin D and calcium supplements are often given as adjuncts to other therapies in osteoporosis.

Calcitriol has been used in the management of psoriasis (see below).

Calciferol derivatives are used as rodenticides.

Administration. Minor differences in the chemistry of the side-chains of ergocalciferol and colecalciferol lead to the production of different metabolites (see Pharmacokinetics, above).[1] Colecalciferol has been reported to raise serum vitamin D concentrations more effectively than ergocalciferol,[2,3] perhaps because of higher affinities of colecalciferol and its metabolites for liver enzymes, plasma vitamin D binding protein, and vitamin D receptors.[1] It has been suggested that 50 000 units of ergocalciferol should be considered equivalent to no more than 15 000 units of colecalciferol, and perhaps closer to 5000 units; the tolerable upper intake level (see UK and US recommended dietary intake, p.1988) ought not to be applied to ergocalciferol.[3] These differences and the inequivalence in units (see Equivalence, under Units, above) may confound optimal vitamin D dosing recommendations.[1,3] The form of vitamin D used in studies should be specified.[2] While ergocalciferol is effective in treating vitamin D deficiency, the differences in potency have led some to suggest that colecalciferol be used as the preferred form of vitamin D.[1,3]

Administration in the elderly. Vitamin D deficiency is common in the elderly,[1-3] especially in housebound patients, and during wintertime.[4] Deficiency is aggravated by a diet low in calcium,[1] lack of sunlight exposure, and decreasing ability of the skin to synthesise vitamin D with advancing age.[3,5] Elderly patients are therefore at risk of secondary hyperparathyroidism, bone loss and osteoporosis, and fractures.[1,6,7] Low serum vitamin D has been associated with increased fracture rates, and there is some evidence from *animal* studies that vitamin D may promote bone healing after fracture, increasing the mechanical strength of bone by promoting mineralisation.[7] Poor muscle strength and weakness may be associated with vitamin D deficiency, and may increase the risk of falling in the elderly.[2,8,9] A meta-analysis[10] of 5 studies found that vitamin D supplementation reduced the risk of falls in the elderly by 22% compared with calcium or placebo. Vitamin D deficiency in the elderly may be less prevalent in the USA, due to fortification of food.[1] Food fortification has therefore been recommended,[1] or supplementation with doses in the region of 10 to 20 micrograms (400 to 800 units) daily;[1,4] 20 micrograms (800 units) daily is considered necessary for reduction of falls and fractures in the elderly.[2,7,11] The 2005 Dietary Guidelines for Americans recommend that elderly people should consume 25 micrograms (1000 units) daily; the upper level of 50 micrograms (2000 units) should not be exceeded.[5] See also Osteomalacia, and Osteoporosis, below.

Cardiovascular disease. Myocardial tissue contains a vitamin D-dependent calcium-binding protein, indicating a role for vitamin D in the regulation of myocardial contractility.[1,2] Lack of vitamin D is considered to play a role in the aetiology and pathogenesis of cardiovascular disease such as congestive heart failure;[2] case reports have shown that vitamin D treatment reduced blood pressure and myocardial hypertrophy.[3] However, there is currently no rationale to prescribe specific vitamin D analogues for patients with congestive heart failure.[2]

Diabetes mellitus. Vitamin D has a role in glucose homoeostasis and in the mechanism of insulin release.[1] Cohort studies[2,3] have suggested that supplementation with vitamin D may have a beneficial role in reducing the risk for developing both type 1 and type 2 diabetes mellitus. However, another study[4] found no significant differences in vitamin D status in Finnish or Karelian children, 2 neighbouring geographical areas with vastly differing incidences of type 1 diabetes.

Hyperparathyroidism. Vitamin D has been used for certain forms of hyperparathyroidism (p.1087). The **secondary hyperparathyroidism** of renal osteodystrophy (p.1086) may respond to treatment with calcitriol, or its analogue alfacalcidol,[1,2] which do not require renal hydroxylation for activation. Calcitriol has been used orally,[3] intravenously,[3,4] and intraperitoneally;[5] percutaneous injection directly into the parathyroid gland has also been reported to be safe and effective.[6-8] However, doses capable of suppressing parathyroid hormone secretion may lead to hypercalcaemia,[1-3,5,9,10] hyperphosphataemia,[1,2,5,9,10] and a decline in renal function;[11] the increase in calcium and phosphate may promote soft tissue and vascular calcification,[1,2] see Hypercalcaemia, under Adverse Effects, above.

Newer analogues for this indication include paricalcitol,[12-15] doxercalciferol,[16-18] falecalcitriol,[19] and maxacalcitol.[20-25] These are reported to have less effect on calcium and phosphate concentrations, while retaining the suppressive effect on parathyroid hormone;[1,5,9,10] however, some[2,18] consider clinically relevant benefit to be lacking. Paricalcitol was found to have a faster effect and cause less hypercalcaemia than calcitriol in patients on haemodialysis,[15] as well as offering a significant survival advantage over calcitriol.[13] A review considered paricalcitol to be as effective and as well tolerated as calcitriol.[14] Maxacalcitol and calcitriol were considered equally effective when given intravenously to haemodialysis patients,[25] while oral falecalcitriol was considered better than oral alfacalcidol at reducing parathyroid hormone concentrations.[19] Intravenous doxercalciferol appears to be safer than oral doxercalciferol;[1] comparative data are lacking.[2,18] A meta-analysis found that the use of vitamin D in chronic kidney disease did not consistently reduce parathyroid hormone concentrations.[26]

Some have cautioned against vitamin D supplementation in **primary hyperparathyroidism** because of concerns about exacerbation of hypercalcaemia and hypercalciuria. However, in a small study in patients with mild primary hyperparathyroidism, correction of vitamin D deficiency did not exacerbate hypercalcaemia, and decreased parathyroid hormone concentrations and bone turnover.[27]

Hypoparathyroidism. Although parenteral calcium salts may be given acutely for hypocalcaemic tetany, long-term treatment of hypoparathyroidism (p.1087) usually aims at correction of associated hypocalcaemia with oral calcium salts and oral vitamin D compounds, which increase the intestinal absorption of calcium.

Hypoparathyroidism in *pregnancy* poses severe risks of fetal hyperparathyroidism with neonatal hypocalcaemic rickets, which may be fatal. Treatment with calcium and either colecalciferol or ergocalciferol in doses of 1.25 to 2.5 mg daily, or dihydrotachysterol 0.25 to 1.0 mg daily is essential.[1] Calcitriol, in doses of between 0.25 to 3 micrograms daily, with calcium supplementation, has also been suggested; the dosage is adjusted to physiological requirements during pregnancy.[2]

Inflammatory bowel disease. Some studies have found a high prevalence of vitamin D deficiency in patients with inflammatory bowel disease (IBD). The aetiology of this is not entirely clear and may be multifactorial.[1,2] Patients with IBD may have decreased exposure to sunlight since the incidence and prevalence of IBD are greatest in northern latitudes. Patients might also have inadequate dietary intake of vitamin D, since IBD patients may avoid foods, such as dairy products, that are generally fortified with this vitamin. Deficiency might also be due to malabsorption, especially in IBD patients that have undergone small-bowel resection, although intestinal absorption was normal in many IBD patients with low vitamin D concentrations. The use of drugs such as colestyramine, and disturbed enterohepatic circulation of vitamin D metabolites have also been proposed as mechanisms for hypovitaminosis D in patients with IBD, as has an increased loss of vitamin D through protein-losing enteropathy.[1,2] A study[3] in children and young adults with IBD also found a high prevalence of vitamin D deficiency in this patient population. Predisposing factors included dark-skinned complexion, winter season, lack of vitamin D supplementation, early stage of disease, more severe disease, and upper gastrointestinal tract involvement in patients with Crohn's disease. Vitamin D concentrations were positively correlated with serum albumin concentrations, leading the authors to conclude protein-losing enteropathy was a leading mechanism for deficiency. If this were so, both enteral and parenteral supplementation of vitamin D might prove inadequate at the usual dose, and in patients with active disease.

However, the American Gastroenterological Association concluded, in a review of osteoporosis in gastrointestinal diseases,[4] that osteomalacia and vitamin D deficiency were not common in IBD patients (including Crohn's disease) and were unlikely to be causes of most cases of diminished bone mineral density in patients with IBD.

Malignant neoplasms. The active form of vitamin D, calcitriol (1,25-dihydroxycholecalciferol) has been found to promote tissue differentiation and to inhibit cellular proliferation *in vitro*. These findings have prompted investigation into the potential role and efficacy of vitamin D metabolites or analogues (sometimes referred to as deltanoids) in malignant neoplasms and in other disorders of cell growth such as psoriasis (see below).

There is laboratory evidence that vitamin D compounds can inhibit the growth of cancer cells, including those of the breast,[1,2] colon,[3] and prostate.[4,5] Epidemiological studies have suggested that vitamin D deficiency may be associated with higher risks of cancer.[6-9] Furthermore, increased sun exposure may be associated with improved survival for some cancers.[7,9] Phase I and II studies of calcitriol either alone, or with antineoplastics, have shown promising results.[10,11] A study in humans has been performed with the calcitriol derivative calcipotriol (p.1591); in this trial calcipotriol used topically in advanced or cutaneous metastatic breast cancer was considered to exert some positive effects and further investigation was considered warranted.[12] Regression of T-cell lymphoma of the skin (mycosis fungoides, p.657) has been reported after application of calcipotriol,[13] and after systemic treatment with calcitriol and a retinoid in a patient who failed to respond to topical calcipotriol.[14] However, 3 other patients with cutaneous T-cell lymphoma failed to respond to calcitriol and isotretinoin,[15] which may have been because of the phenotype or stage of the disease.[16] In a 7-year study in 36 282 postmenopausal women, of whom 18 176 received vitamin D_3 (400 units daily) and calcium, supplementation had no effect on the incidence of colorectal cancer.[17] This study has raised debate as to whether the dose of vitamin D used was insufficient.[7] A later analysis[18] of the study results suggested that supplementation had been of benefit in women in the placebo arms of the study but that this had been offset by an increase in risk in women also taking oestrogens. A smaller 4-year study[19] involving 1179 postmenopausal women given calcium with or without vitamin D_3 1100 units daily, or placebo, found that supplementation reduced all-cancer risk, and baseline and treatment-modified serum concentrations of vitamin D were strong predictors of cancer risk.

Multiple sclerosis. Multiple sclerosis (p.892) is more common in regions further from the equator, and it has been suggested that sunlight exposure and vitamin D exert a protective effect. Studies have also found lower vitamin D concentrations in patients with multiple sclerosis. Results from two large prospective cohorts found an inverse relationship between intake of vitamin D from supplements and risk of the disease; no association was found between vitamin D intake from food and incidence of multiple sclerosis.[1] A prospective, case-control study[2] found that, among whites, the risk of multiple sclerosis significantly decreased with increasing concentrations of vitamin D; no significant association was found among blacks and Hispanics. However, the sample size in the latter groups were smaller and concentrations of vitamin D are lower among blacks. A review[3] found little evidence to support the effectiveness of vitamin D in the treatment of multiple sclerosis; although uncontrolled studies suggest vitamin D may be beneficial, small patient populations and confounding variables have limited the usefulness of the data.

Osteomalacia and rickets. Treatment of osteomalacia and rickets (p.1084) primarily aims at correcting any underlying deficiency states, and vitamin D substances, calcium, or phosphate supplements may be given orally as necessary.

Where **rickets** is due to impaired synthesis of 1,25-dihydroxycholecalciferol (type I pseudodeficiency) or receptor resistance (type II pseudodeficiency) replacement therapy with calcitriol may be indicated (in the latter case with very high dose calcium),[1] while X-linked hypophosphataemic rickets is generally treated with phosphate supplementation and calcitriol.[2] The use of single large doses of a vitamin D substance (Stosstherapie), for the prophylaxis of rickets, is highly controversial because of problems with toxicity, although it may be effective in patients with rickets due to proven[3] or recalcitrant[4] vitamin D deficiency. Factors contributing to reported resurgences in rickets[2,4-8] include increased breast feeding without sufficient vitamin D supplementation, and less exposure to sunlight. A major risk factor for infants is maternal vitamin D deficiency (see Pregnancy and the Neonate, below). In the UK, the Department of Health advises that children aged 5 years and under be supplemented with 7 micrograms (280 units) daily,[8] but renewed public health campaigns have been called for, along with supplementation of infants from high-risk groups with 400 units of vitamin D daily.[6] Similar recommendations have been made in Australia and New Zealand.[4] In the USA, the American Academy of Pediatrics has recommended that all infants have a minimum intake of 200 units daily.[9] Others have commented that even 200 units daily may not be enough as a preventive measure,[2,10] and that, in those children with good exposure to sunlight, calcium supplementation may also be necessary.[11]

In adults, vitamin D deficiency may be asymptomatic. Most patients who present clinically do so because of muscle weakness, or muscles aches and pains.[12] Even severe vitamin D deficiency may result in a syndrome of persistent, non-specific musculoskeletal pain, before the onset of the clinical presentation of **osteomalacia**.[13] However, others[14] have queried the association.

For discussion on doses of vitamin D considered sufficient for prophylaxis, see UK and US Recommended Dietary Intake, above; for treatment, see Uses and Administration, above. Because the process of ageing decreases the skin's ability to synthesise vitamin D, elderly people may be at risk of deficiency (see Administration in the Elderly, above).

PREGNANCY AND THE NEONATE. It has been supposed that most infants receive adequate calcium and vitamin D during pregnancy and during breast feeding or bottle feeding to prevent the development of rickets. However, this has been disputed;[1,2] even infants born to vitamin D replete mothers become vitamin D deficient after 8 weeks if not supplemented, and those born to vitamin D deficient mothers will reach a deficient state more quickly. In many populations where sun exposure is severely limited and there is inadequate corrective vitamin D supplementation, there is also a high prevalence of vitamin D deficiency in nursing mothers.[3] It is accepted that there are certain groups of women whose infants may be at special risk of neonatal rickets; these include those suffering economic deprivation, those living at high latitudes, and Asian immigrants [i.e. from the Indian subcontinent] in northern Europe, especially in winter. It is therefore suggested that pregnant women in such circumstances should receive supplements as the diet and sunshine exposure may not be providing adequate calcium (1 to 1.2 g daily) or vitamin D (400 units daily).[4] Alternatively, 1000 units vitamin D daily during the third trimester, or a single dose of 100 000 to 200 000 units of ergocalciferol during the sixth or seventh month, has been proposed.[5] The Committee on Medical Aspects of Food Policy (COMA) in the UK recommended[6] in 1991 that pregnant women receive supplementary vitamin D to achieve an intake of 10 micrograms daily. However, a 2003 report commissioned by the NICE found insufficient evidence to assess the effectiveness of vitamin D in pregnancy and has recommended against routine vitamin D supplementation in healthy pregnant women.[7] A review[2] of dietary vitamin D requirements during pregnancy and lactation has stated that women who were vitamin D deficient at the beginning of their pregnancy remained deficient despite supplementation with 800 to 1600 units daily. The authors suggested that current recommendations in the UK and the USA were grossly inadequate during pregnancy, especially for ethnic minorities (see UK and US recommended dietary intake, above). Instead, they suggested that doses of about 2000 to 10 000 units daily would be needed in order to achieve normal vitamin D concentrations. Furthermore, routine vitamin D supplementation of infants in high-risk groups has been recommended (see Osteomalacia, above).

Osteopetrosis. For mention of the use of high-dose calcitriol in the management of osteopetrosis, see under Corticosteroids, p.1509.

Osteoporosis. Vitamin D concentrations have been found to correlate positively with bone mineral density (BMD),[1] and supplementation with vitamin D and calcium has led to beneficial increases in BMD in most trials.[2] Sufficient intake of vitamin D and calcium is recommended for prevention of osteoporosis (p.1084), and supplementation is an accepted baseline adjunctive treatment.[2,3] The age-related increase in fracture risk is influenced by BMD changes and an increased propensity to falls, attributable in part to a loss of muscular strength. In addition to its role in calcium homoeostasis, vitamin D status has also been correlated to muscular strength in older people.[3]

Studies using vitamin D (with or without calcium) for the prevention of fractures have produced conflicting results.[4-11] However, in elderly patients, in whom dietary deficiencies are common, calcium and vitamin D supplements are recommended (see Administration in the Elderly, above). Supplementation is also recommended in elderly institutionalised patients.[12] A meta-analysis[13] of fracture prevention trials found that oral vitamin D supplementation with between 700 to 800 units daily reduced the risk of hip and non-vertebral fractures in elderly patients. However, a systematic review[6] has stated that the effectiveness of vitamin D alone in fracture prevention remains unclear. Calcium may be necessary to optimise the clinical efficacy of vitamin D supplementation in terms of reducing fracture risk.[3] A meta-analysis[14] found that oral vitamin D appeared to reduce the risk of hip fractures only when calcium supplementation was added. However, another meta-analysis[15] found that the difference in relative risk reduction for all fracture types when vitamin D was added to calcium supplementation, was very small and statistically insignificant, although those with low vitamin D serum concentrations tended to have a greater risk reduction than those with normal vitamin D concentrations. A significant difference was seen between the effects of different vitamin D doses. While noting that this could be due to statistical artifact, the authors noted that their analysis had been limited by the scarcity of data for vitamin D doses higher than 800 units, and that it was possible that vitamin D would have a beneficial effect if the dose were greater than 800 units daily. It has been suggested[16] that the vitamin D analogues alfacalcidol and calcitriol are more effective for osteoporosis than ergocalciferol or colecalciferol. However, a systematic review[6] found no evidence of benefit for analogues compared with vitamin D.

Vitamin D is also recommended for the prevention of corticosteroid-induced osteoporosis (see Effects on Bones and Joints, p.1491).

Psoriasis. A vitamin D analogue, calcipotriol (p.1591), is often used as an alternative to more traditional topical drugs in the initial management of mild to moderate psoriasis (p.1583). Another vitamin D analogue, tacalcitol (p.1615), is used similarly. Initial studies with topical maxacalcitol,[1] falecalcitriol,[2] and paricalcitol[3] suggest they are safe and effective for psoriasis. Calcitriol itself has been tried, both topically[4-6] and orally.[7] Calcitriol ointment has been found to be as effective as calcipotriol ointment[8] and short-contact dithranol cream; skin irritation was less with calcitriol compared with dithranol.[9] While global improvement and severity scores were found to be better with betamethasone dipropionate ointment, remission times were longer with calcitriol treatment.[10]

Renal osteodystrophy. See under Hyperparathyroidism, above.

Rheumatoid arthritis. A large cohort study[1] found an inverse correlation between vitamin D intake and the risk of developing rheumatoid arthritis. However, a small study[2] of serum vitamin D concentrations in patients with rheumatoid arthritis who had donated blood before the onset of symptoms, found no association between vitamin D deficiency and later development of rheumatoid arthritis, suggesting that vitamin D does not have an important role in the pathogenesis of rheumatoid arthritis.

Rickets. See Osteomalacia and Rickets, above.

Preparations

BP 2008: Calcitriol Capsules; Calcium and Colecalciferol Tablets; Calcium and Ergocalciferol Tablets; Colecalciferol Injection; Colecalciferol Tablets; Ergocalciferol Injection; Ergocalciferol Tablets; Paediatric Vitamins A, C and D Oral Drops;
BPC 1973: Calcium with Vitamin D Tablets; Vitamins A and D Capsules;
USP 31: Calcifediol Capsules; Calcitriol Injection; Calcium with Vitamin D Tablets; Dihydrotachysterol Capsules; Dihydrotachysterol Oral Solution; Dihydrotachysterol Tablets; Ergocalciferol Capsules; Ergocalciferol Oral Solution; Ergocalciferol Tablets; Oleovitamin A and D; Oleovitamin A and D Capsules; Paricalcitol Injection.

Proprietary Preparations (details are given in Part 3)

Vitamin E Substances

Vitamina E.

ATC — A11HA03.

ATC Vet — QA11HA03.

NOTE. The food additive number E306 is used for tocopherols.

Vitamin E is a generic term applied to a large number of natural or synthetic compounds. The most important substances are the **tocopherols** of which **alpha tocopherols** are the most active and widely distributed in nature; other naturally occurring tocopherols include beta, gamma, and delta tocopherols, but these are not used in therapeutics. The other group of compounds with vitamin E activity are the tocotrienols.

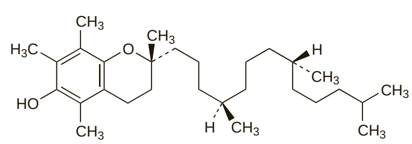
Alpha tocopherols occur naturally in the *d* optical isomer form, which is more active than the synthetic racemic *dl* form; for further details concerning the comparative activities of the different forms and isomers of vitamin E compounds, see under Units, below.

d-Alpha Tocopherol

d-Alfa Tokoferol; (+)-Alpha-Tocopherol; *RRR*-alpha-Tocophérol; *RRR*-alpha-Tocopherolum; Natural Alpha Tocopherol; Natural α-Tocopherol; RRR-α-Tocopherolum; RRR-α-Tokoferol; D-α-Tocoferol; *RRR*-α-Tocopherol; *d*-α-Tocopherol; *RRR*-α-tocopherolum; *RRR*-α-tokoferol; *RRR*-α-Tokoferoli; *RRR*-α-Tokoferolis. (+)-2,5,7,8-Tetramethyl-2-(4,8,12-trimethyltridecyl)chroman-6-ol.

$C_{29}H_{50}O_2$ = 430.7.

CAS — 59-02-9.



Pharmacopoeias. In *Eur.* (see p.vii). *US* allows it under the title Vitamin E.

Ph. Eur. 6.2 (*RRR*-α-Tocopherol; *RRR*-Alpha-Tocopherol BP 2008). A clear, colourless, or yellowish-brown viscous oily liquid. Practically insoluble in water; freely soluble in dehydrated alcohol, in acetone, in dichloromethane, and in fatty oils. Store under an inert gas in airtight containers. Protect from light.

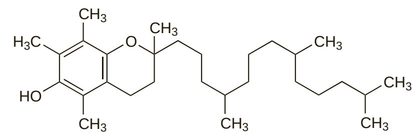
USP 31 (Vitamin E). A clear, yellow, or greenish-yellow, practically odourless, viscous oil. It is unstable to air and light, particularly in alkaline media. Insoluble in water; soluble in alcohol; miscible with acetone, with chloroform, with ether, and with vegetable oils. Store under an inert gas in airtight containers. Protect from light.

dl-Alpha Tocopherol

all-rac-α-Tokoferol; all-*rac*-α-Tocopherol; Alpha Tocopherol; (±)-Alpha-Tocopherol; E307; int-rac-α-Tocopherolum; int-*rac*-α-Tocopherolum; Synthetic Alpha Tocopherol; Synthetic α-Tocopherol; DL-α-Tocoferol; Tocoferolum Alfa; α-Tocopherol; *dl*-α-Tocopherol; α-Tocopherolum; α-Tokoferol; Tokoferol-alfa; tout-*rac*-α-Tocophérol; Visų racematų α-Tokoferolis. (±)-2,5,7,8-Tetramethyl-2-(4,8,12-trimethyltridecyl)chroman-6-ol.

$C_{29}H_{50}O_2$ = 430.7.

CAS — 10191-41-0.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn. US* allows it under the title Vitamin E.

Ph. Eur. 6.2 (all-*rac*-α-Tocopherol; all-*rac*-Alpha Tocopherol BP 2008). A clear, colourless or yellowish-brown viscous oily liquid. Practically insoluble in water; freely soluble in dehydrated alcohol, in acetone, in dichloromethane, and in fatty oils. Store under an inert gas. Protect from light.

USP 31 (Vitamin E). A clear, yellow, or greenish-yellow, practically odourless, viscous oil. It is unstable to air and light, particularly in alkaline media. Insoluble in water; soluble in alcohol; miscible with acetone, with chloroform, with ether, and with vegetable oils. Store under an inert gas in airtight containers. Protect from light.

d-Alpha Tocoferil Acetate

d-Alpha Tocopheryl Acetate; (+)-Alpha-Tocopherol Acetate; (+)-Alpha-Tocopheryl Acetate; *RRR*-alpha-Tocophéryle, acétate de; *RRR*-alpha-Tocopherylis acetas; RRR-α-Tocopherylis acetas; RRR-α-Tokoferylu octan; D-α-Tocoferilo, acetato de; Tocoferoli Alfa *RRR* Acetas; *RRR*-α-Tocopheroli Acetas; *d*-α-Tocopheryl Acetate; *RRR*-α-Tocopheryl Acetate; *RRR*-α-Tocopherylis Acetas; *RRR*-α-Tokoferilio acetatas; *RRR*-α-Tokoferol-acetát; Tokoferol-acetát alfa *RRR*; Tokoferol-alfa-*RRR*-acetát; *RRR*-α-Tokoferylacetat; *RRR*-α-Tokoferyyliasetaatti. (+)-α-Tocopherol acetate.

$C_{31}H_{52}O_3$ = 472.7.

CAS — 58-95-7.

Pharmacopoeias. In *Eur.* (see p.vii). *US* allows it under the title Vitamin E.

Ph. Eur. 6.2 (*RRR*-α-Tocopheryl Acetate; *RRR*-Alpha-Tocopheryl Acetate BP 2008). A clear, colourless or slightly greenish-yellow, viscous oily liquid. Practically insoluble in water; soluble in alcohol; freely soluble in dehydrated alcohol, in acetone, and in fatty oils. Protect from light.

USP 31 (Vitamin E). A clear, yellow, or greenish-yellow, practically odourless, viscous oil. It may solidify in the cold. It is stable to air and light, but unstable to alkali. Insoluble in water; soluble in alcohol; miscible with acetone, with chloroform, with ether, and with vegetable oils. Store in airtight containers. Protect from light.

dl-Alpha Tocoferil Acetate

dl-Alfa Tokoferil Asetat; all-rac-α-Tokoferylu octan; all-*rac*-α-Tocopheryl Acetate; Alpha Tocopheryl Acetate; *dl*-Alpha Tocopheryl Acetate; (±)-Alpha-Tocopherol acetate; int-rac-α-Tocopherylis acetas; int-*rac*-α-Tocopherylis Acetas; DL-α-Tocoferilo, acetato de; Tocoferoli Alfa Acetas; α-Tocopherol Acetate; α-Tocopheroli Acetas; *dl*-α-Tocopheryl Acetate; Tokoferol alfa-acetát; Tokoferolu octan; tout-*rac*-α-Tocophéryle, acétate de; Visų racematų α-Tokoferilio acetatas. (±)-α-Tocopherol acetate.

$C_{31}H_{52}O_3$ = 472.7.

CAS — 7695-91-2; 52225-20-4.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn. US* allows it under the title Vitamin E.

Eur. also has a monograph for the concentrated powdered form.

Ph. Eur. 6.2 (all-*rac*-α-Tocopheryl Acetate; all-*rac*-Alpha Tocopheryl Acetate BP 2008). A clear, colourless or slightly greenish-yellow, viscous, oily liquid. Practically insoluble in water; freely soluble in dehydrated alcohol, in acetone, and in fatty oils. Protect from light.

Ph. Eur. 6.2 (α-Tocopheryl Acetate Concentrate (Powder Form); α-Tocopherylis Acetatis Pulvis; Alpha Tocopheryl Acetate Concentrate (Powder Form) BP 2008). It is prepared either by finely dispersing *dl*-alpha tocoferil acetate in a suitable carrier (e.g. gelatin, acacia, carbohydrates, lactoproteins, or a mixture of these) or by adsorbing *dl*-alpha tocoferil acetate on to silicic acid. The concentrate contains not less than 25% of *dl*-alpha tocoferil acetate. Almost white, yellowish, or light-brown small particles. Depending on the formulation, the powder may be practically insoluble in water or may swell or form a dispersion. Store in well-filled airtight containers. Protect from light.

USP 31 (Vitamin E). A clear, yellow, or greenish-yellow, practically odourless, viscous oil. It is stable to air and light, but unstable to alkali. Insoluble in water; soluble in alcohol; miscible with acetone, with chloroform, with ether, and with vegetable oils. Store in airtight containers. Protect from light.

d-Alpha Tocoferil Acid Succinate

d-Alpha Tocopheryl Acid Succinate; *d*-Alpha-Tocopherol acid succinate; *RRR*-alpha-Tocophéryle, hydrogénosuccinate de; *RRR*-alpha-Tocopherylis hydrogenosuccinas; D-α-Tocoferilo, succinato ácido; Tocoferoli Alfa *RRR* Hydrogenosuccinas; *RRR*-α-Tocopheroli Hydrogenosuccinas; *d*-α-Tocopheryl Acid Succinate; *RRR*-α-Tocopheryl Hydrogen Succinate; *RRR*-α-Tocopherylis Hydrogenosuccinas; *RRR*-α-Tokoferilio-vandenilio sukcinatas; Tokoferol-alfa-*RRR*-hydrogen-sukcinát; *RRR*-α-Tokoferol-hidrogén-szukcinát; *RRR*-α-Tokoferylvätesuccinat; *RRR*-α-Tokoferyylivetysuksinaatti. (+)-α-Tocopherol hydrogen succinate.

$C_{33}H_{54}O_5$ = 530.8.

CAS — 4345-03-3.

Pharmacopoeias. In *Eur.* (see p.vii). *US* allows it under the title Vitamin E.

US also includes Vitamin E Polyethylene Glycol Succinate, a mixture formed by the esterification of *d*-alpha tocoferil acid succinate with a macrogol.

Ph. Eur. 6.2 (*RRR*-α-Tocopheryl Hydrogen Succinate; *RRR*-Alpha Tocopheryl Hydrogen Succinate BP 2008). A white or almost white crystalline powder. Practically insoluble in water; soluble in dehydrated alcohol and in acetone; very soluble in dichloromethane. Protect from light.

USP 31 (Vitamin E). A white, practically odourless, powder. M.p. about 75°; it is unstable when held molten. It is stable to air and light, but unstable to alkali. Insoluble in water; soluble in alcohol, in acetone, in ether, and in vegetable oils; very soluble in chloroform; slightly soluble in alkaline solution. Store in airtight containers. Protect from light.

dl-Alpha Tocoferil Acid Succinate

dl-Alpha Tocopheryl Acid Succinate; Alpha Tocopheryl Hydrogen Succinate; DL-alpha-Tocophéryle, hydrogénosuccinate de; DL-alpha-Tocopherylis hydrogenosuccinas; DL-α-Tocoferilo, succinato ácido; Tocoferoli Alfa Hydrogenosuccinas; DL-α-Tocopheroli Hydrogenosuccinas; *dl*-α-Tocopheryl Acid Succinate; DL-α-Tocopheryl Hydrogen Succinate; DL-α-tocopherylis Hydrogenosuccinas; DL-α-Tokoferilio-vandenilio sukcinatas; Tokoferol-alfa hydrogen sukcinát; DL-α-tokoferol-hidrogén-szukcinát; DL-α-Tokoferylvätesuccinat; DL-α-Tokoferyylivetysuksinaatti. (±)-α-Tocopherol hydrogen succinate.

$C_{33}H_{54}O_5$ = 530.8.

CAS — 17407-37-3.

Pharmacopoeias. In *Eur.* (see p.vii). *US* allows it under the title Vitamin E.

Ph. Eur. 6.2 (DL-α-Tocopheryl Hydrogen Succinate; Alpha Tocopheryl Hydrogen Succinate BP 2008). A white or almost white, crystalline powder. Practically insoluble in water; soluble in dehydrated alcohol and in acetone; very soluble in dichloromethane. Protect from light.

USP 31 (Vitamin E). A white, practically odourless, powder. M.p. about 70°; it is unstable when held molten. It is stable to air and light, but unstable to alkali. Insoluble in water; soluble in alcohol, in acetone, in ether, and in vegetable oils; very soluble in chloroform; slightly soluble in alkaline solution. Store in airtight containers. Protect from light.

Units

Though the potency of preparations of vitamin E is still sometimes expressed in units, the International Standard for vitamin E was discontinued in 1956. The International Unit was the activity contained in 1 mg of a standard preparation of *dl*-alpha-tocoferil acetate. Past editions of the USP have stated that in expressing vitamin E activity of tocopherol products, the following equivalents of 1 mg were to be used:

- *d*-alpha tocopherol, 1.49 units
- *dl*-alpha tocopherol, 1.1 units
- *d*-alpha tocoferil acetate, 1.36 units
- *dl*-alpha tocoferil acetate, 1 unit
- *d*-alpha tocoferil acid succinate, 1.21 units
- *dl*-alpha tocoferil acid succinate, 0.89 unit.

For dietary purposes, vitamin-E activity may now be expressed in terms of alpha tocopherol equivalents (α-TEs). One α-TE is the activity contained in:

- 1 mg of *d*-alpha tocopherol (natural alpha tocopherol; *RRR*-α-tocopherol)
- 1.4 mg *dl*-alpha tocopherol
- 1.1 mg *d*-alpha tocoferil acetate
- 1.5 mg *dl*-alpha tocoferil acetate
- 1.2 mg *d*-alpha tocoferil acid succinate
- 1.7 mg *dl*-alpha tocoferil acid succinate.

Adverse Effects and Precautions

Vitamin E is usually well tolerated. Large doses may cause diarrhoea, abdominal pain, and other gastrointestinal disturbances, and have also been reported to cause blurred vision, dizziness, fatigue and weakness. Contact dermatitis has occurred after topical application.

Large doses of vitamin E have been reported to increase bleeding tendency in vitamin-K deficient patients such as those taking oral anticoagulants. However, it has also been suggested that it may increase the risk of thrombosis in some patients, such as those taking oestrogens. The clinical significance of these effects is not known.

A higher incidence of necrotising enterocolitis has been noted in premature infants weighing less than 1.5 kg treated with vitamin E.

Carcinogenicity. For mention of an *increased* incidence of second primary cancers and reduced cancer-free survival in patients with head and neck cancer receiving vitamin E (and betacarotene initially), see Prophylaxis of Malignant Neoplasms, p.1927.

Effects on mortality. While some studies of antioxidants, including vitamin E, have suggested beneficial effects on the progression of cardiovascular disease and cancer, other studies (including large randomised studies such as the Women's Health Study[1]) have shown little or no effect.[2] Vitamin E may even cause an increased risk of heart failure, or incidence of cancer (see Prophylaxis of Ischaemic Heart Disease, p.1926, and Prophylaxis of Malignant Neoplasms, p.1927). A meta-analysis[3] and a systematic review[4] of vitamin E supplementation found no benefit in terms of mortality. Another meta-analysis[5] found no effect for vitamin E supplementation on all-cause mortality overall. However, in dose-response analysis, high-dosage vitamin E (greater than 400 units daily) showed a significantly increased risk; there was some suggestion of a decreased risk with low doses (less than 400 units daily); all-cause mortality progressively increased for doses greater than 150 units daily. (Such an effect was not seen in the Women's Health Study, in which participants received 600 units on alternate days.) Some have commented[6] that the meta-analysis may not have isolated the effects of vitamin E, since in many of the trials studied, other nutritional supplements had been given, including betacarotene, itself possibly associated with an increased risk of death; however, the use of high-dose vitamin E was considered unjustified. A systematic review of antoxidant supplementation found that vitamin E, either singly or with other antioxidants, increased mortality.[7] A large cohort study in a population aged 65 years or older, after adjustment for age and sex, found that there was no association between vitamin E use and mortality. However, mortality was increased in vitamin E users who had a history of cardiovascular disease, or who were taking nitrates, warfarin, and diuretics. There was a consistent trend towards reduced mortality in vitamin E users without cardiovascular disease or taking these drugs. The authors concluded that vitamin E should be used with caution in those with cardiovascular disease, and that further investigation of the potential interaction between vitamin E and particular drugs was warranted.[8]

Neonatal toxicity. For a review and discussion of liver and kidney toxicity in premature neonates associated with an intravenous preparation of vitamin E (E-Ferol) and attributed to the inclusion of polysorbates, see Effects in Infants, p.1919.

Interactions

Various drugs may interfere with the absorption of vitamin E including colestyramine, colestipol, and orlistat. High doses of vitamin E may increase the effects of oral anticoagulants.

Pharmacokinetics

Absorption of vitamin E from the gastrointestinal tract is dependent on the presence of bile and on normal pancreatic function. The amount of vitamin E absorbed varies widely between about 20% and 80% and appears to decrease as the dose is increased. It enters the blood via the chylomicrons in the lymph and is bound to beta lipoproteins. It is widely distributed to all tissues, and stored in adipose tissue. Some vitamin E is metabolised in the liver to glucuronides of tocopheronic acid and its γ-lactone. Some is excreted in the urine, but most of a dose is slowly excreted in the bile. Vitamin E appears in breast milk but is poorly transferred across the placenta.

Human Requirements

The daily requirement of vitamin E has not been clearly defined but is probably about 3 to 12 mg of *d*-alpha tocopherol or the equivalent of other vitamin E substances. Requirements increase with increased dietary amounts of polyunsaturated fatty acids. There appears to be no evidence that supplements are required in subjects on balanced diets.

Vitamin E is widely distributed in food. The richest sources are vegetable oils especially wheat-germ oil (p.2415), sunflower oil, and cottonseed oil; cereals and nuts are also good sources. Significant losses of vitamin E from food may occur during cooking and storage.

UK and US recommended dietary intake. In the UK neither a reference nutrient intake (RNI—see p.1925) nor an estimated average requirement (EAR) has been set for vitamin E although daily intakes of 4 mg and 3 mg α-tocopherol equivalents (see under Units, above) were considered adequate for men and women, respectively.[1] The Expert Group on Vitamins and Minerals[2] have established a safe upper level (SUL) for vitamin E of 800 units or 540 mg of *d*-alpha tocopherol daily.

In the USA the recommended dietary allowance for adults is 15 mg daily of alpha tocopherol, and the tolerable upper intake level is 1000 mg daily.[3]

Uses and Administration

Vitamin E, a fat-soluble vitamin, prevents the oxidation of polyunsaturated fatty acids. It reacts with free radicals, which are the cause of oxidative damage to cell membranes, without the formation of another free radical in the process.

Vitamin E deficiency is rare but develops when the dietary intake is inadequate. In children with cystic fibrosis or biliary atresia, malabsorption of fat may lead to a vitamin E deficiency; deficiency may also occur in children with abnormalities of lipid transport, as in abetalipoproteinaemia. Low vitamin E concentrations are also found in premature, very low birth-weight infants. In previously healthy adults malabsorption and low intake of vitamin E must continue for a number of years before signs of deficiency appear. The major signs of vitamin E deficiency are the development of myopathic and neurological disorders.

Vitamin E is used in the treatment and prevention of vitamin E deficiency. It is usually given orally, generally the preferred route, but has also been given by intramuscular or intravenous routes. It may be given as *d*- or *dl*-alpha tocopherol or as the respective acetates or acid succinates.

Recommended doses vary, in part because of differences in the activity of different preparations; however, a daily dose of several times the recommended dietary allowance (RDA), or around 40 to 50 mg of *d*-alpha tocopherol, has been suggested for deficiency syndromes; somewhat higher daily doses have been given in cystic fibrosis (100 to 200 mg of *dl*-alpha tocoferil acetate, or about 67 to 135 mg of *d*-alpha tocopherol) and much higher daily doses in abetalipoproteinaemia (50 to 100 mg/kg of *dl*-alpha tocoferil acetate, or about 33 to 67 mg/kg *d*-alpha tocopherol).

Vitamin E has also been tried in retinopathy of prematurity and intraventricular haemorrhage in neonates (see Perinatal Disorders, below), and in many other disorders, for which the evidence of value is generally lacking (see Prophylaxis of Ischaemic Heart Disease, p.1926, and Prophylaxis of Malignant Neoplasms, p.1927).

Other substances with vitamin-E activity that have been used include *dl*-alpha tocoferil palmitate and tocofersolan (tocophersolan), a water-soluble substance which is *d*-alpha tocoferil acid succinate combined with a macrogol. Wheat-germ oil (p.2415) is also widely used as a source of vitamin E.

Vitamin E is often used as an antioxidant in pharmaceutical manufacturing.

Age-related macular degeneration. Dietary supplementation with antioxidants including vitamin E has been promoted for age-related macular degeneration. For further details, see under Betacarotene, p.1931.

Chemotherapy-induced toxicity. A small pilot study[1] found that oral vitamin E 600 mg daily given during chemotherapy and for 3 months afterwards reduced chemotherapy-induced neuropathy in patients given regimens based on platinum (carboplatin or cisplatin), or paclitaxel, or both. The authors considered that similarities exist between neuropathy induced by cisplatin (and possibly paclitaxel) and that seen in vitamin E deficiency states, (see below). Oral vitamin E 300 mg daily alleviated palmar-plantar erythrodysesthesia in 5 patients given capecitabine and docetaxel.[2] In 4 of these patients, chemotherapy was continued without interruption or dose reduction. Improvement was generally noticed after 7 to 10 days of treatment.

Deficiency states. Vitamin E deficiency may cause neurological damage characterised by sensory loss, ataxia and retinitis pigmentosa. In 2 patients with common variable immunodeficiency and an associated enteropathy, vitamin E deficiency developed. Treatment with intramuscular or oral vitamin E led to objective neurological improvement.[1]

Dementia. A hypothesis that free radicals may initiate and maintain mechanisms responsible for neurodegeneration in Alzheimer's disease (p.362) has prompted the investigation of various drugs for antioxidant therapy.[1] Preliminary studies[1,2] have suggested that alpha tocopherol might possibly slow progression. A prospective cohort study found that self-administration of combined vitamin C and vitamin E was associated with a lower risk of vascular dementia in elderly men,[3] although no significant protective effect was seen against Alzheimer's disease. However, other studies have suggested that high intake of vitamins C and E, whether from diet[4] or supplements,[5] may reduce the risk of Alzheimer's disease. Yet another study suggested that dietary vitamin E, but not vitamin C, intake reduced the risk of Alzheimer's disease;[6] a population-based study found vitamin E intake from food and supplements to be associated with reduced cognitive decline.[7] US guidelines suggested[8] that vitamin E 1000 units twice daily by mouth be considered in patients with Alzheimer's disease in an attempt to slow progression of the disease. However, a large randomised trial in patients with amnestic mild cognitive impairment found that vitamin E 2000 units daily provided no benefit over placebo in terms of probability of progression to Alzheimer's disease.[9] Reviewers[10,11] have recommended against the use of vitamin E for Alzheimer's disease.

Malignant neoplasms. For a discussion of studies involving vitamin E in the prophylaxis of malignant neoplasms, see p.1927.

Motor neurone disease. A prospective analysis found that regular use of vitamin E supplements was associated with a decreased risk of amyotrophic lateral sclerosis.[1] However, further studies were considered necessary and significant evidence to support the benefit of antioxidants in motor neurone disease (p.2380) is lacking.[2]

Muscle spasm. Vitamin E is one of several drugs that have been tried in the management of nocturnal cramps (p.1887) but there is little convincing evidence to support its use.[1,2] It has, however, been found to have similar efficacy to quinine for haemodialysis-induced cramp (p.1671).[3] A small study found the combination of vitamins E and C to be more effective than either vitamin alone for reducing haemodialysis-induced cramps; prolonged use was not evaluated.[4]

Muscular dystrophies. Vitamin E substances have been used in some countries in the management of muscular dystrophies, but controlled studies[1] have failed to demonstrate any benefit.

1. Örndahl G, *et al.* Functional deterioration and selenium-vitamin E treatment in myotonic dystrophy: a placebo-controlled study. *J Intern Med* 1994; **235:** 205–10.

Parkinsonism. Vitamin E has been tried (as *dl*-alpha tocopherol) in an attempt to slow neurodegeneration in patients with Parkinson's disease (p.791) but has proved ineffective.[1]

1. The Parkinson Study Group. Effects of tocopherol and deprenyl on the progression of disability in early Parkinson's disease. *N Engl J Med* 1993; **328:** 176–83.

Perinatal disorders. The primary biological action of vitamin E is known to be the protection of polyunsaturated fatty acids, and thus membranes, from oxidation. Two disorders that may particularly affect premature and very low birth-weight infants are *retinopathy of prematurity* (below) and *intraventricular haemorrhage* (p.1050) and as both may have some association with the occurrence of excess oxygen or oxidant stress, there has been interest in the possibility that vitamin E might have a role in their prevention.

Pre-eclampsia. Although preliminary evidence has suggested[1] that women supplemented with vitamin E (with other supplements) may be at decreased risk of developing clinical pre-eclampsia (see Hypertension in Pregnancy, p.1171), large studies[2,3] in women given combined vitamin C and vitamin E supplements failed to show any benefit.

Respiratory-tract infections. A randomised study in elderly patients found that supplementation with vitamin E had no effect on the incidence of lower respiratory-tract infections in elderly nursing home residents, although there was some suggestion of benefit from supplementation on upper respiratory-tract infections, particularly the common cold.[1] In contrast, another study found that, among elderly non-institutionalised people with an acute respiratory-tract infection, vitamin E supplementation increased illness duration, number of symptoms, frequency of fever, and restricted activity.[2]

1. Meydani SN, *et al.* Vitamin E and respiratory tract infections in elderly nursing home residents: a randomized controlled trial. *JAMA* 2004; **292:** 828–36. Correction. *ibid.*; 1305.

Retinitis pigmentosa. Vitamin E has been tried in retinitis pigmentosa (p.1974) with conflicting results.

Retinopathy of prematurity. Retinopathy of prematurity (retrolental fibroplasia) is a disease associated with immature vascularisation of the retina. Formation of retinal lesions may interfere with normal development, resulting in neovascularisation and fibrovascular proliferation. Some cases regress spontaneously but advanced cases can lead to tractional retinal detachment and loss of vision. The pathogenesis of retinopathy of prematurity is not clearly understood, but is likely to be multifactorial;[1,2] greater immaturity, lower birth-weight, and male gender are associated with more severe disease.[3]

After the acknowledgement of a link between retinopathy of prematurity and oxygen therapy, the use of oxygen was reduced and the incidence of this disorder declined. A subsequent rise in incidence probably reflected the increased survival rate of extremely premature infants due to improved neonatal care, and certainly, variations in incidence between countries, or indeed areas, may reflect varying levels of available postnatal care.[2] Despite extensive research (see p.1690), a safe concentration of arterial oxygen has not been defined and antioxidants such as vitamin E have been used prophylactically for several decades. However, this use is controversial. Studies assessing the efficacy of vitamin E prophylaxis have not produced clear results.[4] Some considered that vitamin E prophylaxis had a beneficial effect and recommended[5] routine prophylaxis as soon as possible after birth for infants less than 1.5 kg. However, others feel that there is no data to support prophylaxis with vitamin E[4,6,7] and that antioxidants cannot be recommended for routine use.[1] The various studies have been re-evaluated by meta-analysis, the results of which suggest that vitamin E may reduce the incidence of stage 3+ retinopathy of prematurity,[8] a conclusion supported by a systematic review[9] which noted, however, that supplementation increased the risk of sepsis and could therefore not be recommended. The authors of the meta-analysis recommended that a well-controlled study should be conducted.[8] A systematic review of vitamin A supplementation in very low birth-weight infants concluded that vitamin A may reduce the incidence of retinopathy of prematurity, and that further investigation was warranted.[10]

Other agents tried for prophylaxis include penicillamine and antenatal dexamethasone, with some suggestion of benefit.[11,12] Reduction in ambient-light exposure did not alter the incidence of retinopathy of prematurity.[13,14] Inositol supplementation has also been tried, with conflicting results.[4]

Tardive dyskinesia. Reviews[1,2] on the use of vitamin E in the management of antipsychotic-induced tardive dyskinesia (see under Extrapyramidal Disorders, p.971) concluded that evidence of benefit has generally come from small studies with methodological problems. One review[1] concluded that whereas vitamin E may protect against deterioration of tardive dyskinesia there was no evidence that it produced symptomatic improvement. It was suggested[2] that vitamin E therapy may be most beneficial in those patients with tardive dyskinesia of less than 5-years duration. Some recommend vitamin E as a treatment option in patients with newly diagnosed disease.[3] Further large-scale studies are required to establish its place in treatment.

Vitamin K Substances

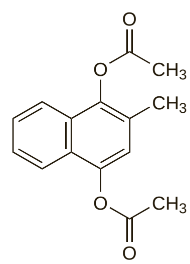
Vitamina K.

The term vitamin K is used for a range of naphthoquinone compounds that includes: acetomenaphthone, menadiol, menadione, menatetrenone, and phytomenadione.

Acetomenaphthone *(BAN)*

Acetomenadione; Acetomenaftona; Acetomenaph.; Menadiol Diacetate; Vitamin K_4 Diacetate. 2-Methyl-1,4-naphthylene diacetate.

$C_{15}H_{14}O_4$ = 258.3.
CAS — 573-20-6.

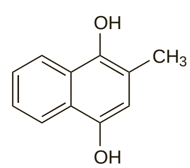


Pharmacopoeias. In *Chin.*

Menadiol Sodium Phosphate *(BANM)*

Menadiol, fosfato sódico de; Menadiol Sodium Diphosphate; Menadiolum Solubile; Vitamin K_4 Sodium Phosphate. 2-Methylnaphthalene-1,4-diyl bis(disodium phosphate) hexahydrate.

$C_{11}H_8Na_4O_8P_2,6H_2O$ = 530.2.
CAS — 481-85-6 (menadiol); 131-13-5 (anhydrous menadiol sodium phosphate); 6700-42-1 (menadiol sodium phosphate hexahydrate); 84-98-0 (menadiol diphosphate).



(menadiol)

NOTE. Menadiol Potassium Sulfate (Potassium Menaphthosulfate) is *BAN* and Menadiol Sodium Sulfate is *rINN.*

Pharmacopoeias. In *Br.* and *US.*

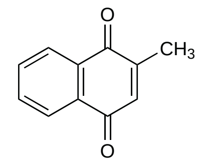
BP 2008 (Menadiol Sodium Phosphate). A white to pink, hygroscopic, crystalline powder with a characteristic odour. Very soluble in water; practically insoluble in alcohol.

USP 31 (Menadiol Sodium Diphosphate). A white to pink, hygroscopic, powder having a characteristic odour. Very soluble in water; insoluble in alcohol. Its solutions in water are neutral or slightly alkaline to litmus having a pH of about 8. Store in airtight containers at a temperature not exceeding 8°. Protect from light.

Menadione *(BAN)*

Menadion; Menadiona; Menadionas; Ménadione; Menadioni; Menadionum; Menaph.; Menaphthene; Menaphthone; Methylnaphthochinonum; Vitamin K_3. 2-Methyl-1,4-naphthoquinone.

$C_{11}H_8O_2$ = 172.2.
CAS — 58-27-5.
ATC — B02BA02.
ATC Vet — QB02BA02.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Menadione). A pale yellow crystalline powder. It is unstable in light. Practically insoluble in water; sparingly soluble in alcohol and in methyl alcohol; freely soluble in toluene. Protect from light.

USP 31 (Menadione). A bright yellow, practically odourless, crystalline powder. It is affected by sunlight. Practically insoluble in water; soluble 1 in 60 of alcohol, 1 in 50 of vegetable oils, and 1 in 10 of benzene; sparingly soluble in chloroform. Store at a temperature of 25°, excursions permitted between 15° and 30°. Protect from light.

Handling. Menadione powder is irritating to the respiratory tract and to the skin. The alcoholic solution has vesicant properties.

Menadione Sodium Bisulfite *(rINN)*

Bisulfito sódico de menadiona; Kavitanum; Menadiol Sodyum Bisülfit; Ménadione, Bisulfite Sodique de; Menadione Sodium Bisulphite *(BANM)*; Menadioni Natrii Bisulfis; Menadioninatriumbisulfiitti; Menadionnatriumbisulfit; Menadionu wodorosiarczyn sodowy; Menaph. Sod. Bisulphite; Menaphthone Sodium Bisulphite; Methylnaphthochinonumnatrium Bisulfurosum; Vikasolum; Vitamin K_3 Sodium Bisulphite. Sodium 1,2,3,4-tetrahydro-2-methyl-1,4-dioxonaphthalene-2-sulphonate trihydrate.

Менадиона Натрия Бисульфит

$C_{11}H_8O_2NaHSO_3,3H_2O$ = 330.3.
CAS — 130-37-0 (anhydrous menadione sodium bisulfite); 6147-37-1 (menadione sodium bisulfite trihydrate).

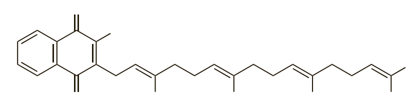
Pharmacopoeias. In *Chin.* and *Pol.*

Menatetrenone *(rINN)*

E-3100; Ea-0167; Menaquinone-4; Menaquinone 4; Menaquinone K4; Menatetren; Menatetrenona; Ménatétrénone; Menatetrenonum; MK-4; Vitamin $K_{2(20)}$; Vitamin MK 4. 2-Methyl-3-(3,7,11,15-tetramethyl-2,6,10,14-hexadeca-tetraenyl)-1,4-naphthoquinone.

Менатетренон

$C_{31}H_{40}O_2$ = 444.6.
CAS — 863-61-6.



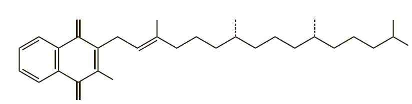
Pharmacopoeias. In *Jpn.*

Phytomenadione *(BAN, rINN)*

Fitomenadion; Fitomenadiona; Fitomenadionas; Fytomenadion; Fytomenadioni; Methylphytylnaphthochinonum; Phylloquinone; Phytomenad.; Phytoménadione; Phytomenadionum; Phytonadione; Vitamin K_1. 2-Methyl-3-[3,7,11,15-tetramethylhexadec-2-enyl] naphthalene-1,4-dione.

Фитоменадион

$C_{31}H_{46}O_2$ = 450.7.
CAS — 84-80-0.
ATC — B02BA01.
ATC Vet — QB02BA01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Ph. Eur. 6.2 (Phytomenadione). A mixture of the *trans* (*E*) and *cis* (*Z*) isomers. It contains not less than 75% of *trans*-phytomenadione, and also allows not more than 4% of *trans*-epoxyphytomenadione.

A clear, intense yellow, viscous, oily liquid, which decomposes on exposure to actinic light. Practically insoluble in water; sparingly soluble in alcohol; miscible with fatty oils. Protect from light.

USP 31 (Phytonadione). A mixture of the *E* and *Z* isomers. It contains not more than 21% of the *Z* isomer. A clear, yellow to amber, very viscous, odourless or practically odourless, liquid. It is stable in air, but decomposes on exposure to sunlight. Insoluble in water; slightly soluble in alcohol; soluble in dehydrated alcohol, in chloroform, in ether, in vegetable oils, and in benzene. Store in airtight containers. Protect from light.

Stability. A polyoxyl castor oil formulation of phytomenadione was stable for at least 30 days at room temperature when repackaged in amber glass dropper bottles.[1] When refrigerated at 4° to 8°, it was stable in both plastic and amber glass bottles.

Adverse Effects and Precautions

Intravenous doses of *phytomenadione* have caused severe reactions resembling hypersensitivity or anaphylaxis. Symptoms have included facial flushing, sweating, chest constriction and chest pain, dyspnoea, cyanosis, and cardiovascular collapse; fatalities have been reported. Anaphylactic reactions have generally been associated with an overly rapid rate of infusion but have also been reported even when the solution was diluted and infused slowly. They are generally thought to be due to polyoxyl castor oil which is present as a surfactant in some parenteral formulations; reports of such reactions with formulations that do not contain polyoxyl castor oil are rare (but see Hypersensitivity, below).

Pain, swelling, and phlebitis may occur at the injection site when phytomenadione is given. Localised skin reactions including atrophy or necrosis have been reported after intramuscular or subcutaneous injection of phytomenadione.

Phytomenadione formulations solubilised with lecithin and a bile salt should be given with caution to patients with severely impaired liver function and to premature neonates weighing less than 2.5 kg, since the bile salt may displace bilirubin.

Giving *menadione* and *menadiol sodium phosphate* to neonates, especially premature infants, or to the mother during late pregnancy has been associated with the development in the infant of haemolytic anaemia, hyperbilirubinaemia, and kernicterus, and such use is not recommended. Phytomenadione has a lower risk of haemolysis. Menadione and menadiol sodium phosphate have also been reported to cause haemolysis in patients with G6PD deficiency or vitamin E deficiency.

Breast feeding. Vitamin K is variably distributed into breast milk; a study found phytomenadione concentrations in the first 10 mL of expressed milk ("fore milk") to be lower than those in the last 10 mL ("hind milk"). These changes may be related to the lipid concentration, which is higher in hind milk. Lipid composition also changes over the course of lactation, with pronounced changes in the first week, and the authors proposed that a mechanism exists whereby vitamin K concentration in milk is higher in the first few days of life so as to meet the neonate's nutritional requirements at a time when vitamin K status is precarious.[1] The American Academy of Pediatrics considers[2] that, as no adverse effects have been seen in breast-fed infants whose mothers were receiving phytomenadione, its use is therefore usually compatible with breast feeding.

Carcinogenicity. A case-control study from the UK[1] suggested an increased risk of cancer in children who had received vitamin K at birth for the prevention of vitamin K deficiency bleeding (see below). A further study[2] by the same authors indicated that this risk was associated with intramuscular, but not oral, dosage, and was strongest for childhood leukaemia. In response to these data, the British Paediatric Association recommended that the oral route should be preferred for prophylaxis,[3] whereas the American Academy of Pediatrics continued to advocate the intramuscular route,[4] and still does so, concluding there is no association between this route and childhood leukaemia or other cancers.[5]

Subsequent studies from the USA,[6] Sweden,[7] Denmark,[7,8] Germany,[9] and England[10] did not confirm an increased risk of childhood cancer, including leukaemias, after the use of intramuscular vitamin K. More recently, 4 further studies were published.[11-14] Two of these, a case-control study in Scotland[11] and an ecological study in Britain,[12] showed no increased risk of any cancers with the use of intramuscular vitamin K. A third case-control study in England and Wales[13] found a borderline association between intramuscular vitamin K and cancers, particularly leukaemia. In the fourth study, a case-control study in northern England,[14] there was an increased risk (odds ratio 1.79) of acute lymphoblastic leukaemia developing 1 to 6 years after birth in children who had received intramuscular vitamin K. In 1998 a review[15] by an expert working group of the UK CSM concluded that there was no increased risk of solid tumours with vitamin K, and that, although an increased risk of leukaemia could not be excluded, observed results were compatible with chance. Moreover, they could not identify a plausible mechanism for a carcinogenic effect of vitamin K. Since then, a pooled analysis of case-control studies in Great Britain and Germany[16] found no convincing evidence that vitamin K given intramuscularly was associated with childhood leukaemia. A national case-control study in the UK[17] concluded there was no evidence that vitamin K, irrespective of the route, influenced the risk of children developing leukaemia or any other cancer. If there is any increased risk, it is likely to manifest only in a very small subpopulation who are at high risk for some as-yet-unidentified biological reason.[18] The UK Department of Health[19] advocates either oral or intramuscular prophylaxis, and recommends that the parents should be involved in the decision on which route is used.

Effects on the blood. Cerebral arterial thrombosis developed in 2 patients with malabsorption syndromes due to coeliac disease during treatment with vitamin K for severe deficiency of vitamin-K-dependent coagulation factors. An increased tendency to thrombotic events had previously been reported to be present in patients with intestinal inflammatory disorders. It was suggested that if bleeding did occur in such patients treatment should be with plasma infusions or small doses of vitamin K but that vitamin K deficiency should not be specifically treated since a gluten-free diet or corticosteroids given for the gastrointestinal disorder will result in a gradual correction.[1]

Hypersensitivity. Hypersensitivity reactions have been reported after subcutaneous,[1-3] intramuscular,[4] intravenous,[5-7] and oral[7] use of vitamin K, although the incidence is low.[6,7]

Subcutaneous doses are considered to pose less risk of **anaphylaxis** than the intravenous route;[5] fatalities have been reported with intravenous use,[7] even after low doses, given slowly, and by dilute infusion.[5,7] There has also been a fatality associated with oral use.[7] While anaphylactoid reactions have been attributed to the polyoxyl castor oil vehicle,[6,7] a direct immune mechanism has also been proposed.[7]

Vitamin K itself appears to be the antigen causing adverse **cutaneous reactions**.[3] Two types of cutaneous reactions have been described: pruritic, erythematous, eczematous plaques usually occurring up to 2 weeks after a dose, and sclerodermoid morphea-like plaques, with or without eczema, which may be delayed.[1,3,4] In addition, there have been rare reports of diffuse maculopapular eruption, but the relationship of this reaction to vitamin K use has been questioned.[3] Despite reports that the eczematous reactions resolve faster than the sclerodermatous reactions,[1] persistent eczema[4] or pruritus has occurred.[3]

Treatment has been largely symptomatic; topical and systemic corticosteroids and antihistamines have been used.[1,3,4] For patients who have previously reacted to phytomenadione injections, the use of menadione either by injection or by mouth has been suggested;[3] cross-reactivity was not anticipated to be a problem. However, cross-reactions on patch testing have been reported.[4] It has been suggested that reactions to vitamin K in patients might signify underlying hepatic disease,[1] although others believe the condition is seen more frequently in patients with liver disease since they are often those requiring vitamin K.[3]

Overdosage. UK licensed product information states that, while there is no known clinical syndrome attributable to hypervitaminosis of phytomenadione, adverse effects have been reported after overdose in neonates and infants. These include jaundice, hyperbilirubinaemia, increases in liver enzyme values, abdominal pain, constipation, soft stools, malaise, agitation, and skin eruptions. Most adverse events were not considered to be serious, and resolved without any treatment.

Interactions

Vitamin K decreases the effects of oral anticoagulants (see p.1432), and is used to counteract excessive effects of these drugs, see Uses and Administration, below. Vitamin K may reduce the response to resumed therapy with anticoagulants for a week or more.

Pharmacokinetics

The fat-soluble vitamin K compounds phytomenadione and menadione require the presence of bile for their absorption from the gastrointestinal tract; the water-soluble derivatives can be absorbed in the absence of bile. Vitamin K accumulates mainly in the liver but is stored in the body only for short periods of time. Vitamin K does not appear to cross the placenta readily and it is variably distributed into breast milk. Phytomenadione is rapidly metabolised to more polar metabolites and is excreted in bile and urine as glucuronide and sulfate conjugates.

Absorption. Absorption of phytomenadione from the colloidal (micellar) preparation was more irregular and unpredictable after intramuscular than intravenous dosage in healthy adults;[1] when used as an antidote to anticoagulant, this formulation should be given intravenously. In neonates, plasma phytomenadione concentrations were within or above the adult fasting plasma range 24 days after receiving a single dose of the colloidal preparation either orally (3 mg) or intramuscularly (1.5 mg).[2]

Human Requirements

The minimum daily requirements of vitamin K are not clearly defined but an intake of about 1 microgram/kg daily appears to be adequate. Vitamin K requirements in normal adults can be met from the average diet and from the synthesis of menaquinones (also known as vitamin K_2) by bacterial action in the intestine. Vitamin K occurs naturally as phytomenadione (vitamin K_1), which is present in many foods, especially leafy green vegetables such as cabbage and spinach, and is also present in avocado, meat, cow's milk, egg-yolk, and some cereals.

UK and US recommended dietary intake. In the UK neither a reference nutrient intake (RNI) nor an estimated average requirement (EAR—see p.1925) has been set for vitamin K although an intake of 1 microgram/kg daily was considered to be both safe and adequate for adults; a higher intake of 10 micrograms daily (about 2 micrograms/kg daily) was believed to be justified in infants because of the absence of hepatic menaquinones in early life and reliance on dietary vitamin K alone. It was stated that all babies should receive prophylactic vitamin K at birth[1] and for further details concerning neonatal use, see Vitamin K Deficiency Bleeding, below.

In the USA, adequate intake levels have been determined to be 120 micrograms daily for adult men and 90 micrograms daily for adult women.[2]

Uses and Administration

Vitamin K is an essential cofactor in the hepatic synthesis of prothrombin (factor II) and other blood clotting factors (factors VII, IX, and X, and proteins C and S) and in the function of proteins such as osteocalcin important for bone development.

Vitamin K deficiency may develop in neonates, but is uncommon in adults, although it may occur in patients with malabsorption syndromes, obstructive jaundice or hepatic disease. Deficiency leads to the development of hypoprothrombinaemia, in which the clotting time of the blood is prolonged and spontaneous bleeding can occur. Coumarin anticoagulants interfere with vitamin K metabolism, and their effects can be antagonised by giving vitamin K.

Vitamin K compounds are used in the treatment and prevention of haemorrhage associated with vitamin K deficiency. The dose of vitamin K should be carefully controlled by prothrombin-time estimations.

Phytomenadione is a naturally occurring vitamin K substance. It is the only vitamin K compound used to reverse hypoprothrombinaemia and haemorrhage caused by anticoagulant therapy. It is not effective as a heparin antidote. For **over-anticoagulation**, the dose depends on the international normalised ratio (INR) and the degree of haemorrhage. Typical doses of phytomenadione are 0.5 to 5 mg by slow intravenous injection or up to 5 mg orally (see also Over-anticoagulation, below). Depending on the solubilising agents used, some formulations of phytomenadione are more suitable for intravenous use than others, and dosage details vary. Phytomenadione has also been used in hypoprothrombinaemia due to certain cephalosporins (see Cefamandole, Adverse Effects, p.221).

In the treatment of **vitamin K deficiency bleeding** in neonates, phytomenadione may be given in a dose of 1 mg intravenously, subcutaneously, or intramuscularly; further doses may be given if necessary. As a prophylactic measure, a single dose of 0.5 to 1 mg may be given intramuscularly to the newborn infant, or 2 mg orally followed by a second dose of 2 mg after 4 to 7 days; for further details see below.

Menadiol sodium phosphate is a water-soluble derivative of menadione, a synthetic lipid-soluble vitamin K analogue. It may be used for the prevention of vitamin K deficiency in patients with malabsorption syndromes in whom oral phytomenadione may be inefficiently absorbed. It is given in usual doses equivalent to 10 to 40 mg of menadiol phosphate daily by mouth.

Menadiol dibutyrate has also been used; menatetrenone is used in the management of osteoporosis. Acetomenaphthone has been used in preparations promoted for the relief of chilblains.

Malignant neoplasms. In a small study in women with viral cirrhosis of the liver to establish the effects of vitamin K on bone loss, those given menatetrenone were found to have a lower incidence of hepatocellular carcinoma; larger controlled studies were advocated, with prevention of carcinoma by menatetrenone as a primary end-point.[1] Another study[2] reported reduced recurrence of hepatocellular carcinoma in patients given menatetrenone.

Neonatal intraventricular haemorrhage. Vitamin K crosses the placenta slowly and to a limited extent, but sufficiently so to warrant studies to assess whether giving phytomenadione to the mother can reduce the incidence or severity of intraventricular haemorrhage (p.1050) in the preterm neonate. Studies have shown conflicting results. A systematic review concluded that vitamin K given to the mother before birth did not significantly prevent periventricular haemorrhage, and could not be recommended for routine clinical use.[1]

Osteoporosis. The effects of vitamin K on bone, and its role in osteoporosis (p.1084) have been reviewed.[1-3] It is widely prescribed for the management of osteoporosis in Japan.[3] A reduced risk of vertebral[4] and nonvertebral[5] fracture has been reported from 2 studies in postmenopausal women given menatetrenone 45 mg daily by mouth. Vitamin K_2 (menaquinones such as menatetrenone) appears to have more marked effects on bone than vitamin K_1 (phytomenadione).[3] A systematic review[6] to assess whether vitamin K supplementation can reduce bone loss and prevent fractures identified 13 studies with data on bone loss; 7 reported fracture data. Most studies were conducted in Japan among postmenopausal women. Vitamin K supplements increased bone mineral density (BMD) in all but 1 study. Meta-analyses of the 7 studies with fracture data showed a reduced fracture incidence with menatetrenone supplementation, especially at the hip. The authors advised caution in interpretation of the data, since the studies were not designed to show fracture effects, and quality of many of the trials was poor. In addition, dietary differences in Japan might confound findings. While patients at risk of fracture should be encouraged to consume a diet high in vitamin K, routine supplementation is not justified until these results can be confirmed in a large randomised study with fracture as a primary outcome.

Over-anticoagulation. Doses of vitamin K for over-anticoagulation with warfarin have traditionally been large, and this continues to be reflected in licensed product information for these products, where recommended oral or parenteral doses range from 2.5 to 25 mg initially, with a maximum dose of 40 to 50 mg. However, large doses of vitamin K may result in overcorrection, and increase the delay before resumed anticoagulant therapy becomes effective. In addition, the time to onset of action is a minimum of 1 to 2 hours, irrespective of dose. There is increasing evidence that lower doses of vitamin K are effective in over-anticoagulation,[1-3] and this is reflected in current guidelines (see Treatment of Adverse Effects of Warfarin, p.1426). The use of vitamin K lowers the elevated INR faster than witholding warfarin alone. However, for patients on phenprocoumon, vitamin K had insufficient effect, and no benefit for those on acenocoumarol; stopping therapy is more effective.[3] The route by which vitamin K is given may also be significant. A meta-analysis[4] of studies of vitamin K for the treatment of over-anticoagulation found that oral or intravenous vitamin K therapy was more effective for warfarin than simply stopping the anticoagulant; however, subcutaneous therapy was not effective. A review[5] noted that over-anticoagulated patients present with a wide range of INR values, and may respond differently to fixed dosing regimens of vitamin K, leaving them outside their target INR 24 hours after treatment and at risk for either haemorrhage or thromboembolism. Patient factors that affect response to vitamin K include age, body-weight, co-morbidity or health status, warfarin daily dose, and genetic polymorphism. The authors called for a more individualised approach to the reversal of over-anticoagulation.

A study has shown that dietary vitamin K intake is an important factor in anticoagulation instability; even brief periods of increased or decreased intake had significant effects on anticoagulation.[6] A high intake of green, leafy vegetables or selected oil-based foods can readily provide a dietary intake of 0.5 mg of vitamin K. Instead of restricting dietary vitamin K, maintenance of a stable intake may result in improved maintenance of therapeutic anticoagulation.[7]

Concern has also been expressed about possible effects on patients taking warfarin if vitamin K is included in their parenteral nutrition.[8]

Vitamin K deficiency bleeding. Vitamin K deficiency bleeding (VKDB; haemorrhagic disease of the newborn; HDN), of which 3 types have been recognised, is associated with a clotting defect due to vitamin K deficiency.[1,2]

- In early VKDB bleeding occurs at the time of delivery or during the first 24 hours of life and is typically seen in infants whose mothers have taken drugs that affect vitamin K metabolism such as warfarin, some antiepileptics, rifampicin, or isoniazid.
- Classic VKDB, the most common type, usually occurs at 2 to 5 days of age and breast feeding is an important factor as human breast milk has a much lower content of vitamin K than either cow's milk or infant formulas.
- Late VKDB presents frequently as intracranial haemorrhage in infants over one month of age. The vitamin-K deficiency in these cases can be either idiopathic (usually in breast-fed infants who did not receive vitamin K at birth) and/or can be a secondary manifestation of other disorders such as chronic diarrhoea, cystic fibrosis or other malabsorption syndromes, biliary atresia, or α_1-antitrypsin deficiency.

Treatment of VKDB involves use of parenteral phytomenadione, usually 1 mg initially with further doses depending on response. More immediate treatment, in the form of blood transfusion or blood clotting factors, may be needed to compensate for severe blood loss and delayed response to vitamin K. VKDB, particularly the late type, carries a high risk of morbidity or death; therefore, the emphasis has been on prevention. It has long been known that giving vitamin K to the neonate soon after birth can reduce the incidence of VKDB. Menadiol sodium phosphate was formerly used, but reports in the 1950s of jaundice and kernicterus in infants given this vitamin K analogue caused concern, and led to the preferential use of phytomenadione either intramuscularly or orally. Giving phytomenadione, usually as a single intramuscular injection, has been standard practice for neonates considered at high risk of VKDB, such as those who had a complicated delivery, those born prematurely, and those whose mothers were receiving antiepileptic therapy. Since it is not possible to selectively identify all neonates that are at risk for VKDB, the routine use of phytomenadione in all neonates has been advocated. However, such practice has been controversial, particularly as regards the route.[2-4] Some have considered that oral dosage is less invasive and more acceptable to parents.[4] However, there has also been concern about the adequacy of absorption of oral phytomenadione, and the lack of a suitable oral formulation. In addition, there was some evidence[2,5-7] to suggest that a single intramuscular dose was more effective than a single oral dose in preventing late VKDB, and that repeated oral doses might be required, which may be less convenient and carry the risk of poor compliance. More recently, a possible increased risk of childhood cancer in neonates treated with intramuscular, but not oral, phytomenadione has been reported (see Carcinogenicity, above). Although the association remains controversial, it led to recommendations for the preferential use of oral vitamin K in neonates at low-risk of VKDB in some countries, including the UK[8] and Germany,[9] whereas other countries, including the USA,[10,11] still preferred the intramuscular route for all neonates.

There is still no agreement on the most effective oral dose and frequency, and study of this has been complicated by the lack of a suitable oral preparation of phytomenadione.[12,13] Options currently available for oral use include the polyoxyl castor oil and polysorbate-80 containing preparations (unlicensed for oral use) and the colloidal, micelle formulation (licensed for oral use in some countries). These preparations are packaged in glass ampoules, therefore are unsuitable for parents to give at home.

The 1992 recommendations of the British Paediatric Society[8] for oral use of the polyoxyl castor oil formulation suggested a single dose of 500 micrograms on the day of birth. For breast-fed babies, additional doses of 500 micrograms at 7 to 10 days and at 4 to 6 weeks, or 200 micrograms at weekly intervals for 26 weeks, or 50 micrograms daily for 26 weeks, were recommended. Current UK doses[14] for the colloidal preparation in healthy term neonates are 2 mg soon after birth, then 2 mg at 4 to 7 days. Exclusively breast-fed infants should be given a third oral dose of 2 mg one month after birth. Further monthly doses of 2 mg have been recommended while the infant remains exclusively breast-fed. A report[15] of the failure of prophylaxis in 3 breast-fed babies (2 of whom had unidentified cholestatic liver disease) who received 2 doses of this formulation, as recommended in Switzerland, emphasises the importance of the third, and possibly, other, follow-up doses. Plasma vitamin K concentrations in breast-fed infants receiving 3 oral doses of this formulation were at least equal to concentrations in those receiving a single intramuscular dose.[16] A study in Germany, however, found the mixed micellar oral formulation to be no more efficacious than older vitamin K preparations,[17] and a pharmacokinetic study found its absorption to be unreliable in infants with conjugated hyperbilirubinaemia;[18] the authors suggest that even 3 oral doses may not provide sufficient protection against VKDB in infants with latent cholestasis. The most recent advice from the UK Department of Health[14] advocates that all newborn infants should receive vitamin K prophylaxis, both oral and intramuscular routes should be available, and that parents should be involved in the decision on which route is used.

Other oral regimens have been investigated or are in use. In the Netherlands a regimen of 1 mg orally or intramuscularly at birth, followed by 25 micrograms daily or 1 mg weekly by mouth from 1 week to 3 months of age has been found satisfactory.[19,20] In Germany[9,20] and Australia[20] the suggested oral regimen for the polyoxyl castor oil formulation was 1 mg at birth, at 3 to 10 days and at weeks 3 to 6, although some failures have been reported in babies receiving this regimen,[9] and the Australian data confirm it is less effective than a single intramuscular dose.[20] One hospital in the USA has satisfactorily used, for many years, a single 2-mg dose given via nasogastric tube to neonates after birth,[21] although the American Academy of Pediatrics still advocates use of the intramuscular route.[11] In Denmark, a 2-mg dose at birth followed by a weekly dose of 1 mg during the first 3 months of life has effectively prevented any late VKDB in healthy breast-fed babies.[22] In France, for formula-fed neonates at no risk of haemorrhage, 2 mg is given orally at birth, followed by a second dose between day 2 and 7; infants who are breast-fed are given weekly oral doses of 2 mg until cessation of exclusive breast feeding. For neonates at high risk of haemorrhage, however, the first dose is given intramuscularly, or even by slow intravenous injection, according to the clinical state of the infant.[2]

Although phytomenadione crosses the placenta slowly and to a limited extent, it is nevertheless recommended that pregnant women receiving drugs that are vitamin K antagonists (particularly antiepileptics) should receive phytomenadione 10 to 20 mg daily from 36 weeks gestation.[2,23] This is in addition to the requirement that their neonates, who are at high risk of VKDB, receive intramuscular phytomenadione soon after birth. Maternal phytomenadione has been investigated as a means of improving vitamin K status in breast-fed neonates. In 1 study,[24] 5 mg daily for 12 weeks was effective for this purpose.

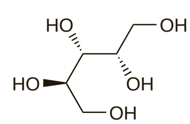
Xylitol *(BAN)*

E967; Ksilitolis; Ksylitol; Ksylitoli; Xilit; Xilitol; Xylit; *meso*-Xylitol; Xylitolum.

$C_5H_{12}O_5$ = 152.1.
CAS — 87-99-0 (xylitol); 16277-71-7 (D-xylitol).



Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Xylitol). A white or almost white crystalline powder or crystals. M.p. 92° to 96°. Very soluble in water; sparingly soluble in alcohol.

USNF 26 (Xylitol). White crystals or crystalline powder. Crystalline xylitol has a melting range between 92° and 96°. It has a sweet taste and produces a cooling sensation in the mouth. Soluble 1 in about 0.65 of water; sparingly soluble in alcohol.

Adverse Effects

Large amounts of xylitol taken orally may cause diarrhoea and flatulence. Hyperoxaluria, which can occur with intravenous infusion, is unlikely after oral use. Hyperuricaemia, changes in liver-function tests, and acidosis (including lactic acidosis) have occurred after intravenous infusion.

Hypersensitivity. A report of oral erosions caused by contact hypersensitivity to xylitol-containing chewing gum.[1]

1. Hanakawa Y, *et al.* Xylitol as a causative agent of oral erosive eczema. *Br J Dermatol* 2005; **152:** 821–2.

Uses and Administration

Xylitol is a polyhydric alcohol (polyol) related to the pentose sugar, xylose (p.2416). It is used as a bulk sweetener in foods and as a sweetener or excipient in pharmaceuticals. Xylitol is also used as a sweetening agent in sugar-free preparations as it is non-cariogenic and is less likely to cause dental caries than sucrose. It is under investigation for the prevention of dental caries and acute otitis media. It was formerly considered as a substitute for glucose in intravenous nutrition but such use has generally been abandoned due to adverse effects.

Dental caries. Chewing-gum containing xylitol appears to have a useful role in the prevention of dental caries (p.180).[1-5]

Otitis media. It has been suggested that xylitol chewing gum[1,2] and xylitol syrup[2,3] may have a preventative effect against acute otitis media (p.182). However, a randomised study[4] found xylitol to be ineffective when given only during an acute respiratory-tract infection.

Dried Yeast

Brewers' Yeast; Cerevisiae Fermentum Siccatum; Faex Siccata; Fermento de Cerveja; Levadura desecada; Levedura Sêca; Levure de Bière; Saccharomyces Siccum; Trockenhefe.

Сушёные Дрожжи

Pharmacopoeias. In *Jpn.*

Profile

Dried yeast consists of unicellular fungi belonging to the family Saccharomycetaceae, dried by a process that avoids decomposition of the vitamins present. The chief species are *Saccharomyces cerevisiae*, *S. carlsbergensis*, and *S. monacensis*. Dried yeast contains thiamine, nicotinic acid, riboflavin, pyridoxine, pantothenic acid, biotin, folic acid, cyanocobalamin, aminobenzoic acid, inositol, and chromium.

Dried yeast is a rich source of vitamins of the B group. It has been used for the prevention and treatment of vitamin B deficiency in doses of 1 to 8 g daily by mouth. Yeast is an ingredient of some preparations for treating haemorrhoids, and some preparations intended to restore normal gastrointestinal flora. Yeast is widely used in brewing.

Antibiotic-associated colitis. Although other organisms, including *Candida* spp., have been implicated in antibiotic-associated diarrhoea, colonisation of the colon with *Clostridium difficile*, a toxin-producing Gram-positive anaerobe, is the most common identifiable cause of antibiotic-associated colitis (p.171) and pseudomembranous colitis. There are reports of benefit with dried yeast in patients with *C. difficile*-associated diarrhoea;[1,2] commercially available brewers' yeast tablets were used, at a dose of 3 tablets three times daily (strength unspecified), in 3 patients refractory to standard treatment,[1] or as adjunctive therapy in 11 patients, using the same dose.[2]

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: *Indon.:* Eyevit; Matovit Fifty; Nuvision; ***Mex.:*** Snelvit.

Zinc

Cynk; Zincum; Zink.

Zn = 65.38.

CAS — 7440-66-6.

Zinc Acetate

Cink-acetát-dihidrát; Cinko acetatas dihidratas; Cynku octan; E650; Octan zinečnatý dihydrát; Sinkkiasetaatti; Zinc (acétate de) dihydraté; Zinc, acetato de; Zinci Acetas; Zinci acetas dihydricus; Zinkacetat.

$(CH_3CO_2)_2Zn,2H_2O$ = 219.5.

CAS — 557-34-6 (anhydrous zinc acetate); 5970-45-6 (zinc acetate dihydrate).

ATC — A16AX05.

ATC Vet — QA16AX05.

NOTE. Zinc Acetate, Basic is *rINN*.

Pharmacopoeias. In *Eur.* (see p.vii) and *US*.

Ph. Eur. 6.2 (Zinc Acetate Dihydrate; Zinc Acetate BP 2008). A white or almost white, crystalline powder or leaflets. Freely soluble in water; soluble in alcohol. A 5% solution in water has a pH of 5.8 to 7.0. Store in nonmetallic containers.

USP 31 (Zinc Acetate). White crystals or granules having a slight acetous odour. Is slightly efflorescent. Soluble 1 in 2.5 of water and 1 in 30 of alcohol; freely soluble in boiling alcohol. pH of a 5% solution in water is between 6.0 and 8.0. Store in airtight containers.

Zinc Chloride

Chlorid zinečnatý; Cink-klorid; Cinko chloridas; Cynku chlorek; Sinkkikloridi; Zinc, chlorure de; Zinc, cloruro de; Zinci chloridum; Zincum Chloratum; Zinkklorid.

$ZnCl_2$ = 136.3.

CAS — 7646-85-7.

ATC — B05XA12.

ATC Vet — QB05XA12.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Zinc Chloride). A white or almost white, deliquescent, crystalline powder or cast in white or almost white sticks. Very soluble in water; freely soluble in alcohol and in glycerol. An approximately 10% solution in water has a pH of 4.6 to 5.5. Store in nonmetallic containers.

USP 31 (Zinc Chloride). A white or practically white, odourless, crystalline powder, or white or practically white crystalline granules. May also be in porcelain-like masses or moulded into cylinders. It is very deliquescent. Soluble 1 in 0.5 of water, 1 in 1.5 of alcohol, and 1 in 2 of glycerol. Its solution in water or in alcohol is usually slightly turbid, but the turbidity disappears when a small quantity of hydrochloric acid is added. A 10% solution in water is acid to litmus. Store in airtight containers.

Turbidity. Zinc chloride almost always contains some oxychloride which produces a slightly turbid aqueous solution. Turbid solutions, except when intended for ophthalmic use, may be cleared by adding gradually a small amount of dilute hydrochloric acid. Solutions of zinc chloride should be filtered through asbestos or sintered glass, since they dissolve paper and cotton wool.

Zinc Citrate

Zinc Citrate Trihydrate. 2-Hydroxy-1,2,3-propanetricarboxylic acid zinc salt.

Цитрат Цинка

$C_{12}H_{10}O_{14}Zn_3,3H_2O$ = 628.4.

CAS — 546-46-3.

Pharmacopoeias. In *Chin.*

Zinc Gluconate

Zinc, gluconate de; Zinc, gluconato de; Zinci gluconas.

$C_{12}H_{22}O_{14}Zn$ = 455.7.

CAS — 4468-02-4.

ATC — A12CB02.

ATC Vet — QA12CB02.

Pharmacopoeias. In *Chin.* and *US*.

USP 31 (Zinc Gluconate). White or practically white powder or granules. Soluble in water; very slightly soluble in alcohol. pH of a 1% solution in water is between 5.5 and 7.5.

Zinc Sulfate

Çinko Sülfat; Cinko sulfatas; Cink-szulfát; Cynku siarczan; Sinkkisulfaatti; Síran zinečnatý; Zinc, sulfate de; Zinc, sulfato de; Zinc Sulphate; Zinci sulfas; Zincum Sulfuricum; Zinksulfat.

$ZnSO_4,7H_2O$ = 287.5.

CAS — 7733-02-0 (anhydrous zinc sulfate); 7446-20-0 (zinc sulfate heptahydrate).

ATC — A12CB01.

ATC Vet — QA12CB01.

NOTE. 'White vitriol' or 'white copperas' is crude zinc sulfate.

ZSU is a code approved by the BP 2008 for use on single unit doses of eye drops containing zinc sulfate where the individual container may be too small to bear all the appropriate labelling information.

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *Viet.*

Eur. also includes the monohydrate and the hexahydrate.

US includes the monohydrate and the heptahydrate in one monograph.

Ph. Eur. 6.2 (Zinc Sulphate Heptahydrate; Zinci Sulfas Heptahydricus). Colourless, transparent, crystals or a white or almost white, crystalline powder; efflorescent. Very soluble in water; practically insoluble in alcohol. A 5% solution in water has a pH of 4.4 to 5.6. Store in nonmetallic airtight containers.

Ph. Eur. 6.2 (Zinc Sulphate Hexahydrate; Zinci Sulfas Hexahydricus). Colourless, transparent, crystals or a white or almost white, crystalline powder; efflorescent. Very soluble in water; practically insoluble in alcohol. A 5% solution in water has a pH of 4.4 to 5.6. Store in nonmetallic airtight containers.

Ph. Eur. 6.2 (Zinc Sulphate Monohydrate; Zinci Sulfas Monohydricus). Colourless, transparent, crystals or a white or almost white crystalline powder. Very soluble in water; practically insoluble in alcohol. A 5% solution in water has a pH of 4.4 to 5.6. Store in nonmetallic containers.

USP 31 (Zinc Sulfate). It contains one or seven molecules of water of hydration. Colourless, transparent, prisms, or small needles. May occur as a white, granular, crystalline powder. It is odourless and is efflorescent in dry air. Very soluble in water (heptahydrate); freely soluble in water (monohydrate); practically insoluble in alcohol (monohydrate); insoluble in alcohol (heptahydrate); freely soluble in glycerol (heptahydrate). Its solutions are acid to litmus. Store in airtight containers.

Adverse Effects, Treatment, and Precautions

The most frequent adverse effects of zinc salts (the gluconate and sulfate) given orally are gastrointestinal and include abdominal pain, dyspepsia, nausea, vomiting, diarrhoea, gastric irritation, and gastritis. These are particularly common if zinc salts are taken on an empty stomach, and may be reduced by giving them with meals.

In acute overdosage zinc salts are corrosive, due to the formation of zinc chloride by stomach acid; treatment consists of giving milk or alkali carbonates and activated charcoal. The use of emetics or gastric lavage should be avoided.

Prolonged use of high doses of zinc supplements, orally or parenterally, leads to copper deficiency with associated sideroblastic anaemia and neutropenia; full blood counts and serum cholesterol should be monitored to detect early signs of copper deficiency. Zinc toxicity has occurred after the use of contaminated water in haemodialysis solutions. High serum zinc concentrations may be reduced by using a chelating drug such as sodium calcium edetate (p.1462).

Metal fume fever is an occupational disease associated with inhalation of freshly-oxidised metal fumes, most commonly from zinc, iron or copper. It is characterised by chills, fever, cough, dyspnoea, myalgia, and chest pain, and is generally self-limiting and does not appear to be associated with long-term sequelae.

Effects on the blood. There have been reports[1-3] of anaemia, leucopenia, and neutropenia in patients consuming excessive amounts of zinc supplements for acne. A patient given zinc-containing enteral feeds as well as zinc supplementation was diagnosed with sideroblastic anaemia due to zinc toxicity.[4] All patients were copper-deficient,[1-4] despite supplementation with copper in one case.[4]

4. Irving JA, *et al.* Element of caution: a case of reversible cytopenias associated with excessive zinc supplementation. *Can Med Assoc J* 2003; **169:** 129–31.

Hypersensitivity. Report of a patient who developed palmoplantar pustulosis about 1 year after receiving dental fillings containing zinc.[1] Zinc hypersensitivity was confirmed by *in vitro* and patch testing. Complete remission occurred on replacing the dental fillings.

1. Yanagi T, *et al.* Zinc dental fillings and palmoplantar pustulosis. *Lancet* 2005; **366:** 1050.

Parenteral nutrition. Zinc was found to be a common contaminant of various components used for total parenteral nutrition (TPN), and rubber stoppers or glass may have been the source.[1] Levels of zinc found may exceed daily requirements even before the addition of supplementary zinc. The authors suggested it may be important to routinely monitor zinc status in patients receiving long-term TPN, particularly infants and children.

1. Hak EB, *et al.* Chromium and zinc contamination of parenteral nutrient solution components commonly used in infants and children. *Am J Health-Syst Pharm* 1998; **55:** 150–4.

Interactions

The absorption of zinc may be reduced by iron supplements (see also Absorption, under Pharmacokinetics, below) , penicillamine, phosphorus-containing preparations, and tetracyclines. Zinc supplements reduce the absorption of copper, fluoroquinolones (see Antacids and Metal Ions, under Interactions of Ciprofloxacin, p.246), iron, penicillamine, and tetracyclines (p.348).

Pharmacokinetics

Absorption of zinc from the gastrointestinal tract is incomplete, and is reduced in the presence of some dietary constituents such as phytates. Bioavailability of dietary zinc varies widely between different sources, but is about 20 to 30%. Zinc is distributed throughout the body with the highest concentrations found in muscle, bone, skin, eye, and prostatic fluids. It is primarily excreted in the faeces, and regulation of faecal losses is important in zinc homoeostasis. Small amounts are lost in urine and perspiration.

Absorption. Although zinc deficiency (see Deficiency States, under Uses and Administration, below) in some cases may be due to inadequate dietary intake, inhibitors of zinc absorption may also be causative.[1] *Phytates*, which are present in cereals, corn, legumes, and rice, inhibit zinc absorption. The animal *protein* in beef, eggs, and cheese counteracts the inhibitory effect of phytate, whereas the casein in milk decreases zinc absorption. Proteins also often contain other constituents such as inorganic *phosphate* that can negatively affect zinc absorption. Long-term use of *calcium* supplements has no effect on zinc status, but dietary calcium may form insoluble complexes with phytate and zinc, thus decreasing the absorption of zinc. *Iron* can reduce zinc absorption, although the effect is apparent only at a very high ratio of iron to zinc, and in aqueous solution, which suggests that iron fortification of foods will not affect zinc absorption. Although it is possible that iron supplementation could affect mechanisms of zinc uptake and transport, studies have not found such an effect, and long-term iron supplementation is not considered to impair zinc status.

Zinc can form complexes with ligands or chelators; if the complex is readily absorbed, this can increase zinc absorption. *Edetic acid* has been found to have variable effects on zinc status depending on the ratio of edetic acid to other cations and phytate, which compete for complex formation with zinc. *Histidine* also chelates with zinc and can increase plasma zinc concentrations; however, the ratio of histidine to zinc is important because high doses of histidine may enhance the urinary excretion of zinc. *Methionine* may improve zinc absorption, although evidence is limited. Adding organic acids such as *citrate* to foods can enhance zinc absorption; zinc citrate has been used as a dietary supplement.

1. Lönnerdal B. Dietary factors influencing zinc absorption. *J Nutr* 2000; **130:** 1378S–1383S.

Human Requirements

UK and US recommended dietary intake. In the UK dietary reference values (DRV)[1] and in the USA recommended dietary allowances (RDA)[2] have been published for zinc (see p.1925 for an explanation of these terms). In the UK the reference nutrient intake (RNI) for adult males and females is 9.5 and 7.0 mg daily respectively; values are also given for infants and children of varying ages and for lactating women. The Expert Group on Vitamins and Minerals[3] have established a safe upper level (SUL) for zinc of 25 mg daily. In the USA the RDA for adults is 11 mg daily for men and 8 mg daily for women.[2] The tolerable upper intake level is 40 mg daily.

WHO recommend lower limits of the safe ranges of population mean intakes of dietary zinc for 3 categories of diets based on high, moderate, and low zinc bioavailability: values are 4.0, 6.5, and 13.1 mg dietary zinc daily for women, and 5.6, 9.4, and 18.7 mg dietary zinc daily for men, respectively.[4] They recommend an upper limit of the safe range of population mean intakes of zinc of 35 mg daily for women, and 45 mg daily for men.

Uses and Administration

Zinc is an essential element of nutrition and traces are present in a wide range of foods. It is a constituent of many enzyme systems and is present in all tissues. Features of zinc deficiency include growth retardation and defects of rapidly-dividing tissues such as the skin, the immune system, and the intestinal mucosa. Water-soluble zinc salts are used as supplements to correct zinc deficiency; for example, in malabsorption syndromes, during parenteral feeding, in conditions with increased body losses (trauma, burns, and protein-losing states), and in acrodermatitis enteropathica (a rare genetic disorder characterised by severe zinc deficiency). They have been tried in the treatment of a large number of conditions that may be related to zinc deficiency.

Doses of zinc salts are usually expressed in terms of elemental zinc, and the following salts contain about 50 mg of zinc:

- zinc acetate (dihydrate) 168 mg
- zinc chloride 104 mg
- zinc citrate (trihydrate) 160 mg
- zinc gluconate 348 mg
- zinc sulfate (heptahydrate) 220 mg

The approximate number of millimoles of zinc contained in these salts are:

- 4.6 mmol in 1 g zinc acetate (dihydrate)
- 7.3 mmol in 1 g zinc chloride
- 4.8 mmol in 1 g zinc citrate (trihydrate)
- 2.2 mmol in 1 g zinc gluconate
- 3.5 mmol in 1 g zinc sulfate (heptahydrate)

In **deficiency states**, zinc is usually given orally as the sulfate, the sulfate monohydrate, or the gluconate, in doses of up to 50 mg of elemental zinc three times daily. When intravenous supplements are required, zinc chloride or zinc sulfate may be given; a suggested dose for parenteral nutrition is 6.5 mg of elemental zinc (100 micromoles) daily.

Oral zinc salts, commonly the acetate, may be used as copper absorption inhibitors in **Wilson's disease** (p.1459). The usual adult dose is 50 mg three times daily up to a maximum of five times daily. Children from 1 to 6 years may be given 25 mg twice daily; those from 6 to 16 years and with a body-weight under 57 kg are given 25 mg three times daily. Adolescents from 16 years of age, or with a body-weight of above 57 kg are given 50 mg three times daily. An effective dose in pregnant women is usually 25 mg three times daily; however, dosage is adjusted based on copper concentrations.

Zinc sulfate is used topically in a variety of skin conditions mainly for its **astringent** properties. The insoluble zinc salts, commonly the oxide (p.1621), are used similarly. A 1.2% solution of zinc acetate is used topically with erythromycin in the treatment of acne vulgaris (p.1577). Zinc sulfate is also used as an astringent in eye drops. Zinc chloride has been used for its powerful caustic and astringent properties, usually in very dilute solution, in, for example, mouthwashes. Zinc citrate has been used in preparations for oral care and as a dietary supplement.

Age-related macular degeneration. High doses of dietary supplements such as betacarotene, vitamin C, vitamin E, and zinc are being promoted for preservation of vision in the elderly but there are no data to suggest any benefit for patients who do not have age-related macular degeneration or have only mild disease and such treatment is not necessarily harmless.[1] For further details, see under Betacarotene, p.1931.

1. Anonymous. Antioxidant vitamins and zinc for macular degeneration. *Med Lett Drugs Ther* 2003; **45:** 45–46.

Common cold. Zinc salts, in the form of lozenges, have been tried in the treatment of the common cold (p.850) with variable results.[1-4] A systematic review of randomised trials found that there was no strong evidence to recommend their use.[5] Similarly, variable results have been obtained with intranasal preparations of zinc gluconate;[6-8] intranasal zinc sulfate has proven ineffective.[9]

DIAGNOSIS AND TESTING. A loss of taste acuity is a sign of zinc deficiency (see Taste Disorders, below) and this has been used as a test for the condition: patients who do not immediately perceive a strong flavour on tasting a dilute (typically 0.1 or 0.2%) solution of zinc sulfate are considered likely to benefit from supplementation. However, a study in pregnant women failed to confirm that the ability to taste such a solution was related to zinc deficiency.[1]

Authors of a small study of Japanese children with short stature evaluated body zinc clearance, and considered those patients with high clearance values but normal serum zinc concentrations to have marginal zinc deficiency.[2]

2. Kaji M, *et al.* Studies to determine the usefulness of the zinc clearance test to diagnose marginal zinc deficiency and the effects of oral zinc supplementation for short children. *J Am Coll Nutr* 1998; **17:** 388–91.

DIARRHOEA. Chronic diarrhoea can be a sign of zinc deficiency, and diarrhoea can lead to excessive zinc losses and zinc deficiency when dietary zinc is inadequate. Zinc supplements have been shown to reduce the incidence, intensity, or duration of acute diarrhoea (p.1694) in children in developing countries.[1-5] Beneficial effects have also been seen with zinc supplementation for persistent diarrhoea.[4,5] A WHO report concluded that zinc supplementation at a dose of about 10 to 20 mg daily for 14 days is efficacious in significantly reducing the severity and duration of diarrhoea; the type of zinc salt does not appear to influence efficacy, although the best formulation should be determined to minimise adverse effects such as vomiting.[6] A further report[7] concluded that there was sufficient evidence to recommend the inclusion of zinc as adjunctive therapy to oral rehydration salts in the standard management of both dysenteric and non-dysenteric acute diarrhoea.

For a report of increased efficacy in reducing persistent diarrhoea and dysentery when zinc is used with vitamin A, see Diarrhoea, under Deficiency states, p.1973. For suggestions that zinc potentiates the effect of vitamin A, see Vitamin A deficiency, below.

GROWTH RETARDATION. Growth retardation in a group of short Japanese children without endocrine abnormalities was found to be associated with mild to moderate zinc deficiency; supplementation with oral zinc sulfate 5 mg/kg daily over 6 months resulted in an improvement in growth velocity despite unchanged growth hormone production.[1] Similarly, supplementation with 10 mg zinc daily for 6 days of each week, for 6 months, increased the growth rate of stunted Ethiopian infants; weight also increased in both stunted and non-stunted children, and the authors commented that these effects were at least partly due to improvements in appetite, and reduced morbidity from infection.[2] Results from a meta-analysis of these 2 studies and 31 others indicated that zinc supplementation resulted in a highly significant increase in both linear growth and weight gain of prepubertal children; weight-for-height index was not affected. Significant increases in serum zinc concentrations were also noted with supplementation, but additional studies were considered necessary in order to determine whether mean serum zinc concentration could accurately predict response to supplementation.[3]

PNEUMONIA. A pooled analysis[1] of 10 studies performed in developing countries found that zinc supplementation reduced the incidence of pneumonia in children by 41%. A randomised study in Bangladesh, in 270 children aged 2 to 23 months, found that 20 mg daily of elemental zinc, given by mouth and adjuvant to standard antimicrobial therapy, accelerated recovery from pneumonia when compared with placebo; children aged 12 months or older resolved their respiratory illness earlier than younger infants.[2] Another study in Bangladesh[3], involving 1621 children 2 to 12 months old, found that prophylaxis with 70 mg of oral zinc acetate [about 20 mg of zinc] given weekly reduced the incidence of pneumonia compared with placebo and also reduced subsequent pneumonia-related mortality; a small reduction in the incidence of diarrhoea was also seen.

PREGNANCY. Zinc requirements are increased in pregnancy. Although it is unclear to what extent this has clinical consequences, some have suggested that supplementation with modest doses of zinc (less than 45 mg daily) during pregnancy may have beneficial effects on fetal growth and development, and lead to improved pregnancy outcomes.[1] A controlled study in Peru found that addition of oral zinc (25 mg of zinc daily as zinc sulfate) to iron and folate supplementation improved fetal bone growth, as measured by femur length.[2] A systematic review[3] concluded that, while zinc supplementation during pregnancy appears to reduce preterm delivery, there was no convincing evidence that it resulted in other useful benefits. Since the association with preterm birth might reflect poor nutrition, improvement in the overall nutritional status of impoverished populations would be more beneficial than zinc supplementation in isolation.

TASTE DISORDERS. Zinc appears to be effective for the treatment of taste disturbances (p.977) associated with zinc deficiency but there is insufficient evidence to determine its efficacy for taste dysfunction secondary to conditions that do not involve low serum zinc concentrations.[1] Zinc picolinate was found to significantly improve objective measurement of taste when compared with placebo, both in patients with zinc deficiency and in those with idiopathic taste disorders (and normal serum zinc concentrations); there were no differences in subjective assessment of taste.[2] A later study[3] also found oral zinc gluconate 140 mg daily [about 20 mg of zinc] to be of benefit in idiopathic dysgeusia.

Vitamin A deficiency. It has been proposed[1] that the inconsistent effects on morbidity of vitamin A supplementation (see Diarrhoea, under Deficiency States, p.1973) may be due to co-existing micronutrient deficiencies, such as zinc deficiency, that affect the bioavailability of vitamin A. The authors found combined zinc and vitamin A supplementation to be more effective in reducing persistent diarrhoea and dysentery than either zinc or vitamin A alone. There is also some suggestion that zinc may potentiate the effects of vitamin A in the treatment of night blindness,[2] but only in those patients already deficient in zinc. A study in Bangladesh[3] found that the proportional improvement in vitamin A status in vitamin A-deficient children was larger in those given zinc with vitamin A than in those given vitamin A or zinc alone, suggesting a synergistic effect. Similarly, a study in Indonesia[4] of supplementation in pregnant women found that betacarotene with zinc, but not betacarotene or zinc alone, improved vitamin A status in both mothers and infants at 6 months postpartum; the authors suggested that zinc may have a specific role in the conversion of betacarotene to retinol.

Obstetric Drugs

Obstetric Drug Groups, p.2002
Ergot alkaloids, p.2002
Oxytocics, p.2002
Prostaglandins, p.2002
Tocolytics, p.2002
Management of Obstetric Conditions, p.2002
Labour induction and augmentation, p.2002
Lactation inhibition and induction, p.2003
Postpartum haemorrhage, p.2003
Premature labour, p.2003
Termination of pregnancy, p.2004

This chapter includes a number of drugs used in obstetrics for the management of labour and postpartum haemorrhage, including various prostaglandins, oxytocics, ergot alkaloids, and tocolytics. Some of these drugs have also been used to terminate pregnancy, as has the antiprogestogen mifepristone (p.2011).

Other drugs with important roles in obstetric management to be found elsewhere in *Martindale* include local anaesthetics (p.1850), opioid analgesics (p.101), and medical gases such as oxygen (p.1690) and nitrous oxide (p.1789). For drugs used in the management of perinatal bacterial infection, see Antibacterials (p.158).

Obstetric Drug Groups

Ergot alkaloids

Some ergot alkaloids have a powerful action on the uterus, causing uterine contractions that are utilised in the active management of the third stage of labour, and to prevent or treat postpartum and postabortal haemorrhage.

Described in this chapter are

Ergometrine, p.2009	Ergotoxine, p.2010
Ergot, p.2010	Methylergometrine, p.2011

Oxytocics

Oxytocics cause contraction of the uterus and may be used for the induction and augmentation of labour, in the management of the third stage of labour, and to prevent and treat postpartum haemorrhage.

Described in this chapter are

Carbetocin, p.2005	Oxytocin, p.2015
Demoxytocin, p.2006	

Prostaglandins

Some prostaglandins soften and dilate the cervix and induce contraction of the uterus. They may be used in labour induction, termination of pregnancy, and the treatment of postpartum haemorrhage.

Described in this chapter are

Carboprost, p.2006	Meteneprost, p.2010
Dinoprost, p.2006	Misoprostol, p.2013
Dinoprostone, p.2007	Sulprostone, p.2018
Gemeprost, p.2010	

Tocolytics

Tocolytics inhibit uterine contractions and are used in premature labour to delay early delivery. Beta agonists other than ritodrine have also been used, and details on salbutamol (p.1131) and terbutaline (p.1138) can be found in the chapter on Bronchodilators and Anti-asthma Drugs. Other drugs that have been tried for their tocolytic actions include calcium-channel blockers (see Nifedipine, p.1350), glyceryl trinitrate (p.1296), magnesium sulfate (p.1679), and NSAIDs (see Indometacin, p.66).

Described in this chapter are

Atosiban, p.2005	Ritodrine, p.2017

Management of Obstetric Conditions

The management of some obstetric conditions is discussed below.

Labour induction and augmentation

The uterus is normally spontaneously contractile but during pregnancy various physiological mechanisms maintain it in a quiescent state; retention of the fetus is also aided by a firm and contracted cervix. During the final 4 to 5 weeks of pregnancy the cervix normally undergoes a 'ripening' process in which it becomes softened and dilated, so that at parturition it is not a barrier to delivery of the fetus. Endogenous prostaglandins play an important role in this process, and also sensitise the uterus in preparation for labour.

- Labour usually begins spontaneously but in some cases it may be necessary to induce labour, for example in pregnancies that go beyond term or where rupture of the membranes occurs without labour. In other cases there may be indications for early delivery such as maternal hypertensive states, antepartum haemorrhage, intra-amniotic infection (chorioamnionitis), or intra-uterine fetal death.[1,2]
- Once labour has started, augmentation of uterine activity may be necessary if contractions fail to progress satisfactorily. A process of active management of labour, including early oxytocin augmentation, has been used in nulliparous women with a single fetus presenting head-first at term and showing no evidence of fetal compromise. Although it may shorten labour without increasing maternal or neonatal harm, it has not been shown to reduce the rate of caesarean section.[3]

Various techniques are available for **induction of labour**, and the choice may be influenced by the ripeness of the cervix and whether the membranes are intact or have ruptured. Mechanical methods are commonly used and may be all that is needed to induce labour. UK guidelines suggest that sweeping of the membranes (manually separating the lower membrane portion from the uterine wall during vaginal examination) should be offered to women at term. It increases the likelihood of spontaneous labour within 48 hours and birth within one week, and reduces the frequency of formal induction of labour.[4] However, it may cause maternal discomfort, irregular contractions, and bleeding.[5] Laminaria tents or hygroscopic cervical dilators may be used to stimulate cervical ripening.[1] Amniotomy (deliberate rupture of the membranes and release of amniotic fluid) may also be used to stimulate labour, once the cervix becomes favourable.[2] When pharmacological induction of labour is required, a prostaglandin or oxytocin is generally used. UK guidelines[4] suggest that, regardless of cervical status, prostaglandins are preferred to oxytocin in all women with intact membranes, but either may be used in women who have ruptured membranes as neither method then offers any particular advantage. However, others[1,2,6] suggest that a ripened cervix improves the chance of successful labour induction, and WHO[7] recommends oxytocin alone if the cervix is favourable but that a prostaglandin or a mechanical method (Foley catheter) should be used to ripen an unfavourable cervix before induction.

As prostaglandins can both ripen the cervix and initiate uterine activity, they induce labour that is similar to spontaneous labour.[1] Overall, compared with oxytocin, prostaglandins seem to improve the rate of successful vaginal delivery, lower the rate of caesarean section, reduce the need for epidural analgesia, and be associated with improved maternal satisfaction.[4] The intravenous and oral routes have been associated with frequent adverse, particularly gastrointestinal, effects[8,9] and intravaginal dosage is now preferred. The intracervical route is no more effective than the intravaginal route, and is no longer recommended.[4] Dinoprostone (prostaglandin E_2) is the most widely used prostaglandin and has been given by various routes. It is usually given intravaginally as gel, vaginal tablets, or pessaries, and a systematic review[10] considered the clinical benefits equivalent; UK guidelines favour use of vaginal tablets.[4]

Whenever possible, amniotomy should be performed in women with intact membranes before giving oxytocin.[4] If vaginal prostaglandins have already been given, usually to ripen the cervix,[2,7] oxytocin should not be started for at least 6 hours.[4] Oxytocin is given by slow intravenous infusion, adjusted according to response.[2,7] Various dosage regimens have been tried, and studies have reported using initial doses ranging from 0.5 to 6 milliunits/minute, dose increases of 1 to 6 milliunits/minute, and intervals between increases of 15 to 40 minutes.[1] Higher doses and shorter intervals between increases can shorten labour and reduce rates of intra-amniotic infection and caesarean delivery, but cause more uterine hyperstimulation.[1] Low-dose regimens are now generally advocated.[1,4,7] There has been some interest in pulsed administration of oxytocin for induction to mimic the pulsatile secretion of endogenous oxytocin that occurs during spontaneous labour, but such use has not been established.[1]

Misoprostol has also been investigated.[1,6,11] Most studies have used the intravaginal route and have suggested it may be more effective than standard methods of labour induction.[12] Oral misoprostol may have a similar efficacy to intravaginal use.[13] However, the risk of uterine hyperstimulation may be increased with misoprostol and there is as yet insufficient evidence of its safety to recommend routine use.

The antiprogestogen mifepristone also produces cervical dilatation and stimulates uterine contraction and has been tried for cervical ripening and for induction of labour. A systematic review of studies found that it may be effective, but its place in therapy has yet to be established.[14]

In pregnancies at term, premature rupture of the fetal membranes may be treated with early induction of labour or expectant management (waiting for labour to occur naturally, which will start within 24 hours in most women[15]). There have been concerns that prolonged rupture of membranes may result in higher rates of maternal and neonatal infection, but that induction may result in more caesarean deliveries.[11] A systematic review[15] of studies in women with premature rupture of membranes at 37 weeks or later, comparing induction (oxytocin infusion or intravaginal dinoprostone) with expectant management found no difference in rates of caesarean section or instrumental vaginal births. There were lower rates of chorioamnionitis and endometritis in women treated with induction. In neonates, there was no difference in infection rate, but fewer admissions to the intensive care unit after oxytocin use. Women were also more satisfied with induction than expectant management. Oral and vaginal misoprostol have also been investigated in this group, and may have a similar efficacy to oxytocin and dinoprostone.[11]

Labour augmentation may be started when labour is abnormally slow (dystocia) due to atony. Oxytocin is generally used, in similar doses to those for induction.[7] As for induction, both high- and low-dose regimens have been described, with higher doses reducing the duration of labour and rate of caesarean deliveries, but causing more hyperstimulation.[3] Augmentation using oxytocin results in normal vaginal delivery in about half of all women treated.[16]

Intravaginal dinoprostone has also been used for augmentation of labour. A placebo-controlled study[17] in women with slow cervical dilatation found doses of 1 or 2 mg to be effective for improving cervical dilatation and reducing the time to delivery; women given the higher dose were less likely to require oxytocin augmentation after 6 hours, but were at greater risk of hyperstimulation.

Once delivery has successfully been initiated, management of the third stage of labour may be considered to reduce the risks of postpartum haemorrhage (see below).

Lactation inhibition and induction

Lactation is the physiological secretion of milk post partum. Milk production by the breast is induced by prolactin while oxytocin promotes milk ejection into the milk ducts; both prolactin and oxytocin secretion are stimulated by suckling.

Lactation inhibition. The breast engorgement with consequent discomfort and galactorrhoea triggered by prolactin secretion post partum can be problematic in women who choose not to breast feed or are unable to do so. Nonsteroidal or synthetic oestrogens were historically used to suppress lactation in such women, but this use is now considered inappropriate because of an increased risk of thromboembolism. Bromocriptine is a potent inhibitor of prolactin secretion: it has been given post partum in short treatment courses (about 14 days) to suppress lactation. However, it has also been associated with severe adverse effects, and its use for lactation suppression is no longer advocated in a number of countries. Other dopaminergics with similar actions such as cabergoline, lisuride, metergoline, and quinagolide have also been used to suppress lactation. Although it has been suggested that cabergoline, which is generally better tolerated than bromocriptine, may be a better choice for lactation inhibition,[1] the same general objections as for bromocriptine apply to all these drugs. A study in HIV-infected women requiring lactation suppression (in order to prevent mother-to-child transmission from breast milk) found that a combined oral contraceptive was as effective as bromocriptine.[2] Non-pharmacological methods include warm showers to induce milk leakage and reduce pressure, ice packs to reduce local pain and swelling, and a well fitting supportive brassiere. The removal of just enough milk to reduce the pressure but not enough to empty the breasts may help to reduce milk production gradually. Active treatments including mild analgesics such as ibuprofen or paracetamol are also advocated.[3] However, a review[4] noted that few non-pharmacological methods were well evaluated, and that mild analgesia might not be enough to prevent the considerable pain experienced by many women.

Lactation induction. Drug therapy has sometimes been used to help stimulate lactation, although mechanical stimulation of the nipple remains the primary method.[5] Dopamine antagonists, of which metoclopramide has been the most widely used, can produce modest increases in breast milk production but carry a risk of adverse effects including dystonias. If used, such therapy should be limited to 1 or 2 weeks; there has also been some concern about the presence of these drugs in breast milk.[5,6] The efficacy of metoclopramide in stimulating lactation in women with preterm deliveries has been questioned by a controlled study.[7] Domperidone has also been reported to increase milk production,[6,8] and may cause fewer adverse central effects than metoclopramide. Nevertheless, the FDA has warned against the use of domperidone because of the potential risks of adverse effects in both mother and infant.[9] Protirelin has been given intranasally to stimulate lactation by increasing serum prolactin concentrations, but is expensive, and a suitable commercial preparation is unavailable.[5] Although oxytocin nasal spray has been tried to promote milk ejection, a double-blind, placebo-controlled study[10] of women expressing milk for preterm infants found that although milk production increased marginally in the first 2 days with oxytocin, there was no difference overall after 5 days. Most mothers also believed that they were receiving the active spray suggesting a significant placebo effect. Others[5] warn that its use may interfere with the mother's ability to learn to eject milk naturally, resulting in some becoming dependent upon its action.

Postpartum haemorrhage

If the uterus fails to contract adequately after delivery (uterine atony), or if retained placental remnants prevent retraction of the placental bed, postpartum haemorrhage may occur. These two causes account for about 80% of cases of postpartum haemorrhage; in the remainder it is usually due to trauma of the genital tract or coagulopathy. *Primary postpartum haemorrhage* has traditionally been defined as vaginal bleeding of more than 500 mL within 24 hours after childbirth. However, the volume of blood loss is often underestimated and the ability of a woman to cope with blood loss may be affected by her previous health, anaemia, and hypovolaemia.[1-3]

Postpartum haemorrhage may be fatal to the mother unless promptly dealt with, and **management** generally involves:

- removal of the placenta if it has not been expelled
- the use of oxytocics to contract the uterus
- transfusion if blood loss is severe

Parenteral oxytocin, or an ergot alkaloid (ergometrine or methylergometrine), is the oxytocic generally used to control bleeding due to uterine atony,[1,2] and oxytocin infusion may be used to maintain uterine contraction.[3] Prostaglandins such as carboprost or dinoprostone may be used for primary postpartum haemorrhage[1,2] that has not been controlled by oxytocin and ergot preparations.[3] Rectal misoprostol has also been shown to be effective,[4] but a subsequent review[5] found that the original study was not large enough to evaluate the effects on maternal mortality, serious morbidity, or hysterectomy rates, and that there was insufficient evidence to support the use of misoprostol instead of a combination of oxytocin and ergometrine. However, there is considerable interest in the use of misoprostol, particularly for developing countries, because of its better stability and ease of administration;[3] further research has been encouraged.[6,7] Surgery may be required if medical management does not control bleeding.[2,3]

Secondary postpartum haemorrhage occurs between 24 hours and 12 weeks after delivery and although associated with maternal morbidity rather than death in developed countries, it is a major contributor to maternal death in developing countries. Antibacterials, oxytocics, hormone therapy, and a variety of surgical treatments are used,[1,2,8] but a systematic review[8] concluded that evidence for the best treatment is lacking.

Risk factors for postpartum haemorrhage include prolonged labour, augmented labour, overdistended uterus (for example in multiple pregnancy), and a history of postpartum haemorrhage.[2] However, atonic postpartum haemorrhage occurs in many women without identifiable risk factors, and authorities recommend that **prophylaxis** should be offered to all women during childbirth.[9,10] *Active management of the third stage of labour* involves prophylactic use of an oxytocic, cord clamping before placental delivery, controlled cord traction, and uterine massage after delivery of the placenta.

The routine use of active management, with oxytocics usually given after delivery of the anterior shoulder or immediately after delivery of the baby, reduces blood loss, the risk of postpartum haemorrhage, and the risk of prolonged third stage of labour.[11] However, despite the widespread use of oxytocics there is limited evidence of high quality comparing different drugs. Oxytocin[12] and ergot alkaloids[13] (usually ergometrine) can both reduce postpartum blood loss and appear to be equally effective,[12] while the fixed combination *Syntometrine* (oxytocin and ergometrine) may be more effective than oxytocin alone in reducing the risk of moderate postpartum haemorrhage (500 to 1000 mL).[14] However, ergot alkaloids and *Syntometrine* cause more adverse effects than oxytocin, particularly nausea, vomiting, and raised blood pressure.[12,14] Although the quality of evidence is low, WHO recommends that oxytocin is generally preferred for prevention of postpartum haemorrhage; an ergot alkaloid (ergometrine or methylergometrine) or *Syntometrine* may be used if oxytocin is not available.[10]

Prostaglandins have also been investigated as an alternative for the routine management of the third stage of labour, and there has been particular interest in misoprostol. Although oral or sublingual misoprostol may reduce the risk of severe postpartum haemorrhage (more than 1000 mL), it is less effective than conventional injectable oxytocics.[15] Data on other prostaglandins are scarce.[15] Based on these findings, a systematic review[15] has suggested that prostaglandins are not preferrable to oxytocin, but that misoprostol may be used where no injectable oxytocic is available. Others have also argued that although misoprostol may be less effective, it would still be useful in developing countries where there are no alternatives,[16] and some authorities include misoprostol as an option when other oxytocics are not available or the birth attendant's skills are limited.[7,9,10]

Where a skilled attendant is not available to provide active management, an appropriately trained healthcare worker may give oxytocin or misoprostol alone for the prevention of postpartum haemorrhage.[10]

Premature labour

Premature labour (preterm labour) is the onset of labour before the expected date, resulting in delivery of an immature infant. Conventionally the definition includes women giving birth before 37 weeks of gestation but in practice most problems arise with births before 32 to 34 weeks.[1-3] Risk factors for premature labour include infection, premature rupture of the membranes, cervical incompetence, and multiple pregnancy. There are few proven measures to *prevent premature labour*, but cervical cerclage (temporary surgical closure of the cervix) may be used for cervical incompetence,[4] and treatment of infections is being investigated.[5] In women with premature rupture of the membranes who have not gone into spontaneous labour there is some evidence that antibacterial therapy may be effective in delaying delivery and improving outcomes (see Premature Labour, p.188). The value of prophylactic tocolysis, using drugs to prevent the onset of uterine contractions, is unclear[6,7] and such therapy is not recommended.[8] In women who have a history of spontaneous premature delivery, there is some evidence to suggest that a prophylactic progestogen such as hydroxyprogesterone caproate may reduce the risk for premature delivery in subsequent pregnancies.[9,10]

A diagnosis of premature labour is not always easy to make and evidence of cervical change should usually be present in addition to uterine activity.[2,3,11] Once a diagnosis has been established, a decision must be made as to whether to postpone delivery by *acute tocolysis*, using drugs that inhibit uterine contractions. It may not be considered appropriate to stop labour in some women. However, in patients of about 24 to 34 weeks of gestation without complications, attempts to postpone delivery are usually worth trying, if only in the short-term, to allow emergency treatment such as corticosteroids to be given to the mother to enhance the maturation of the fetal respiratory system (see Neonatal Respiratory Distress Syndrome, p.1508) and to enable the patient to be transferred to a specialised unit for preterm delivery.[1-3,11] In the presence of ruptured membranes, tocolysis is rarely considered necessary after this time (some recommend 32 weeks of gestation[2] while others recommend 36 weeks[3]).

- The commonest tocolytics have historically been the beta-adrenoceptor agonists, which relax the smooth muscle of the uterus by stimulation of beta$_2$-adrenoceptors.[12] Nonselective agonists, for example orciprenaline and isoxsuprine, have been replaced by more selective beta$_2$ agonists such as ritodrine, salbutamol, and terbutaline. These can postpone labour for a few days[13,14] and the preferred route for starting treatment is subcutaneous or intravenous infusion.[12] Oral or subcutaneous maintenance therapy with beta$_2$ agonists after successful treatment of an episode of acute premature labour produces no further benefit[15,16] (see also Maintenance Therapy, below). There is little evidence that beta$_2$ agonists significantly reduce perinatal mortality rates.[17] The patient may experience adverse cardiovascular and metabolic effects and, in particular, pulmonary oedema has been reported in some women given beta$_2$ agonists intravenously to suppress labour (see p.1132). It is therefore essential that the patient's heart rate and state of hydration are carefully monitored throughout infusion. In the event of caesarean section beta blockers may be needed to combat an increased tendency to uterine bleeding.
- More recently, calcium-channel blockers have been shown to be effective tocolytics, presumably by their action on myometrial calcium.[12] Most experience concerns nifedipine, which has been reported to be at least as effective as, and possibly better than, beta$_2$ agonists or magnesium in delaying labour,[18-20] although a systematic review[21] considered the quality of many of the studies reporting efficacy to be poor. It has the advantage that it can be given orally,[12] and some favour its use as a first-line drug,[1,19] although it is not licensed in the UK for this use. Nicardipine has also produced favourable results.[22] Others have expressed concern about the safety of calcium-channel blockers,[23] and some suggest that they should be used with caution.[2,3]
- Atosiban is a peptide analogue of oxytocin with oxytocin antagonist properties. A pooled analysis[24] of three controlled studies, and a systematic review,[25] found atosiban to be as effective as beta agonists in the management of premature labour, with fewer maternal cardiovascular adverse effects. These findings were supported by a large open-label study[26] of women treated with atosiban or usual care (usually a beta agonist). Some clinicians favour atosiban as a first-line tocolytic in preference to the traditional drugs.[1-3]
- In the USA, magnesium sulfate is the most widely used parenteral tocolytic, and is thought to act by calcium antagonism at the neuromuscular junction.[12] Although it has been generally considered to be as effective as the beta$_2$ agonists,[12] a systematic review[27] concluded that it was ineffective at delaying birth or preventing preterm birth, and it has been suggested that tocolytic use of magnesium may be associated with increased paediatric mortality—see p.1681. To decrease the risk of overdose, magnesium sulfate should only be given from a controlled pump.[12] Oral magnesium has been tried but has not been shown to be effective.[12] Although magnesium sulfate is widely used, the American College of Obstetricians and Gynecologists does not promote it (or any drug) for first-line tocolysis.[11] It is not recommended in Europe,[3] and some in the USA have called for such use to be stopped.[28,29]
- Prostaglandins have a role in the induction of labour as mediators of uterine contractions and cervical softening and dilatation. Cyclo-oxygenase (prostaglandin synthetase) inhibitors, particularly indometacin, have therefore been given orally or rectally to inhibit premature labour.[12,30] Although this treatment may be as effective as ritodrine,[31,32] adverse effects on the fetus have been reported, such as oligohydramnios, intraventricular haemorrhage, necrotising enterocolitis, and oliguria.[30] The most widely reported complication has been constriction of the fetal ductus arteriosus; pulmonary vascular hypertrophy can develop after prolonged constriction. Sensitivity of the ductus arteriosus appears to increase with gestational age, and indometacin therapy should therefore be limited to gestations of less than 32 weeks. If therapy is to continue for longer than 72 hours, the ductus arteriosus should be monitored for evidence of constriction. An increased incidence of persistent patent ductus arteriosus in the newborn has also been reported after indometacin tocolysis, although an association has been questioned.[30] A systematic review[33] of observational and randomised studies found no significant increase overall in the risk of neonatal complications in infants who had been exposed to indometacin tocolysis compared with infants who had not. However, the data had limited statistical power and the review was unable to exclude the possibility that indometacin may increase the risk of adverse neonatal outcomes. The evidence for efficacy of cyclo-oxygenase inhibitors is based on small studies,[34] and because of the potential for adverse effects, indometacin is generally reserved as a second-line drug or given with other tocolytics for an additive effect.[12] More recently it has been suggested that the enzyme isoform cyclo-oxygenase-2 is associated with labour, while cyclo-oxygenase-1 is responsible for constant prostaglandin synthesis in body tissues. The role of cyclo-oxygenase-2 inhibitors in the treatment or prevention of premature labour remains investigational.
- Other drugs are under investigation. Application of patches of the nitric oxide donor glyceryl trinitrate to the abdomen to produce uterine relaxation was reported to be as effective as ritodrine treatment.[35] However, another study[36] found transdermal glyceryl trinitrate to be less effective than beta agonists, and a systematic review[37] concluded that there was insufficient evidence to support its routine use.

When acute tocolysis has successfully suppressed uterine activity, the use of *maintenance therapy* has been tried to prevent recurrent episodes of premature labour. However, a systematic review[38] found that although there was a small but significant increase in the number of days gained before delivery, maintenance therapy did not reduce the incidence of premature birth or recurrent premature labour; there was also a non-significant trend towards an increase in adverse perinatal outcomes. Maintenance therapy is not recommended for routine use.[1,3,11]

Termination of pregnancy

Termination of pregnancy can be achieved medically or surgically. Uterine aspiration is a common method used for *surgical termination*; before 13 weeks of pregnancy it is usually termed suction or vacuum curettage, and after 13 weeks as dilatation and evacuation.[1] Cervical dilatation becomes increasingly necessary as gestation progresses and has been recommended for all pregnancies of more than 10 weeks, for pregnancies over 9 weeks in nulliparous women, and for all women younger than 18 years of age.[2,3] It may be achieved by using mechanical dilators, laminaria or synthetic hygroscopic dilators,[1,3] mifepristone, or a prostaglandin such as gemeprost or misoprostol.[1-3] Various drugs, used alone and in combination, have been tried for *medical termination* of pregnancy. Prostaglandins ripen the cervix and stimulate uterine contractility. They can bring about successful termination when used alone, but the high doses required can cause significant adverse effects.[4-6] The most commonly used prostaglandins are gemeprost and misoprostol;[3,4] others that have been used include carboprost and sulprostone, but these have been associated with more severe adverse effects.[3] The antiprogestogen mifepristone also ripens the cervix and stimulates uterine contractility; in addition, it increases the sensitivity of the myometrium to prostaglandins with a maximum effect about 24 to 48 hours after dosing. Mifepristone is not sufficiently effective to be used as an abortifacient on its own, but is used synergistically with a prostaglandin, usually gemeprost or misoprostol, to achieve expulsion of the uterine contents.[3-5,7] The antimetabolite methotrexate has also been used with misoprostol, but it has a delayed effect and the time from induction to abortion can be several days or weeks.[4,5] Other methods that have been used for termination of pregnancy, particularly in the second trimester, include intra-amniotic use of dinoprost, hypertonic sodium chloride, or hyperosmolar urea augmented with oxytocin, carboprost, or dinoprost.[1]

Uterine cramping and bleeding are associated with both surgical and medical termination processes. Surgical termination may be carried out under conscious sedation,[1,2] local anaesthesia using paracervical block,[1-3] or general anaesthesia.[2] Analgesia requirements in medical termination may be higher in younger women, nulliparous women, and those with longer gestations.[3,4] Analgesics such as paracetamol, NSAIDs, and codeine are commonly used.[6] Generally, bleeding lasts longer after medical termination than after vacuum aspiration.[6] With medical termination using mifepristone plus a prostaglandin, bleeding is initially heavy but gradually diminishes over about 2 weeks, although minor bleeding can continue for longer.[1,6]

Factors influencing the choice of method for termination include the stage of gestation, availability of surgical services and abortifacient drugs, and the woman's preference. The most common approaches are outlined below.

- In the early first trimester (up to 49 days) a medical method, using mifepristone followed by a prostaglandin, is preferred because the failure rate is higher with vacuum aspiration.[2,6] Methotrexate followed by a prostaglandin is an alternative at this early stage,[1,5] but expulsion can take several days or weeks.[4] Either a surgical or medical method can be used between 49 and 63 days of gestation. However, oral misoprostol for medical termination becomes less effective as gestation progresses[4,5] so a vaginal prostaglandin is preferred.[2,5,6]
- In the late first trimester (up to 13 weeks) a surgical or medical method may be used. After 9 or 10 weeks of gestation, cervical preparation is used before surgical procedures and multiple doses of prostaglandin may be needed to achieve medical termination.[2]
- In mid-trimester termination (13 to 24 weeks) a surgical or medical method may be used. Cervical preparation is essential before surgical termination and multiple doses of prostaglandin will generally be required for medical termination.[2,3]

Some of the methods used for termination of pregnancy are also used to hasten miscarriage after pregnancy failure or early fetal death. Surgical evacuation is effective but associated with a higher risk of infection than expectant management.[8] Vaginal misoprostol can also hasten miscarriage, but oral use is less effective.[9] For the management of intra-uterine fetal death in later pregnancy, see Labour Induction and Augmentation, above.

Aglepristone *(rINN)*

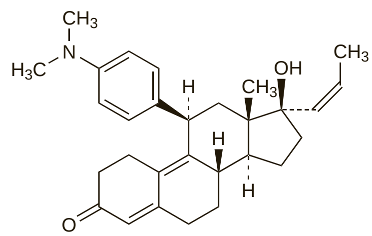
Aglepristona; Aglépristone; Aglepristonum; RU-46534. 11β-[*p*-(Dimethylamino)phenyl]-17β-hydroxy-17-[(*Z*)-propenyl]estra-4,9-dien-3-one.

Аглепристон

$C_{29}H_{37}NO_2$ = 431.6.

CAS — 124478-60-0.

ATC Vet — QG03XB90.



Profile

Aglepristone has antiprogestogenic activity and is used in veterinary medicine as an abortifacient in *dogs*.

Atosiban *(BAN, USAN, rINN)*

Atosibaani; Atosibanum; ORF-22164; RWJ-22164. 1-(3-Mercaptopropionic acid)-2-[3-(*p*-ethoxyphenyl)-D-alanine]-4-L-threonine-8-L-ornithineoxytocin; [1-(3-Sulfanylpropanoyl),2-(4-*O*-ethyltyrosine),4-L-threonine-8-L-ornithine]oxytocin.

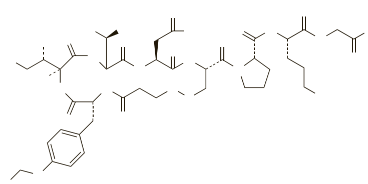
Атозибан

$C_{43}H_{67}N_{11}O_{12}S_2$ = 994.2.

CAS — 90779-69-4.

ATC — G02CX01.

ATC Vet — QG02CX01.



Adverse Effects and Precautions

Adverse effects reported in women receiving atosiban for premature labour include nausea and vomiting, headache, dizziness, flushes, tachycardia, hypotension, hyperglycaemia, and injection site reactions. Atosiban should not be used where continuation of pregnancy is hazardous to mother or fetus, including where gestational age is below 24 or over 33 weeks, in eclampsia or severe pre-eclampsia, intra-uterine growth retardation and abnormal fetal heart rate, suspected intra-uterine infection, placenta praevia, or abruptio placentae. Monitoring of uterine contractions and fetal heart rate is recommended during use, and blood loss should be monitored after delivery.

Although there has been some concern about fetal exposure, licensed product information states that no specific adverse effects on the newborn have been reported.

Pharmacokinetics

In women in premature labour, atosiban reaches steady-state plasma concentrations within one hour of the start of infusion, and has a terminal half-life of 1.7 hours after stopping infusion. Atosiban is 46 to 48% bound to plasma proteins, and crosses the placenta. It is metabolised to an active metabolite, which is excreted in the urine; both atosiban and this metabolite are distributed into breast milk.

Uses and Administration

Atosiban is a peptide analogue of oxytocin (p.2015) but with oxytocin antagonist properties. It is used as a tocolytic in the management of premature labour (p.2003). Atosiban is given intravenously as the acetate, but doses are expressed in terms of the base. An initial bolus dose equivalent to atosiban 6.75 mg is given by intravenous injection (as a solution containing 7.5 mg/mL) over one minute. This is immediately followed by a continuous infusion of 300 micrograms/minute for 3 hours, then 100 micrograms/minute for up to 45 hours, as a solution containing 750 micrograms/mL. The total duration of treatment should not exceed 48 hours, and the total dose should not exceed 330 mg.

Carbetocin *(BAN, rINN)*

Carbetocina; Carbétocine; Carbetocinum; Karbetocin; Karbetosiini. 2,1-Desamino-4,1-desthio-$O^{4,2}$-methyl[1-homocysteine]-oxytocin; 1-Butyric acid-2-[3-(*p*-methoxyphenyl)-L-alanine]oxytocin.

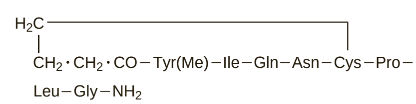
Карбетоцин

$C_{45}H_{69}N_{11}O_{12}S$ = 988.2.

CAS — 37025-55-1.

ATC — H01BB03.

ATC Vet — QH01BB03.



Adverse Effects and Precautions

Carbetocin has similar adverse effects and precautions to those associated with oxytocin when it is used after caesarean section (see p.2015). However, carbetocin should not be used at any stage of labour before delivery of the infant because its effects on the uterus last for several hours.

Breast feeding. In 5 women who were 7 to 14 weeks postpartum, carbetocin was measured in the breast milk within 90 minutes of a single 70-microgram intramuscular dose.[1] The ratio of milk to plasma concentrations was low, suggesting that very little carbetocin was distributed into breast milk. Licensed UK product information states that no significant effects on milk ejection were reported during clinical studies, and that any carbetocin ingested by a breast-fed infant would probably be degraded by enzymes in the gastrointestinal tract. The American Academy of Pediatrics considers that the use of carbetocin is usually compatible with breast feeding.[2]

2. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 30/06/08)

Interactions

Although reports are lacking, carbetocin may be involved in similar interactions to those that can occur with oxytocin (p.2016).

Pharmacokinetics

After intravenous injection of carbetocin, firm uterine contraction occurs within 2 minutes and lasts for several hours. Carbetocin undergoes a biphasic elimination, with a terminal elimination half-life of about 40 minutes. Less than 1% of a dose is excreted unchanged by the kidney. Carbetocin is distributed into breast milk.

Uses and Administration

Carbetocin is a synthetic analogue of oxytocin (p.2016) reported to have a longer duration of action. For the prevention of uterine atony and excessive bleeding after caesarean section under epidural or spinal anaesthesia, a single dose of 100 micrograms may be given by slow intravenous injection over 1 minute. Carbetocin must only be given after delivery of the infant, preferably before removal of the placenta.

ATC — G02AD04.
ATC Vet — QG02AD04.

Description. Carboprost trometamol is a compound of carboprost with trometamol in a ratio of 1:1.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Carboprost Trometamol). A white or almost white powder. Soluble in water. Store at a temperature below −15°.

USP 31 (Carboprost Tromethamine). A white to off-white powder. Soluble in water. Store at −25° to −10°.

Adverse Effects and Precautions

As for Dinoprostone, p.2007.

Carboprost may cause bronchospasm and, less frequently, dyspnoea and pulmonary oedema. Patients with cardiopulmonary disorders should be monitored for reductions in arterial-oxygen content.

Once a prostaglandin has been given to terminate pregnancy it is essential that termination take place; if the prostaglandin is unsuccessful other measures should be used.

Effects on the fetus. Congenital abnormalities have been reported in pregnancies carried to term after failed termination using prostaglandins, including carboprost (see under Dinoprostone, p.2007).

Effects on the neonate. For a report of inadvertent intramuscular administration of carboprost to a neonate, see under Dinoprostone, p.2007.

Effects on the uterus. For reference to hyperstimulation and uterine rupture after use of prostaglandins, including carboprost, for termination of pregnancy or induction of labour, see Dinoprostone, p.2007.

Uses and Administration

Carboprost is a synthetic 15-methyl analogue of dinoprost (prostaglandin F$_{2α}$; below). It is a uterine stimulant with a more prolonged action than dinoprost; the presence of the methyl group delays inactivation by enzymic dehydrogenation.

Carboprost is used for the termination of pregnancy (p.2004) and for the treatment of refractory postpartum haemorrhage due to uterine atony (p.2003) that is not controlled by oxytocin and ergot preparations. It is usually given intramuscularly as the trometamol salt but doses are expressed in terms of carboprost. Carboprost trometamol 1.3 micrograms is equivalent to about 1 microgram of carboprost.

For the **termination** of second trimester pregnancy (between 13 and 20 weeks of gestation) the equivalent of 250 micrograms of carboprost is given by deep intramuscular injection and repeated every 1½ to 3½ hours depending on the uterine response. If necessary the dose may be increased to 500 micrograms, but the total dose given should not exceed 12 mg, and continuous use for more than 2 days is not recommended. If preferred, a test dose of 100 micrograms may be given initially. Carboprost trometamol has also been given intra-amniotically in a dose equivalent to 1 mg of carboprost over five minutes; this dose may be repeated after 24 hours if termination has not occurred and the membranes are intact. A total dose of 5 mg should not be exceeded.

Carboprost methyl given as vaginal pessaries has been tried for termination of pregnancy in the second trimester.

For the treatment of **postpartum haemorrhage** the equivalent of 250 micrograms of carboprost is given by deep intramuscular injection as the trometamol salt at intervals of about 90 minutes; the interval may be reduced if necessary, but should not be less than 15 minutes. A total dose of 2 mg should not be exceeded.

Haemorrhagic cystitis. Carboprost trometamol instilled into the bladder successfully controlled cyclophosphamide-induced haemorrhagic cystitis (p.702) in 15 of 24 bone marrow transplant patients.[1] The dose consisted of 50 mL of solutions containing 2 to 10 micrograms/mL instilled four times daily for 7 days.

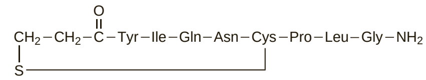
Demoxytocin *(rINN)*

Deamino-oxytocin; Demoksitosiini; Demoxitocina; Démoxytocine; Demoxytocinum; Desaminocitocina; Desamino-oxytocin; ODA-914. 1-(3-Mercaptopropionic acid)-oxytocin.

Демокситоцин

$C_{43}H_{65}N_{11}O_{12}S_2$ = 992.2.
CAS — 113-78-0.
ATC — H01BB01.
ATC Vet — QH01BB01.



Profile

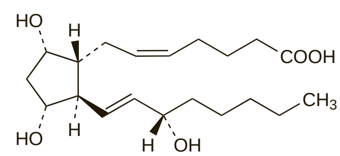
Demoxytocin is a synthetic analogue of oxytocin (p.2015) and has similar properties. It has been given as buccal tablets for the induction and augmentation of labour. It has also been given before nursing to stimulate milk ejection, although it is generally recommended that oxytocics should not be used for this purpose (see p.2003).

Dinoprost *(BAN, USAN, rINN)*

Dinoprosti; Dinoprostum; PGF$_{2α}$; Prostaglandin F$_{2α}$; U-14583. (5*Z*,13*E*)-(8*R*,9*S*,11*R*,12*R*,15*S*)-9,11,15-Trihydroxyprosta-5,13-dienoic acid; (*Z*)-7-{(1*R*,2*R*,3*R*,5*S*)-3,5-Dihydroxy-2-[(*E*)-(3*S*)-3-hydroxyoct-1-enyl]cyclopentyl}hept-5-enoic acid.

Динопрост

$C_{20}H_{34}O_5$ = 354.5.
CAS — 551-11-1.
ATC — G02AD01.
ATC Vet — QG02AD01.



NOTE. In *Martindale* the term dinoprost is used for the exogenous substance and prostaglandin F$_{2α}$ for the endogenous substance.

Pharmacopoeias. In *Jpn.*

Dinoprost Trometamol *(BANM, rINNM)*

Dinoprost trométamol; Dinoprost Tromethamine *(USAN)*; Dinoprostas trometamolis; Dinoprostitrometamoli; Dinoprost-trometamol; Dinoprost-trometamol; Dinoprostum Trometamoli; Dinoprostum trometamolum; Dinoproszt-trometamol; PGF$_{2α}$ THAM; Prostaglandin F$_{2α}$ Trometamol; U-14583E.

Динопрост Трометамол

$C_{20}H_{34}O_5,C_4H_{11}NO_3$ = 475.6.
CAS — 38562-01-5.
ATC — G02AD01.
ATC Vet — QG02AD01.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Dinoprost Trometamol). A white or almost white powder. Very soluble in water; freely soluble in alcohol; practically insoluble in acetonitrile.

USP 31 (Dinoprost Tromethamine). A white to off-white crystalline powder. Very soluble in water; slightly soluble in chloroform; freely soluble in dimethylformamide; soluble in methyl alcohol. Store in airtight containers.

Adverse Effects and Precautions

As for Dinoprostone, p.2007.

Dinoprost can cause bronchoconstriction, and bronchospasm with wheezing and dyspnoea has occurred, especially in asthmatic patients.

Once a prostaglandin has been given to terminate pregnancy it is essential that termination take place; if the prostaglandin is unsuccessful other measures should be used.

Interactions

As for Dinoprostone, p.2008. Alcohol and beta agonists may reduce the efficacy of dinoprost.

◊ For a report of a severe reaction after the use of oxytocin, methylergometrine, and dinoprost, see under Dinoprostone, p.2008.

Uses and Administration

Dinoprost is a prostaglandin of the F series (p.2374) with actions on smooth muscle; the endogenous substance is termed prostaglandin F$_{2α}$ and is rapidly metabolised in the body. It induces contraction of uterine muscle at any stage of pregnancy and is reported to act mainly as a vasoconstrictor on blood vessels and as a bronchoconstrictor on bronchial muscle.

Dinoprost is used principally for the termination of pregnancy (p.2004). It may also be used for missed abortion, hydatidiform mole, and intra-uterine fetal death. Dinoprost has also been given for the induction of labour but has a higher incidence of adverse effects than dinoprostone, and is no longer routinely recommended; more appropriate treatment is discussed on p.2002.

Dinoprost is usually given intra-amniotically for termination of pregnancy. It has been given intravenously, but with a high incidence of adverse effects. The extra-amniotic route has also been used. Dinoprost is given as the trometamol salt, but doses are described in terms of the base; 1.3 mg of dinoprost trometamol is equivalent to about 1 mg of dinoprost.

For the termination of pregnancy during the second trimester 40 mg of dinoprost is given intra-amniotically by slowly injecting 8 mL of a solution containing 5 mg/mL into the amniotic sac. A further dose of 10 to 40 mg may be given after 24 hours if the termination process has not been established or completed and the membranes are still intact. It should not be given continuously for more than 2 days.

Ileus. Ileus induced by vinca alkaloids in 3 patients with carcinoma of the lung was successfully relieved by the intravenous infusion of dinoprost 300 to 500 nanograms/kg per minute for 2 hours twice daily.[1]

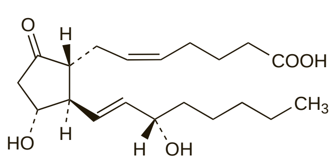
ATC — G02AD02.

ATC Vet — QG02AD02.



NOTE. In *Martindale* the term dinoprostone is used for the exogenous substance and prostaglandin E_2 for the endogenous substance.

Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Dinoprostone). A white or almost white, crystalline powder or colourless crystals. Practically insoluble in water; freely soluble in alcohol; very soluble in methyl alcohol. Store at a temperature not exceeding −15°.

USP 31 (Dinoprostone). A white to off-white, crystalline powder. Freely soluble in alcohol, in acetone, in dichloromethane, in ether, in ethyl acetate, in isopropyl alcohol, in methyl alcohol; soluble in diisopropyl ether and in toluene; practically insoluble in hexanes. Protect from light.

Adverse Effects

The incidence and severity of adverse reactions to dinoprostone are dose-related and also depend to some extent on the route; the intravenous route has been associated with a high incidence of adverse effects. Nausea, vomiting, diarrhoea, and abdominal pain are common by all routes. Back pain and rash can occur. Transient cardiovascular (vasovagal) symptoms have included flushing, shivering, headache, dizziness, and hypotension; there have been rare reports of myocardial infarction and cardiac arrest. Hypertension has also been reported. Convulsions and EEG changes have occurred rarely. Local tissue irritation and erythema, as well as pyrexia and raised white cell count, may follow intravenous doses but generally revert to normal after termination of the infusion. Transient pyrexia and raised white cell count may also occur after intravaginal use. Local infection may follow intra- or extra-amniotic therapy. Excessive uterine activity may occur and there have been occasional reports of uterine rupture after the use of prostaglandins to terminate pregnancy or induce labour; fetal distress and, rarely, fetal death have occurred during induction. Disseminated intravascular coagulation has occurred rarely.

Dinoprostone, although generally acting as a bronchodilator, may cause bronchoconstriction in some individuals. Hypersensitivity reactions have occurred.

Incidence of adverse effects. Adverse effects were evaluated in 626 patients[1] undergoing abortion (usually in the second trimester), using extra-amniotic or intra-amniotic dinoprost or dinoprostone, often with oxytocin. Vomiting occurred in 291, diarrhoea in 28, pyrexia in 34, transient hypotension (fall in systolic blood pressure of at least 20 mmHg) in 25, transient bronchospasm in 2 patients given extra-amniotic dinoprost, and blood loss exceeding 250 mL in 68 (38 lost more than 500 mL). No patients had convulsions even though 8 were being treated for epilepsy. Three patients sustained lacerations to the cervix. Five patients complained of breast soreness or lactation; these symptoms may have been under-reported. Overall 14 patients were re-admitted; 13 because of excessive vaginal bleeding and 1 because of pelvic infection.

A later report describes the cumulative experience in 3313 pregnancies[2] in which dinoprostone gel was used for induction of term labour or cervical ripening. Adverse effects were rare. Vomiting, fever, and diarrhoea occurred in about 0.2% of mothers and were difficult to distinguish from the effects of concurrent drug therapy. Detectable myometrial activity was dose-related and more common after intravaginal than after intracervical use. Myometrial activity was reported in 0.6 to 6% of patients following intravaginal application and hyperstimulation was virtually non-existent at an intracervical dose of 500 micrograms. Fetal effects were negligible in the absence of uterine hyperstimulation.

Effects on the bones. Reversible periosteal reactions of the long bones and bone thickening have occurred in infants receiving long-term therapy with prostaglandins of the E series (see Alprostadil, p.2183). In addition, reversible widening of cranial sutures was reported[1] in 2 neonates given dinoprostone intravenously for 95 and 97 days respectively.

1. Hoevels-Guerich H, *et al.* Widening of cranial sutures after long-term prostaglandin E therapy in two newborn infants. *J Pediatr* 1984; **105:** 72–4.

Effects on the cardiovascular system. Cardiovascular adverse effects are most common after intravenous dinoprostone but may also occur with other routes. Severe cardiovascular disorders reported with the intra-amniotic or intravaginal use of dinoprost or dinoprostone have included: cardiac arrhythmias in 3 patients,[1,2] fatal in 2 of them;[2] hypotension, tachypnoea, and tachycardia in 3 patients[3,4] with associated pyrexias in 2 patients;[3] and fatal myocardial infarction in a patient who had several high-risk factors for ischaemic heart disease.[5]

Severe hypertension occurred in a patient[6] who received dinoprostone by direct myometrial injection and by intravenous infusion concomitantly for postpartum haemorrhage.

Adverse cardiovascular effects have also been reported with other prostaglandins used in gynaecological or obstetric indications (see under Gemeprost, p.2010, and Sulprostone, p.2018).

Effects on the fetus. A woman who failed to abort despite receiving carboprost intravaginally 7 weeks after conception gave birth at 34 weeks of gestation to an infant with hydrocephalus and abnormal digits.[1] There have been reports of 2 infants born, without congenital abnormality, to women who continued with the pregnancy after attempted mid-trimester termination using intravaginal gemeprost.[2,3] However, abnormalities including limb deformities, cleft palate, anencephaly, cerebellar atrophy, and heart malformation were reported in a review[4] of 71 cases of pregnancy that were continued after attempted termination using mifepristone either alone or with a prostaglandin. Of the 8 cases of abnormality that were reported, 7 occurred in the group of 10 women who had been given intravaginal gemeprost. A case of cerebellar agenesis has also been described[5] after a failed medical termination using mifepristone and gemeprost. For abnormalities reported after the failed misuse of misoprostol alone for termination of pregnancy, see p.2013.

Effects on the gastrointestinal system. Necrotising enterocolitis has been associated with the use of intravenous[1] or oral[2] dinoprostone, or intravenous alprostadil,[2] in infants with symptomatic congenital heart disease. It has been suggested that induced hypotension and apnoea may be responsible,[1] although others[3] did not support this view, or that pulmonary vasodilatation may produce systemic to pulmonary shunting, rendering the gastrointestinal tract relatively ischaemic.[2]

3. Miller MJS, Clark DA. Congenital heart disease and necrotizing enterocolitis. *J Pediatr* 1989; **115:** 335–6.

Effects on the neonate. Aspiration of the undissolved remnants of a dinoprostone vaginal tablet caused neonatal respiratory distress due to mechanical obstruction of the airways; there was no evidence to suggest absorption of dinoprostone from the tablet matrix.[1]

Inadvertent intramuscular injection of carboprost 250 micrograms caused hypertension, bronchospasm, diarrhoea, and hyperthermia in a neonate. There was also an adverse neurological effect that was either a dystonic reaction or seizure activity. The neonate was treated symptomatically and discharged 24 hours later; neurological and developmental examinations were normal at 3 months of age.[2] The authors of this report also learned of 2 other cases that had been reported to the manufacturer, in which neonates given injections of 125 micrograms and 63 micrograms remained asymptomatic.

2. Mrvos R, *et al.* Carboprost exposure in a newborn with recovery. *J Toxicol Clin Toxicol* 1999; **37:** 865–7.

Effects on the nervous system. Convulsions and EEG changes have been occasionally reported during the use of prostaglandins for termination of pregnancy. Convulsions occurred[1] in 5 of 320 women after intra-amniotic dinoprost, but in other large series[2-4] of patients given dinoprost or dinoprostone by various routes no problems occurred despite the inclusion of patients with a history of epilepsy. However, convulsions were reported[5] in 3 of 4 epileptic patients given sulprostone intramuscularly.

Effects on the uterus. Use of prostaglandins to induce labour or to terminate pregnancy is associated with an increased risk of hyperstimulation of the uterus. Uterine rupture has occurred with carboprost,[1] dinoprost or dinoprostone,[2-7] gemeprost,[8-10] misoprostol,[11-14] and sulprostone.[15-17] These effects have been reported with parenteral, local, and oral dosage. The risk of rupture and associated complications is increased in grand multiparae[4] and those with uterine scarring from previous caesarean section.[5,7] Studies have reported relative risks of between 6 and 10 times those of spontaneous labour after labour induction with dinoprostone in the latter group.[5,7] In addition to rupture, with the risk of potentially fatal maternal haemorrhage, hyperstimulation has been associated with fetal distress and death,[18-20] and maternal death due to amniotic fluid embolism.[18,21]

Overdosage. Severe adverse effects associated with intra-amniotic prostaglandins have been attributed to absorption into the systemic circulation of doses higher than would normally be given systemically. Rigors, vomiting, severe abdominal pain, and an intense desire to urinate and defaecate occurred[1] in 3 patients given dinoprostone intra-amniotically for mid-trimester abortion; one patient had peripheral vasoconstriction and a rapid low-volume pulse, with hypotension, and another had peripheral cyanosis. It was suggested[2] that this might have been due to displacement of the needle or cannula outside the amniotic sac. In 2 of the patients prior use of urea may have increased the rate of absorption of prostaglandins from the amniotic cavity. In a further report[3] flushing, severe headache, and nausea immediately after a test dose of dinoprost 2.5 mg was also thought to be due to incorrect positioning of the needle and consequent injection into the systemic circulation; at least part of the dose might have been injected into the peritoneal cavity.[4]

Severe reactions have also been reported with prostaglandins given to abort hydatidiform moles. A 20-year-old woman given 20 mg of dinoprostone by injection into the uterine cavity developed profound hypotension, bradycardia, and rigors, followed by nausea, vomiting, suprapubic pain, an increased pulse rate, pyrexia, and generalised flushing.[5] Since there are no fetal membranes in a molar pregnancy, intra-uterine administration is similar to extra-amniotic administration and the dose used was 100 times higher than the usual extra-amniotic dose.[4] However, in a similar patient[6] 'extra-amniotic' instillation of dinoprostone 200 micrograms was followed immediately by nausea, retching, severe abdominal pain, dizziness, difficulty in breathing and the production of frothy blood-stained sputum, an imperceptible pulse, and hypotension; the dinoprostone had probably been injected directly into the maternal circulation.

Precautions

Dinoprostone should not be given to patients in whom oxytocic drugs are generally contra-indicated (see also Oxytocin, p.2016), because spontaneous labour or vaginal delivery are liable to harm either the mother or the fetus. This includes significant cephalopelvic disproportion or unfavourable presentation of the fetus, placenta praevia, or fetal distress. It should not be used where there is a predisposition to uterine rupture, as in high parity or the presence of a uterine scar from previous caesarean section or major uterine surgery, or in those with a history of pelvic inflammatory disease. Since prostaglandins enhance the effects of oxytocin, use of these drugs together or in sequence should be carefully monitored.

Dinoprostone is contra-indicated in active cardiac, pulmonary, renal, or hepatic disease. It should be used with caution in patients with glaucoma or raised intra-ocular pressure, a history of asthma or epilepsy, hepatic or renal impairment, or cardiovascular disease.

In the induction of labour cephalopelvic relationships should be carefully evaluated before use. During use uterine activity, fetal status, and the progress of cervical dilatation should be carefully monitored to detect adverse responses, such as hypertonus, sustained uterine contractions, or fetal distress. In patients with a history of hypertonic uterine contractility or tetanic uterine contractions, uterine activity and the state of the fetus should be continuously monitored throughout labour. Where high-tone myometrial contractions are sustained the possibility of uterine rupture should be considered.

Dinoprostone should not be given by the myometrial route, since there is a possible association with cardiac arrest in severely ill patients. The extra-amniotic route should not be used in patients with cervicitis or vaginal infections. Vaginal preparations of dinoprostone should not be used in the induction of labour once the membranes are ruptured. In some countries, intravenous prostaglandins are considered to be contra-indicated in women who smoke.

Dinoprostone should be used with caution in women over 35 years of age, those with complications during pregnancy, such as gestational diabetes, hypertension, or hypothyroidism, and in those past the fortieth week of pregnancy as their condition may further enhance the increased risk of disseminated intravascular coagulation in the immediate postpartum period associated with pharmacologically induced labour.

In the therapeutic termination of pregnancy, fetal damage has been seen in cases of incomplete termination and the appropriate treatment for complete evacuation of the uterus should therefore be instituted whenever termination is unsuccessful or incomplete. Dinoprostone should not be used for termination in patients with pelvic infection, unless adequate treatment has already been started.

Administration. For the hazards of unintentional systemic absorption of prostaglandins after intra-uterine use for the termination of pregnancy and abortion of hydatidiform moles, see Overdosage in Adverse Effects, above.

Interactions

Dinoprostone enhances the effects of oxytocin on the uterus. There is a theoretical risk that prostaglandin synthetase inhibitors, such as aspirin and NSAIDs, might alter the efficacy of dinoprostone.

Uterine stimulants. Marked hypertension, vomiting, and severe dyspnoea occurred after the sequential use of *oxytocin*, *methylergometrine*, and *dinoprost* within the space of 10 minutes to a woman with postpartum haemorrhage.[1]

1. Cohen S, *et al.* Severe systemic reactions following administration of different ureotonic [uterotonic] drugs. *N Y State J Med* 1983; **83:** 1060–1.

Uses and Administration

Dinoprostone is a prostaglandin of the E series (p.2374) with actions on smooth muscle; the endogenous substance is termed prostaglandin E_2 and is rapidly metabolised in the body. It induces contraction of uterine muscle at any stage of pregnancy and is reported to act mainly as a vasodilator and as a bronchodilator. In the UK, dinoprostone is used principally in the induction of labour (p.2002); it may also be used for the termination of pregnancy (p.2004), missed abortion, hydatidiform mole, and intra-uterine fetal death.

Dinoprostone is usually given vaginally. It may also be given intravenously, extra-amniotically, or orally, but the intravenous route has been associated with a high incidence of adverse effects and is generally only used for missed abortion or hydatidiform mole; continuous use for more than 2 days is not recommended.

For the **induction of labour** dinoprostone is used to ripen (soften and dilate) the cervix before the membranes are ruptured and to induce labour at term. The cervical gel used for cervical ripening contains 500 micrograms in 2.5 mL, whereas the vaginal gel used for induction of labour contains 1 or 2 mg in 2.5 mL; the vaginal gel should not be used in the cervical canal. Pessaries are also available for both cervical ripening and labour induction. These are not bioequivalent to the gels and their dosage is different.

To soften and dilate the cervix before induction of labour dinoprostone 500 micrograms is given as *cervical gel*. This dose may be repeated after 6 hours if there was no response to the initial dose; in some cases a third dose may be used to a maximum cumulative dose of 1.5 mg in 24 hours.

For induction of labour the dose as *vaginal gel* is 1 mg (or 2 mg in primigravid patients with unfavourable induction features) followed, if necessary, by a further 1 or 2 mg after 6 hours; a total dose of 3 mg (or 4 mg in unfavourable primigravid patients) should not be exceeded. Alternatively a *vaginal pessary* containing 3 mg may be used and this may be followed, if necessary, by a further 3 mg after 6 to 8 hours; a total dose of 6 mg should not be exceeded.

A *modified-release vaginal pessary* containing 10 mg and delivering about 300 micrograms/hour can be used for cervical ripening and subsequent labour induction. If satisfactory cervical ripening does not occur within 12 or 24 hours, depending on the preparation, then it should be removed.

Dinoprostone may be given *orally* for the induction of labour in an initial dose of 500 micrograms, repeated hourly, and increased if necessary to 1 mg hourly until an adequate response is achieved; single doses of 1.5 mg should not be exceeded. Oral use has, however, generally been replaced by intravaginal dosage since the latter is associated with fewer gastrointestinal adverse effects.

Dinoprostone has been given *intravenously* for the induction of labour but is no longer recommended for routine use by most authorities. A suggested intravenous dosage has been 250 nanograms/minute infused as a solution containing 1.5 micrograms/mL for 30 minutes, the dose being subsequently maintained or increased according to the patient's response; in intra-uterine fetal death higher doses may be required and an initial rate of 500 nanograms/minute has been used with increases at intervals of not less than 1 hour.

For the **termination of pregnancy** in the second trimester 1 mL of a solution containing dinoprostone 100 micrograms/mL may be instilled *extra-amniotically* through a suitable Foley catheter, with subsequent doses of 1 or 2 mL given at intervals usually of 2 hours, according to response. Dinoprostone has also been given *intravenously* for the termination of pregnancy and for missed abortion or hydatidiform mole. A solution containing 5 micrograms/mL may be infused at a rate of 2.5 micrograms/minute for 30 minutes, the infusion then being maintained or increased to a rate of 5 micrograms/minute; this rate should be maintained for at least 4 hours before making further increases.

In the USA dinoprostone pessaries are used for the termination of second trimester pregnancy. A dose of 20 mg is given *intravaginally* and repeated every 3 to 5 hours according to response for up to 2 days; a total dose of 240 mg should not be exceeded. Pessaries are also used in the USA in missed abortion, intra-uterine fetal death, and benign hydatidiform mole.

Dinoprostone is used in some centres to maintain the patency of the ductus arteriosus (see below).

Haemorrhagic cystitis. Dinoprostone instilled into the bladder for 4 hours and repeated for 4 days successfully improved severe cyclophosphamide-induced haemorrhagic cystitis (p.702) in a bone marrow transplant recipient.[1] Similar results were obtained in another series of 10 patients.[2]

1. Mohiuddin J, *et al.* Treatment of cyclophosphamide-induced cystitis with prostaglandin E . *Ann Intern Med* 1984; **101:** 142.
2. Laszlo D, *et al.* Prostaglandin E2 bladder instillation for the treatment of hemorrhagic cystitis after allogeneic bone marrow transplantation. *Haematologica* 1995; **80:** 421–5.

Hepatic disorders. See under Alprostadil, p.2184, for reference to the use of prostaglandins, including dinoprostone, in the treatment of viral hepatitis.

Patent ductus arteriosus. Prostaglandins, particularly alprostadil (p.2184) and dinoprostone, may be used to maintain the patency of the ductus arteriosus in infants with congenital heart disease until surgery can be performed to correct the malformation. Treatment for a longer period, especially with oral dinoprostone, may facilitate later surgery by allowing growth of the infants and their pulmonary arteries.

Beneficial responses to long-term use of dinoprostone have been reported.[1,2] Dinoprostone has been given orally in an initial dose of 20 to 25 micrograms/kg hourly, decreasing the frequency of doses after the first week; it was suggested that treatment should be continued for up to 4 weeks initially and a decision then made whether to proceed with surgery or to plan a longer course of treatment to encourage further growth. When gastrointestinal absorption is expected to be poor or when oral treatment is ineffective, dinoprostone has been given by intravenous infusion. The *BNFC* recommends an initial dose of 5 to 10 nanograms/kg per minute increased as necessary, in steps of 5 nanograms/kg per minute, to 20 nanograms/kg per minute; further increases may be needed and doses of up to 100 nanograms/kg per minute have been used, however, these are associated with an increased risk of adverse effects.

2. Thanopoulos BD, *et al.* Prostaglandin E administration in infants with ductus-dependent cyanotic congenital heart disease. *Eur J Pediatr* 1987; **146:** 279–82.

Pemphigus. Erosive oral lesions in 3 patients[1] with pemphigus vulgaris (p.1582), that had previously been refractory to standard corticosteroid therapy, resolved on sucking oral dinoprostone tablets 1.5 to 3 mg daily. Symptoms recurred within weeks of ceasing dinoprostone but could be controlled by courses of 0.5 to 1 mg daily for 1 to 2 weeks, when required. In a group of 10 patients,[2] topical dinoprostone produced similar results in 6 patients, but disease was exacerbated in the others; the dinoprostone was applied twice daily, but details of the dosage form and dose were not reported.

2. Kumaran MS, Kanwar AJ. Efficacy of topical PGE2 in recalcitrant oral lesions of pemphigus vulgaris: a clinical trial. *J Eur Acad Dermatol Venereol* 2006; **20:** 898–9.

Peripheral vascular disease. Various prostaglandins have been used in the treatment of peripheral vascular disease (p.1178), particularly in severe Raynaud's syndrome (see Vasospastic Arterial Disorders, p.1188), but do not constitute mainline therapy.

Postpartum haemorrhage. Dinoprostone and other prostaglandins have been used to control severe postpartum haemorrhage (p.2003) unresponsive to ergometrine and oxytocin.

Beneficial response to continuous intra-uterine irrigation with dinoprostone solution 1.5 micrograms/mL was seen in 22 patients with postpartum haemorrhage unresponsive to other treatment.[1] Postpartum haemorrhage was controlled in another patient using a dinoprostone 3-mg vaginal suppository held against the uterine wall.[2]

Ergometrine Maleate *(BANM, rINNM)*

Ergobasine Maleate; Ergometriinimaleaatti; Ergométrine, maléate d'; Ergometrinhydrogenmaleat; Ergometrini maleas; Ergometrin-maleat; Ergometrin-maleát; Ergometrin-maleinát; Ergometrino maleatas; Ergonovine Bimaleate; Ergonovine Maleate; Ergostetrine Maleate; Ergotocine Maleate; Maleato de ergobasina; Maleato de ergometrina; Maleato de Ergonovina. *N*-[(*S*)-2-Hydroxy-1-methylethyl]-D-lysergamide hydrogen maleate; 9,10-Didehydro-*N*-[(*S*)-2-hydroxy-1-methylethyl]-6-methylergoline-8β-carboxamide hydrogen maleate.

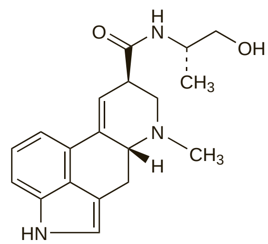
Эргометрина Малеат

$C_{19}H_{23}N_3O_2,C_4H_4O_4$ = 441.5.

CAS — 60-79-7 (ergometrine); 129-51-1 (ergometrine maleate).

ATC — G02AB03.

ATC Vet — QG02AB03.



(ergometrine)

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Ergometrine Maleate). A white or almost white or slightly coloured, crystalline powder. Sparingly soluble in water; slightly soluble in alcohol. A 1% solution in water has a pH of 3.6 to 4.4. Store in airtight glass containers at a temperature of 2° to 8°. Protect from light.

USP 31 (Ergonovine Maleate). A white to greyish-white or faintly yellow, odourless, microcrystalline powder. It darkens with age and on exposure to light. Sparingly soluble in water; slightly soluble in alcohol; insoluble in chloroform and in ether. Store in airtight containers at a temperature not exceeding 8°. Protect from light.

Stability. Deterioration and degradation of ergometrine-containing injections has been seen when exposed to high temperatures in the tropics.[1-4] The mean loss in one study[3] of ergometrine injection under shipment to the tropics was 5.8%, but in some individual samples the loss was more marked: 18 of 80 test samples contained less than 80% of the stated content, and in 3 cases the content was less than 60%. A similar but much less significant pattern was seen with methylergometrine: the content varied from 98.6 to 99.5% of the labelled amount. Tablets of ergometrine and methylergometrine were also shown to be unstable under simulated tropical conditions, with humidity as the main adverse factor.[5]

5. de Goot ANJA, *et al.* Ergometrine and methylergometrine tablets are not stable under simulated tropical conditions. *J Clin Pharm Ther* 1995; **20:** 109–13.

Adverse Effects and Treatment

Nausea and vomiting, abdominal pain, diarrhoea, headache, dizziness, tinnitus, chest pain, palpitations, bradycardia and other cardiac arrhythmias, coronary artery vasospasm, myocardial infarction, dyspnoea, and pulmonary oedema have been reported after use of ergometrine. Hypertension may occur, particularly after rapid intravenous dosage; hypotension has also been reported. Hypersensitivity reactions, including shock, have occurred. Ergometrine shows less tendency to produce gangrene than ergotamine, but ergotism has been reported and symptoms of acute poisoning are similar (see p.620).

Adverse effects should be treated as for ergotamine, p.620.

Effects on the respiratory system. Bronchospasm has been reported after use of ergometrine.[1] Although studies *in vitro* on *canine* bronchi have suggested a direct action on smooth muscle, this could not be confirmed in studies using human bronchi.

1. Hill H, *et al.* Ergometrine and bronchospasm. *Anaesthesia* 1987; **42:** 1115–16.

Overdosage. Ergometrine maleate has been given accidentally in adult doses to neonates,[1-5] sometimes instead of vitamin K. Symptoms have included peripheral vasoconstriction, encephalopathy, convulsions, respiratory failure, acute renal failure, and temporary lactose intolerance. When given with oxytocin, water intoxication has also been reported.[1] In all of these cases, recovery occurred after intensive symptomatic treatment including assisted ventilation and anticonvulsants. However, deaths have also been recorded.[5] The long-term outcome of ergometrine overdosage has been reported for 6 infants.[5] Their ages at follow-up ranged from 18 months to 5 years; all had normal physical and behavioural development and neurological outcomes.

5. Dargaville PA, Campbell NT. Overdose of ergometrine in the newborn infant: acute symptomatology and long-term outcome. *J Paediatr Child Health* 1998; **34:** 83–9.

Precautions

As for Ergotamine Tartrate, p.620. Ergometrine should also be used with caution in patients with veno-atrial shunts or mitral valve stenosis. Ergometrine is contra-indicated for the induction of labour or for use during the first stage of labour. If used at the end of the second stage of labour, before delivery of the placenta, there must be expert obstetric supervision. Its use should be avoided in patients with pre-eclampsia, eclampsia, or threatened spontaneous abortion.

Porphyria. Ergometrine maleate has been associated with acute attacks of porphyria and is considered unsafe in porphyric patients.

Interactions

As for Ergotamine Tartrate, p.621. Halothane has been considered to diminish the effects of ergometrine on the uterus.

Sympathomimetics. Use of *dopamine* in a patient treated with ergometrine was associated with subsequent development of gangrene in both hands and feet.[1] In another case,[2] the use of ergometrine with *noradrenaline* resulted in cyanosis of the hands and necrosis in some of the fingers.

1. Buchanan N, *et al.* Symmetrical gangrene of the extremities associated with the use of dopamine subsequent to ergometrine administration. *Intensive Care Med* 1977; **3:** 55–6.
2. Chuang S-S. Finger ischemia secondary to the synergistic agonist effect of norepinephrine and ergonovine and in a burn patient. *Burns* 2003; **29:** 92–4.

Pharmacokinetics

Ergometrine is reported to be rapidly absorbed after doses by mouth and by intramuscular injection, with onset of uterine contractions in about 5 to 15 minutes and 2 to 7 minutes, respectively. Elimination appears to be principally by hepatic metabolism.

Uses and Administration

Ergometrine has a much more powerful action on the uterus than most other ergot alkaloids, especially on the puerperal uterus. Its main action is the production of intense contractions, which at higher doses are sustained, in contrast to the more physiological rhythmic uterine contractions induced by oxytocin; its action is more prolonged than that of oxytocin.

Ergometrine maleate is used in the active management of the third stage of labour, and to prevent or treat postpartum or postabortal haemorrhage (p.2003) caused by uterine atony; by maintaining uterine contraction and tone, blood vessels in the uterine wall are compressed, and blood flow reduced.

In the **active management of the third stage of labour**, ergometrine maleate and oxytocin are given together under full obstetric supervision. A dose of ergometrine maleate 500 micrograms and oxytocin 5 units is injected intramuscularly after delivery of the anterior shoulder, or, at the latest, immediately after delivery of the infant; contractions are reported to occur within 2 to 7 minutes. Delivery of the placenta is actively assisted while the uterus is firmly contracted.

In the prevention or treatment of **postpartum haemorrhage**, a similar dose of ergometrine maleate with oxytocin is given intramuscularly following delivery of the placenta or when bleeding occurs. A combined intravenous preparation of ergometrine maleate with oxytocin has been used but is no longer recommended. Ergometrine maleate alone is used for prevention or treatment of postpartum or postabortal haemorrhage in a usual intramuscular dose of 200 micrograms. The dose may be repeated in severe bleeding, but is rarely needed more often than once in 2 to 4 hours. In emergencies such as excessive uterine bleeding, ergometrine maleate has been given intravenously in a dose of 200 micrograms; single doses of 250 to 500 micrograms have also been used. Intravenous doses should be given over at least 1 minute to reduce the risk of adverse effects, particularly hypertension. Parenteral treatment of haemorrhage may be followed by ergometrine maleate 200 to 400 micrograms orally 2 to 4 times daily until the danger of atony and haemorrhage has passed, which is usually 48 hours. Tablets have also been given sublingually.

In the treatment of mild secondary postpartum haemorrhage, ergometrine maleate has been given orally.

Ergometrine tartrate was formerly used.

Diagnosis and testing. Ergometrine maleate[1-8] or methylergometrine maleate[9,10] have been used in a provocation test for the diagnosis of Prinzmetal's angina (variant angina) (p.1157).

Multi-ingredient: ***Austral.:*** Syntometrine; ***Hong Kong:*** Syntometrine†; ***Irl.:*** Syntometrine; ***Malaysia:*** Syntometrine; ***NZ:*** Syntometrine; ***S.Afr.:*** Syntometrine; ***UK:*** Syntometrine.

Ergot

Cornezuelo del centeno; Secale Cornutum.

Спорынья

Description. Ergot consists of the sclerotium of the fungus *Claviceps purpurea* (Hypocreaceae) developed in the ovary of the rye, *Secale cereale* (Gramineae). It contains not less than 0.15% of total alkaloids, calculated as ergotoxine, and not less than 0.01% of water-soluble alkaloids, calculated as ergometrine. Some authorities have expressed alkaloidal content in terms of ergotamine and ergometrine.

Adverse Effects and Treatment

As for Ergotamine Tartrate, p.620.

Epidemic ergot poisoning, arising from the ingestion of ergotised rye bread, is now seldom seen. Two forms of epidemic toxicity, which rarely occur together, have been described: a gangrenous form characterised by agonising pain of the extremities of the body followed by dry gangrene of the peripheral parts, and a rarer nervous type giving rise to paroxysmal epileptiform convulsions.

Poisoning. A report of an outbreak of ergotism, attributed to the ingestion of infected wild oats (*Avena abyssinica*), in Ethiopia.[1]

1. King B. Outbreak of ergotism in Wollo, Ethiopia. *Lancet* 1979; **ii:** 1411.

Uses and Administration

Ergot has the vasoconstricting and oxytocic actions of its constituent alkaloids, especially ergotamine (p.620) and ergometrine (above). A liquid extract or tablets of prepared ergot were formerly used as an oxytocic. Preparations containing ergot extracts have been promoted for use in dyspepsia and nervous disorders.

Preparations

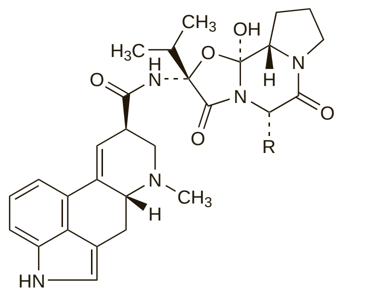
Proprietary Preparations (details are given in Part 3)
India: Ergotab.

Ergotoxine

Ecboline; Ergotoxina.

Эрготоксин

CAS — 8006-25-5 (ergotoxine); 8047-28-7 (ergotoxine esilate); 8047-29-8 (ergotoxine phosphate); 564-36-3 (ergocornine); 511-08-0 (ergocristine); 511-09-1 (α-ergocryptine); 20315-46-2 (β-ergocryptine).



Ergocornine	R = $CH(CH_3)_2$
Ergocristine	R = $CH_2C_6H_5$
α-Ergocryptine	R = $CH_2CH(CH_3)_2$
β-Ergocryptine	R = $CH(CH_3)CH_2CH_3$

Profile

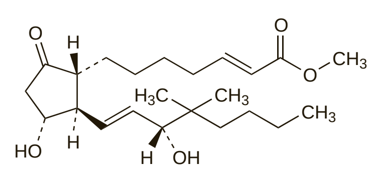
Ergotoxine is a mixture of naturally occurring ergot alkaloids. It contains equal proportions of ergocornine ($C_{31}H_{39}N_5O_5$ = 561.7), ergocristine ($C_{35}H_{39}N_5O_5$ = 609.7), and ergocryptine ($C_{32}H_{41}N_5O_5$ = 575.7) as the α- and β-isomers. The esilate was formerly used as an oxytocic and in the treatment of migraine. Ergotoxine phosphate has also been used.

Gemeprost *(BAN, USAN, rINN)*

16,16-Dimethyl-*trans*-Δ^2-prostaglandin E_1 methyl ester; Géméprost; Gemeprosti; Gemeprostum; ONO-802; SC-37681. Methyl (2*E*,13*E*)-(8*R*,11*R*,12*R*,15*R*)-11,15-dihydroxy-16,16-dimethyl-9-oxoprosta-2,13-dienoate; Methyl (*E*)-7-{(1*R*,2*R*,3*R*)-3-hydroxy-2-[(*E*)-(3*R*)-3-hydroxy-4,4-dimethyloct-1-enyl]-5-oxocyclopentyl}hept-2-enoate.

Гемепрост

$C_{23}H_{38}O_5$ = 394.5.
CAS — 64318-79-2.
ATC — G02AD03.
ATC Vet — QG02AD03.



Adverse Effects and Precautions

As for Dinoprostone, p.2007. Vaginal bleeding and mild uterine pain may occur. Pulse and blood pressure should be monitored in patients given gemeprost.

The effects of gemeprost on the fetus are not known. Once a prostaglandin has been given to terminate pregnancy it is essential that termination take place; if the prostaglandin is unsuccessful other measures should be used.

Incidence of adverse effects. The incidence of vomiting (19 or 35%) and diarrhoea (12 or 19%) in 2 studies of patients treated with gemeprost pessaries was similar to that seen with other prostaglandins, but gemeprost was reported to cause less uterine pain.[1,2]

1. Cameron IT, Baird DT. The use of 16,16-dimethyl-trans-Δ prostaglandin E methyl ester (gemeprost) vaginal pessaries for the termination of pregnancy in the early second trimester: a comparison with extra-amniotic prostaglandin E . *Br J Obstet Gynaecol* 1984; **91:** 1136–40.
2. Andersen LF, *et al.* Termination of second trimester pregnancy with gemeprost vaginal pessaries and intra-amniotic PGF : a comparative study. *Eur J Obstet Gynecol Reprod Biol* 1989; **31:** 1–7.

Effects on the cardiovascular system. Periods of ventricular standstill of up to 6 seconds were seen in a patient during treatment with gemeprost vaginal pessaries.[1] The patient required temporary cardiac pacing, but no persistent cardiac rhythm disturbances were detected on follow-up. Severe cardiogenic shock due to vasospasm, and subsequent stroke, has been reported in a patient who had received gemeprost pessaries some hours earlier; myocardial infarction ensuing from coronary spasm was reported in a second patient.[2]

1. Kalra PA, *et al.* Cardiac standstill induced by prostaglandin pessaries. *Lancet* 1989; **i:** 1460–1.
2. Schulte-Sasse U. Life threatening myocardial ischaemia associated with the use of prostaglandin E to induce abortion. *Br J Obstet Gynaecol* 2000; **107:** 700–2.

Effects on the fetus. Congenital abnormalities have been reported in pregnancies carried to term after failed termination using prostaglandins, including gemeprost (see under Dinoprostone, p.2007).

Effects on the uterus. For reference to hyperstimulation and uterine rupture after use of prostaglandins, including gemeprost, for termination of pregnancy or induction of labour, see under Dinoprostone, p.2007.

Interactions

As for Dinoprostone, p.2008.

Uses and Administration

Gemeprost is a synthetic analogue of alprostadil (prostaglandin E_1; p.2183). It is used to soften and dilate the cervix and as a uterine stimulant in the termination of pregnancy (p.2004). In the first trimester, a pessary containing gemeprost 1 mg is inserted into the vagina 3 hours before surgery to ripen the cervix. Gemeprost may also be used for termination of pregnancy in the second trimester when a 1-mg pessary is inserted every 3 hours to a maximum of 5 pessaries. If this is ineffective, one further course may be given starting 24 hours after the beginning of the first course. If termination is not well established after 10 pessaries, alternative treatment should be used to complete uterine evacuation. In the case of intra-uterine fetal death in the second trimester, only one course of up to 5 pessaries should be given. Vaginal gemeprost is also used after oral mifepristone (p.2012) in the termination of pregnancy.

Preparations

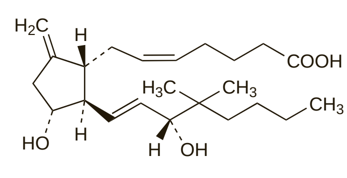
Proprietary Preparations (details are given in Part 3)
Austral.: Cervagem; ***Denm.:*** Cervagem; ***Fin.:*** Cervagem†; ***Fr.:*** Cervageme; ***Ger.:*** Cergem; ***Hong Kong:*** Cervagem†; ***Ital.:*** Cervidil; ***Jpn:*** Preglandin; ***Malaysia:*** Cervagem; ***Norw.:*** Cervagem†; ***NZ:*** Cervagem; ***Singapore:*** Cervagem; ***Swed.:*** Cervagem.

Meteneprost *(USAN, rINN)*

9-Deoxo-16,16-dimethyl-9-methylene-prostaglandin E_2; Méténéprost; Meteneprostum; U-46785. (5*Z*,13*E*)-(8*R*,11*R*,12*R*,15*R*)-11,15-Dihydroxy-16,16-dimethyl-9-methyleneprosta-5,13-dienoic acid; (*Z*)-7-{(1*R*,2*R*,3*R*)-3-Hydroxy-2-[(*E*)-(3*R*)-3-hydroxy-4,4-dimethyloct-1-enyl]-5-methylenecyclopentyl}hept-5-enoic acid.

Метенепрост

$C_{23}H_{38}O_4$ = 378.5.
CAS — 61263-35-2.



Profile

Meteneprost is a synthetic derivative of dinoprostone (prostaglandin E_2; p.2007). It is a uterine stimulant and has been studied for the termination of pregnancy.

(methylergometrine)

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Methylergometrine Maleate). A white or almost white, hygroscopic, crystalline powder. Soluble in water; slightly soluble in anhydrous alcohol. pH of a 0.5% solution is 4.4 to 5.2. Store in airtight containers. Protect from light.

USP 31 (Methylergonovine Maleate). A white to pinkish-tan, odourless, microcrystalline powder. Soluble 1 in 100 of water, 1 in 175 of alcohol, 1 in 1900 of chloroform, and 1 in 8400 of ether. pH of a 0.02% solution in water is between 4.4 and 5.2. Store in airtight containers at a temperature not exceeding 8°. Protect from light.

Stability. For mention of slight variations in the methylergometrine content of the injection after transport to a tropical climate, see under Ergometrine Maleate, p.2009.

Adverse Effects, Treatment, and Precautions

As for Ergometrine Maleate, p.2009.

Overdosage. References.

2. Bangh SA, *et al.* Neonatal ergot poisoning: a persistent iatrogenic illness. *Am J Perinatol* 2005; **22:** 239–43.

Pharmacokinetics

Methylergometrine maleate is reported to be rapidly absorbed when given orally or intramuscularly, with onset of uterine contractions in about 5 to 15 minutes and 2 to 5 minutes, respectively. Oral bioavailability may show considerable interindividual variation. It undergoes extensive first-pass hepatic metabolism and only small amounts of unchanged drug are excreted in the urine. The elimination half-life is reported to be about 2 to 3 hours.

◊ The pharmacokinetics of methylergometrine maleate have been studied after oral doses in healthy subjects[1,2] and in postpartum women.[3] Small amounts of methylergometrine have been detected in breast milk.[4,5]

Uses and Administration

Methylergometrine maleate has an action on the uterus similar to that of ergometrine maleate (p.2009) and is used similarly in the active management of the third stage of labour, and in the prevention and treatment of postpartum or postabortal haemorrhage (p.2003). In the management of the third stage of labour, it may be given in a dose of 200 micrograms intramuscularly after delivery of the anterior shoulder or, at the latest, immediately after delivery of the infant. The same dose may be used for the prevention or treatment of postpartum or postabortal haemorrhage, and may be repeated every 2 to 4 hours as necessary up to a maximum of 5 doses. In emergencies it may be given in similar doses by slow intravenous injection over at least 1 minute to reduce the risk of adverse effects, particularly hypertension. During the puerperium, methylergometrine maleate has been given in oral doses of 200 micrograms 3 or 4 times daily for up to a week or 125 to 250 micrograms up to 3 times daily.

Methylergometrine is a metabolite of methysergide (p.623).

Diagnosis and testing. For reference to the use of methylergometrine maleate in the diagnosis of variant angina, see Ergometrine Maleate, p.2010.

Preparations

USP 31: Methylergonovine Maleate Injection; Methylergonovine Maleate Tablets.

Mifepristone *(BAN, USAN, rINN)*

C-1073; Mifepriston; Mifepristona; Mifépristone; Mifepristoni; Mifepristonum; RU-486; RU-38486. 11β-(4-Dimethylaminophenyl)-17β-hydroxy-17α-prop-1-ynylestra-4,9-dien-3-one.

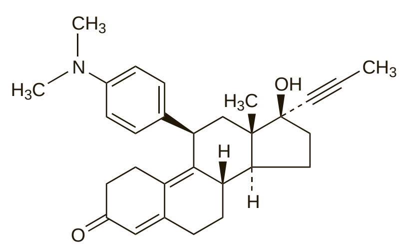
Мифепристон

$C_{29}H_{35}NO_2$ = 429.6.

CAS — 84371-65-3.

ATC — G03XB01.

ATC Vet — QG03XB01.



Pharmacopoeias. In *Chin.*

Adverse Effects

Uterine bleeding and cramps often occur after the use of mifepristone in procedures for the termination of pregnancy, and will occur in almost all patients after the addition of a prostaglandin. Bleeding typically continues for about 9 to 16 days, and may be severe enough to warrant curettage and transfusion in a small proportion of patients. However, prolonged heavy bleeding may also be a sign of incomplete abortion or other complications that require medical or surgical intervention. Other adverse effects of mifepristone include malaise, dizziness, chills, fever, headache, diarrhoea, nausea, vomiting, skin rashes, and urticaria; although some of these effects may be caused by the prostaglandin given after mifepristone.

Serious, sometimes fatal, infections have occurred in women undergoing abortion, although no causal relationship has been established between these events and the use of mifepristone.

Effects on the cardiovascular system. For a report of a woman who died from cardiovascular shock during an abortion induced by mifepristone followed by sulprostone, see p.2018.

Effects on the fetus. Studies in *rabbits*, but not *rats* or *mice*, suggest mifepristone causes fetal malformation. There have been reports of normal fetal development after the use of mifepristone alone in mothers who subsequently decided to continue their pregnancy.[1,2] However, in two reports, use of mifepristone was possibly related to malformations of the fetus including sirenomelia.[2,3] Cerebellar agenesis has been reported after a failed medical termination using mifepristone and gemeprost (see under Dinoprostone, p.2007).

3. Sitruk-Ware R, *et al.* Fetal malformation and failed medical termination of pregnancy. *Lancet* 1998; **352:** 323.

Toxic shock syndrome. Fatal toxic shock syndrome occurred in 5 women who underwent medical termination of pregnancy using mifepristone and misoprostol.[1,2] In 4 cases it was specified that mifepristone 200 mg had been given orally, followed by misoprostol 800 micrograms vaginally.[2] Within a week of termination, these patients presented with signs and symptoms that included abdominal pain, nausea and vomiting, tachycardia, hypotension, oedema, haemoconcentration, profound leucocytosis, and absence of fever. Postmortem examination found evidence of endometritis and toxic shock syndrome that was attributed to *Clostridium sordellii* infection. This is an infrequent human pathogen, but the authors of one report[2] noted that *C. sordellii* infection of the genital tract had also been reported in 8 women after delivery, suggesting that pregnancy, childbirth, or termination of pregnancy may predispose a small number of women to acquire this organism, and that associated dilatation of the cervix may allow for ascending infection. Although there has also been some speculation about the possible mechanisms, both pharmacological[3] and physical,[4] by which oral mifepristone or vaginal misoprostol might potentiate *C. sordellii* infection, a causal relationship between these drugs and the 5 reported deaths has not been established.[5]

Precautions

The use of mifepristone is contra-indicated in women with a confirmed or suspected ectopic pregnancy, because medical termination using mifepristone and a prostaglandin will not be effective (for use with methotrexate, see below). The expected symptoms of a medical termination may also be similar to those of a ruptured ectopic pregnancy. Mifepristone is also contra-indicated in patients with chronic adrenal failure or severe uncontrolled asthma. Use in those with renal or hepatic impairment is also not recommended. Mifepristone should be given with care to patients with less severe asthma or with chronic obstructive airways diseases, haemorrhagic or cardiovascular disease or associated risk factors, or anaemia. Therapy may need to be adjusted in patients receiving long-term corticosteroid treatment; a corticosteroid may need to be given if acute adrenal suppression is suspected. Care is also required in patients receiving anticoagulants because of the increased risk of severe bleeding. Patients with prosthetic heart valves or those with a history of infective endocarditis should be given chemoprophylaxis when undergoing pregnancy termination. As with other means of terminating pregnancy, rhesus-negative women who have not been rhesus immunised will require protection with anti-D immunoglobulin.

Porphyria. Mifepristone is considered to be unsafe in patients with porphyria although there is conflicting experimental evidence of porphyrinogenicity.

Interactions

The metabolism of mifepristone is mediated by the cytochrome P450 isoenzyme CYP3A4. Theoretically, use with other drugs that inhibit or induce this isoenzyme may result in changes in plasma concentration of mifepristone. *In-vitro* studies indicate that mifepristone itself inhibits CYP3A4; it should be used cautiously with CYP3A4 substrates that have a narrow therapeutic index.

NSAIDs. The effects of mifepristone on the uterus and cervix may be mediated by increased prostanoid synthesis resulting from its inhibitory effect on progesterone. It has been suggested that *aspirin* and *NSAIDs*, which are prostaglandin synthetase inhibitors, might alter the efficacy of mifepristone. However, a placebo-controlled study[1] in 28 women found that in the 13 given *naproxen* 500 mg orally 60, 48, 36, 24, and 12 hours before surgical termination of pregnancy the efficacy of mifepristone 100 mg given orally to soften the cervix was not reduced. Also, NSAIDs did not affect medical termination using mifepristone followed by misoprostol (see p.2013).

Pharmacokinetics

After oral doses peak plasma concentrations of mifepristone occur after about 1 to 2 hours; bioavailability is about 70%. Mifepristone is about 98% bound to plasma proteins, mainly α_1-acid glycoprotein. Elimination is biphasic; a slow phase is followed by a more rapid terminal phase, with an elimination half-life of about 18 hours. Mifepristone undergoes hepatic oxidative metabolism, mainly by the cytochrome P450 isoenzyme CYP3A4, and metabolites are excreted in the bile and eliminated in the faeces. Only a small fraction is detected in the urine.

Uses and Administration

Mifepristone is a steroid derived from norethisterone that has potent antiprogestogenic activity. It is used in termination of pregnancy (see below), for either medical termination or for softening and dilatation of the cervix before surgical termination of pregnancy. Mifepristone is also used for labour induction after intra-uterine fetal death (see below).

In the UK the licensed regimen for the **termination** of pregnancies of up to 49 days is a single oral dose of 600 mg of mifepristone followed by a prostaglandin 36 to 48 hours later; prostaglandin treatment may be with either misoprostol 400 micrograms orally or gemeprost 1 mg vaginally. Alternatively, 200 mg of mifepristone may be given as a single dose followed, 36 to 48 hours later, by gemeprost 1 mg vaginally. Regimens containing vaginal gemeprost may also be used for the termination of pregnancies of up to 63 days. In the USA the licensed regimen for the termination of pregnancies up to 49 days of gestation is a single oral dose of 600 mg of mifepristone followed 2 days later by 400 micrograms of misoprostol orally, unless abortion has already been completed. As an adjunct to prostaglandin termination of pregnancy beyond the first trimester, the licensed dose in the UK is a single oral dose of mifepristone 600 mg; this is given 36 to 48 hours before scheduled prostaglandin administration, thus shortening the duration of the procedure and reducing the dose of prostaglandin required.

For **softening** and **dilatation of the cervix** before surgical termination of pregnancy during the first trimester, a single 200-mg dose of mifepristone is given 36 to 48 hours before the procedure.

For labour induction following intra-uterine **fetal death**, mifepristone 600 mg is given daily for 2 consecutive days; if labour has not started within 72 hours of the first dose, other methods of induction should be used.

Mifepristone has been tried for **other uses** such as postcoital contraception, endometriosis, uterine fibroids (leiomyomas), and for progestogen-dependent neoplasms such as meningiomas (see below). Mifepristone also has anti-glucocorticoid activity so it has been used in the treatment of Cushing's syndrome (below), and is under investigation in psychotic major depression (below).

Contraception. Mifepristone has been established as an effective emergency contraceptive (p.2071). Initial studies found a dose of 600 mg given within 72 hours of coitus to be effective.[1,2] Subsequently lower doses, given up to 120 hours after coitus, have been shown to be well tolerated and as effective as standard emergency contraceptive regimens.[3-5] Studies[3,5,6] and meta-analyses[7,8] have confirmed the effectiveness of a dose of 10 mg. There was some evidence of a slight dose-response effect; it was calculated that there would be 1 extra pregnancy per 146 women treated if the dose were reduced from 25 to 10 mg, but the associated increase in availability of the drug might outweigh this.[8]

The development of a mifepristone-based standard contraceptive (p.2070) has been less successful. Regimens based on daily,[9] weekly,[10,11] or monthly[12,13] doses of mifepristone have been investigated.

Ectopic pregnancy. Methotrexate with mifepristone may be more effective than methotrexate alone[1,2] for the medical treatment of ectopic pregnancy (p.749), although some have not found the combination to produce any benefit over methotrexate alone in the majority of women.[3]

Fibroids. Mifepristone has been reported to produce significant decreases in uterine and leiomyoma volumes, and to reduce symptoms such as dysmenorrhoea and menorrhagia, when given to patients with fibroids (p.2107). However, data are from small uncontrolled studies using oral doses ranging from 5 to 50 mg daily, and endometrial hyperplasia has been noted.[1]

1. Steinauer J, *et al.* Systematic review of mifepristone for the treatment of uterine leiomyomata. *Obstet Gynecol* 2004; **103:** 1331–6.

Labour induction. A few studies[1-4] have reported that mifepristone was effective for cervical ripening and labour induction (p.2002) at term. A systematic review[5] considered that mifepristone was better than placebo but that there was still insufficient evidence to support its use. A later dose-finding study[6] found that single oral doses ranging from 50 to 600 mg were no more effective than placebo for inducing labour.

Mifepristone is used for cervical ripening and labour induction where intra-uterine fetal death has occurred,[7] usually in oral doses of 600 mg given daily for 2 days. The effective use of a lower single dose of 200 mg, followed by misoprostol given orally and/or vaginally, has also been described.[8,9]

Malignant neoplasms. Mifepristone has been used successfully in some patients with inoperable meningioma,[1-4] a brain tumour that may be progestogen-receptor positive. It has been given long term in oral doses of 200 mg daily, in some cases for more than 10 years. Adverse effects from long-term therapy have included fatigue, hot flushes, nausea, and depression; gynaecomastia has occurred in men and breast tenderness in women. Cessation of menstruation during mifepristone therapy occurs in premenopausal women, and there have been isolated cases of endometrial hyperplasia in pre- and postmenopausal women.

Termination of pregnancy. Mifepristone sensitises the myometrium to prostaglandins, increases uterine contractility, and softens and dilates the cervix.[1] It is not sufficiently effective to be used as an abortifacient on its own, but is used synergistically with prostaglandins for the termination of pregnancy (p.2004). Mifepristone has also been tried with methotrexate in the treatment of ectopic pregnancy (see above) and may be used to induce labour where intra-uterine fetal death has occurred (see above).

Mifepristone, followed 36 to 48 hours later by a prostaglandin, is an effective medical alternative to surgical methods for the termination of pregnancy in the *first trimester*.[1] Efficacy decreases with increasing gestational age, and the success rate may be affected by the choice of prostaglandin, its dose, and route of administration. Termination success rates are highest for gestations of up to 49 days; after this the success rate for mifepristone with oral misoprostol tends to decrease compared with other regimens.[2] Vaginal gemeprost may be used with mifepristone for gestations of up to 63 days.[1] The usual dose of oral mifepristone is 600 mg, although lower doses of 200 and 400 mg have been studied in various regimens with prostaglandins and found to be as effective. However, a further reduction to 50 mg significantly reduced efficacy.[1,3]

Although surgical termination is commonly used for pregnancies of 9 to 13 weeks, there is increasing evidence to support the use of medical termination using mifepristone followed by misoprostol. A regimen using oral mifepristone 200 mg, followed 36 to 48 hours later by misoprostol 800 micrograms vaginally, has been described.[4,5] Two further vaginal doses of misoprostol 400 micrograms were given at intervals of 3 hours if the products of conception had not been passed (these doses could be given orally if vaginal bleeding was heavier than a normal period[5]). Surgical evacuation was then used if necessary. In a large case series of 1076 women,[6] medical abortion was successful in 95.8%. A regimen of oral mifepristone 200 mg, followed 36 to 48 hours later by misoprostol 800 micrograms vaginally (or 600 micrograms sublingually), was used, with up to 5 further doses of misoprostol 400 micrograms (vaginally or sublingually) given at intervals of 3 hours if needed. The mean number of misoprostol doses used was 2.31.

Mifepristone is also used to ripen the cervix before vacuum aspiration for surgical termination in the first trimester. Oral doses of 600 mg have been used, but lower doses were also found to be more effective than placebo[7,8] and as effective as prostaglandins;[9-11] consequently, a dose of 200 mg is now often used.

Mifepristone followed by a prostaglandin may also be used for medical termination in the *second trimester* (mid-trimester termination; gestation of 13 to 24 weeks).[12,13] Similarly to early termination, a study found mifepristone 200 mg orally to be as effective as 600 mg when followed by misoprostol.[14] Further retrospective reviews have also reported mifepristone 200 mg followed by misoprostol[15] or gemeprost[16] to be effective.

In the UK the Royal College of Obstetricians and Gynaecologists' guidelines[17] for both early and mid-trimester terminations include the following regimens:

- for gestation up to 63 days (9 weeks), mifepristone 200 mg orally followed 24 to 72 hours later by misoprostol 800 micrograms vaginally; if abortion has not occurred 4 hours after administration of misoprostol in women at 49 to 63 days of gestation, a further dose of misoprostol 400 micrograms may be given orally or vaginally
- for gestation between 9 and 13 weeks, mifepristone 200 mg orally followed 36 to 48 hours later by misoprostol 800 micrograms vaginally; a maximum of 4 further doses of misoprostol 400 micrograms may be given every 3 hours, orally or vaginally, if necessary
- for mid-trimester termination (13 to 24 weeks), mifepristone 200 mg orally followed 36 to 48 hours later by misoprostol 800 micrograms vaginally, then up to 4 further doses of misoprostol 400 micrograms given every 3 hours orally

Mifepristone followed by a prostaglandin has also been used as an effective alternative to surgical evacuation[18,19] in the management of first trimester *pregnancy failure*. As for termination, mifepristone doses of 200 and 600 mg orally, followed by misoprostol, appear to be equally effective,[20] although some studies[21,22] suggest that pretreatment with mifepristone does not improve the expulsion rate compared with vaginal or oral misoprostol alone.

Misoprostol *(BAN, USAN, rINN)*

Misoprostoli; Misoprostolum; Mizoprostol; SC-29333. (±)-Methyl 7-{(1*R*,2*R*,3*R*)-3-hydroxy-2-[(*E*)-(4*RS*)-4-hydroxy-4-methyloct-1-enyl]-5-oxocyclopentyl}heptanoate; (±)-Methyl (13*E*)-11,16-dihydroxy-16-methyl-9-oxoprost-13-enoate.

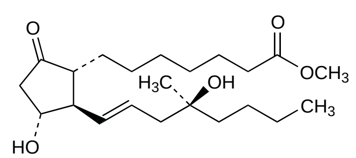
Мизопростол

$C_{22}H_{38}O_5$ = 382.5.

CAS — 59122-46-2.

ATC — A02BB01; G02AD06.

ATC Vet — QA02BB01; QG02AD06.



(11*R*, 16*S*)-Form

Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Misoprostol). A clear, colourless or yellowish, hygroscopic, oily liquid. Practically insoluble in water; soluble in alcohol; sparingly soluble in acetonitrile. Store in airtight containers at –20°.

Adverse Effects

The commonest adverse effect of misoprostol is diarrhoea. Other gastrointestinal effects include abdominal pain, dyspepsia, flatulence, and nausea and vomiting. Increased uterine contractility and abnormal vaginal bleeding (including menorrhagia and intermenstrual bleeding) have been reported. Other adverse effects include skin rashes, headache, and dizziness. Hypotension is rarely seen at doses recommended for peptic ulcer disease.

Incidence of adverse effects. Data on misoprostol presented to the FDA have been summarised.[1] During controlled studies the most common adverse effect was diarrhoea (8.2% compared with 3.1% for placebo); it was dose-related but usually mild, only 8 of 2003 subjects receiving misoprostol having withdrawn because of incapacitating diarrhoea. Headaches and abdominal discomfort were also reported. The effects of misoprostol on the uterus and the potential risks of uterine bleeding or abortion in pregnant women were of more concern. In nonpregnant women taking part in the controlled studies there were menstrual complaints in 15 of 410 (3.7%) receiving misoprostol compared with 2 of 115 (1.7%) given placebo. In a study in pregnant women who had elected to undergo first trimester abortion, all 6 who had a spontaneous expulsion of the uterine contents had received 1 or 2 doses of misoprostol 400 micrograms the previous evening, while none of those given placebo aborted spontaneously; overall 25 of the 56 women given misoprostol had uterine bleeding compared with only 2 of 55 on placebo.

Effects on the fetus. Misoprostol on its own is only a weak abortifacient and is often ineffective when used alone for the termination of pregnancy (see below). However, it has been widely misused for this purpose in some countries, notably Brazil,[1,2] and anecdotal reports have associated congenital malformations with such misuse during the first trimester of pregnancy. A systematic review[3] of 4 case-control studies confirmed that misoprostol was associated with an increased risk of congenital abnormality, particularly Möbius syndrome and terminal transverse limb defects.

Effects on the uterus. For reference to uterine rupture in women given misoprostol to induce labour or terminate pregnancy, see under Dinoprostone, p.2007.

Toxic shock syndrome. Fatal toxic shock syndrome has occurred in a few women who underwent medical termination of pregnancy using oral mifepristone and vaginal misoprostol, although a causal relationship between these drugs and the deaths has not been established (see under Mifepristone, p.2011).

Precautions

Misoprostol should not be used to treat peptic ulcer disease in patients who are pregnant or who may become pregnant because it can cause uterine contraction. It should be used with caution in patients in whom hypotension might cause severe complications. Patients with conditions such as inflammatory bowel disease, for whom profound diarrhoea could be dangerous, should be monitored carefully if misoprostol is given.

Like other prostaglandins used in the termination of pregnancy (see Dinoprostone, p.2008), misoprostol should not be used in women at increased risk of uterine rupture, such as those with multiple pregnancy or a uterus scarred by previous caesarean section. Once a prostaglandin has been given to terminate pregnancy it is essential that termination take place; if the prostaglandin is unsuccessful other measures should be used.

Breast feeding. Misoprostol acid was detected in the breast milk of 10 women given a single oral dose of misoprostol for postpartum uterine atony.[1] The concentration rose rapidly, peaked at about 1 hour, and had fallen towards the detection limit by about 5 hours after the dose. Product information for misoprostol licensed for use in gastric ulceration advises that it should not be given to breast-feeding women because misoprostol acid could potentially cause diarrhoea in the infant.

1. Vogel D, *et al.* Misoprostol versus methylergometrine: pharmacokinetics in human milk. *Am J Obstet Gynecol* 2004; **191:** 2168–73.

Inflammatory bowel disease. Life-threatening diarrhoea was reported in a patient with unrecognised Crohn's disease after 6 doses of misoprostol.[1] Abdominal cramps, pain, and profuse watery diarrhoea also occurred after 3 doses of misoprostol in a woman with Crohn's disease.[2] In a cohort study of misoprostol taken with NSAIDs for arthritis there were 13 patients with a history of inflammatory bowel disease; 7 did not develop diarrhoea, 3 developed mild diarrhoea, 1 developed severe diarrhoea that stopped when misoprostol was withdrawn, and 2 developed bloody diarrhoea.[3]

Interactions

NSAIDs. It has been suggested that *aspirin* and *NSAIDs*, which are prostaglandin synthetase inhibitors, might alter the efficacy of misoprostol used for termination of pregnancy by inhibiting uterine cramping. However, studies in women undergoing medical[1] or surgical[2] termination found that NSAIDs did not reduce the efficacy of misoprostol. In another study,[3] *diclofenac* did not reduce the efficacy of medical termination using mifepristone followed by misoprostol.

Pharmacokinetics

Misoprostol is reported to be rapidly absorbed and metabolised to its active form (misoprostol acid; SC-30695) after oral doses; peak plasma concentrations of misoprostol acid occur after about 15 to 30 minutes. Food reduces the rate but not the extent of absorption. Misoprostol acid is further metabolised by oxidation in a number of body organs and is excreted mainly in the urine. The plasma elimination half-life is reported to be between 20 and 40 minutes. Misoprostol acid is distributed into breast milk.

Uses and Administration

Misoprostol is a synthetic analogue of alprostadil (prostaglandin E_1; p.2183).

It is used in the treatment of benign gastric and duodenal **ulceration** (below) including that associated with NSAIDs. The usual oral dose is 800 micrograms daily in two to four divided doses with food. Treatment is initially given for at least 4 weeks, even if symptoms are relieved sooner, and may continue for up to 8 weeks if necessary. Further courses may be used to treat relapse.

Misoprostol is also used prophylactically with NSAIDs to prevent NSAID-induced ulcers. The usual oral dose is 200 micrograms two to four times daily. A dose of 100 micrograms four times daily may be used in patients not tolerating the higher dose. Some preparations of NSAIDs contain misoprostol in an attempt to limit their adverse effects on the gastrointestinal mucosa.

Misoprostol may be used to ripen the cervix before surgical **termination of pregnancy** (below) in the first trimester. A single oral dose of misoprostol 400 micrograms is given 3 to 4 hours before surgery. It may also be used for medical termination of pregnancy at up to 49 days of amenorrhoea, in a single oral dose of 400 micrograms given 36 to 48 hours after mifepristone. Misoprostol has also been used for induction of labour and in the management of postpartum haemorrhage (see below).

Labour induction and augmentation. Prostaglandins are well established for the induction of labour (p.2002) and misoprostol has been widely investigated for this indication. A systematic review[1] of studies of misoprostol given *vaginally* found that it increased cervical ripening and induced labour. It was more effective than vaginal or intracervical dinoprostone, reducing the need for oxytocin augmentation and improving the rate of vaginal delivery achieved within 24 hours. It was also found to be more effective than intravenous oxytocin. Most studies used misoprostol tablets in a dose of 50 micrograms vaginally every 4 hours, but reported doses have varied from 25 micrograms every 2 to 3 hours, to 100 micrograms every 6 to 12 hours. Low doses of misoprostol resulted in more use of oxytocin, but caused less uterine hyperstimulation. Although unlicensed, misoprostol is reported to be used outside clinical studies particularly in the USA, and the American College of Obstetricians and Gynecologists has recommended a dose of 25 micrograms intravaginally every 3 to 6 hours.[2] Misoprostol has also been given *orally* but this route is less well established. A wide range of doses have been reported but most studies have used 50 micrograms every 4 hours. Some reviews have found oral to be less effective than vaginal misoprostol.[2,3] However, others[4] have concluded that oral use produces similar outcomes to vaginal misoprostol, with less hyperstimulation, but that comparison is complicated by the wide variation in doses. Overall, oral misoprostol appears to be at least as effective as vaginal dinoprostone, but because of limited data it should be used with caution.[4] The risk of uterine hyperstimulation may be increased with misoprostol by either route, particularly at higher doses,[1,4] and it should not be used in women with scarred uteri from previous caesarean delivery or uterine surgery[2] (see also Effects on the Uterus, under Adverse Effects of Dinoprostone, p.2007). There has also been some limited investigation of misoprostol given *sublingually*.[3,5,6]

Misoprostol has been tried for labour induction after intra-uterine fetal death, generally in higher doses than those used for labour at term. It has been used successfully in doses of 400 micrograms every 4 hours orally[7] and 400 micrograms every 12 hours vaginally.[8] A comparison of 200 micrograms given either orally or vaginally every 6 hours, to a maximum of 4 doses or until labour was established, found the time from induction to delivery to be shorter, and fewer women needed oxytocin augmentation, with vaginal use.[9]

Misoprostol may also be used for active management of the third stage of labour (see Postpartum Haemorrhage, below).

Organ and tissue transplantation. Misoprostol 200 micrograms orally four times daily improved renal function in ciclosporin-treated recipients of renal transplants.[1] The number of patients who had acute graft rejection was lower in the misoprostol group than in the placebo group. However, another study[2] did not indicate any difference in the incidence of rejection episodes or in renal function when misoprostol was added to immunosuppressant regimens for kidney transplantation, and misoprostol does not appear to have gained a role in the usual management of renal transplantation (p.1813).

Peptic ulcer disease. Misoprostol is used in the prophylaxis and treatment of peptic ulceration (p.1702) in patients taking NSAIDs. There is good evidence that misoprostol can reduce the risk of gastric and duodenal ulcer formation in patients on long-term NSAID treatment,[1-4] and it appears more effective in this respect than histamine H_2-antagonists,[1] for which evidence of benefit against gastric injury is less persuasive. However, misoprostol's abdominal adverse effects, particularly diarrhoea and abdominal cramps, may limit its usefulness and patient acceptability. Omeprazole, which is equally effective in preventing NSAID-induced ulceration, is better tolerated.[3] Improved formulations, in which the active isomer of misoprostol is bound to a polymer, may reduce adverse effects.[5]

Postpartum haemorrhage. Prostaglandins, usually given parenterally, have an accepted role in the management of established postpartum haemorrhage (p.2003) not controlled by oxytocin and ergot preparations. There have been reports[1-3] of the successful use of rectal misoprostol to control postpartum haemorrhage, using single doses of 800 or 1000 micrograms. A review[4] found that there was some evidence for reduced blood loss with lower doses of misoprostol, and suggested that oral, sublingual, rectal, or a combination of these, might be the most effective routes; possible regimens were 200 to 400 micrograms sublingually or rectally, or similar doses plus 200 micrograms orally. It also suggested that the oral dose of misoprostol should not exceed 600 micrograms because of the risk of hyperpyrexia. There have also been a few cases in which intra-uterine misoprostol 800 micrograms has controlled refractory secondary postpartum haemorrhage.[5,6]

Misoprostol has also been given immediately after delivery in the active management of third-stage labour. In a study[7] of more than 18 500 women treated in hospital, which compared oral misoprostol 600 micrograms with intramuscular or intravenous oxytocin, a higher proportion of women who received misoprostol had blood loss of at least 1000 mL and required additional oxytocics. Misoprostol was also associated with significantly more shivering and pyrexia. The results of this large study suggest that parenteral oxytocin is preferred for active management, but it has been argued that misoprostol may be particularly useful in preventing postpartum haemorrhage in developing countries where there is limited access to healthcare facilities and parenteral oxytocics.[8-10] Two placebo-controlled studies have addressed this argument, reporting that oral[11] or sublingual[12] misoprostol used in rural primary healthcare settings reduced postpartum haemorrhage, particularly severe haemorrhage (1000 mL or more). A systematic review[13] concluded that oral misoprostol was less effective than injectable oxytocics in reducing blood loss and the use of additional oxytocics, but that it may be used where no injectable uterotonic is available.

Termination of pregnancy. Prostaglandins are widely used for the termination of pregnancy (p.2004) and misoprostol has been studied both for cervical preparation and for inducing uterine contractions.

In the *first trimester*, misoprostol is used for cervical ripening before surgical termination; it has been reported to be effective when given orally, sublingually, or vaginally,[1-4] usually in a dose of 400 micrograms. Oral misoprostol (400 micrograms) given after mifepristone is effective in medical termination of early pregnancy of up to 63 days, and especially so at up to 49 days.[5,6] Misoprostol 800 micrograms has also been given vaginally after mifepristone,[7-10] and a regimen of 2 or 3 doses of sublingual misoprostol after oral mifepristone has been reported to be effective.[11] Successful use of vaginal misoprostol with intramuscular or oral methotrexate has also been described.[12-15]

Misoprostol on its own is only a weak abortifacient, particularly when given orally, and congenital malformations have been reported after failed abortion attempts using misoprostol alone (see Effects on the Fetus, above). However, there is interest in finding a regimen that is effective, particularly in countries where mifepristone is unavailable. A dose of 800 micrograms vaginally, repeated after 24 hours, has been suggested for pregnancy of up to 63 days.[16,17] A large study[18] has also reported that 800 micrograms given every 12 hours for 3 doses was less effective when given sublingually than vaginally; the routes were equally effective when misoprostol was given every 3 hours, but sublingual administration caused more adverse effects such as fever, chills, shivering, and diarrhoea.

Misoprostol has also been studied for termination of pregnancy during the *second trimester*. It has been used in various regimens to induce medical termination, given either alone[19,20] or after oral mifepristone,[21,22] and reported to be effective when given vaginally, sublingually, or orally. The time to complete abortion may depend on the dose, dosage interval, and route of administration. Compared with other prostaglandins, intravaginal misoprostol alone (generally as a single dose of 200 micrograms or repeated after 12 hours if necessary) has been reported to be as effective as dinoprostone for medical termination.[23] Another study[24] found 400 micrograms intravaginally every 3 hours, up to 5 doses, to be at least as effective as intra-amniotic carboprost. The use of buccal misoprostol to prepare the cervix before surgical termination has also been described.[25]

In the management of first trimester *pregnancy failure*, intravaginal misoprostol has been proposed as an alternative to surgery for evacuation of the uterus.[26] Doses have ranged from 400 to 800 micrograms, but the lower doses tend to be less effective.[27] Misoprostol has also been used with mifepristone for uterine evacuation after pregnancy failure (see Termination of Pregnancy, p.2012) and to induce labour where late *intra-uterine fetal death* has occurred (see Labour Induction, p.2012).

Pharmacopoeias. In *Chin.*, *Eur.* (see p.vii), *Jpn*, and *US*.

Ph. Eur. 6.2 (Oxytocin). A cyclic nonapeptide having the structure of the hormone produced by the posterior lobe of the pituitary that stimulates contraction of the uterus and milk ejection in receptive mammals. It is obtained by chemical synthesis and is available in the freeze-dried form as an acetate. A white or almost white, hygroscopic powder. Very soluble in water and in dilute solutions of dehydrated alcohol and of acetic acid. A 2% solution in water has a pH of 3.0 to 6.0. Store at 2° to 8° in airtight containers. Protect from light.

Ph. Eur. 6.2 (Oxytocin Concentrated Solution). A solution of oxytocin with a concentration of not less than 250 micrograms of oxytocin per mL. It may contain a suitable antimicrobial preservative. A clear colourless liquid with a pH of 3.0 to 5.0. Store at 2° to 8°. Protect from light.

USP 31 (Oxytocin). A nonapeptide hormone having the property of causing the contraction of uterine smooth muscle and of the myoepithelial cells within the mammary glands. It is prepared by synthesis or obtained from the posterior lobe of the pituitary of healthy domestic animals used for food by man. Its oxytocic activity is not less than 400 units/mg. Store in airtight containers at 2° to 8°.

Units

12.5 units of oxytocin for bioassay are contained in about 21.4 micrograms of synthetic peptide (with human albumin 5 mg and citric acid) in one ampoule of the fourth International Standard (1978).

Adverse Effects

Oxytocin given in high doses, or to women who are hypersensitive to it, may cause uterine hyperstimulation with hypertonic or tetanic contractions, leading to uterine rupture and soft tissue damage. Effects in the fetus include bradycardia, arrhythmias, asphyxiation, and perhaps death.

Maternal deaths from severe hypertension and subarachnoid haemorrhage have occurred. Rapid intravenous injection of oxytocin has produced acute transient hypotension with flushing and reflex tachycardia. Postpartum haemorrhage, fatal afibrinogenaemia, and disseminated intravascular coagulation have been reported, but may be due to complications of labour induction rather than oxytocin itself.

High doses of oxytocin infused over prolonged periods can also cause water retention leading to hyponatraemia and intoxication, which may progress to convulsions, coma, and even death. Vasopressin-like activity (see p.2412) is more likely with oxytocin of natural origin but may occur even with the synthetic peptide.

Other adverse effects include headache, nausea and vomiting, skin rashes, cardiac arrhythmias, pelvic haematoma, and anaphylactic and other hypersensitivity reactions.

There are reports of neonatal jaundice and retinal haemorrhage associated with the use of oxytocin in the management of labour.

Adverse effects after intranasal use of oxytocin have included nasal irritation, rhinorrhoea, lachrymation, uterine bleeding, and violent uterine contractions.

Inappropriate use. In a 1988 comment on the misuse of oxytocin in labour,[1] it was noted that statements on the management of labour were often misinterpreted as meaning that all women who failed to make adequate progress in terms of cervical dilatation should be given oxytocin. This was only true if poor progress was due to poor uterine action, and would be dangerous where there was disproportion; the decision to use oxytocin required careful assessment by an experienced obstetrician. In the previous 2 years the authors had seen one case of fractured pelvis, 2 of ruptured uterus, and 7 of cerebral palsy from fetal hypoxia, all of which were thought to be due to the ill-advised use of oxytocin to augment labour. More than a decade later the injudicious use of oxytocin during labour, with adverse outcomes including neonatal brain damage and death, continues to be reported. A review[2] of obstetric malpractice claims in Sweden found that the incorrect use of oxytocin was obvious in 37 of 54 cases; often, the oxytocin infusion had been increased despite a non-reassuring fetal heart-rate pattern with or without overly frequent uterine contractions, or fetal monitoring was inadequate and hence fetal distress not recognised.

For reference to haemorrhage and to neonatal hyperbilirubinaemia occurring after an oxytocin challenge test, see under Uses and Administration, below.

Neonatal jaundice. Analysis of neonatal jaundice in 12 461 single births confirmed a higher incidence of jaundice in offspring of mothers given oxytocin, independent of gestational age at birth, sex, race, epidural analgesia, method of delivery, and birth-weight, which were also associated with jaundice.[1] A later review[2] of 12 023 single births also found some of these factors to be associated with neonatal hyperbilirubinaemia, but not epidural analgesia or the use of oxytocin. Another smaller population study[3] also concluded that oxytocin was not significantly related to neonatal jaundice. In a total of 90 infants born to mothers after oxytocin-induced labour in 2 studies,[4,5] haematological disturbances were noted. These included erythrocyte fragility or reduction in erythrocyte deformability, hyponatraemia, hypo-osmolality, and an increase in serum-bilirubin concentration. Glucose injection, used as a vehicle for oxytocin may have further aggravated these changes.[5] A comparison[6] of women who received oxytocin infusion in either glucose 5% or sodium chloride 0.9% found the use of glucose to be associated with more cases of hyponatraemia in cord plasma, and neonatal hyperbilirubinaemia. In contrast, another study[7] found no difference between these diluents, but did report that neonatal bilirubin concentrations were higher when oxytocin had been used for augmentation of labour, compared with labour induction.

The symbol † denotes a preparation no longer actively marketed

Water intoxication. Oxytocin-induced water intoxication is most likely to arise as a result of prolonged attempts to empty the uterus in missed abortion or mid-trimester termination of pregnancy, but it has also been described after oxytocin infusion in other conditions including induction of labour.[1] Irrespective of the oxytocin concentration, patients in virtually all the reported cases have received more than 3.5 litres of infused fluid. Convulsions and somnolence associated with hyponatraemia have also been reported in a patient who was drinking more than 5 litres of herbal tea daily while using intranasal oxytocin 8 times or more daily.[2]

Another factor contributing to hyponatraemia is the antidiuretic effect of the pethidine and morphine commonly used for analgesia with oxytocin infusions. Water intoxication usually presents with fits and loss of consciousness but in some cases there may be preceding signs such as raised venous pressure, bounding pulse, and tachycardia. Diagnosis is confirmed by profound hyponatraemia; the mechanism appears to be more complex than simply haemodilution by the infused water. Treatment consists of controlling convulsions and maintaining an airway; oxytocin infusion must be stopped and isotonic, or even hypertonic, saline may be infused. Diuresis may then be assisted with furosemide. The prime objective, however, should be prevention; no patient should receive more than 3 litres of fluid containing oxytocin, and a careful fluid balance record is essential.

2. Mayer-Hubner B. Pseudotumour cerebri from intranasal oxytocin and excessive fluid intake. *Lancet* 1996; **347:** 623.

Precautions

Oxytocin should not be given where spontaneous labour or vaginal delivery are liable to harm either the mother or the fetus. This includes significant cephalopelvic disproportion or unfavourable presentation of the fetus, placenta praevia or vasa praevia, placental abruption, cord presentation or prolapse, mechanical obstruction to delivery, fetal distress or hypertonic uterine contractions. It should not be used where there is a predisposition to uterine rupture, as in multiple pregnancy or high parity, polyhydramnios, or the presence of a uterine scar from previous caesarean section. Oxytocin should not be used for prolonged periods in resistant uterine inertia, severe pre-eclampsia, or severe cardiovascular disorders.

When given for induction or enhancement of labour particular care is needed in borderline cephalopelvic disproportion, less severe degrees of cardiovascular disease, and in patients over 35 years of age or with other risk factors. Careful monitoring of fetal heart rate and uterine motility is essential so that dosage of oxytocin can be adjusted to individual response; the drug should be given by intravenous infusion, preferably by means of an infusion pump. Infusion should be stopped immediately if fetal distress or uterine hyperactivity occur.

Over-vigorous labour should be avoided in cases of intra-uterine fetal death, or where there is meconium-stained amniotic fluid, because there is a risk of amniotic fluid embolism.

The risk of water intoxication should be borne in mind, particularly when high doses of oxytocin are given over a long time. Infusion volumes should be kept low, and in such circumstances an electrolyte-based infusion fluid should be used rather than glucose solution. Fluid intake by mouth should be restricted and a fluid balance chart maintained; serum electrolytes should be measured if electrolyte imbalance is suspected.

Oxytocin challenge test. For the suggestion that oxytocin challenge testing should be used with caution in women whose offspring might be at risk of hyperbilirubinaemia, see under Uses and Administration, below.

Interactions

Oxytocin may enhance the vasopressor effects of sympathomimetics. Some inhalational anaesthetics, such as cyclopropane or halothane, may enhance the hypotensive effect of oxytocin and reduce its oxytocic effect; cardiac arrhythmias may occur. Prostaglandins and oxytocin may potentiate the effects of each other on the uterus; the UK licensed product information for oxytocin states that it should not be started for 6 hours after use of vaginal prostaglandins.

Pharmacokinetics

Oxytocin undergoes enzymatic destruction in the gastrointestinal tract but it is rapidly absorbed from the mucous membranes when given intranasally. It is metabolised by the liver and kidneys with a plasma half-life of only a few minutes. Only small amounts are excreted unchanged in the urine.

Uses and Administration

Oxytocin is a cyclic nonapeptide secreted by the hypothalamus and stored in the posterior lobe of the pituitary gland. It may be prepared from the gland of mammals or by synthesis.

Oxytocin causes contraction of the uterus, the effect increasing with the duration of pregnancy due to proliferation of oxytocin receptors. Small doses increase the tone and amplitude of the uterine contractions; large or repeated doses result in tetany. Oxytocin also stimulates the smooth muscle associated with the secretory epithelium of the lactating breast causing the ejection of milk but having no direct effect on milk secretion. It has a weak antidiuretic action.

Oxytocin is used for the induction and augmentation of labour, to control postpartum bleeding and uterine hypotonicity in the third stage of labour, and to promote lactation in cases of faulty milk ejection. It is also used in missed abortions, but other measures may be preferred.

For the **induction** or **augmentation of labour** (below) oxytocin may be given by slow intravenous infusion preferably by means of an infusion pump. A solution containing 5 units in 500 mL of a physiological electrolyte solution such as sodium chloride 0.9% has been recommended but more concentrated solutions may be given via infusion pump, and current UK guidelines suggest 10 or 30 units in 500 mL of diluent. Infusion is begun at a recommended initial rate of 1 to 2 milliunits/minute and then gradually increased at intervals of at least 30 minutes, until a maximum of 3 or 4 contractions are occurring every 10 minutes. A rate of up to 6 milliunits/minute is reported to produce plasma oxytocin concentrations comparable to those in natural labour, and 12 milliunits/minute is usually the most that is needed but doses of up to 20 milliunits/minute or more may be required. UK guidelines suggest that 32 milliunits/minute should not be exceeded, and no more than a total of 5 units should be given in 1 day. Oxytocin should not be started for 6 hours after vaginal prostaglandins have been given. Fetal heart rate and uterine contractions should be monitored continuously. Once labour is progressing, oxytocin infusion may be gradually withdrawn.

For the treatment and prevention of **postpartum haemorrhage** (below) oxytocin may be given by slow intravenous injection in a dose of 5 units; this may be followed in severe cases by intravenous infusion of 5 to 20 units in 500 mL of a suitable non-hydrating diluent. The *BNF* suggests that in the treatment of uterine bleeding, higher doses may also be considered: a single dose of 10 units by slow intravenous injection may be used, followed if necessary by an infusion containing up to 30 units in 500 mL. A single dose of 5 units by slow intravenous injection has also been given during caesarean section, immediately after delivery of the child. An alternative for the prophylaxis of postpartum haemorrhage in the routine management of the third stage of labour is the intramuscular injection of oxytocin 5 units with ergometrine maleate 500 micrograms after delivery of the anterior shoulder, or, at the latest, immediately after delivery of the infant; the *BNF* suggests a single intramuscular dose of oxytocin 10 units used alone if ergometrine is contra-indicated. In the USA a dose of 10 units of oxytocin, by intravenous infusion at a rate of 20 to 40 milliunits/minute, or as an intramuscular injection, has been recommended for treatment of postpartum haemorrhage.

In **missed abortion** a suggested dose in the UK is 5 units by slow intravenous injection, followed if necessary by intravenous infusion at a rate of 20 to 40 milliunits/minute or higher.

Oxytocin nasal spray is used to facilitate **lactation**; a dose of one spray, delivering 4 units, into one nostril 5 minutes before suckling has been used. However, evidence for its efficacy is limited and there is a danger that the mother may become dependent upon its action; such usage is not generally recommended (see p.2003).

An **oxytocin challenge test** (below) has been used to evaluate fetal distress in pregnant patients at high risk.

Synthetic derivatives of oxytocin such as demoxytocin (p.2006) have been used similarly.

Labour induction and augmentation. Oxytocin infusions have proved to be one of the most successful agents for induction and augmentation of labour, as discussed on p.2002. There have been numerous studies on the dosage of oxytocin required to induce or augment labour. Various dosage regimens have been tried, and studies have reported using initial doses ranging from 0.5 to 6 milliunits/minute, dose increases of 1 to 6 milliunits/minute, and intervals between increases of 15 to 40 minutes.[1] Higher doses and shorter intervals between increases can shorten labour and reduce rates of intra-amniotic infection and caesarean delivery, but result in more uterine hyperstimulation and emergency caesarean deliveries for fetal distress.[1] Low-dose regimens are now generally advocated; for example, UK guidelines[2] favour a starting dose of 1 to 2 milliunits/minute, increased at intervals of 30 minutes, and titrated against contractions to a maximum of 32 milliunits/minute. WHO[3] suggests a starting dose of 2.5 milliunits/minute, increased at intervals of 30 minutes, and titrated against contractions to a maximum of 60 milliunits/minute. However, it has been pointed out that no one regimen has been clearly proved superior.[1,4,5]

Oxytocin challenge test. The oxytocin challenge test (OCT) is designed to detect placental insufficiency, and identify fetuses at risk of still-birth or complications during labour. In a study, it was performed on 399 occasions in 305 women with pregnancies at risk and a gestational age of 36 weeks or more.[1] Oxytocin 1 milliunit/minute was given by infusion pump and increased every 5 to 10 minutes until a contraction rate of 3 per 10 minutes was achieved. Less than 10% of late or variable decelerations of fetal heart rate (FHR) was judged negative; 10 to 29% was judged equivocal; and 30% or more was judged positive. The finding of a positive or equivocal response to the OCT was considered a prediction of decelerations of the FHR during parturition, though the type of risk might vary. After 100 OCTs in 90 pregnant women considered at risk[2] it was concluded that a negative result is a reliable test of fetal well-being which should encourage obstetricians to await spontaneous onset of labour in preference to intervention. However, there have been reports of fetal death occurring despite a negative response to the OCT.[3-5] Another study[6] found that in 239 women with an unequivocal OCT result, a negative response was a reliable test for a good outcome, but that a positive result was not a reliable predictor of poor outcome.

Adverse effects associated with the OCT have included haemorrhage occurring in a patient after the second of two tests (the patient was found to have a major placenta praevia)[7] and neonatal hyperbilirubinaemia.[8] The latter effect led to the suggestion that the OCT should be used with caution in women whose babies might be at risk from hyperbilirubinaemia.

Postpartum haemorrhage. Oxytocin is used for the prophylaxis and treatment of postpartum haemorrhage (p.2003). In the active management of the third stage of labour, the combination of oxytocin and ergometrine may be associated with a small reduction in the risk of postpartum haemorrhage compared with oxytocin alone, but a higher incidence of nausea, vomiting, and hypertension.

Retained placenta. Oxytocin injected into the vein of the umbilical cord has been used to assist the removal of retained placenta. A meta-analysis[1] of 12 studies found evidence that oxytocin reduced the incidence of manual removal of the retained placenta, although there was no apparent benefit in terms of other measures including blood loss, curettage, and infection. The removal of the placenta is important to allow contraction of the myometrium and prevention of excessive blood loss, and is one reason for the use of oxytocin in the active management of the third stage of labour, as discussed under Postpartum Haemorrhage—see above and on p.2003.

Prolactin

Galactin; Galactina; Hormona lactogénica; Hormona luteotrópica; Lactoestimulina; Lactogen; Lactogenic Hormone; Lactógeno; Lactotropin; LMTH; LTH; Luteomammotropic Hormone; Luteotrophic Hormone; Luteotropin; Luteotropina; Mammotropin; Mamotropina; Prolactina.

Пролактин

CAS — 9002-62-4; 12585-34-1 (sheep); 56832-36-1 (ox); 9046-05-3 (pig).

Profile

Prolactin is a water-soluble protein from the anterior pituitary; it is structurally related to growth hormone (p.1799). In *animals*, prolactin has many actions and is involved in reproduction, parental care, feeding of the young, electrolyte balance, and growth and development. In humans it has a definite role in inducing milk production; oxytocin (p.2016) stimulates milk ejection. Relatively high concentrations of prolactin have been found in amniotic fluid. Placental lactogen has been shown to have prolactin-like activity. Prolactin secretion is stimulated by suckling and, for a few months after delivery, it has an inhibitory effect on the ovaries, acting as a natural contraceptive.

The hypothalamus can both stimulate and inhibit prolactin secretion by the anterior pituitary; the inhibitory influence is predominant and is mediated through a dopaminergic system. Dopamine binds to the lactotrope D_2 receptor to inhibit prolactin synthesis and release. Noradrenaline and gamma-aminobutyric acid are also inhibitory as are dopaminergic drugs such as bromocriptine. Although protirelin (p.2176) has prolactin-releasing activity, there is evidence for the existence of a separate hypothalamic releasing factor (PRF). Prolactin secretion may also be stimulated by methyldopa, metoclopramide, reserpine, opioid analgesics, and phenothiazine or butyrophenone antipsychotics.

Hyperprolactinaemia, which is associated with a variety of other endocrine disorders, is discussed on p.2079.

Prolactin has been given by intramuscular injection in the management of lactation disorders and some forms of menstrual disturbance.

Ritodrine Hydrochloride

(BANM, USAN, rINNM) ⊗

DU-21220 (ritodrine); Hidrocloruro de ritodrina; Ritodrin Hidroklorür; Ritodrine, Chlorhydrate de; Ritodrini Hydrochloridum. *erythro*-2-(4-Hydroxyphenethylamino)-1-(4-hydroxyphenyl)propan-1-ol hydrochloride.

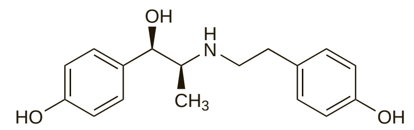
Ритодрина Гидрохлорид

$C_{17}H_{21}NO_3$,HCl = 323.8.

CAS — 26652-09-5 (ritodrine); 23239-51-2 (ritodrine hydrochloride).

ATC — G02CA01.

ATC Vet — QG02CA01.



(ritodrine)

Pharmacopoeias. In *Br.*, *Jpn*, and *US*.

BP 2008 (Ritodrine Hydrochloride). A white or almost white, crystalline powder. Freely soluble in water; soluble in dehydrated alcohol; practically insoluble in acetone and in ether. A 2% solution in water has a pH of 4.5 to 6.0. Store in airtight containers.

USP 31 (Ritodrine Hydrochloride). A white to nearly white, odourless or practically odourless, crystalline powder. Freely soluble in water and in alcohol; practically insoluble in ether; soluble in propyl alcohol. pH of a 2% solution in water is between 4.5 and 6.0. Store in airtight containers at a temperature of 25°, excursions permitted between 15° and 30°.

Adverse Effects and Precautions

As for Salbutamol Sulfate, p.1131. Leucopenia or agranulocytosis has been reported occasionally with prolonged intravenous use.

In women given ritodrine for premature labour, the risk of pulmonary oedema means that extreme caution is required and the precautions and risk factors discussed under Salbutamol Sulfate, p.1132, apply.

Effects on the eyes. Ritodrine and to a lesser extent salbutamol have been implicated in retinopathy in the premature infant when used for premature labour.[1]

1. Michie CA, *et al.* Do maternal β-sympathomimetics influence the development of retinopathy in the premature infant? *Arch Dis Child* 1994; **71:** F149.

Effects on the heart. Myocardial ischaemia or signs of myocardial ischaemia have been reported in patients given ritodrine.[1-3] Sinus tachycardia and ST-segment depression commonly occur in patients given ritodrine, but the relationship between these changes and ischaemia remains unclear.[3]

1. Brosset P, *et al*. Cardiac complications of ritodrine in mother and baby. *Lancet* 1982; **i:** 1468.
2. Ben-Shlomo I, *et al.* Myocardial ischaemia during intravenous ritodrine treatment: is it so rare? *Lancet* 1986; **ii:** 917–18.
3. Verhaert D, Van Acker R. Acute myocardial infarction during pregnancy. *Acta Cardiol* 2004; **59:** 331–9.

Effects on skeletal muscle. Elevated serum-creatine kinase concentrations have been found in women given ritodrine tocolysis,[1] and there have been rare reports of rhabdomyolysis.[1,2]

1. Matsuda Y, *et al.* Evaluation of creatine kinase level during long-term tocolysis. *J Perinat Med* 2002; **30:** 476–9.
2. Nasu K, *et al.* Rhabdomyolysis caused by tocolysis with oral ritodrine hydrochloride in a pregnant patient with myotonic dystrophy. *Gynecol Obstet Invest* 2006; **61:** 53–5.

Pulmonary oedema. Several cases of pulmonary oedema have been reported in patients given a $beta_2$ agonist, including ritodrine, for premature labour.[1-4] In 1995 the UK CSM[4] commented that it had received 10 reports of pulmonary oedema, fatal in 2 patients. The CSM considered that fluid overload was the most important predisposing factor. Other risk factors included multiple pregnancies, a history of cardiac disease, and maternal infection. For further discussion of the precautions necessary in the use of $beta_2$ agonists to treat premature labour, and the risk factors involved, see Salbutamol, p.1132.

4. Committee on Safety of Medicines/Medicines Control Agency. Reminder: ritodrine and pulmonary oedema. *Current Problems* 1995; **21:** 7. Also available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2015619&RevisionSelectionMethod=LatestReleased (accessed 30/06/08)

Interactions

As for Salbutamol Sulfate, p.1132.

Pharmacokinetics

Ritodrine is rapidly absorbed from the gastrointestinal tract but is subject to fairly extensive first-pass metabolism; about 30% of an oral dose is bioavailable. It is metabolised in the liver primarily by conjugation with glucuronic acid or sulfate and excreted in urine as unchanged drug and metabolites. About 70 to 90% of a dose is reported to be excreted in the urine within 10 to 12 hours. It crosses the placenta.

Uses and Administration

Ritodrine hydrochloride is a direct-acting sympathomimetic with mainly beta-adrenergic activity and a selective action on $beta_2$ receptors (a $beta_2$ agonist). It has general properties similar to those of salbutamol (see p.1133). It decreases uterine contractility and is used to arrest premature labour (p.2003).

Ritodrine hydrochloride is usually given by intravenous infusion. Where possible this should be with the aid of a **syringe pump**, when the concentration should be 3 mg/mL, using glucose 5% as the diluent. A recommended initial rate of infusion is 50 micrograms/minute increased at intervals of 10 minutes by increments of 50 micrograms/minute until there is evidence of patient response, which is usually at a rate of 150 to 350 micrograms/minute, the latter figure being the maximum recommended rate. If no syringe pump is available then the infusion may be made using a **controlled infusion device** to deliver a more dilute solution of 300 micrograms/mL, with glucose 5% being used once again as the diluent. The same dose is used as with the syringe pump.

The maternal pulse should be monitored throughout the infusion and the rate adjusted to avoid a maternal heart rate of more than 140 beats/minute. A close watch should also be kept on the patient's state of hydration since fluid overload is considered to be a key risk factor for pulmonary oedema. The infusion should be continued for 12 to 48 hours after the contractions have stopped. Ritodrine hydrochloride may subsequently be given **by mouth** in an initial dose of 10 mg every 2 hours for 24 hours, starting 30 minutes before the end of the intravenous infusion. Thereafter, 10 to 20 mg may be given every 4 to 6 hours according to the patient's response. The total daily oral dose should not exceed 120 mg.

If intravenous infusion is inappropriate, 10 mg may be given **intramuscularly** every 3 to 8 hours and continued for 12 to 48 hours after the contractions have stopped.

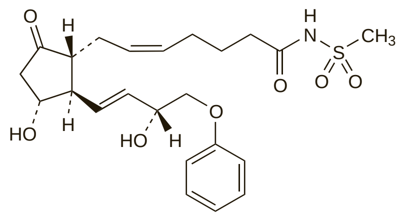
Sulprostone *(USAN, rINN)*

CP-34089; 16-Phenoxy-ω-17,18,19,20-tetranor-prostaglandin E_2-methylsulfonylamide; SHB-286; Sulproston; Sulprostona; Sulprostoni; Sulprostonum; ZK-57671. (*Z*)-7-{(1*R*,2*R*,3*R*)-3-Hydroxy-2-[(*E*)-(3*R*)-3-hydroxy-4-phenoxybut-1-enyl]-5-oxocyclopentyl}-*N*-(methylsulphonyl)hept-5-enamide.

Сульпростон

$C_{23}H_{31}NO_7S$ = 465.6.
CAS — 60325-46-4.
ATC — G02AD05.
ATC Vet — QG02AD05.



Adverse Effects and Precautions

As for Dinoprostone, p.2007. In some countries, such as France, the licensed product information for sulprostone contra-indicates its use in smokers or those who have smoked in the last 2 years, and in women over 35 years of age.

Once a prostaglandin has been given to terminate pregnancy it is essential that termination take place; if the prostaglandin is unsuccessful other measures should be used.

Effects on the cardiovascular system. A 31-year-old woman died from cardiovascular shock during an abortion induced by mifepristone followed by sulprostone. She had 12 children, one previous abortion, and was a heavy cigarette smoker.[1] Four other deaths with sulprostone had not been associated with abortion. Other reported cases that did not result in death have included myocardial infarction in a 32-year-old woman given sulprostone for intra-uterine fetal death,[2] and cardiac arrest in a 38-year-old woman, with no history of smoking, after sulprostone was given by both intramyometrial and intravenous bolus injection for postpartum haemorrhage;[3] in both cases the authors suggested that sulprostone had caused coronary artery spasm.

Inadvertent subcutaneous infusion of sulprostone was thought to have caused arterial spasm with pain and oedema in the arm of a woman being treated for postpartum haemorrhage; she recovered after treatment with iloprost infusion.[4]

4. de Koning YWCM, *et al.* Critical limb ischemia after accidental subcutaneous infusion of sulprostone. *Eur J Obstet Gynecol Reprod Biol* 1995; **61:** 171–3.

Effects on the nervous system. For a report of convulsions in epileptic patients given sulprostone, see under Dinoprostone, p.2007.

Effects on the uterus. For reference to hyperstimulation and uterine rupture after use of prostaglandins, including sulprostone, for termination of pregnancy or induction of labour, see under Dinoprostone, p.2007.

Interactions

As for Dinoprostone, p.2008.

Uses and Administration

Sulprostone is a synthetic derivative of dinoprostone (prostaglandin E_2; p.2007) that has uterine stimulant effects. It is used for dilatation of the cervix before surgical termination of pregnancy in the first trimester, for medical termination of pregnancy in the second trimester (p.2004), and to empty the uterus in missed abortion, hydatidiform mole, and intra-uterine fetal death. It is also used to control postpartum haemorrhage (p.2003).

Sulprostone is given by intravenous infusion. A dose of 500 micrograms over 3 to 6 hours is used for cervical dilatation in the first trimester. For termination of pregnancy in the second trimester, or to empty the uterus, sulprostone is infused at a rate of 100 micrograms/hour for up to 10 hours; if necessary the infusion rate may be increased to up to 500 micrograms/hour, to a maximum total dose of 1.5 mg in 24 hours. If termination is unsuccessful the course may be repeated once, 12 to 24 hours after the end of the first infusion.

To control postpartum haemorrhage, an initial infusion of 100 micrograms/hour is given. This may be increased to 500 micrograms/hour if necessary to control bleeding, then reduced to a maintenance dose of 100 micrograms/hour. A total dose of 1.5 mg in 24 hours should not be exceeded.

Sulprostone has also been given extra-amniotically and locally into the cervix. It has also been given by the intramuscular route, but this is no longer recommended.

Organic Solvents

Most of the solvents described in this chapter have no specific therapeutic use. Additional solvents used in pharmacy and described in other chapters include alcohols, chlorinated hydrocarbons such as chloroform and trichloroethylene, fixed oils, glycols, paraffins, and water.

Organic solvents are widely used in industry and toxicity has been associated with acute or chronic exposure. due to inhalation, ingestion, or absorption through the skin. Organic solvents are irritant to the skin and mucous membranes, and often affect the CNS. They may sensitise the myocardium to catecholamines and cardiac arrhythmias may occur. Chronic exposure may lead to central and peripheral neurotoxicity, as well as to renal toxicity and hepatotoxicity.

◊ References.

1. White RF, Proctor SP. Solvents and neurotoxicity. *Lancet* 1997; **349:** 1239–43.

Abuse. Since they are volatile liquids and have CNS effects many organic solvents are implicated in volatile substance abuse. Clinical features of intoxication are similar to those of alcohol intoxication, with initial CNS stimulation followed by CNS depression, which may progress to delirium, convulsions, coma, and death. Sudden death due to cardiac arrhythmias has also been reported.

References.

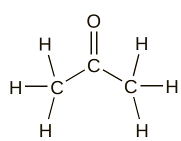
Acetone

Aceton; Acetona; Acetonas; Acétone; Acetonum; Asetoni; Dimethyl Ketone; Propanone; 2-Propanone.

Ацетон

$C_3H_6O = 58.08.$

CAS — 67-64-1.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Acetone). A volatile, clear, colourless liquid; the vapour is flammable. Miscible with water and with alcohol. Protect from light.

USNF 26 (Acetone). A transparent, colourless, mobile, volatile, very flammable liquid, having a characteristic odour. Sp. gr. not more than 0.789. Miscible with water, with alcohol, with chloroform, with ether, and with most volatile oils. A 50% solution in water is neutral to litmus. Store in airtight containers remote from fire.

Adverse Effects and Treatment

Inhalation of acetone vapour causes excitement followed by CNS depression with headache, restlessness, fatigue, and possibly convulsions, leading to coma and respiratory depression in severe cases. Vomiting and haematemesis may occur. There may be a latent period before the onset of symptoms of acetone poisoning. Similar symptoms may be seen after ingestion of acetone although hyperglycaemia has also been reported. The vapour is irritant to mucous membranes in high concentrations.

Acetone is commonly implicated in volatile substance abuse (see above).

Treatment of adverse effects consists of removal from exposure and general supportive and symptomatic measures; activated charcoal may be given if the patient presents within 1 hour of ingestion.

◊ For the possible effect of acetone on the metabolism of acetonitrile, see under Acetonitrile, below.

Pharmacokinetics

Acetone is absorbed through the lungs after inhalation. Some absorption occurs from the gastrointestinal tract. It is mostly excreted unchanged, predominantly through the lungs and also in the urine.

Uses

Acetone is widely used as an industrial, pharmaceutical, and domestic solvent; it is also used as an extraction solvent in food processing.

Acetonitrile

Acetonitrilo; Acetonitryl; Ethanenitrile; Methyl Cyanide.

Ацетонитрил

$C_2H_3N = 41.05.$

CAS — 75-05-8.

Description. Acetonitrile is a colourless liquid with an aromatic odour. Wt per mL about 0.79 g. B.p. about 81°. It emits highly toxic fumes of hydrogen cyanide when heated to decomposition or when reacted with acids or oxidising agents. Store in airtight containers.

Adverse Effects and Treatment

As for cyanides (see Hydrocyanic Acid, p.2045).

◊ Cyanide poisoning, including a fatality, has been reported[1,2] in a number of infants after ingestion of artificial nail removers containing acetonitrile. As acetonitrile is slowly metabolised to cyanide, serious toxic effects may not occur until several hours after ingestion and there is the danger that these products may be confused with acetone-based nail polish removers which are less toxic. In a report[3] of an adult who died after ingestion of acetonitrile, the onset of symptoms was delayed for 24 hours. It was considered that concomitant ingestion of acetone had slowed the metabolism of acetonitrile. In another case[4] vomiting, diarrhoea, convulsions, and reduced consciousness developed in a 35-year-old man 15 hours after occupational exposure to acetonitrile. Despite treatment for cyanide poisoning, acute renal failure and rhabdomyolysis subsequently developed.

1. Caravati EM, Litovitz TL. Pediatric cyanide intoxication and death from an acetonitrile-containing cosmetic. *JAMA* 1988; **260:** 3470–3.
2. Losek JD, *et al.* Cyanide poisoning from a cosmetic nail remover. *Pediatrics* 1991; **88:** 337–40.
3. Boggild MD, *et al.* Acetonitrile ingestion: delayed onset of cyanide poisoning due to concurrent ingestion of acetone. *Postgrad Med J* 1990; **66:** 40–1.
4. Muraki K, *et al.* Massive rhabdomyolysis and acute renal failure after acetonitrile exposure. *Intern Med* 2001; **40:** 936–9.

Pharmacokinetics

Acetonitrile is absorbed by inhalation, ingestion, and through the skin. It undergoes metabolism to cyanide, which is responsible for the toxicity of acetonitrile.

Uses

Acetonitrile is used as an industrial solvent. It may also be present in artificial nail removers.

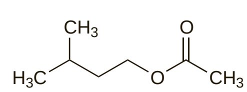
Amyl Acetate

Acetato de amilo.

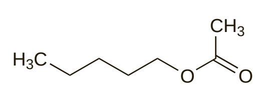
Амилацетат

$C_7H_{14}O_2 = 130.2.$

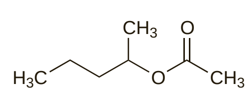
CAS — 123-92-2 (iso-amyl acetate); 53496-15-4 (sec-amyl acetate); 628-63-7 (n-amyl acetate).



iso-amyl acetate



n-amyl acetate



sec-amyl acetate

Description. Amyl acetate is a mixture of isomers, principally *iso*-, *sec*-, and *n*-amyl acetate. *iso*-Amyl acetate is a clear colourless liquid with a sharp, fruity odour. Wt per mL about 0.87 g. B.p. about 140°. Slightly soluble in water; miscible with alcohol and with ether. Store in airtight containers.

Adverse Effects and Treatment

Prolonged exposure to amyl acetate may produce headache, fatigue, and depression of the CNS. Irritation of mucous membranes may also occur.

Treatment of adverse effects consists of removal from exposure and general supportive and symptomatic measures; activated charcoal may be given if the patient presents within 1 hour of ingestion.

Effects on the heart. A 27-year-old man developed headache, nausea, and vomiting after using a paint containing amyl acetate as the solvent in an unventilated room.[1] Some days later chest pain and dyspnoea developed; he was admitted to hospital 2 weeks after exposure with heart failure which slowly responded to treatment.

1. Weissberg PL, Green ID. Methyl-cellulose paint possibly causing heart failure. *BMJ* 1979; **ii:** 1113–14.

Uses

Amyl acetate is used as a pharmaceutical and industrial solvent.

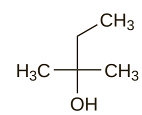
Amylene Hydrate

Aethyldimethylmethanolum; Dimethylethyl Carbinol; Hidrato de amileno; Tertiary Amyl Alcohol. 2-Methylbutan-2-ol.

Амилгидрат

$C_5H_{12}O = 88.15.$

CAS — 75-85-4.



Pharmacopoeias. In *USNF.*

USNF 26 (Amylene Hydrate). A clear, colourless liquid having a camphoraceous odour. Sp. gr. 0.803 to 0.807. Distilling range 97° to 103°. Freely soluble in water; miscible with alcohol, with chloroform, with ether, and with glycerol. Its solutions are neutral to litmus. Store in airtight containers.

Adverse Effects

Amylene hydrate is irritant and has a depressant effect on the CNS.

Uses

Amylene hydrate is used as a pharmaceutical solvent. It was formerly used as a hypnotic.

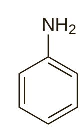
Aniline

Anilina; Phenylamine.

Анилин

$C_6H_7N = 93.13.$

CAS — 62-53-3.



Description. Aniline is a colourless or pale yellow oily liquid with a characteristic odour, readily darkening to brown on exposure to air and light. Wt per mL about 1.02 g. B.p. about 183°. Store in airtight containers. Protect from light.

Adverse Effects, Treatment, and Precautions

Inhalation, ingestion, or cutaneous absorption of aniline results in methaemoglobinaemia, with cyanosis, headache, weakness, stupor, convulsions, and coma. Irritation of the skin or mucous membranes, nausea and vomiting, and cardiac arrhythmias may occur. Haemolysis has been reported and may give rise to renal damage or jaundice. Death is usually a result of cardiovascular collapse.

Treatment may involve oxygen, methylthioninium chloride (p.1451), transfusions, or possibly haemodialysis. Gastric aspiration or activated charcoal may be considered in patients who present within 1 hour of ingestion.

Bladder papillomas have been reported in workers previously exposed to aniline. Commercial aniline may be contaminated with β-naphthylamine, a potential carcinogen.

Handling. Suitable precautions should be taken to avoid skin contact with aniline as it can penetrate skin and produce systemic toxicity.

Uses

Aniline is a solvent with wide industrial applications.

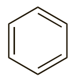
Benzene

Benceno; Benzen; Phenyl Hydride.

Бензол

C_6H_6 = 78.11.

CAS — 71-43-2.



NOTE. Benzene may be known as 'benzina', 'benzol', 'benzole', or 'benzolum'. However, 'benzol' is also used to describe a mixture of hydrocarbons and 'benzin' or 'benzine' is used as a name for a petroleum distillate (see also Petroleum Spirit, p.2026).

Description. Benzene is a clear colourless flammable liquid with a characteristic aromatic odour. Wt per mL about 0.88 g. B.p. about 80°. Store in airtight containers.

Adverse Effects, Treatment, and Precautions

Symptoms of acute poisoning after inhalation or ingestion of benzene include initial excitement or euphoria followed by CNS depression with headache, dizziness, blurred vision, and ataxia, which in severe cases may progress to coma (accompanied by hyperactive reflexes), convulsions, and death from respiratory failure. Other symptoms include nausea and irritation of the mucous membranes; ventricular arrhythmias may occur. Direct skin contact with liquid benzene may result in marked irritation, and dermatitis may develop on prolonged or repeated exposure.

Prolonged industrial exposure to benzene vapour has been associated with adverse effects on the gastrointestinal tract and the CNS but in particular with marked effects on the bone marrow and blood. Decreases in the numbers of red or white blood cells or of platelets may occur, producing symptoms of headache, fatigue, anorexia, pallor, and petechiae. In severe cases pancytopenia or aplastic anaemia may develop. Leukaemia, particularly acute myeloid leukaemia, has also developed, often many years after exposure to benzene has ceased. These effects have been reported in workers exposed to relatively high concentrations of the vapour (around 200 ppm or more) but reduced red blood cell counts and anaemia have also been reported at lower concentrations. Chromosome abnormalities have been observed after prolonged exposure to benzene, particularly at the higher concentrations associated with blood dyscrasias; however, the significance of these abnormalities in the development of leukaemia is unclear.

Treatment of poisoning consists of symptomatic and supportive measures. The UK National Poisons Information Service considers that gut decontamination (gastric lavage) is contra-indicated because it may increase the risk of aspiration. In chronic poisoning, repeated blood transfusions may be necessary. Adrenaline and other sympathomimetics should be avoided because of the risk of precipitating cardiac arrhythmias.

◊ Reviews.

Malignant neoplasms. Epidemiological data support an association between benzene exposure and acute myeloid leukaemia, but the risk after low levels of exposure (1 to 10 ppm) is less clear.[1] However, a large cohort study[2] suggested that there is an increased risk of acute myeloid leukaemia and of non-Hodgkin's lymphoma with benzene exposure at levels below 10 ppm.

2. Hayes RB, *et al.* Benzene and the dose-related incidence of hematologic neoplasms in China. *J Natl Cancer Inst* 1997; **89:** 1065–71.

Pregnancy. An evaluation of the USA National Natality and Fetal Mortality Survey noted that maternal or paternal occupational exposure to agents such as benzene was associated with an increased risk of still-birth and that paternal exposure to benzene increased the risk of low-birth-weight infants.[1]

1. Savitz DA, *et al.* Effect of parents' occupational exposures on risk of stillbirth, preterm delivery, and small-for-gestational-age infants. *Am J Epidemiol* 1989; **129:** 1201–18.

Pharmacokinetics

Benzene is absorbed after inhalation and ingestion, but is not significantly absorbed through the skin. Some is excreted unchanged from the lungs. Oxidation to phenol and related quinol compounds occurs, the metabolites being excreted in the urine as conjugates of sulfuric or glucuronic acid.

Uses

Benzene was formerly applied as a pediculicide. Its use as an industrial solvent is decreasing.

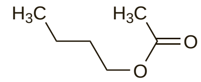
Butyl Acetate

Acetato de butilo; Butylu octan. *n*-Butyl acetate.

Бутилацетат

$C_6H_{12}O_2$ = 116.2.

CAS — 123-86-4.



Description. Butyl acetate is a clear, colourless flammable liquid with a strong fruity odour. Wt per mL about 0.88 g. B.p. 123° to 126°. Slightly soluble in water; miscible with alcohol. Store in airtight containers.

Adverse Effects

Butyl acetate is irritant. High concentrations may cause CNS depression.

Uses

Butyl acetate is used as an industrial solvent and as an extraction solvent in food processing.

Butyl Alcohol

Alcohol butílico; *n*-Butanol; *n*-Butyl Alcohol. Butan-1-ol.

Бутиловый Спирт

$C_4H_{10}O$ = 74.12.

CAS — 71-36-3.

Pharmacopoeias. In *USNF.*

USNF 26 (Butyl Alcohol). A clear, colourless, mobile liquid having a characteristic, penetrating vinous odour. Sp. gr. 0.807 to 0.809. It distils within a range of 1.5°, including 117.7°. Soluble in water; miscible with alcohol, with ether, and with many other organic solvents. Store in airtight containers at a temperature not exceeding 40°.

Adverse Effects and Precautions

Butyl alcohol may be irritant and may cause mild CNS depression with headache, dizziness, and drowsiness.

◊ References to the toxicity of butyl alcohol.

1. WHO. Butanols—four isomers: 1-butanol, 2-butanol, tert-butanol, isobutanol. *Environmental Health Criteria 65.* Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/ehc/ehc/ehc65.htm (accessed 29/06/04)
2. WHO. 1-Butanol health and safety guide. *IPCS Health and Safety Guide 3.* Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/hsg/hsg/hsg003.htm (accessed 29/06/04)

Handling. Suitable precautions should be taken to avoid skin contact with butyl alcohol as it can penetrate skin and produce systemic toxicity.

Uses

Butyl alcohol is used as an industrial and pharmaceutical solvent and as an extraction solvent in food processing.

Butylamine

Butilamina; *n*-Butylamine; Butyloamina.

Бутиламин

$C_4H_{11}N$ = 73.14.

CAS — 109-73-9.

Description. Butylamine is a colourless to pale yellow flammable liquid with an ammoniacal odour. Wt per mL about 0.744 g. B.p. about 78°. Miscible with water, with alcohol, and with ether. Store in airtight containers.

Adverse Effects and Precautions

Butylamine is irritant. Symptoms of CNS depression may be observed after exposure to high concentrations of the vapour.

Handling. Suitable precautions should be taken to avoid skin contact with butylamine as it can penetrate skin and produce systemic toxicity.

Uses

Butylamine is used as a solvent.

Carbon Disulfide

Carbon Bisulphide; Carbon Disulphide; Carbonei Sulfidum; Carboneum Bisulfuratum; Carboneum Sulfuratum; Disulfuro de carbono; Schwefelkohlenstoff; Węgla disiarczek.

Сероуглерод

CS_2 = 76.14.

CAS — 75-15-0.

S=C=S

Description. Carbon disulfide is a clear, colourless, volatile, flammable liquid with a chloroform-like odour. Commercial grades have an unpleasant odour described by some as being reminiscent of decaying radishes. Wt per mL about 1.26 g. B.p. about 46°. Store in airtight containers.

Stability. The vapour of carbon disulfide when mixed with air in the proportions of 1 to 50% is highly explosive.

Adverse Effects, Treatment, and Precautions

Carbon disulfide is irritant. Toxic effects may occur as a result of inhalation, ingestion, or absorption through the skin.

Acute poisoning may result in gastrointestinal disturbances and euphoria, followed by CNS depression. Symptoms include headache, dizziness, mood changes, and in severe cases, manic psychoses, delirium, hallucinations, coma, convulsions, and death due to respiratory failure.

Chronic poisoning has been associated with occupational exposure to carbon disulfide vapour for prolonged periods. It is characterised by peripheral neuropathies; CNS effects such as headache, fatigue, insomnia, tremor, emotional lability, extrapyramidal disorders, bipolar disorder, and encephalopathy; gastrointestinal effects including anorexia, dyspepsia, and ulcerative changes; and effects on the eye. Occupational exposure to carbon disulfide has been shown to be associated with an increased incidence of mortality from coronary heart disease. The action of carbon disulfide on endocrine function has resulted in menstrual irregularities, an increased incidence of spontaneous abortions and premature births, loss of libido, sperm abnormalities, and decreased serum-thyroxine concentrations; there is limited evidence of impaired glucose tolerance.

Treatment consists of removal from exposure and general supportive and symptomatic measures. Gastric lavage should be avoided. Adrenaline and other sympathomimetics should also be avoided because of the risk of precipitating cardiac arrhythmias. Peripheral neuropathies may be only slowly reversible.

◊ Reviews of the toxicity of carbon disulfide.

1. WHO. Carbon Disulfide. *Environmental Health Criteria 10.* Geneva: WHO, 1979. Available at: http://www.inchem.org/documents/ehc/ehc/ehc010.htm (accessed 29/06/04)
2. WHO. Recommended health-based limits in occupational exposure to selected organic solvents. *WHO Tech Rep Ser 664* 1981. Available at: http://libdoc.who.int/trs/WHO_TRS_664.pdf (accessed 03/09/08)
3. Health and Safety Executive. Carbon disulphide. *Toxicity Review 3.* London: HMSO, 1981.
4. Beauchamp RO, *et al.* A critical review of the literature on carbon disulfide toxicity. *Crit Rev Toxicol* 1983; **11:** 169–278.

Effects on endocrine function. The effects of exposure to carbon disulfide were studied retrospectively in 265 female workers in the rayon industry exposed for at least 1 year, and 291 non-exposed female workers.[1] Levels of exposure varied over the study period from 0.7 to 30.6 mg/m^3. Women exposed to carbon disulfide had a higher risk of menstrual disturbances than non-exposed women. However, there was no difference between the 2 groups in incidence of toxaemia, emesis gravidarum, spontaneous abortion, premature or overdue delivery, or congenital malformation.

1. Zhou SY, *et al.* Effects of occupational exposure to low-level carbon disulfide (CS) on menstruation and pregnancy. *Ind Health* 1988; **26:** 203–14.

Effects on the heart. An increased incidence of mortality from cardiovascular disease has been found in workers occupationally exposed to carbon disulfide.[1-3] The evidence suggested that the risk decreases after cessation of exposure. However, the association has been critically reviewed.[4]

1. Nurminen M, Hernberg S. Effects of intervention on the cardiovascular mortality of workers exposed to carbon disulphide: a 15 year follow up. *Br J Ind Med* 1985; **42:** 32–5.

4. Sulsky SI, *et al.* Critical review of the epidemiological literature on the potential cardiovascular effects of occupational carbon disulfide exposure. *Int Arch Occup Environ Health* 2002; **75:** 365–80.

Handling. Suitable precautions should be taken to avoid skin contact with carbon disulfide as it can penetrate skin and produce systemic toxicity.

Pharmacokinetics

Carbon disulfide is rapidly absorbed after inhalation and ingestion, and is also absorbed through intact skin. It is excreted unchanged through the lungs and in the urine mainly as metabolites.

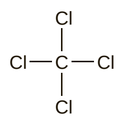
Uses
Carbon disulfide is used as an industrial solvent and has been used, in the vapour form, as an insecticide.

Carbon Tetrachloride
Tetracloruro de carbono; Węgla tetrachlorek. Tetrachloromethane.

Четырёххлористый Углерод

CCl_4 = 153.8.

CAS — 56-23-5.



Description. Carbon tetrachloride is a clear, colourless, mobile, liquid with a chloroform-like odour. Sp. gr. 1.588 to 1.590. B.p. 76° to 78°. Practically insoluble in water; miscible with alcohol, chloroform, ether, petroleum spirit, and fixed and volatile oils. Store in airtight containers at a temperature not exceeding 30°. Protect from light.

Handling. Avoid contact with carbon tetrachloride; the vapour and liquid are poisonous. Care should be taken not to vaporise carbon tetrachloride in the presence of a flame because of the production of harmful gases, mainly phosgene.

Adverse Effects
Individual response to carbon tetrachloride varies widely; inhalation or ingestion of a few mL of carbon tetrachloride has proved fatal and its toxicity appears to be increased by alcohol. Poisoning may follow inhalation, ingestion, or topical application but develops more rapidly after inhalation.

Carbon tetrachloride is irritant; repeated application of carbon tetrachloride to the skin may result in dermatitis. Aspiration may result in pulmonary oedema.

Adverse effects after acute exposure from any route include gastrointestinal disturbances such as nausea, vomiting, and abdominal pain, and CNS disturbances such as headache, dizziness, and drowsiness, with progression to convulsions, coma, and death from respiratory depression or circulatory collapse. Death may also occur as a result of ventricular arrhythmia. Hepatic and renal cellular necrosis can occur and are associated with free radical production; symptoms usually begin a few days or up to 2 weeks after acute exposure to carbon tetrachloride. Renal damage may present as oliguria, progressing to proteinuria, anuria, weight gain, and oedema. Symptoms of hepatic damage include anorexia, jaundice, and hepatomegaly. If hepatorenal necrosis is not fatal recovery is eventually complete.

Symptoms of chronic poisoning are similar to those of acute poisoning; in addition, paraesthesias, visual disturbances, anaemia, and aplastic anaemia have occurred. Carcinogenicity has been demonstrated in *animals.*

Treatment of Adverse Effects
If carbon tetrachloride vapour has been inhaled the patient should be removed to the fresh air. Clothing contaminated by liquid should be removed and the skin washed. If carbon tetrachloride has been ingested gastric lavage may be performed if the patient presents within 1 hour and activated charcoal may be given.

The usual symptomatic and supportive measures should be instituted. Hepatic and renal function should be monitored closely. Haemodialysis or peritoneal dialysis may be needed if renal function is impaired. Adrenaline or other sympathomimetics should be avoided because of the risk of precipitating cardiac arrhythmias.

Acetylcysteine (p.1550) may be given to patients recently exposed to carbon tetrachloride in an attempt to prevent or modify hepatic and renal damage.

Pharmacokinetics
Carbon tetrachloride is readily absorbed after inhalation and ingestion. It is also absorbed through the skin. Metabolism to reactive free radicals is thought to account for the hepatorenal toxicity of carbon tetrachloride.

Carbon tetrachloride is slowly excreted from the body via the lungs and the urine.

Uses
Carbon tetrachloride is employed in industry as a solvent and degreaser. It was formerly used in certain types of fire extinguisher and as an industrial and domestic dry cleaner but has been largely replaced for this purpose by less toxic substances. Carbon tetrachloride has also been used for the fumigation of cereals.

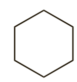
Carbon tetrachloride was formerly given orally as an anthelmintic but it has been superseded by equally effective and less toxic drugs.

Cyclohexane
Ciclohexano; Cykloheksan; Hexahydrobenzene; Hexamethylene.

Циклогексан

C_6H_{12} = 84.16.

CAS — 110-82-7.



Description. Cyclohexane is a colourless, flammable liquid. Wt per mL about 0.78 g. B.p. about 81°. Store in airtight containers.

Adverse Effects
Cyclohexane is irritant, and may also have effects on the CNS.

◊ Reviews of the toxicity of cyclohexane.

1. Health and Safety Executive. Cyclohexane, cumene, para-dichlorobenzene (p-DCB), chlorodifluoromethane (CFC 22). *Toxicity Review 25*. London: HMSO, 1991.

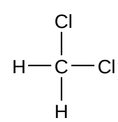
Uses
Cyclohexane is used as an industrial solvent.

Dichloromethane
Cloruro de metileno; Dichlormethan; Diclorometano; Diklórmetán; Methylene Chloride; Méthylène, chlorure de; Methyleni chloridum; Metileno chloridas; Metyleenikloridi; Metylenklorid; Metylenu chlorek.

Дихлорметан

CH_2Cl_2 = 84.93.

CAS — 75-09-2.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Methylene Chloride; Dichloromethane BP 2008). A clear, colourless, volatile liquid. Relative density 1.320 to 1.332. It may contain not more than 2% of alcohol and/or not more than 0.03% of 2-methylbut-2-ene as stabiliser. Sparingly soluble in water; miscible with alcohol. Store in airtight containers. Protect from light.

USNF 26 (Methylene Chloride). A clear, colourless, mobile liquid having an odour resembling chloroform. Sp. gr. 1.318 to 1.322. Miscible with alcohol, with ether, and with fixed and volatile oils. Store in airtight containers.

Stability. Phosgene is produced on heating of dichloromethane.

Adverse Effects and Treatment
Acute exposure to dichloromethane vapour may depress the CNS; symptoms progress from headache and dizziness to coma and death in severe cases. Pulmonary oedema has been reported. Significant exposure may result in raised blood concentrations of carboxyhaemoglobin and symptoms of carbon monoxide poisoning. Cardiovascular effects have been attributed to hypoxia secondary to carboxyhaemoglobinaemia. There has been a report of haemolysis after acute ingestion of dichloromethane.

Chronic occupational exposure to dichloromethane vapour has produced gastrointestinal disturbances in addition to symptoms observed after acute poisoning. Dichloromethane is a common constituent of paint strippers and may be implicated in volatile substance abuse (p.2019).

The liquid is irritant and high concentrations of the vapour are irritant to the eyes.

Treatment of acute poisoning consists of removal from exposure and supportive and symptomatic measures. Carboxyhaemoglobinaemia should be managed as for carbon monoxide poisoning (p.1688) by giving 100% oxygen; hyperbaric oxygen may be indicated. After ingestion gastric lavage or activated charcoal are generally contra-indicated, although gastric aspiration may be considered in serious cases if the airway can be protected. Adrenaline and other sympathomimetics should also be avoided because of the risk of precipitating cardiac arrhythmias.

8. Jacubovich RM, *et al.* Facial nerve palsy after acute exposure to dichloromethane. *Am J Ind Med* 2005; **48:** 389–92.

Pharmacokinetics
Dichloromethane is rapidly absorbed after inhalation and is also absorbed after ingestion and slowly through intact skin. It appears to be partially metabolised to carbon dioxide and carbon monoxide which are exhaled, although significant blood-carboxyhaemoglobin concentrations may be attained. Some unchanged dichloromethane is exhaled and small amounts are excreted in the urine.

Uses
Dichloromethane is used as a pharmaceutical and industrial solvent. It is also employed as an extraction solvent in food processing.

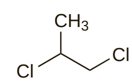
Dichloromethane is widely used in paint strippers.

Dichloropropane
Dicloropropano; Propylene Dichloride. 1,2-Dichloropropane.

Дихлорпропан

$C_3H_6Cl_2$ = 113.0.

CAS — 78-87-5.



Description. Dichloropropane is a colourless, mobile, flammable liquid. Wt per mL about 1.16 g. B.p. about 96°. Store in airtight containers.

Adverse Effects
Dichloropropane is irritant; high concentrations may result in CNS depression.

◊ Acute renal failure, haemolytic anaemia, acute liver disease, and disseminated intravascular coagulation has been reported[1] after intentional inhalation of a stain remover containing dichloropropane; the patient recovered after blood transfusions and haemodialysis.

1. Locatelli F, Pozzi C. Relapsing haemolytic-uraemic syndrome after organic solvent sniffing. *Lancet* 1983; **ii:** 220.

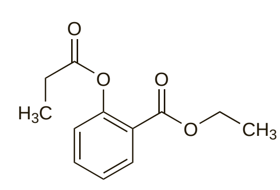
Uses
Dichloropropane is used as an industrial solvent, dry cleaning agent, and agricultural defumigant.

Diethyl Phthalate
Diéthyle, phtalate de; Diethyl-ftalát; Diethylis phthalas; Dietilftalát; Dietilo ftalatas; Dietylftalat; Dietyyliftalaatti; Ethyl Phthalate; Ftalato de dietilo. Benzene-1,2-dicarboxylic acid diethyl ester.

Диэтилфталат

$C_{12}H_{14}O_4$ = 222.2.

CAS — 84-66-2.



Pharmacopoeias. In *Eur.* (see p.vii) and *Viet.* Also in *USNF.*

Ph. Eur. 6.2 (Diethyl Phthalate). A clear, colourless or very slightly yellow, oily liquid. Relative density 1.117 to 1.121. Practically insoluble in water; miscible with alcohol. Store in airtight containers.

USNF 26 (Diethyl Phthalate). A colourless, practically odourless, oily liquid. Sp. gr. 1.118 to 1.122 at 20°. Insoluble in water; miscible with alcohol, with ether, and with other usual organic solvents. Store in airtight containers.

Adverse Effects

Diethyl phthalate is irritant and, in high concentrations, causes CNS depression. There has been concern about potential toxicity resulting from exposure to phthalates used as plasticisers.

◊ References.

1. Health and Safety Executive. Review of the toxicity of the esters of o-phthalic acid (phthalate esters). *Toxicity Review 14*. London: HMSO, 1986.

3. Shea KM, *et al.* American Academy of Pediatrics Technical Report. Pediatric exposure and potential toxicity of phthalate plasticizers. *Pediatrics* 2003; **111:** 1467–74. [Re-affirmed May 2007]

Uses

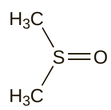
Diethyl phthalate is used as a denaturant of alcohol, for example in surgical spirit, and as a solvent and plasticiser.

Dimethyl Sulfoxide *(BAN, USAN, rINN)*

Dimethyl Sulphoxide; Dimethyli Sulfoxidum; Dimethylis sulfoxidum; Dimethylsulfoxid; Diméthylsulfoxyde; Dimetil sulfóxido; Dimetilsulfoksidas; Dimetil-szulfoxid; Dimetylosulfotlenek; Dimetylsulfoxid; Dimetyylisulfoksidi; DMSO; Methyl Sulphoxide; NSC-763; SQ-9453; Sulphinylbismethane.

Диметилсульфоксид

C_2H_6OS = 78.13.
CAS — 67-68-5.
ATC — G04BX13; M02AX03.
ATC Vet — QG04BX13; QM02AX03.



Pharmacopoeias. In *Eur.* (see p.vii) and *US.*

Ph. Eur. 6.2 (Dimethyl Sulfoxide). A colourless hygroscopic liquid or crystals. F.p. not lower than 18.3°. Relative density 1.100 to 1.104. Miscible with water and with alcohol. Store in airtight glass containers. Protect from light.

USP 31 (Dimethyl Sulfoxide). A clear, colourless, odourless, hygroscopic liquid. M.p. about 18.4°. Sp. gr. 1.095 to 1.097. Soluble in water; practically insoluble in alcohol, in acetone, in chloroform, in ether, and in benzene. Store in airtight containers. Protect from light.

Adverse Effects and Treatment

High concentrations of dimethyl sulfoxide applied to the skin may cause burning discomfort, itching, erythema, vesiculation, and urticaria. Continued use may result in scaling.

Systemic effects, including gastrointestinal disturbances, drowsiness, headache, and hypersensitivity reactions, may occur after use by any route. A garlic-like odour on the breath and skin is attributed to the formation of dimethyl sulfide (see Pharmacokinetics, below). Intravascular haemolysis has followed intravenous use. Local discomfort and spasm may occur when given by bladder instillation.

Treatment of adverse effects consists of symptomatic and supportive measures. Gastric lavage may be helpful after acute ingestion, although it should be remembered that absorption is rapid.

◊ Reviews.

2. Willhite CC, Katz PI. Toxicology updates: dimethyl sulfoxide. *J Appl Toxicol* 1984; **4:** 155–60.

◊ Dimethyl sulfoxide given by intravenous infusion for spinal cord injury to 14 patients caused transient haemolysis and haemoglobinuria.[1] Infusion strengths greater than 10% were associated with grossly discoloured urine but there was no evidence of renal damage. In 2 patients, raised liver and muscle enzyme concentrations, mild jaundice, and evidence of haemolysis developed when given dimethyl sulfoxide intravenously for arthritis.[2] One also developed acute renal tubular necrosis, deterioration in level of consciousness, and evidence of cerebral infarction. Acute, reversible neurological deterioration in a patient has been associated with intravenous dimethyl sulfoxide.[3]

Adverse effects have also been reported in patients given haematopoietic stem cells cryopreserved in dimethyl sulfoxide. A patient with pre-existing diabetes insipidus[4] developed serum hyperosmolality when given stem cells after chemotherapy for a malignant germ-cell tumour; symptoms included severe headache, confusion, and abdominal pain. Acute neurotoxicity has also been reported,[5,6] although it appears to be rare;[5] 2 patients also had myocardial damage.[6]

Precautions

When used as a penetrating basis for other drugs applied topically, dimethyl sulfoxide may enhance their toxic effects.

Since dimethyl sulfoxide has been associated with lens changes in *animals*, licensed product information recommends assessment of ophthalmic function every 6 months during long-term treatment of cystitis with intravesical instillation of dimethyl sulfoxide. Hepatic and renal function should also be assessed at intervals of 6 months. Bladder instillation may be harmful in patients with urinary-tract malignancy because of vasodilatation.

Interactions

◊ For mention of an interaction between dimethyl sulfoxide and *sulindac*, see p.127.

Pharmacokinetics

Dimethyl sulfoxide is readily absorbed by all routes. It is metabolised by oxidation to dimethyl sulfone (p.2294) and by reduction to dimethyl sulfide. Dimethyl sulfoxide and the sulfone metabolite are excreted in the urine and faeces. Dimethyl sulfide is excreted through the lungs and skin and is responsible for the characteristic odour from patients.

Uses and Administration

Dimethyl sulfoxide is a highly polar substance with exceptional solvent properties for both organic and inorganic chemicals, and is widely used as an industrial solvent.

It has been reported to have a wide spectrum of pharmacological activity including membrane penetration, anti-inflammatory effects, local analgesia, weak bacteriostasis, diuresis, vasodilatation, dissolution of collagen, and free-radical scavenging.

The principal use of dimethyl sulfoxide is as a vehicle for drugs such as idoxuridine (p.881); it aids penetration of the drug into the skin, and so may enhance the drug's effect. It is also used as a 50% aqueous solution for bladder instillation for the symptomatic relief of interstitial cystitis; doses of 50 mL are instilled and allowed to remain for 15 minutes. Treatment is repeated every 2 weeks initially.

Dimethyl sulfoxide has been given orally, intravenously, or topically for a wide range of indications including cutaneous and musculoskeletal disorders, but evidence of beneficial effects is limited.

Dimethyl sulfoxide is used as a cryoprotectant for various human tissues.

Amyloidosis. Oral or local dimethyl sulfoxide has been tried[1-3] as part of the management of some forms of amyloidosis (p.743).

1. Ichida M, *et al.* Successful treatment of multiple myeloma-associated amyloidosis by interferon-alpha, dimethyl sulfoxide, and VAD (vincristine, adriamycin, and dexamethasone). *Int J Hematol* 2000; **72:** 491–3.

4. Bertelli G, *et al.* Dimethylsulphoxide and cooling after extravasation of antitumour agents. *Lancet* 1993; **341:** 1098.

Gallstones. For mention of the use of a mixture containing dimethyl sulfoxide to dissolve gallstones, see Methyl *tert*-Butyl Ether, p.2025.

Interstitial cystitis. Bladder instillation of dimethyl sulfoxide is used[1,2] in the symptomatic management of interstitial cystitis (p.2179). Treatment usually consists of 50 mL of a 50% aqueous solution that is retained in the bladder for 15 minutes. This may be repeated every 1 to 2 weeks for 4 to 8 treatments, and overall response rates of 50 to 90% have been reported. Although relapse rates after a 4 to 8 week course of treatment are high (35 to 40%), about half of these patients will respond to additional dimethyl sulfoxide treatment. Maintenance therapy on either a regular or intermittent basis may be used.[1]

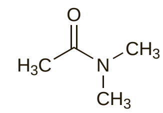
Dimethylacetamide

Acetyldimethylamine; Dimethylacetamid; Diméthylacétamide; Dimethylacetamidum; Dimetilacetamida; Dimetilacetamidas; Dimetylacetamid; Dimetyloacetamid; Dimetyyliasetamidi; DMAC. *NN*-Dimethylacetamide.

Диметилацетамид

C_4H_9NO = 87.12.
CAS — 127-19-5.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Dimethylacetamide). A clear, colourless, slightly hygroscopic liquid. Relative density 0.941 to 0.944. B.p. about 165°. Miscible with water, with alcohol, and with most common organic solvents. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

As for Dimethylformamide (below), although a disulfiram-like reaction with alcohol has not been reported.

◊ A review[1] of the toxicology of dimethylacetamide with reference to its use as a vehicle for antineoplastics.

1. Kim S-N. Preclinical toxicology and pharmacology of dimethylacetamide, with clinical notes. *Drug Metab Rev* 1988; **19:** 345–68.

Handling. Suitable precautions should be taken to avoid skin contact with dimethylacetamide as it can penetrate skin and produce systemic toxicity.

Uses

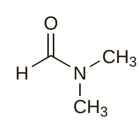
Dimethylacetamide is used as an industrial and pharmaceutical solvent.

Dimethylformamide

Dimetilformamida; Dimetyloformamid; DMF. *NN*-Dimethylformamide.

Диметилформамид

C_3H_7NO = 73.09.
CAS — 68-12-2.



Description. Dimethylformamide is a colourless liquid. Wt per mL about 0.95 g. B.p. about 153°.

Adverse Effects and Precautions

Dimethylformamide is irritant. Gastrointestinal effects including nausea, vomiting, loss of appetite, and abdominal pain, CNS effects such as headache, dizziness, and weakness, and liver damage have been reported in workers occupationally exposed to the liquid or vapour. Some workers exposed to dimethylformamide have experienced a disulfiram-like effect after consumption of alcohol.

◊ Reviews of the adverse effects of dimethylformamide.

1. WHO. Dimethylformamide. *Environmental Health Criteria 114*. Geneva: WHO, 1991. Available at: http://www.inchem.org/documents/ehc/ehc/ehc114.htm (accessed 30/06/04)

Effects on the liver. Exposure to dimethylformamide was considered to be the most likely cause of elevated liver enzyme values in 36 of 58 (62%) workers in a fabric coating factory.[1] Symptoms reported were generally mild and included anorexia, abdominal pain, nausea, headache, dizziness, and a disulfiram-type reaction to alcohol.

Hepatotoxicity has occurred after acute poisoning with a veterinary drug formulated in dimethylformamide. There were only minor increases in liver enzyme values in a patient who was treated early with acetylcysteine.[2]

1. Redlich CA, *et al.* Liver disease associated with occupational exposure to the solvent dimethylformamide. *Ann Intern Med* 1988; **108:** 680–6.
2. Buylaert W, *et al.* Hepatotoxicity of N,N-dimethylformamide (DMF) in acute poisoning with the veterinary euthanasia drug T-61. *Hum Exp Toxicol* 1996; **15:** 607–11.

Handling. Suitable precautions should be taken to avoid skin contact with dimethylformamide as it can penetrate skin and produce systemic toxicity.

Malignant neoplasms. There have been reports of testicular cancer in men occupationally exposed to dimethylformamide.[1] Such an association could not, however, be substantiated by epidemiological data[2] on 3859 male employees exposed to dimethylformamide between 1950 and 1970 and followed up to 1984. It has been suggested that although dimethylformamide may not itself be carcinogenic, it may increase absorption through the skin of heavy metal carcinogens, possibly including chromates.[3]

1. Levin SM, *et al.* Testicular cancer in leather tanners exposed to dimethylformamide. *Lancet* 1987; **ii:** 1153.
2. Chen JL, Kennedy GL. Dimethylformamide and testicular cancer. *Lancet* 1988; **i:** 55.
3. Ducatman AM. Dimethylformamide, metal dyes, and testicular cancer. *Lancet* 1989; **i:** 911.

Pharmacokinetics

Dimethylformamide is absorbed after inhalation and through intact skin. It is excreted mainly in the urine as metabolites.

Uses

Dimethylformamide is used as an industrial solvent.

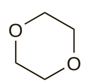
Dioxan

Diethylene Dioxide; Diethylene Ether; Dioksan; Dioxane; Dioxano. 1,4-Dioxane.

Диоксан

$C_4H_8O_2$ = 88.11.

CAS — 123-91-1.



NOTE. Do not confuse dioxan and dioxin (p.2295).

Description. Dioxan is a colourless flammable liquid with an ethereal odour. Wt per mL about 1.03 g. B.p. about 101°. Store in airtight containers.

Stability. It is dangerous to distil or evaporate dioxan unless precautions have been taken to remove explosive peroxides.

Adverse Effects, Treatment, and Precautions

Dioxan vapour is irritant to mucous membranes. High concentrations may cause nausea and vomiting, and CNS depression with headache, dizziness, drowsiness, and in severe cases unconsciousness. On repeated exposure, severe hepatic and renal damage, including necrotic changes, can occur and may be fatal. Direct contact with liquid dioxan can result in dermatitis. Dioxan has been shown to be carcinogenic in *animals.*

Treatment consists of removal from exposure and general supportive and symptomatic measures.

Handling. Suitable precautions should be taken to avoid skin contact with dioxan as it can penetrate skin and produce systemic toxicity.

Pharmacokinetics

Dioxan is absorbed after inhalation and through the skin. It is metabolised by oxidation to β-hydroxyethoxy-acetic acid.

Uses

Dioxan is used as an industrial solvent.

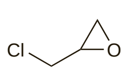
Epichlorohydrin

Epiclorhidrina. 1-Chloro-2,3-epoxypropane.

Эпихлоргидрин

C_3H_5ClO = 92.52.

CAS — 106-89-8.



Description. Epichlorohydrin is a colourless, flammable liquid. Wt per mL about 1.18 g. B.p. 115° to 118°. Store in airtight containers.

Stability. The vapour of epichlorohydrin forms explosive mixtures with air. Harmful gases including phosgene are liberated on heating of epichlorohydrin.

Adverse Effects and Precautions

Epichlorohydrin is irritant. It has been shown to be carcinogenic in *animals.*

◊ References to the toxicity of epichlorohydrin.

1. WHO. Epichlorohydrin. *Environmental Health Criteria 33.* Geneva: WHO, 1984. Available at: http://www.inchem.org/documents/ehc/ehc/ehc33.htm (accessed 30/06/04)
2. WHO. Epichlorohydrin health and safety guide. *IPCS Health and Safety Guide 8.* Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/hsg/hsg/hsg008.htm (accessed 30/06/04)
3. Health and Safety Executive. Ammonia, 1-chloro-2,3-epoxypropane (epichlorohydrin), carcinogenicity of cadmium and its compounds. *Toxicity Review 24.* London: HMSO, 1991.

Handling. Suitable precautions should be taken to avoid skin contact with epichlorohydrin as it can penetrate skin and produce systemic toxicity.

Uses

Epichlorohydrin is used as an industrial solvent.

Solvent Ether

Aether; Aether Aethylicus; Aether Solvens; Diethyl Ether; Eetteri; Éter; Eter; Éter disolvente; Eteris; Éther; Ether; Éther rectifié; Ethyl Ether; Ethyl Oxide.

Диэтиловый Эфир; Этиловый Эфир

$(C_2H_5)_2O$ = 74.12.

CAS — 60-29-7.

NOTE. Solvent ether is not intended for anaesthesia; only ether of a suitable quality (see p.1783) should be so used.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Ether). A colourless, clear, volatile, highly flammable liquid. It may contain a suitable non-volatile antioxidant at a suitable concentration. Relative density 0.714 to 0.716. Distillation range 34° to 35°. Soluble in water; miscible with alcohol, with dichloromethane, and with fatty oils. Store at 8° to 15° in airtight containers. Protect from light.

USP 31 (Ether). A colourless, mobile, volatile, flammable liquid, having a characteristic sweet, pungent odour. It is slowly oxidised by the action of air and light, with the formation of peroxides. B.p. about 35°. Sp. gr. 0.713 to 0.716. Soluble 1 in 12 of water; miscible with alcohol, with chloroform, with dichloromethane, with petroleum spirit, with benzene, and with fixed and volatile oils; soluble in hydrochloric acid. Store in partly filled airtight containers at a temperature not exceeding 30° and remote from fire. Protect from light.

Stability. Though ether is one of the lightest of liquids, its vapour is very heavy, being 2⁄ times heavier than air.

Ether is very volatile and flammable and mixtures of its vapour with oxygen, nitrous oxide, or air at certain concentrations are explosive. It should not be used in the presence of an open flame or any electrical apparatus liable to produce a spark; precautions should be taken against the production of static electrical discharge. Explosive peroxides are generated by the atmospheric oxidation of solvent ether and it is dangerous to distil a sample which contains peroxides.

Adverse Effects

As for Anaesthetic Ether, p.1783. Ingestion of 30 to 60 mL may be fatal.

Uses

Solvent ether is widely used as a pharmaceutical and industrial solvent, and is used as an extraction solvent in food processing.

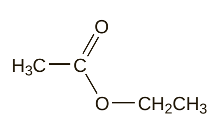
Ethyl Acetate

Acetato de etilo; Acetic Ether; Aethylis Acetas; Aethylium Aceticum; Ethyl Ethanoate; Ethyl-acetát; Éthyle, acétate d'; Ethylis acetas; Etil-acetát; Etilacetatas; Etylacetat; Etylu octan; Etyyliasetaatti.

Этилацетат

$C_4H_8O_2$ = 88.11.

CAS — 141-78-6.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Ethyl Acetate). A colourless, clear, volatile liquid. Relative density 0.898 to 0.902. B.p. 76° to 78°. Soluble in water; miscible with alcohol, with acetone, and with dichloromethane. Store at a temperature not exceeding 30°. Protect from light.

USNF 26 (Ethyl Acetate). A transparent, colourless, flammable liquid having a fragrant, refreshing, slightly acetous odour. Sp. gr. 0.894 to 0.898. Soluble in water; miscible with alcohol, with ether, and with fixed and volatile oils. Store in airtight containers at a temperature not exceeding 40°.

Adverse Effects

Ethyl acetate is irritant to mucous membranes. High concentrations may cause CNS depression. Ethyl acetate may be implicated in volatile substance abuse (p.2019).

◊ For discussion of neurotoxicity after occupational exposure to solvents and the absence of such an effect with ethyl acetate, see under Toluene, p.2026.

Uses

Ethyl acetate is used as a flavour and solvent in pharmaceutical preparations. It is also used in industry as a solvent and as an extraction solvent in food processing.

Formamide

Carbamaldehyde; Formamid; Formamida; Methanamide.

Формамид

CH_3NO = 45.04.

CAS — 75-12-7.

Description. Formamide is a colourless, oily liquid. B.p. 210°. Wt per mL, about 1.13 g.

Profile

Formamide is used as an industrial solvent. It is reported to be irritant.

Glycerol Formal

Glycérol formal; Glycerol-formalum. A mixture of the two isomers 4-hydroxymethyl-1,3-dioxolane and 5-hydroxy-1,3-dioxane present in a constant ratio of 40:60 respectively.

Глицерол Формаль

$C_4H_8O_3$ = 104.1.

CAS — 4740-78-7 (5-hydroxy-1,3-dioxane); 5464-28-8 (4-hydroxymethyl-1,3-dioxolane).

(5-hydroxy-1,3-dioxane) (4-hydroxymethyl-1,3-dioxolane)

Profile

Glycerol formal is used as a pharmaceutical solvent.

Glycofurol

Glicofurol; Glycofural; Glycofurol 75; Tetrahydrofurfuryl Alcohol Polyethylene Glycol Ether. α-(Tetrahydrofuranyl)-ω-hydroxypoly(oxyethylene).

Гликофурфурол

$C_5H_9O.(C_2H_4O)_n.OH$.

CAS — 9004-76-6; 31692-85-0.

Description. Glycofurol is a clear, colourless, almost odourless liquid. Wt per mL about 1.08 g. B.p. 80° to 100°. Incompatible with oxidising agents. Store under nitrogen in airtight containers. Protect from light.

Profile

Glycofurol is used as a pharmaceutical solvent for injections.

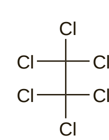
Hexachloroethane

Hexacloroetano.

Гексахлорэтан

C_2Cl_6 = 236.7.

CAS — 67-72-1.



Profile

Hexachloroethane is a chlorinated hydrocarbon used in industry as a solvent. Eye irritation and photophobia have resulted from industrial exposure to the vapour. It was formerly used in veterinary medicine as an anthelmintic, but has been superseded by less toxic drugs.

n-Hexane

n-Hexano.

н-Гексан

C_6H_{14} = 86.18.

CAS — 110-54-3.

Description. *n*-Hexane is a colourless, flammable, volatile liquid with a faint odour. Wt per mL about 0.66 g. B.p. about 69°. Store in airtight containers.

Adverse Effects

n-Hexane is irritant. Acute exposure to the vapour may result in CNS depression with headache, drowsiness, dizziness, and in severe cases unconsciousness. Chronic occupational exposure and abuse of *n*-hexane have been associated with the development of peripheral neuropathies. *n*-Hexane is a constituent of some adhesives and may be implicated in volatile substance abuse (p.2019). Some adverse effects of petrol have been attributed to its content of *n*-hexane.

◊ References.

1. Health and Safety Executive. *n*-Hexane. *Toxicity Review 18*. London: HMSO, 1987.
2. WHO. *n*-Hexane. *Environmental Health Criteria 122*. Geneva: WHO, 1991. Available at: http://www.inchem.org/documents/ehc/ehc/ehc122.htm (accessed 30/06/04)
3. WHO. *n*-Hexane health and safety guide. *IPCS Health and Safety Guide 59*. Geneva: WHO, 1991. Available at: http://www.inchem.org/documents/hsg/hsg/hsg059.htm (accessed 30/06/04)

Effects on the nervous system. There have been many reports of peripheral neuropathy attributed to the abuse of, and occupational exposure to, *n*-hexane, although symptoms tend to be milder in the latter.[1] Tetraplegia has occurred in severe cases. There is typically a clinical deterioration several weeks after exposure followed by a slow recovery which, in severe cases, may not be complete. It has been suggested that methyl ethyl ketone potentiates the peripheral neuropathy induced by *n*-hexane. Occupational exposure to *n*-hexane has also been associated with cranial nerve neuropathy.

Parkinsonism in a leather worker, possibly associated with exposure to solvents, mainly *n*-hexane, has been noted.[2]

For further discussion of neurotoxicity after occupational exposure to solvents including *n*-hexane, see under Toluene, p.2026.

1. Lolin Y. Chronic neurological toxicity associated with exposure to volatile substances. *Hum Toxicol* 1989; **8:** 293–300.
2. Pezzoli G, *et al.* Parkinsonism due to n-hexane exposure. *Lancet* 1989; **ii:** 874.

Pharmacokinetics

n-Hexane is absorbed after inhalation and to a limited extent through the skin. Oxidative metabolites, including 2,5-hexanedione are excreted in the urine largely as conjugates. Some unchanged *n*-hexane is excreted via the lungs.

Uses

n-Hexane is widely used as an industrial solvent, as a solvent in glues, and as an extraction solvent in food processing.

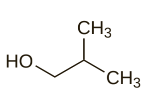
Isobutyl Alcohol

Alcohol isobutílico; Isobutanol.

Изобутиловый Спирт

$C_4H_{10}O$ = 74.12.

CAS — 78-83-1.



Profile

Isobutyl alcohol is used as an industrial solvent. It is also used as an anaesthetic in the American lobster, *Homarus americanus*.

◊ References.

1. WHO. Butanols—four isomers: 1-butanol, 2-butanol, tert-butanol, isobutanol. *Environmental Health Criteria 65*. Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/ehc/ehc/ehc65.htm (accessed 30/06/04)
2. WHO. Isobutanol health and safety guide. *IPCS Health and Safety Guide 9*. Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/hsg/hsg/hsg009.htm (accessed 30/06/04)

Kerosene

Kerosine; 'Paraffin'; Queroseno.

Керосин

CAS — 8008-20-6.

Description. Kerosene is a mixture of hydrocarbons, chiefly members of the alkane series, distilled from petroleum. It is a clear, colourless liquid with a characteristic odour. Sp. gr. about 0.8 g. B.p. 180° to 300°. An odourless grade is available. Store in airtight containers.

Adverse Effects

The chief danger from ingestion of kerosene is pneumonitis and attendant pulmonary complications resulting from aspiration. Spontaneous or induced vomiting increases the risk of aspiration. Ingestion of kerosene results in a burning sensation in the mouth and throat, gastrointestinal disturbances, and possibly cough, dyspnoea, and transient cyanosis. There may be excitation followed by CNS depression, with weakness, dizziness, drowsiness, confusion, incoordination, and restlessness progressing to convulsions, coma, and respiratory depression in severe cases. Cardiac arrhythmias have been reported.

The course of poisoning from inhalation is similar to that following ingestion although CNS and cardiac effects are more likely. Kerosene is irritant.

Abuse. A case of volatile substance abuse (p.2019) involving inhalation and ingestion of kerosene has been reported.[1]

1. Das PS, *et al.* Kerosene abuse by inhalation and ingestion. *Am J Psychiatry* 1992; **149:** 710.

Treatment of Adverse Effects

Treatment of kerosene poisoning is supportive and symptomatic. Every precaution should be taken to avoid aspiration of kerosene into the lungs. The UK National Poisons Information Service considers that gastric lavage should not be used. If large amounts have been taken or there is concern about another toxin, gastric aspiration may be considered if it can be carried out within 1 hour of ingestion and the airway can be protected. Adrenaline and other sympathomimetics should also be avoided because of the risk of precipitating cardiac arrhythmias.

Uses

Kerosene is used as a degreaser and cleaner and as an illuminating and fuel oil in kerosene ('paraffin') lamps and stoves. The odourless grade has been used as a solvent in the preparation of some insecticide sprays.

2-Methoxyethanol

Eter monometylowy glikolu etylenowego; Ethylene Glycol Monomethyl Ether; 2-Metoxietanol.

2-Метоксиэтанол

$C_3H_8O_2$ = 76.09.

CAS — 109-86-4.

Description. 2-Methoxyethanol is a clear, colourless to slightly yellow liquid. Wt per mL about 0.96 g. B.p. about 125°. Miscible with water, with alcohol, with acetone, with dimethylformamide, with ether, and with glycerol. Store in airtight containers.

Adverse Effects and Precautions

2-Methoxyethanol is irritant to mucous membranes. Ingestion may result in CNS depression with confusion, weakness, and in severe cases coma and death from respiratory depression. Nausea, metabolic acidosis, and renal damage may also occur. Prolonged industrial exposure to the vapour has been associated with severe effects on the CNS characterised by headache, dizziness, lethargy, weakness, ataxia, tremor, disorientation, mental changes, weight loss, and visual disturbances. Anaemia has also been reported. There has been concern about the potential for reproductive toxicity.

◊ References to the toxicity of 2-methoxyethanol and other glycol ethers.

5. Bagchi G, Waxman DJ. Toxicity of ethylene glycol monomethyl ether: impact on testicular gene expression. *Int J Androl* 2008; **31:** 269–74.

Handling. Suitable precautions should be taken to avoid skin contact with 2-methoxyethanol as it can penetrate skin and produce systemic toxicity.

Uses

2-Methoxyethanol is used as an industrial solvent.

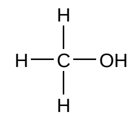
Methyl Alcohol

Metanol; Metanoli; Metanolis; Méthanol; Methanol; Methanolum.

Метиловый Спирт

CH_3OH = 32.04.

CAS — 67-56-1.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Methanol). A colourless, clear, volatile, hygroscopic liquid. It is flammable. B.p. about 64°. Relative density 0.791 to 0.793. Miscible with water and with dichloromethane. Store in airtight containers.

The BP 2008 gives Methyl Alcohol as an approved synonym.

USNF 26 (Methyl Alcohol). A clear, colourless, flammable liquid having a characteristic odour. Miscible with water, with alcohol, with ether, with benzene, and with most other organic solvents. Store in airtight containers remote from heat, sparks, and open flames.

Adverse Effects

Immediate signs of acute poisoning after ingestion of methyl alcohol resemble those of ethanol (alcohol; ethyl alcohol) intoxication (see p.1625), but are milder. Characteristic symptoms of methyl alcohol poisoning are caused by toxic metabolites and develop after a latent period of about 12 to 24 hours, or longer if taken with ethanol. The outstanding features of poisoning are metabolic acidosis with rapid, shallow breathing, visual disturbances which often proceed to irreversible blindness, and severe abdominal pain. Other symptoms include headache, gastrointestinal disturbances, pain in the back and extremities, and coma which in severe cases may result in death due to respiratory failure or, rarely, to circulatory collapse. Mania and convulsions occasionally occur. Individual response to methyl alcohol varies widely. Ingestion of 30 mL is considered to be potentially fatal.

Absorption of methyl alcohol through the skin or inhalation of the vapour may also lead to toxic systemic effects.

9. Hantson PE. Intoxication aiguë par le méthanol : physiopathologie, pronostic et traitement. *Bull Mem Acad R Med Belg* 2006; **161:** 425–34.

Handling. Suitable precautions should be taken to avoid skin contact with methyl alcohol as it can penetrate skin and produce systemic toxicity.

Treatment of Adverse Effects

Gastric aspiration may be considered if the patient presents within 1 hour of ingesting methyl alcohol. Activated charcoal is probably of little use as it does not absorb significant amounts of methyl alcohol. Metabolic acidosis (p.1667) should be corrected immediately with intravenous sodium bicarbonate. If significant amounts of methyl alcohol have been ingested, early treatment with an antidote (ethanol or fomepizole) is recommended. Ethanol delays the oxidation of methyl alcohol to its toxic metabolites formaldehyde and formic acid; dosage is adjusted to achieve and maintain a blood-ethanol concentration of 1 to 1.5 mg/mL. An **oral** dose for a 70-kg adult of about 150 mL of an ethanolic solution containing 40% v/v of C_2H_5OH has been suggested. Alcoholic spirits (such as whisky, gin, or vodka) may often be of the suitable strength. If required, an ethanolic **infusion** containing 10% v/v of C_2H_5OH may then be given as maintenance for which the following doses have been used:

- for an average adult, 1.38 mL/kg per hour
- for a non-drinker or child, 0.83 mL/kg per hour
- for a chronic drinker, 1.96 mL/kg per hour

The infusion should be continued until methyl alcohol concentrations are undetectable, or fall below 50 micrograms/mL with resolution of systemic toxicity.

Fomepizole (p.1446), an inhibitor of alcohol dehydrogenase, is also used; it inhibits the metabolism of methyl alcohol to its toxic metabolites.

Haemodialysis may be indicated to increase the removal of methyl alcohol and its toxic metabolites. Peritoneal dialysis has been used but is less efficient. Haemodialysis may be considered if the blood-methyl alcohol concentration is greater than 500 micrograms/mL, if there is severe metabolic acidosis unresponsive to sodium bicarbonate, or there is visual disturbance, CNS toxicity, renal failure, or severe electrolyte disturbance. If haemodialysis is used, a constant blood-ethanol concentration may be ensured either by increasing the ethanol infusion rate or by addition of ethanol to the dialysate fluid.

Treatment should not be stopped prematurely since oxidation and excretion of methyl alcohol may continue for several days; patients should, therefore, be closely observed and monitored. Suitable supportive treatment should be carried out as required.

Folinic acid and folic acid have been given in the treatment of methyl alcohol toxicity because they may enhance the metabolism of formic acid.

◊ References.

1. Barceloux DG, *et al.* American Academy of Clinical Toxicology Ad Hoc Committee on the Treatment Guidelines for Methanol Poisoning. American Academy of Clinical Toxicology practice guidelines on the treatment of methanol poisoning. *J Toxicol Clin Toxicol* 2002; **40:** 415–46.

Pharmacokinetics

Methyl alcohol is readily absorbed from the gastrointestinal tract and distributed throughout the body fluids. It may also be absorbed after inhalation or through large areas of skin. Oxidation by alcohol dehydrogenase with formation of formaldehyde and formic acid takes place mainly in the liver and also in the kidneys. These metabolites are thought to be largely responsible for the characteristic symptoms of methyl alcohol poisoning. Metabolism is much slower than for ethanol, which competitively inhibits the metabolism of methyl alcohol. Oxidation and excretion may continue for several days after ingestion. Elimination of unchanged methyl alcohol via the lungs and in the urine is a minor route of excretion.

Uses

Methyl alcohol is used as a pharmaceutical and industrial solvent. It is also used as 'wood naphtha' to denature ethanol in the preparation of industrial methylated spirits. Methyl alcohol is also used as an extraction solvent in food processing.

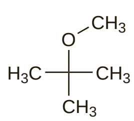
Methyl *tert*-Butyl Ether

Éter metilterbutílico; Methyl Terbutyl Ether; Methyl Tertiary Butyl Ether; MTBE. 2-Methoxy-2-methylpropane.

Метил-трет-бутиловый Эфир

$C_5H_{12}O$ = 88.15.

CAS — 1634-04-4.



Description. Methyl *tert*-butyl ether is a volatile, flammable liquid. Wt per mL about 0.74 g. B.p. about 55°. Store in airtight containers.

Stability. Explosive peroxides may be generated by the atmospheric oxidation of methyl tert-butyl ether, but the risk is lower than with solvent ether.

Adverse Effects

Methyl *tert*-butyl ether is irritant and may cause CNS depression. Adverse effects that have been reported after use as a gallstone solvent are described under Uses and Administration, below.

Uses and Administration

Methyl *tert*-butyl ether is a solvent that has been used for the rapid dissolution of cholesterol gallstones.

Gallstones. An alternative to bile acid therapy in patients with gallstones (p.2409) who are not considered suitable for surgery is direct instillation of a solvent into the gallbladder.

Methyl *tert*-butyl ether has been used to dissolve cholesterol gallstones; stones rich in calcium or pigments are not dissolved.[1] Unfortunately incomplete dissolution and residual debris can lead to recurrence of stone formation.[2] The solvent is usually instilled via a percutaneous transhepatic catheter,[1,3] although other routes have been used.[4] Gallbladder stones were treated in 75 patients with continuous infusion and aspiration of methyl *tert*-butyl ether 4 to 6 times/minute for an average of 5 hours daily for 1 to 3 days.[1] At least 95% of the stone mass was dissolved in 72 patients. Gallbladder stones recurred in 4 patients between 6 and 16 months after the procedure; 7 of 51 patients with residual stone fragments had an episode of biliary colic during 6 to 42 months of follow-up. Nausea, sometimes with emesis, occurred in about one-third of patients. Overflow of solvent from the gallbladder can result in absorption from the gastrointestinal tract; methyl *tert*-butyl ether is detected on the breath and sedation can occur. One patient in whom overflow occurred developed ulcerative duodenitis and intravascular haemolysis. Coma and acute renal failure have also complicated treatment and have been attributed to leakage alongside the catheter rather than overflow of solvent.[5] Other workers[6,7] have obtained similar results for the dissolution of gallstones. One group[6] found that nausea and vomiting could be reduced if the treatment time was kept short and the perfusion volume was kept as low as possible; they also managed to prevent bile leakage and haemorrhage using a tissue adhesive or subcutaneous ceruletide to contract the gallbladder. Dissolution of gallbladder stones with methyl *tert*-butyl ether is likely to remain confined to specialist centres for use in patients unsuitable for surgical treatment.[1,8] A combination of litholytic modalities such as dissolution with solvents or bile acids, or lithotripsy may overcome some of the disadvantages of individual treatments.[9]

Methyl *tert*-butyl ether has been instilled via a nasobiliary catheter to dissolve stones in the common bile duct. Although effective in some cases,[10] further study has indicated disappointing overall results.[1,11]

Various combinations of drugs have been investigated to dissolve pigment-rich or mixed stones. For common bile-duct stones these include a cocktail of dimethyl sulfoxide 60%, methyl *tert*-butyl ether 20%, and sodium bicarbonate 20%, and a regimen of alternating infusions of pentyl ether and edetic acid-urea 10%.[12] A similar regimen of methyl hexyl ether and edetic acid-urea has been used successfully in 2 patients with calcified gallbladder stones.[13]

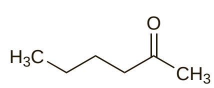
Methyl Butyl Ketone

2-Hexanone; Methyl *n*-Butyl Ketone; Metilbutilcetona; Propylacetone. Hexan-2-one.

Метилбутилкетон

$C_6H_{12}O$ = 100.2.

CAS — 591-78-6.



Description. Methyl butyl ketone is a colourless, volatile liquid. Wt per mL about 0.82 g. B.p. about 127°. Store in airtight containers.

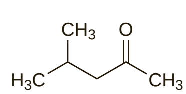
Methyl Isobutyl Ketone

Hexone; Isobutilmetilcetona; Isopropylacetone; Metilisobutilcetona; MIBK. 4-Methylpentan-2-one.

Метилизобутилкетон

$C_6H_{12}O$ = 100.2.

CAS — 108-10-1.



Pharmacopoeias. In *USNF.*

USNF 26 (Methyl Isobutyl Ketone). A transparent, colourless, mobile, volatile liquid having a faint ketonic and camphoraceous odour. Sp. gr. not more than 0.799. Distilling range 114° to 117°. Slightly soluble in water; miscible with alcohol, with ether, and with benzene. Store in airtight containers.

Adverse Effects and Precautions

Methyl butyl ketone and methyl isobutyl ketone may depress the CNS in high concentrations. Their vapours are irritating to mucous membranes. Methyl isobutyl ketone may be implicated in volatile substance abuse (p.2019).

◊ References.

1. WHO. Methyl isobutyl ketone. *Environmental Health Criteria 117*. Geneva: WHO, 1990. Available at: http://www.inchem.org/documents/ehc/ehc/ehc117.htm (accessed 30/06/04)
2. WHO. Methyl isobutyl ketone health and safety guide. *IPCS Health and Safety Guide 58*. Geneva: WHO, 1991. Available at: http://www.inchem.org/documents/hsg/hsg/hsg058.htm (accessed 30/06/04)

Effects on the nervous system. Peripheral neuropathy[1] has occurred after occupational exposure to methyl butyl ketone, particularly an outbreak of neuropathy in a printing plant after the replacement of methyl isobutyl ketone by methyl butyl ketone in a solvent mixture with methyl ethyl ketone. Methyl ethyl ketone may have potentiated the neurotoxicity induced by methyl butyl ketone.

For further discussion of neurotoxicity after occupational exposure to solvents including methyl butyl ketone, see under Toluene, p.2026.

1. Lolin Y. Chronic neurological toxicity associated with exposure to volatile substances. *Hum Toxicol* 1989; **8:** 293–300.

Handling. Suitable precautions should be taken to avoid skin contact with methyl butyl ketone or methyl isobutyl ketone as they can penetrate skin and produce systemic toxicity.

Uses

Methyl isobutyl ketone is used as an industrial and pharmaceutical solvent and also as an alcohol denaturant. Methyl butyl ketone is used as an industrial solvent.

Methyl Chloride

Cloruro de metilo; Monochloromethane. Chloromethane.

Метилхлорид

CH_3Cl = 50.49.

CAS — 74-87-3.

Description. Methyl chloride is a colourless gas compressed to a colourless liquid with an ethereal odour. B.p. about –24°. Store in airtight containers.

Adverse Effects and Treatment

Symptoms of methyl chloride intoxication often appear after a latent period of several hours and are similar after acute or chronic exposure to the vapour. Symptoms include gastrointestinal disturbances such as nausea, vomiting, and abdominal pain, and signs of CNS depression including headache, weakness, drowsiness, confusion, visual disturbances, and incoordination progressing to convulsions, coma, and death from respiratory depression in severe cases. There have been a few reports of hepatic and renal damage.

Treatment consists of removal from exposure and supportive and symptomatic measures. Neurological effects may persist for many months.

◊ References to the toxicity of methyl chloride.

1. Repko JD, Lasley SM. Behavioral, neurological, and toxic effects of methyl chloride: a review of the literature. *CRC Crit Rev Toxicol* 1979; **6:** 283–302.

Uses

Methyl chloride is used as an industrial solvent. It has been used as an aerosol propellant and refrigerant and was formerly used as a local anaesthetic.

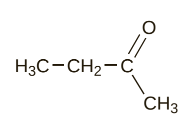
Methyl Ethyl Ketone

Ethyl Methyl Ketone; Etylometyloketon; MEK; Metiletilcetona; Metyloetyloketon. Butan-2-one.

Метилэтилкетон

C_4H_8O = 72.11.

CAS — 78-93-3.



Description. Methyl ethyl ketone is a colourless flammable liquid with an acetone-like odour. Wt per mL about 0.81 g. B.p. 79° to 81°. Soluble in water; miscible with alcohol and with ether. Store in airtight containers.

Adverse Effects

Methyl ethyl ketone is irritant. Inhalation may result in mild CNS effects including headache and dizziness; nausea and vomiting may also occur.

Methyl ethyl ketone may be implicated in volatile substance abuse (p.2019).

◊ References.

1. WHO. Methyl ethyl ketone. *Environmental Health Criteria 143*. Geneva: WHO, 1992. Available at: http://www.inchem.org/documents/ehc/ehc/ehc143.htm (accessed 30/06/04)

Effects on the nervous system. There are isolated reports of neurotoxicity produced by methyl ethyl ketone alone.[1] These include 1 of retrobulbar neuritis and 1 of peripheral neuropathy. It has been suggested, however, that methyl ethyl ketone potentiates the peripheral neuropathy induced by methyl butyl ketone and *n*-hexane.

For further discussion of neurotoxicity after occupational exposure to solvents including methyl ethyl ketone, see under Toluene, p.2026.

1. Lolin Y. Chronic neurological toxicity associated with exposure to volatile substances. *Hum Toxicol* 1989; **8:** 293–300.

Uses

Methyl ethyl ketone is used as an industrial solvent and as an extraction solvent in food processing.

Octyldodecanol

Octildodecanol; Octyldodécanol; Octyldodecanolum; Oktildodekanol; Oktildodekanolis; Oktyldodekanol; Oktylododekanol; Oktyylidodekanoli.

Октилдодеканол

$C_{20}H_{42}O = 298.5$.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Octyldodecanol). A condensation product of saturated liquid fatty alcohols. It contains not less than 90% of (*RS*)-2-octyldodecan-1-ol, the remainder consisting mainly of related alcohols. A clear, colourless to yellowish, oily liquid. Relative density 0.830 to 0.850. Practically insoluble in water; miscible with alcohol. Protect from light.

USNF 26 (Octyldodecanol). It contains not less than 90% of 2-octyldodecanol, the remainder consisting chiefly of related alcohols. A clear, water-white, free-flowing liquid. Insoluble in water; soluble in alcohol and in ether. Store in airtight containers.

Profile

Octyldodecanol is used as a pharmaceutical solvent.

Pentane

Amyl Hydride; Pentan; *n*-Pentane.

Пентан

$C_5H_{12} = 72.15$.

CAS — 109-66-0.

Profile

Pentane is used as a solvent and as a fuel. It is highly volatile and has also been used topically for its cooling effects.

◊ References.

1. McKee R, *et al.* Toxicology of n-pentane (CAS no. 109-66-0). *J Appl Toxicol* 1998; **18:** 431–42.

Petroleum Spirit

Benzyna; Éter de petróleo; Light Petroleum; Petroleum Benzin; Petroleum Ether; Solvent Hexane.

Бензин; Петролейный Эфир

Description. Petroleum spirit is a purified distillate of petroleum, consisting of a mixture of the lower members of the paraffin series of hydrocarbons. It is a colourless, transparent, very volatile, highly flammable liquid with a characteristic odour. It is available in a variety of boiling ranges.

Pharmacopoeias. In *Ger.*, *Jpn.*, and *Pol*. Various boiling ranges are specified.

Swiss describes Benzinum Medicinale, consisting mainly of hexane and heptane.

◊ NOTE. The motor fuel termed 'petrol' in the UK and 'gasoline' in the USA is a mixture of volatile hydrocarbons of variable composition containing paraffins (alkanes), olefins (alkenes), cycloparaffins, and aromatic compounds.

Adverse Effects and Treatment

As for Kerosene, p.2024. Petroleum spirit and petrol, being more volatile and of lower viscosity than kerosene, are more likely to be inhaled and to cause aspiration pneumonitis. The toxicity of petrol varies with its composition; some adverse effects have been attributed to lead additives or to the content of *n*-hexane or benzene. Petrol may be implicated in volatile solvent abuse (p.2019).

◊ References to the toxicity of petroleum spirit.[1-3]

For discussion of neurotoxicity after occupational exposure to solvents including petrol, see under Toluene, p.2026.

1. WHO. Selected petroleum products. *Environmental Health Criteria 20*. Geneva: WHO, 1982. Available at: http://www.inchem.org/documents/ehc/ehc/ehc020.htm (accessed 30/06/04)
2. Daniels AM, Latcham RW. Petrol sniffing and schizophrenia in a Pacific island paradise. *Lancet* 1984; **i:** 389.
3. Eastwell HD. Elevated lead levels in petrol "sniffers". *Med J Aust* 1985; **143** (suppl): S63–4.

Uses

Petroleum spirit and other petroleum distillates are used as pharmaceutical solvents.

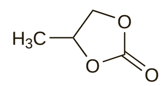
Propylene Carbonate

Carbonato de propileno. 4-Methyl-1,3-dioxolan-2-one.

Пропиленкарбонат

$C_4H_6O_3 = 102.1$.

CAS — 108-32-7.



Description. Propylene carbonate is a clear colourless mobile liquid. Freely soluble in water; miscible with alcohol and with chloroform; practically insoluble in petroleum spirit.

Pharmacopoeias. In *USNF.*

USNF 26 (Propylene Carbonate). Sp. gr. 1.203 to 1.210 at 20°. Store in airtight containers.

Profile

Propylene carbonate is used as a solvent in oral and topical pharmaceuticals and for cellulose-based polymers and plasticisers. It has been used as a nonvolatile, stabilising liquid carrier in hard gelatin capsules.

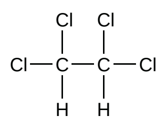
Tetrachloroethane

Acetylene Tetrachloride; Tetrachloroetan; Tetracloroetano. 1,1,2,2-Tetrachloroethane.

Тетрахлорэтан

$C_2H_2Cl_4 = 167.8$.

CAS — 79-34-5.



Description. Tetrachloroethane is a colourless liquid with a chloroform-like odour. B.p. about 146°. Wt per mL about 1.59 g. Store in airtight containers.

Adverse Effects and Treatment

As for Carbon Tetrachloride, p.2021. Tetrachloroethane is probably the most toxic of the chlorinated hydrocarbons. Poisoning can occur through percutaneous absorption as well as after ingestion or inhalation.

Handling. Suitable precautions should be taken to avoid skin contact with tetrachloroethane as it can penetrate skin and produce systemic toxicity.

Uses

Tetrachloroethane is used as an industrial solvent.

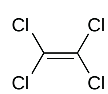
Tetrachloroethylene

Perchloroethylene; Tetrachloroethene; Tetrachloroethylenum; Tetracloroetileno.

Тетрахлорэтилен

$C_2Cl_4 = 165.8$.

CAS — 127-18-4.



Adverse Effects and Treatment

As for Carbon Tetrachloride, p.2021. Symptoms, especially after ingestion, are less severe with tetrachloroethylene than with carbon tetrachloride.

The vapour or liquid may be irritating to skin or mucous membranes.

Tetrachloroethylene may be implicated in volatile substance abuse (p.2019). Dependence may follow habitual inhalation of small quantities of tetrachloroethylene vapour.

◊ References to adverse effects of tetrachloroethylene.

1. Bagnell PC, Ellenberger HA. Obstructive jaundice due to a chlorinated hydrocarbon in breast milk. *Can Med Assoc J* 1977; **117:** 1047–8.
2. WHO. Tetrachloroethylene. *Environmental Health Criteria 31*. Geneva: WHO, 1984. Available at: http://www.inchem.org/documents/ehc/ehc/ehc31.htm (accessed 30/06/04)
3. WHO. Tetrachloroethylene health and safety guide. *IPCS Health and Safety Guide 10*. Geneva: WHO, 1987. Available at: http://www.inchem.org/documents/hsg/hsg/hsg010.htm (accessed 30/06/04)
4. Health and Safety Executive. Tetrachloroethylene (tetrachloroethene, perchloroethylene). *Toxicity Review 17*. London: HMSO, 1987.
5. Mutti A, *et al.* Nephropathies and exposure to perchloroethylene in dry-cleaners. *Lancet* 1992; **340:** 189–93.

Pharmacokinetics

Tetrachloroethylene is slightly absorbed from the gastrointestinal tract; absorption is increased in the presence of alcohol and fats or oils. It is absorbed after inhalation and after direct contact with the skin. It is excreted unchanged in expired air; initial elimination is rapid but a proportion may be retained and excreted slowly.

Metabolites of tetrachloroethylene, mainly trichloroacetic acid, have been found in the urine.

Uses and Administration

Tetrachloroethylene is a chlorinated hydrocarbon widely used as a solvent in industry. It was formerly given orally as an anthelmintic, but has been superseded by equally effective and less toxic drugs.

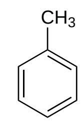
Toluene

Methylbenzene; Phenylmethane; Toluen; Tolueno; Toluol; Toluole.

Толуол

$C_7H_8 = 92.14$.

CAS — 108-88-3.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of toluene:

Tolley; Tolly; Tooly.

Description. Toluene is a colourless, volatile, flammable liquid with a characteristic odour. Wt per mL about 0.87 g. B.p. about 111°. Store in airtight containers.

Adverse Effects, Treatment, and Precautions

Toluene has similar acute toxicity to benzene (p.2020) but is a less serious industrial hazard. Adverse effects are treated similarly to benzene. It is a common constituent of adhesives and is frequently implicated in volatile substance abuse (p.2019). Commercial toluene may contain benzene, and this may perhaps influence the pattern of adverse effects. In addition to acute toxic effects, toluene abuse has been associated with damage to the nervous system, kidneys, liver, heart, and lungs (see below). Chronic poisoning caused by occupational exposure to toluene has resulted mainly in nervous system disorders.

◊ Reviews.

1. WHO. Recommended health-based limits in occupational exposure to selected organic solvents. *WHO Tech Rep Ser 664* 1981. Available at: http://libdoc.who.int/trs/WHO_TRS_664.pdf (accessed 03/09/08)
2. WHO. Toluene. *Environmental Health Criteria 52*. Geneva: WHO, 1985. Available at: http://www.inchem.org/documents/ehc/ehc/ehc52.htm (accessed 30/06/04)
3. Health and Safety Executive. Toluene. *Toxicity Review 20*. London: HMSO, 1989.

◊ The non-neurological toxicity after volatile substance abuse has been reviewed.[1] Chronic toluene abuse may result in damage to the *kidneys*; renal tubular acidosis and glomerulonephritis have been described, although evidence for the latter is only circumstantial. Renal tubular acidosis has been regarded as reversible; however, there are reports suggesting that damage to renal tubules is permanent.

The few reports linking chronic toluene abuse with *liver* damage cover hepatomegaly and hepatorenal failure. Effects on the *heart* are usually acute; sudden death has resulted from ventricular arrhythmias. Chronic myocarditis with fibrosis has been reported. Chronic toluene inhalation can cause damage to the *lungs.* Autopsies in a few patients have shown changes indicative of emphysema.

Nervous system toxicity has also been reviewed.[2,3] Cerebellar dysfunction has occurred after toluene abuse; an acute intoxication phase, which usually subsides within weeks of abstinence, is followed by a chronic phase which may be permanent. Diffuse CNS disease such as encephalopathy, dementia, and multifocal brain injury may also develop. An association between toluene abuse and peripheral neuropathy has not been confirmed; muscle weakness may be a result of electrolyte and fluid disturbances. Choreoathetosis, epilepsy, and optic atrophy with anosmia and deafness have been reported after toluene abuse. Some of these neurological effects, particularly cerebellar effects and diffuse

CNS disease have also occurred after occupational exposure to toluene.

Some studies have noted an excess mortality from motor neurone diseases among leather workers,[4] although this has not been confirmed by others.[5] Occupational exposure to solvents has been postulated as the cause.[4] Of the many agents currently used in leather work, those with known or probable neurotoxic effects are *n*-hexane, methyl butyl ketone, toluene, and methyl ethyl ketone. Ethyl acetate is commonly used but has no recognised neurological adverse effects.[4] A Swedish study of workers in a range of occupations has found some support for an increased risk of amyotrophic lateral sclerosis after occupational exposure to solvents, probably toluene and petrol.[6] Another Swedish study found an association between multiple sclerosis and occupational exposure to solvents, especially white spirit and petrol.[6]

5. Martyn CN. Motoneuron disease and exposure to solvents. *Lancet* 1989; **i:** 394.
6. Gunnarsson L-G, Lindberg G. Amyotrophic lateral sclerosis in Sweden 1970-83 and solvent exposure. *Lancet* 1989; **i:** 958.

Handling. Suitable precautions should be taken to avoid skin contact with toluene as it can penetrate skin and produce systemic toxicity.

Pregnancy. Retrospective surveys of pregnancies in mothers with a history of solvent abuse suggested that toluene abuse during pregnancy can cause preterm delivery and perinatal death. It was suggested that toluene may be teratogenic as intra-uterine exposure was associated with prenatal and postnatal growth retardation, microcephaly, impairment of mental development, and facial dysmorphia.[1-3] It is uncertain if these results can be extrapolated to cover occupational exposure. Although some studies of occupational exposure to solvents during pregnancy have suggested an association,[4,5] exposure is usually to a number of solvents[5] and there is little consistent evidence to link exposure to any particular one with spontaneous abortion, retarded fetal development, still-birth, or congenital malformation.[6]

6. Scott A. *BMJ* 1992; **304:** 369.

Pharmacokinetics

Toluene is absorbed after inhalation and ingestion, and to some extent through the skin. It is rapidly metabolised mainly by oxidation to benzoic acid which is excreted in the urine largely as the glycine conjugate hippuric acid; *o*-, *m*-, and *p*-cresol are minor urinary metabolites. Some unchanged toluene is excreted through the lungs.

Uses

Toluene is widely used as an industrial solvent.

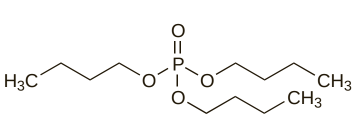
Tri-*n*-butyl Phosphate

Fosfato de tributilo; Tributyl Phosphate; Tributyl-fosfát; Tributylis Phosphas; Tri-*n*-butylis Phosphas; Tri(*n*-butyl)phosphate; Tri-n-butilo fosfatas; Tri-n-butyle, phosphate de; Tri-n-butylfosfat; Tri-n-butylis phosphas; Tri-n-butyylifosfaatti. Phosphoric acid tributyl ester.

Три-н-бутилфосфат

$C_{12}H_{27}O_4P$ = 266.3.

CAS — 126-73-8.



Pharmacopoeias. In *Eur.* (see p.vii).

Ph. Eur. 6.2 (Tri-*n*-butyl Phosphate; Tributyl Phosphate BP 2008). A clear, colourless to pale yellow liquid. Slightly soluble in water; miscible with alcohol. Protect from light.

Profile

Tri-*n*-butyl phosphate is an organophosphate that is used as a solvent and plasticiser.

◊ References.

1. WHO. Tri-*n*-butyl phosphate. *Environmental Health Criteria 112*. Geneva: WHO, 1991. Available at: http://www.inchem.org/documents/ehc/ehc/ehc112.htm (accessed 29/06/04)

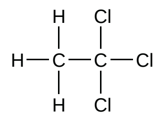
Trichloroethane

Methylchloroform; α-Trichloroethane; Tricloroetano. 1,1,1-Trichloroethane.

Трихлорэтан

$C_2H_3Cl_3$ = 133.4.

CAS — 71-55-6.



Description. Trichloroethane is a colourless, slightly hygroscopic liquid. Sp. gr. about 1.31. B.p. about 74°. Practically insoluble in water; miscible with alcohol, with chloroform, and with ether. Non-flammable. Store in airtight containers.

Adverse Effects and Treatment

Acute intoxication with trichloroethane may result in initial excitement followed by CNS depression with dizziness, drowsiness, headache, lightheadedness, and ataxia, progressing to coma and death from respiratory depression in severe cases. Death may also occur from ventricular arrhythmias. Fatalities have occurred after accidental exposure to high concentrations of trichloroethane in confined spaces. Trichloroethane is commonly used in dry cleaning, type correction fluids, and as a solvent for plaster removal and is frequently implicated in volatile substance abuse (p.2019).

Nausea, vomiting, and diarrhoea have been reported after ingestion. Trichloroethane is a mild irritant.

Treatment of adverse effects consists of removal from exposure and general supportive and symptomatic measures. Activated charcoal is unlikely to be of benefit after ingestion and gastric lavage is contra-indicated. Adrenaline and other sympathomimetics should be avoided because of the risk of precipitating cardiac arrhythmias.

◊ Reviews.

1. Health and Safety Executive. 1,1,1-Trichloroethane. *Toxicity Review 9*. London: HMSO, 1984.
2. WHO. 1,1,1-Trichloroethane. *Environmental Health Criteria 136*. Geneva: WHO, 1992. Available at: http://www.inchem.org/documents/ehc/ehc/ehc136.htm (accessed 30/06/04)

Effects on the heart. Effects on the heart of trichloroethane abuse were considered usually to be acute, and sudden death from ventricular arrhythmias had occurred in abusers. There have, however, been a few cases of chronic cardiac toxicity after both abuse and occupational exposure.[1]

1. Marjot R, McLeod AA. Chronic non-neurological toxicity from volatile substance abuse. *Hum Toxicol* 1989; **8:** 301–6.

Effects on the liver. According to a brief review of non-neurological toxicity from volatile substance abuse,[1] there were no reports of damage to the liver after the abuse of trichloroethane. There was a report of hepatotoxicity after acute occupational exposure, but this might have been a hypersensitivity reaction. There was another report[2] of fatty liver disease in 4 patients with a history of occupational exposure to trichloroethane although there has been some debate over the validity of the association for 2 of these cases.[3,4] Chronic active hepatitis associated with trichloroethane exposure has since been reported.[5]

1. Marjot R, McLeod AA. Chronic non-neurological toxicity from volatile substance abuse. *Hum Toxicol* 1989; **8:** 301–6.
2. Hodgson MJ, *et al.* Liver disease associated with exposure to 1,1,1-trichloroethane. *Arch Intern Med* 1989; **149:** 1793–8.
3. Guzelian PS. 1,1,1-Trichloroethane and the liver. *Arch Intern Med* 1991; **151:** 2321–2.
4. Hodgson MJ, Vanthiel DH. 1,1,1-Trichloroethane and the liver. *Arch Intern Med* 1991; **151:** 2322 and 2325–6.
5. Croquet V, *et al.* Hépatite chronique active probablement induite par le 1,1, 1-trichloroéthane. *Gastroenterol Clin Biol* 2003; **27:** 120–2.

Effects on the skin. Scleroderma has been reported[1] in 3 patients occupationally exposed to trichloroethylene and, in 2 cases, also to trichloroethane.

1. Flindt-Hansen H, Isager H. Scleroderma after occupational exposure to trichlorethylene and trichlorethane. *Acta Derm Venereol (Stockh)* 1987; **67:** 263–4.

Pharmacokinetics

Trichloroethane is absorbed after inhalation and ingestion, and through intact skin. Small amounts are metabolised to trichloroethanol and trichloroacetic acid and excreted in the urine, but it is largely excreted unchanged through the lungs over a period of days.

Uses

Trichloroethane has wide applications as an industrial solvent. It is commonly used in dry cleaning, typewriter correction fluids, and as a solvent for plaster removal.

White Spirit

Stoddard Solvent; Trementina.

Уайтспирит

CAS — 64742-82-1 (white spirit type 1); 64741-92-0 (white spirit type 2); 64742-48-9 (white spirit type 3); 64742-88-7 (white spirit type 0); 8052-41-3 (Stoddard solvent).

Description. White spirit is a mixture of hydrocarbons available as a colourless liquid. Store in airtight containers.

Adverse Effects and Treatment

As for Kerosene, p.2024.

◊ References to the toxicity of white spirit.[1]

For discussion of neurotoxicity after occupational exposure to solvents including white spirit, see under Toluene, p.2026.

1. WHO. Selected petroleum products. *Environmental Health Criteria 20*. Geneva: WHO, 1982. Available at: http://www.inchem.org/documents/ehc/ehc/ehc020.htm (accessed 30/06/04)

Uses

White spirit is used as an industrial solvent. It is available in various grades. One grade available in the USA is known as Stoddard solvent.

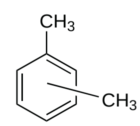
Xylene

Dimethylbenzene; Ksylen; Xileno; Xylol; Xylole.

Ксилол

C_8H_{10} = 106.2.

CAS — 1330-20-7; 108-38-3 (m-xylene); 95-47-6 (o-xylene); 106-42-3 (p-xylene).



Description. Xylene is a mixture of the *o*-, *m*-, and *p*-isomers in which the *m*-isomer predominates. It is a colourless, volatile, flammable liquid. Wt per mL about 0.86 g. B.p. about 138° to 142°. Store in airtight containers.

Adverse Effects, Treatment, and Precautions

The acute toxicity of xylene is similar to that of benzene (p.2020) but is less marked. Adverse effects are treated similarly to benzene.

Xylene has been implicated in volatile substance abuse (p.2019). Commercial xylene may contain benzene, and this may perhaps influence the pattern of adverse effects.

Xylene should not be used to dissolve ear wax if the tympanic membrane is perforated.

Effects on the eyes. Eye injuries due to accidental contact with paints containing xylene have been reported.[1] The injuries resembled alkali burns and were treated in a similar manner. Xylene-induced keratopathy has been reviewed.[2]

Handling. Suitable precautions should be taken to avoid skin contact with xylene as it can penetrate skin and produce systemic toxicity.

Pharmacokinetics

Xylene is absorbed after inhalation, ingestion, and to some extent through the skin. It is rapidly metabolised by oxidation to the corresponding *o*-, *m*-, or *p*-methylbenzoic (toluic) acids and excreted in the urine largely as the glycine conjugate, methylhippuric acid (toluric acid). Xylenols are minor metabolites and are excreted in the urine as the glucuronide and sulfate conjugates. Some unchanged xylene is excreted through the lungs.

Uses

Xylene is used as an industrial and pharmaceutical solvent and in preparations to dissolve ear wax.

Paraffins and Similar Bases

This chapter includes substances used mainly as bases for the preparation of creams, ointments, other topical preparations, and suppositories. They may act as inert carriers for drugs or have emulsifying and emollient properties. Some are also used to improve the texture, stability, or water repellent properties of the final preparation. The bases discussed include petroleum hydrocarbons, animal fats and waxes, vegetable oils, and silicones. Other substances used in the preparation of bases can be found in Soaps and other Anionic Surfactants (p.2138) and in Nonionic Surfactants (p.1914).

Alkyl Benzoate

Alkyl (C12-15) Benzoate; Benzoato de alquilo.

Алкил Бензоат

CAS — 68411-27-8 (C_{12}-C_{15} alkyl ester).

Pharmacopoeias. In *USNF.*

USNF 26 (Alkyl (C12-15) Benzoate). It consists of esters of a mixture of C_{12} to C_{15} primary and branched alcohols and benzoic acid (average molecular formula $C_{20}H_{32}O_2$ = 304.5). It is a clear, practically colourless, oily liquid. Insoluble in water, in glycerol, and in propylene glycol; soluble in alcohol, in acetone, in ethyl acetate, in isopropyl alcohol, in isopropyl myristate, in isopropyl palmitate, in liquid paraffin, in vegetable oils, in volatile silicones, and in wool fat. Store in airtight containers. Protect from light.

Profile

Alkyl benzoate has emollient properties. It may be used as an oily vehicle.

White Beeswax

Baltasis vaškas; Bleached Wax; Cera alba; Cera Blanca; Cêra Branca; Cera de abejas; Cire Blanche; Cire d'abeille blanche; E901; Fehér viasz; Gebleichtes Wachs; Valkovaha; Vax, vitt; Vosk bílý; White Wax; Wosk biały.

Осветлённый Пчелиный Воск

CAS — 8012-89-3.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Beeswax, White). It is bleached yellow beeswax. It occurs as white or yellowish-white pieces or plates, translucent when thin, with an odour similar to that of yellow beeswax, though fainter and never rancid, and with a fine-grained, matt and non-crystalline fracture, becoming soft and malleable when warmed in the hand. Drop point 61° to 66°. Practically insoluble in water; partially soluble in hot alcohol; completely soluble in fatty and essential oils.

USNF 26 (White Wax). It is bleached and purified yellow beeswax. A yellowish-white solid, somewhat translucent in thin layers. It has a faint characteristic odour and is free from rancidity. M.p. 62° to 65°. Insoluble in water; sparingly soluble in cold alcohol; boiling alcohol dissolves the cerotic acid and a portion of the myricin that are constituents of the wax; completely soluble in chloroform, in ether, in fixed oils, and in volatile oils; partly soluble in cold benzene and in cold carbon disulfide; completely soluble in these liquids at about 30°.

Yellow Beeswax

Cêra Amarela; Cera Amarilla; Cera de abejas amarilla; Cera flava; Cire d'abeille jaune; Cire Jaune; E901; Gelbes Wachs; Geltonasis vaškas; Keltavaha; Refined Wax; Sárga viasz; Vax, gult; Vosk žlutý; Wosk żółty; Yellow Wax.

Жёлтый Пчелиный Воск

CAS — 8012-89-3.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Beeswax, Yellow). The wax obtained by melting with hot water the walls of the honeycomb of the bee, *Apis mellifera*, and removing the foreign matter. It occurs as yellow or light brown pieces or plates with a faint and characteristic odour of honey, and with a fine-grained, matt and non-crystalline fracture, becoming soft and malleable when warmed in the hand. Drop point 61° to 66°. Practically insoluble in water; partially soluble in hot alcohol; completely soluble in fatty and essential oils.

USNF 26 (Yellow Wax). The purified wax from the honeycomb of the bee, *Apis mellifera* (Apidae). It is a solid, varying in colour from yellow to greyish-brown with an agreeable honey-like odour, somewhat brittle when cold, pliable when warmed in the hand, and presenting a dull, granular, noncrystalline fracture when broken. M.p. 62° to 65°. Insoluble in water; sparingly soluble in cold alcohol; boiling alcohol dissolves the cerotic acid and a portion of the myricin that are constituents of the wax; completely soluble in chloroform, in ether, in fixed oils, and in volatile oils; partly soluble in cold benzene and in cold carbon disulfide; completely soluble in these liquids at about 30°.

Profile

Yellow beeswax is used as a stiffening agent in ointments and creams, and enables water to be incorporated to produce water-in-oil emulsions. It is also used as a coating in the manufacture of modified-release oral preparations. White beeswax has similar uses; it is occasionally used to adjust the melting-point of suppositories.

A sterile preparation of white beeswax, hard paraffin, and isopropyl palmitate (Sterile Surgical Bone Wax) is used to control bleeding from damaged bone during surgery. It should not be confused with Aseptic Surgical Wax (BPC 1949), also known as Horsley's Wax, which contained yellow beeswax, olive oil, and phenol in a mercuric chloride solution and was used to control haemorrhage in bone or cranial surgery.

Beeswaxes are also used in foods and cosmetics.

Hypersensitivity to beeswax has been reported.

Granuloma formation. Use of surgical bone wax has been associated with an inflammatory response in some patients. Formation of granuloma tissue at the site of application to the orbit,[1] foot,[2] and sternum[3] has been reported. Seven patients developed local pain and tenderness after use of bone wax in foot surgery; further surgery to remove granulomatous tissue 4 to 52 months later resolved pain in 5 patients.[2] In an autopsy study of 18 cadavers with evidence of sternotomy, 17 of which had macroscopic evidence of bone wax use, signs of inflammation or granuloma formation were found in all but one. The authors concluded that bone wax is non-resorbable and can cause chronic inflammation up to 10 years after application.[3]

1. Katz SE, Rootman J. Adverse effects of bone wax in surgery of the orbit. *Ophthal Plast Reconstr Surg* 1996; **12:** 121–6.
2. Anfinsen O-G, *et al.* Complications secondary to the use of standard bone wax in seven patients. *J Foot Ankle Surg* 1993; **32:** 505–8.
3. Sudmann B, *et al.* Histologically verified bone wax (beeswax) granuloma after median sternotomy in 17 of 18 autopsy cases. *Pathology* 2006; **38:** 138–41.

Hypersensitivity. Sensitivity reactions to topical beeswax products have been reported rarely. Contact dermatitis from use of a beeswax-based nipple protector has been reported,[1] and cheilitis from a beeswax lip product has also occurred.[2]

1. García M, *et al.* Allergic contact dermatitis from a beeswax nipple-protective. *Contact Dermatitis* 1995; **33:** 440–1.
2. Lucente P, *et al.* Contact cheilitis due to beeswax. *Contact Dermatitis* 1996; **35:** 258.

Candelilla Wax

E902.

Канделильский Воск

CAS — 8006-44-8.

Pharmacopoeias. In *USNF.*

USNF 26 (Candelilla Wax). The purified wax from the leaves of the plant *Euphorbia antisyphilitica*. It is a hard, yellowish-brown, opaque to translucent wax. M.p. between 68.5° and 72.5°. Insoluble in water; soluble in chloroform and in toluene.

Profile

Candelilla wax is used as a pharmaceutical excipient and in the food industry.

Cetostearyl Alcohol

Alcohol cetoestearílico; Alcohol cetylicus et stearylicus; Alcohol Cetylstearylicus; Alcool Cetostearilico; Alkohol cetostearylowy; Cetearyl Alcohol; Cetil-sztearil-alkohol; Cetostearilo alkoholis; Cetostearyl Alc.; Cetostearylalkohol; Cétostéarylique alcool; Cétostéarylique, alcool; Cetylstearylalkohol; Setostearyylialkoholi.

Цетостеариловый Спирт

CAS — 8005-44-5; 67762-27-0.

Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*

Ph. Eur. 6.2 (Cetostearyl Alcohol). A mixture of solid aliphatic alcohols, mainly stearyl alcohol and cetyl alcohol. It contains not less than 90% of stearyl plus cetyl alcohols and not less than 40% of stearyl alcohol. A white or pale yellow wax-like mass, plates, flakes, or granules. M.p. 49° to 56°. Practically insoluble in water; soluble in alcohol and in petroleum spirit. When melted, it is miscible with fatty oils, with liquid paraffin, and with melted wool fat.

Ph. Eur. 6.2 (Cetostearyl Alcohol (Type A), Emulsifying; Alcohol Cetylicus et Stearylicus Emulsificans A). A mixture containing not less than 80% cetostearyl alcohol and not less than 7% sodium cetostearyl sulfate, both calculated with reference to the anhydrous substance. A suitable buffer may be added. White or pale yellow, wax-like mass, plates, flakes, or granules. Soluble in hot water giving an opalescent solution; practically insoluble in cold water; slightly soluble in alcohol.

Ph. Eur. 6.2 (Cetostearyl Alcohol (Type B), Emulsifying; Alcohol Cetylicus et Stearylicus Emulsificans B). A mixture containing not less than 80% cetostearyl alcohol and not less than 7% sodium laurilsulfate, both calculated with reference to the anhydrous substance. A suitable buffer may be added. White or pale yellow, wax-like mass, plates, flakes, or granules. Soluble in hot water giving an opalescent solution; practically insoluble in cold water; slightly soluble in alcohol.

USNF 26 (Cetostearyl Alcohol). It contains not less than 40% of stearyl alcohol ($C_{18}H_{38}O$ = 270.5) and the sum of the stearyl alcohol content and the cetyl alcohol ($C_{16}H_{34}O$ = 242.4) content is not less than 90%. Unctuous, white flakes or granules, having a faint, characteristic odour. M.p. 48° to 55°. Insoluble in water; soluble in alcohol and in ether.

Profile

Cetostearyl alcohol is used in creams, ointments, and other topical preparations as a stiffening agent and emulsion stabiliser. Used with suitable hydrophilic substances, as in Emulsifying Wax, it produces oil-in-water emulsions that are stable over a wide pH range. It is also used to improve the emollient properties of paraffin ointments. It is used in the formulation of modified-release oral preparations.

Cetostearyl alcohol can cause hypersensitivity.

Hypersensitivity. Sensitivity reactions to cetostearyl alcohol in topical preparations have been reported rarely.[1-3]

1. Pecegueiro M, *et al.* Contact dermatitis to Hirudoid cream. *Contact Dermatitis* 1987; **17:** 290–3.

USNF 26: Emulsifying Wax.

Cetyl Alcohol

Alcohol cetílico; Alcohol cetylicus; Alcohol Hexadecílico; Álcool Cetílico; Alkohol cetylowy; Cetanol; Cetil-alkohol; Cetilo alkoholis; Cetylalkohol; Cétylique, alcool; Ethal; Ethol; 1-Hexadecanol; Hexadecan-1-ol; Hexadecyl Alcohol; *n*-Hexadecyl Alcohol; Palmityl Alcohol; Setyylialkoholi.

Цетиловый Спирт

$C_{16}H_{34}O$ = 242.4.

CAS — 36653-82-4; 124-29-8.

Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*

Ph. Eur. 6.2 (Cetyl Alcohol). A mixture of solid alcohols, mainly cetyl alcohol, of animal or vegetable origin. It occurs as a white or almost white, unctuous mass, powder, flakes, or granules. M.p. 46° to 52°. Practically insoluble in water; freely to sparingly soluble in alcohol; miscible when melted with animal and vegetable oils, with liquid paraffin, and with melted wool fat.

USNF 26 (Cetyl Alcohol). A mixture containing not less than 90% of cetyl alcohol the remainder consisting chiefly of related alcohols. White unctuous flakes, cubes, granules, or castings, with a faint characteristic odour. M.p. 45° to 50°. Insoluble in water; soluble in alcohol and in ether, the solubility increasing with increasing temperature.

Profile

Cetyl alcohol is used in topical preparations for its emollient, water absorptive, stiffening, and weak emulsifying properties. It may be incorporated into suppositories to raise the melting-point and may be used in the coating of modified-release solid dose forms. It is also used in cosmetics.

Cetyl alcohol can cause hypersensitivity.

Hypersensitivity. Hypersensitivity reactions have occasionally been attributed to the presence of cetyl alcohol in topical preparations.[1-4] One report suggested that minor impurities in the cetyl alcohol may be responsible.[1]

1. Komamura H, *et al.* A case of contact dermatitis due to impurities of cetyl alcohol. *Contact Dermatitis* 1997; **36:** 44–6.

2. Oiso N, *et al.* Concomitant allergic reaction to cetyl alcohol and crotamiton. *Contact Dermatitis* 2003; **49:** 261.
3. Soga F, *et al.* Contact dermatitis due to lanoconazole, cetyl alcohol and diethyl sebacate in lanoconazole cream. *Contact Dermatitis* 2004; **50:** 49–50.

Cetyl Esters Wax

Cera Cetyla; Cera de ésteres cetílicos; Cera de ésteres del alcohol cetílico; Esperma de ballena sintético; Spermaceti Wax Replacement; Synthetic Spermaceti.

Воск Сложных Цетиловых Эфиров

CAS — 85566-24-1.

Pharmacopoeias. In *Int.* Also in *USNF.*
USNF 26 (Cetyl Esters Wax). A mixture consisting primarily of esters of saturated fatty alcohols (C_{14} to C_{18}) and saturated fatty acids (C_{14} to C_{18}). White to off-white somewhat translucent flakes with a crystalline structure and a pearly lustre when caked; it has a faint odour and is free from rancidity. M.p. 43° to 47°. Insoluble in water; practically insoluble in cold alcohol; soluble in boiling alcohol, in chloroform, in ether, and in fixed and volatile oils; slightly soluble in cold petroleum spirit. Store in a dry place at a temperature not exceeding 40°.

Profile

Cetyl esters wax is used mainly as a stiffening agent and emollient in creams and ointments. It is also used in the coating of some oral dosage forms. It is a synthetic replacement for natural spermaceti obtained from the sperm whale and the bottle-nosed whale.

Preparations

USP 31: Rose Water Ointment.

Proprietary Preparations (details are given in Part 3)

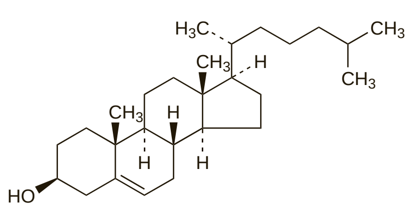
Multi-ingredient: *Arg.:* Cold Cream Naturel†.

Cholesterol

Cholesterin; Cholestérol; Cholesterolis; Cholesterolum; Colesterina; Colesterol; Kolesterol; Kolesteroli; Koleszterin; Koleszterin. Cholest-5-en-3β-ol.

Холестерин; Холестерол

$C_{27}H_{46}O = 386.7.$
CAS — 57-88-5.



Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Cholesterol). A white or almost white, crystalline powder. It is sensitive to light. M.p. 147° to 150°. Practically insoluble in water; sparingly soluble in alcohol and in acetone. Protect from light.
USNF 26 (Cholesterol). White or faintly yellow, practically odourless, pearly leaflets, needles, powder, or granules. It acquires a yellow to pale tan colour on prolonged exposure to light. M.p. 147° to 150°. Insoluble in water; slowly soluble 1 in 100 of alcohol; soluble 1 in 50 of dehydrated alcohol; soluble in acetone, in chloroform, in dioxan, in ether, in ethyl acetate, in petroleum spirit, and in vegetable oils. Protect from light.

Profile

Cholesterol imparts water-absorbing power to pharmaceutical preparations and is used as an emulsifying agent. It has emollient activity and is used mainly in topical preparations. It is also used in ophthalmic and vaginal formulations, and in preparations for parenteral use.

Cholesteryl benzoate has been used as an ingredient in dermatological preparations.

Preparations

Proprietary Preparations (details are given in Part 3)

Кокосовое Масло

CAS — 8001-31-8.

Pharmacopoeias. In *Eur.* (see p.vii), *Jpn.*, and *USNF.*
Ph. Eur. 6.2 (Coconut Oil, Refined). The refined fatty oil obtained from the dried, solid part of the endosperm of *Cocos nucifera*. A white or almost white, unctuous mass. M.p. 23° to 26°. Practically insoluble in water; very slightly soluble in alcohol; freely soluble in dichloromethane and in petroleum spirit (b.p. 65° to 70°). Store in well-filled containers. Protect from light.
USNF 26 (Coconut oil). The refined fixed oil obtained from the seeds of *Cocos nucifera*. A clear, white to light yellow-tan, viscous liquid. Practically insoluble in water; very slightly soluble in alcohol; freely soluble in dichloromethane and in light petroleum. M.p. 23° to 26°. Store in airtight, well-filled containers. Protect from light.

Profile

Coconut oil is used as a basis for topical creams and ointments, in rectal and vaginal suppositories, and in solid dosage forms. It is also used in food manufacturing. Topical preparations have been used for pediculosis.

Fractionated coconut oil (thin vegetable oil) is used as a source of medium-chain triglycerides (p.1956).

Hypersensitivity. Sensitivity reactions to coconut products, including coconut oil,[1] have been reported rarely. Cases of anaphylaxis have been reported.[2,3]

1. Couturier P, *et al.* Un cas d'allergie à l'huile de noix de coco chez un nourrisson: responsabilité des laits materrisés. *Allerg Immunol (Paris)* 1994; **26:** 386–7.

Emulsifying Wax

Anionic Emulsifying Wax; Cera emulgente; Cera Emulsificans; Cera emulsionante; Cetylanum; Emulsif. Wax.

Эмульгирующий Воск

CAS — 8014-38-8.

Pharmacopoeias. In *Br.* Also in *USNF.*
BP 2008 (Emulsifying Wax). It is prepared from 9 parts of cetostearyl alcohol and 1 part of sodium laurilsulfate or sodium salts of similar sulfated higher primary aliphatic alcohols. An almost white or pale yellow, waxy solid or flakes, becoming plastic when warmed, with a faint characteristic odour. Practically insoluble in water, forming an emulsion; partly soluble in alcohol.
USNF 26 (Emulsifying Wax). It is prepared from cetostearyl alcohol containing a polyoxyethylene derivative of a fatty acid ester of sorbitan. M.p. 50° to 54°. It is a creamy-white, wax-like solid, with a mild characteristic odour. Insoluble in water; soluble in alcohol; freely soluble in chloroform, in ether, in most hydrocarbon solvents, and in aerosol propellants.

Profile

Emulsifying wax added to fatty or paraffin bases facilitates the preparation of oil-in-water emulsions which are absorbed and are nongreasy when rubbed into the skin. It is a constituent of many hydrophilic ointment bases for so-called 'washable' ointments, and is also used in rectal preparations, and in cosmetics.

Sunscreen activity. Emulsifying ointment, which contains emulsifying wax with white soft paraffin and liquid paraffin, was found to have major sunscreen activity in clinically normal skin.[1] It should not be used before phototherapy or in phototesting procedures.

Hard Fat

Adeps Neutralis; Adeps solidus; Glicéridos semisintéticos sólidos; Glycérides hémi-synthétiques solides; Glycérides Semi-synthétiques Solides; Grasa sólida; Hårdfett; Hartfett; Kietieji riebalai; Kovarasva; Massa Estearínica; Neutralfett; Szilárd zsír; Tuk ztužený; Tłuszcz obojętny.

Твёрдый Жир

Pharmacopoeias. In *Eur.* (see p.vii) and *Int.* Also in *USNF.*
Ph. Eur. 6.2 (Hard Fat). A mixture of triglycerides, diglycerides, and monoglycerides obtained either by esterification of fatty acids of natural origin with glycerol or by transesterification of natural fats. A white or almost white, waxy, brittle mass. M.p. 30° to 45°; it does not differ by more than 2° from the nominal value. Practically insoluble in water; slightly soluble in dehydrated alcohol. When heated to 50°, it melts giving a colourless or slightly yellowish liquid. Protect from light and heat.
USNF 26 (Hard Fat). A mixture of glycerides of saturated fatty acids. A white mass, almost odourless and free from rancid odour, and greasy to the touch. M.p. is between 27° and 44° and does not differ by more than 2° from the nominal value. The melted substance is colourless or slightly yellowish and forms a white emulsion when shaken with an equal amount of hot water. Practically insoluble in water; slightly soluble in alcohol; freely soluble in ether. Store in airtight containers at a temperature 5° or more below the melting-point.

Profile

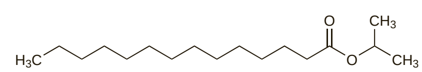
The name Hard Fat is applied to a range of bases with varying degrees of hardness and differing melting ranges used for the preparation of suppositories and vaginal pessaries. Hard fat is also used in some topical preparations.

Isopropyl Myristate *(USAN)*

Isopropyl myristát; Isopropyle, myristate d'; Isopropylis myristas; Isopropylmyristat; Isopropyylimyristaatti; Izopropil-mirisztát; Izopropilo miristatas; Izopropylu mirystynian; Miristato de isopropilo. Tetradecanoic acid 1-methylethyl ester; Isopropyl tetradecanoate.

Изопропилмиристат

$C_{17}H_{34}O_2 = 270.5.$
CAS — 110-27-0.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Isopropyl Myristate). A clear, colourless, oily liquid. Relative density about 0.853. Immiscible with water; miscible with alcohol, with dichloromethane, with fatty oils, and with liquid paraffin. Protect from light.
USNF 26 (Isopropyl Myristate). A clear practically colourless, almost odourless, oily liquid; congeals at about 5°. Insoluble in water, in glycerol and in propylene glycol; freely soluble in alcohol. Miscible with most organic solvents and with fixed oils. Store in airtight containers. Protect from light.

Incompatibility. Isopropyl myristate is incompatible with hard paraffin.

Profile

Isopropyl myristate is resistant to oxidation and hydrolysis and does not become rancid. It is absorbed fairly readily by the skin and is used as a basis for relatively nongreasy emollient ointments and creams. It is also used as a penetration enhancer for many substances applied externally as creams, sprays, or transdermal patches.

Other isopropyl fatty acid esters, including di-isopropyl adipate, isopropyl laurate, isopropyl linoleate, and isopropyl palmitate (below) have similar properties and are used for similar purposes to those of isopropyl myristate.

Hypersensitivity. A case of sensitivity to isopropyl myristate has been reported[1] in a 64-year-old woman. She developed a rash after using a sunscreen containing isopropyl myristate for 3 days, and patch testing confirmed a sensitivity both to this substance and to isohexadecane (a mixture of C_{16} paraffins).

1. Bharati A, King CM. Allergic contact dermatitis from isohexadecane and isopropyl myristate. *Contact Dermatitis* 2004; **50:** 256–7.

Preparations

Proprietary Preparations (details are given in Part 3)
Spain: Nucoa.

Isopropyl Palmitate

Isopropyl palmitát; Isopropyle, palmitate d'; Isopropylis palmitas; Isopropylpalmitat; Isopropyylipalmitaatti; Izopropilo palmitatas; Izopropil-palmitát; Palmitato de isopropilo. Hexadecanoic acid 1-methylethyl ester; Isopropyl hexadecanoate.

Изопропилпальмитат

$C_{19}H_{38}O_2$ = 298.5.

CAS — 142-91-6.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Isopropyl Palmitate). A clear, colourless, oily liquid. Relative density about 0.854. Immiscible with water; miscible with alcohol, with dichloromethane, with fatty oils, and with liquid paraffin. Protect from light.

USNF 26 (Isopropyl Palmitate). A colourless, mobile, liquid with a very slight odour. Insoluble in water, in glycerol, and in propylene glycol; soluble in alcohol, in acetone, in castor oil, in chloroform, in cottonseed oil, in ethyl acetate, and in mineral oil. Store in airtight containers. Protect from light.

Profile

Isopropyl palmitate has properties and uses similar to those of isopropyl myristate (above).

Hypersensitivity. Sensitivity reactions to isopropyl palmitate have been reported rarely.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Chile:*** Fotoprotector Isdin Extrem.

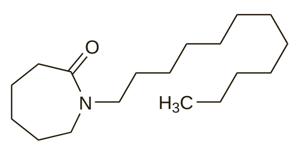
Laurocapram *(USAN, rINN)*

Azone; Laurocapramum; N-0252. 1-Dodecylazacycloheptan-2-one; 1-Dodecylhexahydro-2*H*-azepin-2-one.

Лаурокапрам

$C_{18}H_{35}NO$ = 281.5.

CAS — 59227-89-3.



Pharmacopoeias. In *Chin.*

Profile

Laurocapram has been investigated for enhancing the penetration of drugs through the skin.

Microcrystalline Wax

Amorphous Wax; Cera microcristalina; Cerum microcrystallinum; Cire microcristalline; E905; Petroleum Ceresin; Petroleum Wax (microcrystalline).

Микрокристаллический Воск

CAS — 63231-60-7.

Pharmacopoeias. In *USNF.*

USNF 26 (Microcrystalline Wax). A mixture of straight-chain, branched-chain, and cyclic hydrocarbons, obtained by solvent fractionation of the still bottom fraction of petroleum by suitable dewaxing or de-oiling means. A white or cream-coloured odourless waxy solid. Melting range 54° to 102°. Insoluble in water; sparingly soluble in dehydrated alcohol; soluble in chloroform, in ether, in volatile oils, and in most warm fixed oils. Store in airtight containers.

Profile

Microcrystalline wax is used as a stiffening agent in creams and ointments and as a coating agent for solid dosage forms, including modified-release preparations. Microcrystalline wax is also used in foods and cosmetics.

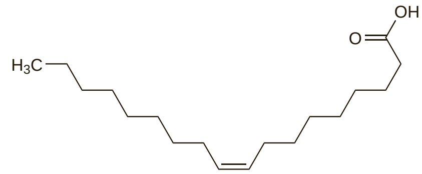
Oleic Acid

Acide oléique; Acidum oleicum; Elaic Acid; Kwas oleinowy; Kyselina olejová; Olajsav; Oleico, ácido; Oleinic Acid; Oleino rūgštis; Oljesyra; Öljyhappo; Ölsäure. (*Z*)-9-Octadecanoic acid.

Масляная Кислота; Олеиновая Кислота

$C_{18}H_{34}O_2$ = 282.5.

CAS — 112-80-1.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Oleic Acid). It contains 65 to 88% of oleic acid together with varying amounts of saturated and other unsaturated fatty acids. It may contain a suitable antoxidant. It is a clear, yellowish or brownish, oily liquid. Practically insoluble in water; miscible with alcohol and with dichloromethane. Store in well-filled airtight containers. Protect from light.

USNF 26 (Oleic Acid). It is manufactured from fats and oils derived from edible sources, animal or vegetable, and consists chiefly of oleic acid. It may contain suitable stabilisers. Oleic acid solely for external use is exempt from the requirement that it be prepared from edible sources. It is a colourless to pale yellow oily liquid when freshly prepared with a characteristic lard-like odour. On exposure to air it gradually absorbs oxygen and darkens in colour. When strongly heated in air, it is decomposed with the production of acid vapours. Congealing point between 3° and 10° for oleic acid from animal sources and between 10° and 16° for oleic acid from vegetable sources. Practically insoluble in water; miscible with alcohol, with chloroform, with ether, with benzene and with fixed and volatile oils. Store in airtight containers.

Profile

Oleic acid forms soaps with alkaline substances and is used as an emulsifying or solubilising agent. It occurs in edible fats and oils which are used as foods or food components. Oleic acid is used in topical preparations, including transdermal films and patches, and in oral and inhalation preparations. It has also been used as a choleretic.

Preparations

BP 2008: Chloroxylenol Solution; White Liniment.

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Braz.:*** Glavit; Primoris; ***Chile:*** Acnoxyl Jabon†.

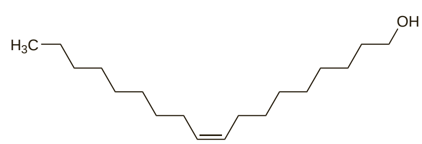
Oleyl Alcohol

Alcohol oleico; Alcohol oleicus; *cis*-9-Octadecen-1-ol; Oleic Alcohol; Oleilo alkoholis; Oléique (alcool); Oleo Alcohol; Oleol; Oleylalkohol; Oleyylialkoholi. (*Z*)-Octadec-9-en-1-ol.

Олеиловый Спирт

$C_{18}H_{36}O$ = 268.5.

CAS — 143-28-2.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Oleyl Alcohol). A mixture of unsaturated and saturated long-chain fatty alcohols consisting mainly of oleyl alcohol and elaidyl alcohol; (*E*-octadec-9-en-1-ol; *trans*-9-octadecenol) It may be of vegetable or animal origin. A colourless or light yellow liquid.

USNF 26 (Oleyl Alcohol). A mixture of unsaturated and saturated high molecular weight fatty alcohols consisting chiefly of oleyl alcohol. A clear, colourless to light yellow, oily liquid with a faint characteristic odour. Insoluble in water; soluble in alcohol, in ether, in isopropyl alcohol, and in light liquid paraffin. Store in well-filled airtight containers at a temperature not exceeding 25°.

Profile

Oleyl alcohol is used as an emollient, as an emulsifying and solubilising agent, and as a penetration enhancer in substances applied externally, including some delivered via transdermal patches. Oleyl alcohol has also been used in aerosol preparations for rectal use. The acetate has also been used.

Fractionated Palm Kernel Oil

Aceite de palma refinado.

Масло Пальмовое Косточковое Фракционированное; Фракционированное Пальмоядровое Масло

Pharmacopoeias. In *Br.*

BP 2008 (Fractionated Palm Kernel Oil). It is obtained by expression of the natural oil from the kernels of *Elaeis guineensis* followed by selective solvent fractionation and hydrogenation. A white, odourless or almost odourless, solid, brittle fat. M.p. 31° to 36°. Practically insoluble in water and in alcohol; miscible with chloroform, with ether, and with petroleum spirit (boiling range, 40° to 60°). Store at a temperature not exceeding 25°.

Profile

Fractionated palm kernel oil is used as a basis for suppositories. It is also used in food manufacturing. The unfractionated oil has been used as an emollient and as an ointment basis.

The oil obtained from the flesh of the fruit is known as palm oil and is also used in cooking; the composition and properties of these 2 oils are, however, different.

Hard Paraffin

Cera de parafina; Hard Wax; Hartparaffin; Kietasis parafinas; Paraff. Dur.; Paraffin; Paraffin, fast; Paraffin Wax; Paraffine solide; Paraffinum Durum; Paraffinum solidum; Parafiini, kiinteä; Parafin tvrdý; Parafina sólida; Parafina stała; Szilárd paraffin.

Твёрдый Парафин

CAS — 8002-74-2.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.*, and *Jpn.* Also in *USNF.*

USNF also includes Synthetic Paraffin.

Ph. Eur. 6.2 (Paraffin, Hard). A purified mixture of solid saturated hydrocarbons, generally obtained from petroleum. M.p. 50° to 61°. It is a colourless or white mass. The melted substance is free from fluorescence in daylight. Practically insoluble in water and in alcohol; freely soluble in dichloromethane. Protect from light.

USNF 26 (Paraffin). A purified mixture of solid saturated hydrocarbons obtained from petroleum. It may contain suitable antoxidants. It is a colourless or white, odourless, more or less translucent mass showing a crystalline structure, and is slightly greasy to the touch. It has a congealing range of 47° to 65°. Insoluble in water and in alcohol; slightly soluble in dehydrated alcohol; freely soluble in chloroform, in ether, in volatile oils, and in most warm fixed oils. An alcoholic extract is neutral to litmus. Store at a temperature not exceeding 40°. Protect from light.

USNF 26 (Synthetic Paraffin). A very hard odourless white wax containing mostly long-chain, unbranched, saturated hydrocarbons, with a small amount of branched hydrocarbons. The average molecular weight may range from 400 to 1400. Insoluble in water; very slightly soluble in aliphatic, oxygenated, and halogenated hydrocarbon solvents; slightly soluble in aromatic and normal paraffinic solvents.

Profile

Hard paraffin is used mainly as a stiffening agent in ointment bases. It is also used in creams, and as a coating for capsules and tablets.

Hard paraffin is used in physiotherapy in the form of paraffin-wax baths for the relief of pain in inflamed joints and sprains.

The injection of paraffins may produce granulomatous reactions.

Preparations

BP 2008: Paraffin Ointment; Simple Ointment; Wool Alcohols Ointment.

Proprietary Preparations (details are given in Part 3)

Fr.: Cuticerin.

Multi-ingredient: ***Fr.:*** Grassolind Neutral; ***UK:*** Melrose.

Liquid Paraffin

905 (mineral hydrocarbons); Aceite de parafina; Aceite de vaselina; Aceite mineral; Aceite mineral blanco; Dickflüssiges Paraffin; Folyékony paraffin; Heavy Liquid Petrolatum; Heavy Mineral Oil; Huile de Vaseline Épaisse; Liquid Petrolatum; Mineral Oil; Oleum Petrolei; Oleum Vaselini; Paraffin, flytande; Paraffin Oil; Paraffine liquide; Paraffinum liquidum; Paraffinum Subliquidum; Parafiini, nestemäinen; Parafin tekutý; Parafina ciekła; Parafina líquida; Skystasis parafinas; Sıvı Parafin; Vaselinöl; Vaselinum Liquidum; White Mineral Oil.

Вазелиновое Масло; Жидкий Вазелин; Медицинское Парафиновое Масло; Парафин Жидкий

CAS — 8012-95-1.

ATC — A06AA01.

ATC Vet — QA06AA01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Paraffin, Liquid). A purified mixture of liquid saturated hydrocarbons obtained from petroleum. It is a transparent, colourless, oily liquid, free from fluorescence in daylight. Relative density 0.827 to 0.890. Viscosity 110 to 230 mPa s. Practically insoluble in water; slightly soluble in alcohol; miscible with hydrocarbons. Protect from light.

USP 31 (Mineral Oil). A purified mixture of liquid hydrocarbons obtained from petroleum. It may contain a suitable stabiliser. It is a transparent, colourless, odourless or almost odourless, oily liquid, free, or practically free, from fluorescence. Insoluble in water and in alcohol; soluble in volatile oils; miscible with fixed oils (except castor oil). Store in airtight containers. Protect from light.

Light Liquid Paraffin

Dünnflüssiges Paraffin; Hígan folyó paraffin; Huile de Vaseline Fluide; Light Liquid Petrolatum; Light Mineral Oil; Light White Mineral Oil; Paraff. Liq. Lev.; Paraffin, lättflytande; Paraffine liquide légère; Paraffinum Liquidum Leve; Paraffinum Liquidum Tenue; Paraffinum perliquidum; Parafiini, kevyt nestemäinen; Parafín tekutý lehký; Skystasis lengvas parafinas; Spray Paraffin; Vaselina líquida.

ATC — A06AA01.
ATC Vet — QA06AA01.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF. US* also includes Topical Light Mineral Oil .

Ph. Eur. 6.2 (Paraffin, Light Liquid). A purified mixture of liquid saturated hydrocarbons obtained from petroleum. It is a transparent, colourless, oily liquid, free from fluorescence in daylight. Relative density 0.810 to 0.875. Viscosity 25 to 80 mPa s. Practically insoluble in water; slightly soluble in alcohol; miscible with hydrocarbons. Protect from light.

USNF 26 (Light Mineral Oil). A purified mixture of liquid hydrocarbons obtained from petroleum. It may contain a suitable stabiliser. It has similar characteristics to Mineral Oil but a lower kinematic viscosity. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Excessive oral or rectal dosage with liquid paraffin may result in anal seepage and irritation, excessive purgation, and watery diarrhoea. Liquid paraffin is absorbed to a slight extent and may give rise to foreign-body granulomatous reactions. Similar reactions have followed the injection of liquid paraffin and may be considerably delayed in onset. Injection may also cause vasospasm and prompt surgical removal may be required to prevent severe damage. Lipoid pneumonia has been reported after aspiration of liquid paraffin. Because of the risk of aspiration, oral liquid paraffin should not be given to patients who have difficulty swallowing, or to those with impaired neurodevelopment.

Some licensed product information warns that chronic ingestion of liquid paraffin may rarely be associated with impaired absorption of fat-soluble vitamins and possibly other compounds. There is little published evidence to support this. Prolonged use should, however, be avoided. Liquid paraffin should not be used when abdominal pain, nausea, or vomiting is present. The UK CSM considers that it should not be used in children under 3 years of age.

Uses and Administration

Taken orally, liquid paraffin acts as a lubricant and, since it keeps the stools soft, it has been used in the symptomatic treatment of constipation (p.1693), although it should be used with caution because of its adverse effects. The recommended daily oral dose is 10 to 30 mL in divided doses, preferably before breakfast and at night. An emulsion of liquid paraffin may also be used in a dose of 10 to 30 mL at night. Liquid paraffin and its preparations should not, however, be taken immediately before going to bed. Liquid paraffin is an ingredient of several preparations that contain other laxatives such as cascara, magnesium hydroxide, or phenolphthalein. It has also been given as an enema in a usual dose of 120 mL.

Externally, liquid paraffin may be used as an ingredient of ointment bases, as an emollient and cleanser in certain skin conditions, and as an ophthalmic lubricant in the management of dry eye (p.2140).

Light liquid paraffin has similar uses to liquid paraffin.

Administration in children. UK licensed product information gives the following oral doses of liquid paraffin for constipation in children, to be taken at night:

- under 3 years: not recommended
- 3 to 5 years: 2.5 to 5 mL
- 5 to 12 years: 5 to 10 mL
- over 12 years: as for adults

For light liquid paraffin, the *BNFC* recommends a daily oral dose of 0.5 to 1 mL/kg, up to a maximum of 45 mL, for children aged 3 to 18 years. It should be taken after the evening meal but not immediately before going to bed, and may be mixed with ice-cream or yogurt to improve palatability.

The *BNFC* gives the following oral doses of liquid paraffin emulsion, to be taken once daily but not immediately before going to bed:

- under 3 years: not recommended
- 3 to 12 years: 0.5 to 1 mL/kg, up to a maximum of 30 mL
- 12 to 18 years: as for adults

Preparations

White Soft Paraffin

905 (mineral hydrocarbons); Minkštasis baltas parafinas; Paraff. Moll. Alb.; Paraffinum Molle Album; Parafina blanda blanca; Valkovaseliini; Vaselin, vitt; Vaselina blanca; Vaselina Branca; Vaselina filante; Vaseline blanche; Vaseline Officinale; Vaselinum album; Vazelína bílá; Wazelina biała; White Petrolatum; White Petroleum Jelly.

Белый Вазелин

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.*

Many pharmacopoeias use the title Vaselinum Album; in some countries the name 'Vaseline' is a trade-mark.

Ph. Eur. 6.2 (Paraffin, White Soft). Purified and wholly or nearly decolorised mixture of semi-solid hydrocarbons, obtained from petroleum. It may contain a suitable antioxidant. It is not suitable for oral use. A white or almost white, translucent, soft unctuous mass, slightly fluorescent in daylight when melted. Drop point 35° to 70°. Practically insoluble in water, in alcohol, and in glycerol; slightly soluble in dichloromethane. Protect from light.

The BP 2008 gives White Petroleum Jelly as an approved synonym.

USP 31 (White Petrolatum). A purified mixture of semisolid hydrocarbons obtained from petroleum, and wholly or nearly decolorised. It may contain a suitable stabiliser. A white or faintly yellowish unctuous mass, transparent in thin layers even after cooling to 0°. Insoluble in water; slightly soluble in cold or hot alcohol and in cold dehydrated alcohol; freely soluble in chloroform, in benzene, and in carbon disulfide; soluble in ether, in petroleum spirit, and in most fixed and volatile oils.

Yellow Soft Paraffin

Keltavaseliini; Minkštasis geltonas parafinas; Paraff. Moll. Flav.; Paraffinum Molle Flavum; Petrolatum; Petroleum Jelly; Sárga vazelin; Vaselin, gult; Vaselina Amarela; Vaselina amarilla; Vaselina filante amarilla; Vaseline jaune; Vaselinum flavum; Vazelína žlutá; Wazelina żółta; Yellow Petrolatum; Yellow Petroleum Jelly.

Жёлтый Вазелин

CAS — 8009-03-8.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Many pharmacopoeias use the title Vaselinum Flavum; in some countries the name 'Vaseline' is a trade-mark.

Ph. Eur. 6.2 (Paraffin, Yellow Soft). A purified mixture of semi-solid hydrocarbons obtained from petroleum. A yellow, translucent, unctuous mass, slightly fluorescent in daylight when melted. It has a drop point of 40° to 60°. Practically insoluble in water, in alcohol, and in glycerol; slightly soluble in dichloromethane. Protect from light.

USP 31 (Petrolatum). A purified mixture of semi-solid hydrocarbons obtained from petroleum. It may contain a suitable stabiliser. It is an unctuous yellowish to light amber mass, having not more than a slight fluorescence even after being melted. It is transparent in thin layers. It is free or practically free from odour. M.p. 38° to 60°. Insoluble in water; practically insoluble in cold or hot alcohol and in cold dehydrated alcohol; freely soluble in benzene, in carbon disulfide, in chloroform, and in turpentine oil; soluble in ether, in petroleum spirit, and in most fixed and volatile oils.

Adverse Effects

Adverse effects of soft paraffin are rare when used in topical preparations, but sensitivity reactions and acne have been reported after topical use. Granulomatous reactions after absorption or injection and lipoid pneumonia after aspiration have occurred.

Fire risk. Burns to the scalp, face, and hands have been reported[1] in 5 patients who accidentally ignited their hair after the application of paraffin-based hair grease. Four patients suffered inhalation injury, 2 of whom required intubation. The death of a patient who, while smoking, ignited bandages covering a paraffin-based ointment for psoriasis,[2] prompted the *BNF* to recommend that patients should be told not to smoke and to keep away from flames when using paraffin-based emollients.

Hypersensitivity. The allergenicity of soft paraffin products has been investigated.[1-4] Considering their widespread use there are very few reports of sensitivity;[4] of nearly 80 000 patients patch tested with white soft paraffin, only 29 showed a positive reaction. White soft paraffin is generally less sensitising than yellow soft paraffin, although allergenicity differs from product to product. The allergenic components are probably polycyclic aromatic hydrocarbons present as impurities and quantities found in a particular paraffin depend on the source and purification method. Only the purest forms should be used in pharmaceuticals, cosmetics, and for patch testing, and highly purified white soft paraffin is preferred to yellow soft paraffin.

Uses and Administration

Soft paraffin is used as an ointment basis and as an emollient in the management of skin disorders. It is not readily absorbed by the skin. Sterile dressings containing soft paraffin are used for wound dressing and as a packing material. Soft paraffin is also included in ointments used as ophthalmic lubricants in the management of dry eye (p.2140). Application of soft paraffin has been used for the eradication of pubic lice from the eyelashes (see Pediculosis, p.2034). It has been used as a contact medium to reduce pain during extracorporeal shock wave lithotripsy. Soft paraffin is also used in food manufacturing.

Preparations

BP 2008: Cetomacrogol Emulsifying Ointment; Cetrimide Emulsifying Ointment; Emulsifying Ointment; Paraffin Ointment; Simple Eye Ointment; Simple Ointment; Wool Alcohols Ointment;

Shea Butter

Manteca de Karité.

Карите; Масло Ши

Profile

Shea butter is a natural fat obtained from the kernel of the fruit of *Vitellaria paradoxa* (*Butyrospermum parkii*) (Sapotaceae) indigenous to West Africa. It is used as an ointment and cream basis. Shea butter is widely used in cosmetics. It is also used in cooking oil, and as a substitute for theobroma oil in chocolate manufacturing.

Preparations

Silicones

Siliconas.

Силиконы

ATC — A03AX13.
ATC Vet — QA03AX13.

Description. Silicones are polymers with a structure consisting of alternate atoms of silicon and oxygen, with organic groups attached to the silicon atoms. As the degree of polymerisation increases, the products become more viscous and the various grades are distinguished by a number, approximately corresponding to the viscosity of the particular grade. Silicones may be fluids, greases, waxes, resins, or rubbers depending on the degree of polymerisation.

Cyclomethicone

Dimethylcyclopolysiloxane.

Циклометикон

$(C_2H_6OSi)_n$.
CAS — 69430-24-6.

Pharmacopoeias. In *USNF.*
USNF 26 (Cyclomethicone). A fully methylated cyclic siloxane containing repeating units of the formula $[-(CH_3)_2SiO-]_n$, in which *n* is 4, 5, or 6, or a mixture of them. Store in airtight containers.

Dimeticone *(BAN, rINN)*

Dimethicone *(USAN)*; Dimethyl Silicone Fluid; Dimethylpolysiloxane; Dimethylsiloxane; Dimeticona; Diméticone; Dimeticonum; Dimetikon; Dimetikonas; Dimetikoni; Dimetilpolisiloxano; Dimetykon; E900; Huile de Silicone; Methyl Polysiloxane; Metilpolisiloksan; Metilpolisiloxano; Permethylpolysiloxane; Polidimetilsiloxano; Silicone Oil; Siliconum Liquidum. Poly(dimethylsiloxane).

Диметикон

$CH_3.[Si(CH_3)_2.O]_nSi(CH_3)_3$.
CAS — 9006-65-9.
ATC — A03AX13.
ATC Vet — QA03AX13.

Description. Dimeticones are fluid silicones in which the organic group is a methyl radical.
Simeticone (activated dimeticone), a mixture of liquid dimeticones with silicon dioxide, is described on p.1770.

Pharmacopoeias. In *Chin.* and *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Dimeticone). The degree of polymerisation is such that the kinematic viscosities are nominally between 20 and 1300 mm^2/second; dimeticones with a nominal viscosity of 50 mm^2/second or lower are intended for external use only. Dimeticones are clear, colourless, liquids of various viscosities. Practically insoluble in water; very slightly soluble to practically insoluble in dehydrated alcohol; miscible with ethyl acetate, with methyl ethyl ketone, and with toluene.
USNF 26 (Dimethicone). A mixture of fully methylated linear siloxane polymers containing repeating units of the formula $[-(CH_3)_2SiO-]_n$, stabilised with trimethylsiloxy end-blocking units of the formula $[(CH_3)_3SiO-]$, wherein *n* has an average value such that the corresponding nominal viscosity is in a discrete range between 20 and 30 000 centistokes. It is a clear colourless, odourless liquid. Insoluble in water, in alcohol, in acetone, and in methyl alcohol; very slightly soluble in isopropyl alcohol; soluble in amyl acetate, in chlorinated hydrocarbons, in ether, in *n*-hexane, in petroleum spirit, in benzene, in toluene, and in xylene. Store in airtight containers.

Adverse Effects and Precautions

Adverse effects from the clinical use of silicones appear to be rare. Foreign-body reactions have been reported after their use as joint implants. Other implants, notably breast implants used for reconstruction after mastectomy or for cosmetic purposes, carry the risk of migration of silicone with cyst formation and other complications; accidental intravascular injection has been fatal. Late adverse ocular effects can follow the intravitreal injection of liquid silicone in the management of retinal detachment (see below).

Breast feeding. Concern has been raised regarding the possible effects on infants of mothers with silicone breast implants who breast feed. Oesophageal dysfunction has been reported in a number of such children,[1] although this finding has not been confirmed by subsequent reports. The American Academy of Pediatrics therefore states[2] that the current evidence does not justify classifying silicone implants as a contra-indication to breast feeding.

Connective tissue disorders. Since the introduction of silicone breast implants in the early 1960s there have been numerous anecdotal reports of connective tissue disorders in women who have undergone breast reconstruction or augmentation with these implants. Scleroderma has been the most frequently reported disorder; others have included SLE, rheumatoid arthritis, and inflammatory myopathies. A syndrome of vague musculoskeletal symptoms, fever, and fatigue has also been reported. These cases led the FDA to call for a moratorium in the USA on the use of silicone breast implants in January 1992. However, with the exception of one study of self-reported symptoms which showed only a small increase in risk,[1] large epidemiological studies,[2-5] meta-analyses,[6-8] and a review by the Medical Devices Agency in the UK have so far failed to show any association between silicone breast implants and connective tissue disorders. After conducting a review of the evidence, the FDA in 2006 re-approved the sale of silicone breast implants, for use in women of all ages for breast reconstruction, and for cosmetic use in women aged 22 years or more;[9] the approval obliges the manufacturers to conduct a 10-year post-approval safety study.

Uses and Administration

Dimeticones and other silicones are water-repellent and have a low surface tension. They are used in topical barrier preparations for protecting the skin against water-soluble irritants. Creams, lotions, and ointments containing a dimeticone are used for the prevention of bedsores and napkin rash and to protect the skin against trauma due to incontinence or stoma discharge. A 4% solution of dimeticone is used for the treatment of head pediculosis in adults and children aged over 6 months. Silicone preparations should not be applied where free drainage is necessary or to inflamed or abraded skin. Silicones, usually a dimeticone, are also used topically as wound dressings, and to reduce scar elevation and pigmentation. They are also used in oral solid dosage forms, including modified-release preparations.

Silicones have also been used for arthroplasty in rheumatic disorders, by intravitreal injection for retinal detachment, and by subcutaneous injection or implantation in reconstructive or cosmetic surgery.

Dimeticones, in particular simeticone (activated dimeticone) (p.1770), are used in the treatment of flatulence.

Retinal detachment. Retinal detachment is separation of the retina from the underlying retinal pigmentary epithelium and usually requires surgical repair. Intravitreal injection of liquid silicone, either alone or with a gas,[1] is used for retinal tamponade with or after surgery in complicated or persistent detachment of the retina.[2] In most cases, the silicone fluid is later removed from the eye.[3] High-density silicone fluids are increasingly being used.[4] Use of silicone fluid is reported to trigger a local inflammatory response, which may persist after the fluid is removed.[5] Other late complications after its use may include cataract, glaucoma, and keratopathy.

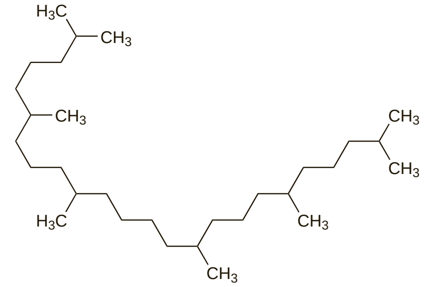
Squalane

Cosbiol; Dodecahydrosqualene; Escualano; Perhidroescualeno; Perhydrosqualène; Skvalaani; Skvalan; Skvalanas; Skwalan; Spinacane; Squalanum; Szkvalán. 2,6,10,15,19,23-Hexamethyltetracosane.

Сквалан

$C_{30}H_{62}$ = 422.8.
CAS — 111-01-3.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Squalane). A clear, colourless, oily liquid. Relative density about 0.815. It may be of vegetable (unsaponifiable matter of olive oil) or animal (shark liver oil) origin. Practically insoluble in water and in alcohol; freely soluble in acetone and in cyclohexane; miscible with most fats and oils.
USNF 26 (Squalane). A saturated hydrocarbon obtained by hydrogenation of squalene, an aliphatic triterpene occurring in some fish oils. It is a colourless, almost odourless, transparent oil. Insoluble in water; very slightly soluble in dehydrated alcohol; miscible with chloroform and with ether; slightly soluble in acetone. Store in airtight containers.

Profile

Squalane is a saturated derivative of squalene, a constituent of human sebum. It is miscible with human sebum and is included in topical preparations to increase skin permeability. It is also used as an emollient.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Arg.:*** Cremisona†; ***Hong Kong:*** Apaisac; Physiogel; ***Israel:*** CleanEars; ***Port.:*** Creme Laser Hidrante; Lactonico†.

Stearyl Alcohol

Alcohol estearílico; Alcohol octadecílico; Alcohol stearylicus; Alcool Stéarylique; Alkohol stearylowy; 1-Octadecanol; Octadecan-1-ol; Octadecyl Alcohol; Stearilo alkoholis; Stearylalkohol; Stéarylique, alcool; Stearyylialkoholi; Sztearil-alkohol.

Стеариловый Спирт

$C_{18}H_{38}O = 270.5.$
CAS — 112-92-5.

Pharmacopoeias. In *Eur.* (see p.vii) and *Jpn.* Also in *USNF.*
Ph. Eur. 6.2 (Stearyl Alcohol). A mixture of solid alcohols; it contains not less than 95.0% of stearyl alcohol. White or almost white, unctuous flakes, granules, or mass. M.p. 57° to 60°. Practically insoluble in water; soluble in alcohol. When melted, it is miscible with fatty oils, with liquid paraffin, and with melted wool fat.
USNF 26 (Stearyl Alcohol). It contains not less than 90% of stearyl alcohol the remainder consisting chiefly of related alcohols. White unctuous flakes or granules with a faint characteristic odour. M.p. 55° to 60°. Insoluble in water; soluble in alcohol and in ether.

Profile

Stearyl alcohol is used to thicken topical and vaginal ointments and creams, and to increase their water-holding capacity; it has emollient and weak emulsifying properties. Stearyl alcohol is also used in oral solid dosage forms, including modified-release preparations.

Stearyl alcohol can cause hypersensitivity.

Hypersensitivity. Stearyl alcohol is usually considered to have a low potential for sensitisation although there have been isolated case reports of contact dermatitis to topical products containing it.[1-3]

1. Black H. Contact dermatitis from stearyl alcohol in Metosyn (fluocinonide) cream. *Contact Dermatitis* 1975; **1:** 125.

Preparations

Proprietary Preparations (details are given in Part 3)
USA: SFC Lotion.

Multi-ingredient: ***Arg.:*** Caien.

Theobroma Oil

Beurre de Cacao; Burro di Cacao; Butyrum Cacao; Cacao Butter; Cacao Oleum; Cocoa Butter; Kakaobutter; Kakaový olej; Manteca de cacao; Manteiga de Cacau; Ol. Theobrom.; Olej kakaowy; Oleum Cacao; Oleum Theobromatis.

Какао-Масло; Масло Какао

CAS — 8002-31-1.

Pharmacopoeias. In *Br., Fr., Ger., Jpn,* and *Pol.* Also in *USNF.*
BP 2008 (Theobroma Oil). The solid fat obtained from the roasted seeds of *Theobroma cacao.* A yellowish-white, somewhat brittle, solid fat, with a slight odour of cocoa. M.p. 31° to 34°. Slightly soluble in alcohol; freely soluble in chloroform, in ether, and in petroleum spirit (boiling range, 40° to 60°). Store at a temperature not exceeding 25°.
USNF 26 (Cocoa Butter). A fat obtained from the seeds of *Theobroma cacao* (Sterculiaceae). It is a yellowish-white, usually brittle solid with a faint agreeable odour. M.p. 31° to 35°. Slightly soluble in alcohol; soluble in boiling dehydrated alcohol; freely soluble in chloroform and in ether.

Profile

Theobroma oil is used as a basis for suppositories. If it is heated to more than 36° during preparation the solidification point will be appreciably lowered due to the formation of metastable states; this leads to subsequent difficulty in setting. Theobroma oil is a major ingredient of chocolate.

Preparations

Proprietary Preparations (details are given in Part 3)
Spain: Lapiz Gras†.

Multi-ingredient: ***Malaysia:*** Palmer's Cocoa Butter Formula; Palmer's Cocoa Butter Formula Scar Serum.

Wool Alcohols

Alcoholes adipis lanae; Alcoholes de lana; Alcoholes de lanolina; Alcoholia Lanae; Alcolanum; Alcools de graisse de laine; Alkoholy tuku z ovčí vlny; Gyapjúviaszalkoholok; Lanalcolum; Lanolin Alcohols; Ullfettalkoholer; Villa-alkoholit; Vilnų riebalų alkoholiai; Wollwachsalkohole; Wool Wax Alcohols.

Спирты Шерстяного Жира

CAS — 8027-33-6.

Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*
Ph. Eur. 6.2 (Wool Alcohols). A mixture of sterols and higher aliphatic alcohols obtained from wool fat and containing not less than 30.0% of cholesterol. It may contain not more than 200 ppm of butylated hydroxytoluene. A pale yellow to brownish-yellow, brittle mass becoming plastic on heating. M.p. not lower than 58°. Practically insoluble in water; slightly soluble in alcohol (90%); soluble in boiling dehydrated alcohol, and in dichloromethane. Store in well-filled containers. Protect from light.
USNF 26 (Lanolin Alcohols). A mixture of sterols, aliphatic alcohols, and triterpenoid alcohols obtained by the hydrolysis of wool fat. It may contain not more than 0.1% of a suitable antioxidant. It is a hard, waxy amber solid with a characteristic odour. M.p. not below 56°. Insoluble in water; slightly soluble in alcohol; freely soluble in chloroform, in ether, and in petroleum spirit. Store at a temperature not exceeding 25°. Protect from light.

Incompatibility. Wool alcohols is incompatible with coal tar, ichthammol, resorcinol, and phenol.

Profile

Wool alcohols is an emulsifying agent and emulsion stabiliser used in the preparation of water-in-oil creams and ointments. It increases the water absorbing capacity of hydrocarbon mixtures; the addition of 5% of wool alcohols permits a threefold increase in the amount of water that can be incorporated in soft paraffin and such emulsions are not 'cracked' by the addition of weak acids.

It has an emollient action on the skin and is used in preparations for dry skin and dry eyes.

Derivatives of wool alcohols with similar uses include acetylated wool alcohols and ethoxylated wool alcohols.

Wool alcohols may cause hypersensitivity (but see also under Wool Fat, below).

Preparations

BP 2008: Wool Alcohols Ointment.

Multi-ingredient: ***Arg.:*** Macoderm; ***Canad.:*** Refresh Lacri-Lube; ***Fin.:*** Lacri-Lube; ***Ger.:*** Coliquifilm; ***Irl.:*** Oilatum Emollient; ***Israel:*** Adinol; ***Ital.:*** Lacrilube; ***NZ:*** Lacrilube; ***Switz.:*** Coliquifilm; ***UK:*** Ashbourne Emollient Medicinal Bath Oil†; Dermalo; Lacri-Lube; Oilatum Emollient; ***USA:*** Hydrocerin; Refresh PM.

Wool Fat

Adeps lanae; Adeps lanae hydrogenatus (wool fat, hydrogenated); Anhydrous Lanolin; Cera Lanae; Graisse de laine; Graisse de laine hydrogénée (wool fat, hydrogenated); Graisse de Suint Purifiée; Gyapjúviasz; Lanoléine; Lanolin; Lanolina; Lanolina anhidra; Lanolinum; Purified Lanolin; Refined Wool Fat; Suarda; Tuk z ovčí vlny; Tuk z ovčí vlny hydrogenovaný (wool fat, hydrogenated); Ullfett; Villarasva; Vilnų riebalai; Wollfett; Wollwachs.

Ланолин; Шерстяной Жир

CAS — 8006-54-0.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn, US,* and *Viet.* Some pharmacopoeias include Hydrous Wool Fat which is prepared by the addition of water to wool fat.
Eur. also includes Hydrogenated Wool Fat.
US also includes Modified Lanolin.
Ph. Eur. 6.2 (Wool Fat). A purified, anhydrous, waxy material obtained from the wool of the sheep (*Ovis aries*). It may contain not more than 200 ppm of butylated hydroxytoluene. A yellow, unctuous substance. When melted, it is a clear or almost clear, yellow liquid. Drop point 38° to 44°. 10 g absorbs not less than 20 mL of water. Practically insoluble in water; slightly soluble in boiling dehydrated alcohol; it forms an opalescent solution in petroleum spirit. Store at a temperature not exceeding 25°.
Ph. Eur. 6.2 (Wool Fat, Hydrogenated; Adeps Lanae Hydrogenatus). A mixture of higher aliphatic alcohols and sterols obtained from the direct, high-pressure, high-temperature hydrogenation of anhydrous wool fat during which the esters and acids present are reduced to corresponding alcohols. It may contain butylated hydroxytoluene. A white or pale yellow, unctuous substance. M.p. 45° to 55°. Practically insoluble in water; soluble in boiling alcohol and in petroleum spirit. Store in well-filled containers. Protect from light.
Ph. Eur. 6.2 (Wool Fat, Hydrous; Adeps Lanae Cum Aqua). A mixture of 75% of wool fat and 25% of water. It may contain not more than 150 ppm of butylated hydroxytoluene. A pale yellow, unctuous substance. Drop point 38° to 44°. Store at a temperature not exceeding 25°.
USP 31 (Lanolin). A purified wax-like substance obtained from the wool of the sheep, *Ovis aries* (Bovidae). It is a yellow tenacious unctuous mass with a slight characteristic odour. Melting range 38° to 44°. It contains not more than 0.25% of water. It may contain not more than 0.02% of a suitable antoxidant. Insoluble in water, but mixes without separation with about twice its weight of water; sparingly soluble in cold alcohol; more soluble in hot alcohol; freely soluble in chloroform and in ether. Store at a temperature preferably between 15° and 30°.
USP 31 (Modified Lanolin). It is Lanolin that has been processed to reduce the contents of free lanolin alcohols and detergent and pesticide residues. It contains not more than 0.25% of water. It may contain not more than 0.02% of a suitable antoxidant. Store in airtight, preferably rust-proof, containers and preferably at a temperature of 15° to 30°.

Profile

Wool fat is used in the formulation of water-in-oil creams and ointments. When mixed with a suitable vegetable oil or with soft paraffin it gives emollient creams that penetrate the skin. It can absorb about 30% of water. Wool fat is also used in other topical, vaginal, rectal, and ophthalmic preparations.

Derivatives and modifications of wool fat include hydrogenated wool fat (hydrogenated lanolin), hydrous wool fat (hydrous lanolin), poloxyl lanolin (ethoxylated lanolin), isopropyl lanolate, lanolin oil, and lanolin wax.

Wool fat can cause sensitivity reactions.

Hypersensitivity. Wool fat is widely regarded as a common sensitising agent, but the true extent of allergy to it is controversial. Suspected sensitivity reactions have proved difficult to reproduce in skin patch testing.[1] The allergens are unknown but are thought to be in the alcoholic fraction. A retrospective study[2] of more than 24 000 patients with eczema who received skin patch testing found that sensitivity reactions to a standard patch reagent of wool alcohols 30% in soft paraffin were rare; an average of 1.7% of patients per year showed sensitivity.

2. Wakelin SH, *et al.* A retrospective analysis of contact allergy to lanolin. *Br J Dermatol* 2001; **145:** 28–31.

Pesticide residues. Concerns have been raised in the past about pesticide residues in wool fat,[1-3] because of the possible risk to breast-fed infants whose mothers were using wool fat-based nipple ointments. Official published standards such as Ph. Eur. and USP now include limits for pesticide levels in wool fat.

Pesticides and Repellents

Pediculosis, p.2034
Scabies, p.2035
Vector control, p.2035

This chapter describes compounds used as pesticides and as insect repellents. The term pesticide covers fungicides, herbicides, insecticides (including acaricides), molluscicides, and rodenticides, among others. Most of the pesticides included here are used in clinical or veterinary practice or in vector control against human or animal disease. Some are used primarily in an agricultural or horticultural setting and are included because of their potential toxicity.

Pesticides can be absorbed during application, by consumption of treated or contaminated products or by accidental contamination, and they may be stored or retained in the tissues. International regulations and controls operate to reduce the risk to both public and user. Values for acceptable daily intakes of pesticides have been published by the Food and Agriculture Organization of the United Nations and the WHO Health Organization (WHO) through the WHO Technical Report series of publications or through *Pesticides Residues in Food: yearly evaluations*, FAO Plant Production and Protection Papers, Rome.

Classification of the main pesticides included in this chapter is given in Table 1 below.

The **fungicides** included in this chapter are some of those used in the management of plant disease.

Herbicides are used for weed control both in the domestic setting and professionally in agriculture and horticulture. Those here have been included primarily because they are toxic and have been associated with many cases of poisoning.

Insect repellents can help to avoid insect bites and the unpleasant reactions they may produce. Perhaps more importantly, the correct use of insect repellents plays a major role in personal protection against a number of communicable diseases transmitted by insect vectors. Examples are babesiosis (ticks), Lyme disease (ticks), malaria (mosquitoes), relapsing fevers (lice and ticks), spotted fevers (ticks), and typhus fever (fleas, lice, and mites). Some compounds, such as diethyltoluamide and dimethyl phthalate, are effective as repellents while others, such as benzyl benzoate and some of the pyrethroids, are effective both as repellents and as insecticides.

Insecticides have numerous applications. They are used in the treatment of ectoparasitic infections such as pediculosis (lice infections) (below) and in the vector control (below) of a number of communicable diseases that are spread by insects. Acaricides are used to treat scabies (mite infections) (see, below) and are included within the broad classification of insecticides, although acari (mites) are not, technically, insects. Insecticides are also widely used in veterinary practice and in agriculture and horticulture.

The insecticides used in veterinary practice are often classified as topical or systemic ectoparasiticides. Topical ectoparasiticides are applied topically to the host animal (such as dogs or cats) to kill its ectoparasites (such as fleas). In the case of systemic ectoparasiticides the term 'systemic' refers to the ingestion of the insecticide by the ectoparasite from the host's blood; the insecticide may be present in the host's blood either as a result of absorption through the skin after topical application or after systemic dosage.

Table 1. Classification of pesticides.

Fungicides	Benomyl, cicloheximide, copper naphthenate, hexachlorobenzene, pentachlorophenol
Herbicides	Dichlorophenoxyacetic acid, dinitro-*o*-cresol, dinitrophenol, diquat, glyphosate, paraquat, pentachlorophenol, trichlorophenoxyacetic acid
Insect repellents	Butopyronoxyl, dibutyl phthalate, diethyltoluamide, dimethyl phthalate, dioctyl adipate, ethohexadiol, piperonal
Insecticides	
Carbamate	Bendiocarb, carbaryl, carbosulfan, methomyl, propoxur
Chlorinated	Chlordane, clofenotane, dieldrin, endosulfan, endrin, heptachlor, lindane, methoxychlor
Organophosphorus	Azamethiphos, bromophos, chlorpyrifos, clofenvinfos, coumafos, cythioate, dichlorvos, dimethoate, dimpylate, dioxation, ethion, famphur, fenitrothion, fenthion, heptenophos, iodofenphos, malathion, naled, parathion, phosmet, phoxim, pirimiphos-methyl, propetamphos, pyraclofos, temefos
Pyrethroid	Alpha-cypermethrin, bioallethrin, cyfluthrin, cyhalothrin, cypermethrin, deltamethrin, esdepallethrine, etofenprox, fenvalerate, flumethrin, permethrin, phenothrin, pyrethrum flower, resmethrin, tetramethrin
Miscellaneous	Amitraz, benzyl benzoate, chloropicrin, copper oleate, cymiazole, cyromazine, diflubenzuron, emamectin, ethylene dibromide, ethylene dichloride, fipronil, fluazuron, fluvalinate, lufenuron, methoprene, methyl bromide, pyriproxyfen, rotenone, sulfiram, triflumuron
Molluscicides	Endod, metaldehyde, pentachlorophenol
Rodenticides	Aluminium phosphide, antu, brodifacoum, bromadiolone, chloralose, chlorophacinone, coumatetralyl, difenacoum, diphenadione, flocoumafen, fluoroacetamide, norbormide, red squill, sodium fluoroacetate

Molluscicides are used in agriculture or horticulture or in the domestic garden to control snail and slug pests. Additionally, molluscicides such as niclosamide (described in the Anthelmintics chapter on p.151) are used against the freshwater snail vector *Bulinus* in the control of schistosomiasis.

Rodenticides may be used to exterminate rats and mice which may be vectors for diseases such as leptospirosis, plague, rat-bite fever, and some haemorrhagic fevers. Many rodenticides are anticoagulants. Warfarin (p.1425) is a commonly used rodenticide.

Clinical Uses of Pesticides and Repellents

Pediculosis

Two species of louse cause pediculosis[1-7] in man; these are *Pediculus humanus* with its two varieties, *Pediculus humanus capitis* (the head louse) and *Pediculus humanus humanus* (the body louse), and *Pthirus pubis* (*Phthirus pubis*) (the pubic or crab louse). Unlike the head louse, the body louse is an important vector for a number of infections including epidemic typhus (p.198), trench fever (p.196), and relapsing fever (p.189).

Insecticides used in the treatment of head lice include the organophosphate malathion, and some pyrethroids such as bioallethrin, permethrin, phenothrin, and tetramethrin. The carbamate, carbaryl, is also effective, although there has been some concern over a theoretical risk of carcinogenicity. Lindane has been used but is no longer recommended as a first-line treatment due to its neurotoxicity and resistance. To be effective insecticide products need to be applied correctly; a quantity of 50 to 100 mL should be applied thoroughly to the hair from hair root to the tip and left on for 8 to 12 hours. Insecticide products kill only adult lice and not the ova, therefore treatment is usually repeated 7 days later. Close contacts should be screened and if infected with living lice should also receive treatment.

Resistance has been reported to the currently used insecticides. Resistance is considered to be most likely to pyrethroids, intermediate to malathion, and least likely to carbaryl. In the UK the policy of rotating insecticides on a district-wide basis in order to overcome the development of resistance is now considered outdated. The current recommendation in the case of suspected resistance and treatment failure is to use an insecticide from a different class for the next course. Lotions are preferred to shampoos for head lice since contact time with the insecticide is longer and treatment is thus more effective. A head louse repellent containing piperonal is available. Non-insecticide treatments include a 4% dimeticone lotion[8] (see p.2032) and wet-combing (also called 'bug-busting') with conditioner.[9] Dimeticone is thought to act by disrupting the ability of the lice to manage their water balance. Dimeticone is applied similarly to the insecticide products and 2 treatments are also required to kill any newly hatched nymphs. A dry-on, suffocation-based pediculicide has also been claimed to be effective,[10,11] although some have questioned the claims.[12]

Infestations of crab lice and body lice respond to the same insecticides as head lice. Aqueous solutions are generally preferred to alcoholic for crab louse infestations, since the latter may irritate excoriated skin and genitalia.

Malathion has also been suggested for treatment of infestation of the eye lashes and brows with pubic lice (pthiriasis or phthiriasis palpebrarum). Other treatments have included the application of a thick layer of yellow soft paraffin or application of yellow mercuric oxide 1% eye ointment twice daily for about 7 or 8 days or a single application of fluorescein eye drops.

Body louse infestations in the developed world are mainly seen in homeless individuals, and often respond to the provision of opportunities for simple hygiene. Clothing and bed linen of persons with body lice should be washed at high temperature or dry cleaned or treated with insecticides. There is some evidence that oral ivermectin may be effective in killing body lice.

Topical or systemic antimicrobials should be given as necessary for secondary infections.

Scabies

Scabies is a parasitic infection of the skin by the mite *Sarcoptes scabiei*. The main symptom is pruritus, which is caused by an allergic reaction to the parasite and may not occur until several weeks after infection for the first time. Subsequent infections usually result in pruritus after a few days. Pruritus may persist for some months after effective treatment with an acaricide, but is not necessarily an indication for further acaricidal treatment; rather, antipruritics should be used. A severe crusted form (Norwegian scabies) may occur rarely, particularly in immunocompromised or incapacitated patients.

Treatment is with the acaricides permethrin or malathion applied, preferably as aqueous lotions, to clean, cool, dry skin over the entire body and left on for 8 to 24 hours, depending upon the preparation. The preparation should be reapplied to the hands whenever they are washed during this period. In adults, it is not usually necessary to treat the face and scalp, but these areas should be treated in young children or patients with atypical or crusted scabies. A single treatment may be effective, but treatment is usually repeated after 7 to 10 days if necessary. Other drugs used topically in the treatment of scabies include benzyl benzoate, crotamiton, lindane, and sulfur; sulfiram is used with benzyl benzoate. A single oral dose of ivermectin may be effective. Close family and personal contacts should be treated at the same time and all clothes, towels, and bedding used by the infected person 2 days before treatment should be washed in hot water and dried in a hot dryer.

In addition to treatment with an acaricide, symptomatic treatment of the itching with crotamiton, calamine lotion, or systemic antihistamines or corticosteroids may be required.

Vector control

Many pests are involved in the transmission of communicable diseases, and vector control[1,2] is an important part of the fight against such diseases. Insecticides are used in the control of filariasis (p.137) (*Aedes*, *Anopheles*, *Culex*, and *Mansonia* mosquitoes);[3] leishmaniasis (p.824) (*Phlebotomus* or *Lutzomyia* sandflies);[4] malaria (p.594) (*Anopheles* mosquitoes);[5-8] dengue fever (see Haemorrhagic Fevers, p.850) (*Aedes* mosquitoes);[9,10] onchocerciasis (p.137) (*Simulium* blackflies);[11] African trypanosomiasis (p.827) (*Glossina* tsetse flies);[12] and American trypanosomiasis (p.827) (*Triatoma* bugs).[13] The insecticide temefos is useful in dracunculiasis (p.136) (crustacean host to the guinea worm larvae). In some cases, as in filariasis or onchocerciasis, the insecticides used act mainly against the larval stage of the insect vector, whereas in other situations, as in malaria, activity is against the adult insect; in trypanosomiasis, activity is directed against both adult and immature stages. The majority of the experience gained in insecticidal vector control has probably been in malaria, and, for instance, a positive effect seen in the control of leishmaniasis has been considered to be mainly a byproduct of the concomitant malaria control programmes.

Insect repellents can provide personal protection against many insect vectors. For example, in malaria, insect repellents as well as the use of insecticides are important in preventing mosquito bites.

Molluscicides are used in the control of schistosomiasis (p.138) (*Bulinus* snails).[14]

Rodenticides are also extremely valuable in the vector control of some diseases such as leptospirosis (p.177), plague (p.186), rat-bite fever (p.164), and some haemorrhagic fevers (p.850).

Aluminium Phosphide

Aluminum Phosphide; Fosfuro de aluminio.

$AlP = 57.96$.

CAS — 20859-73-8 (aluminium phosphide); 7803-51-2 (phosphine); 1314-84-7 (zinc phosphide).

Profile

Aluminium phosphide is used for the fumigation of grain and as a rodenticide. It releases phosphine (PH_3) in the presence of moisture and this accounts for its pesticidal activity. Phosphine gas has a garlic-like odour repulsive to man and domestic animals but apparently not to *rats*. Zinc phosphide is used similarly.

Amitraz *(BAN, USAN, pINN)*

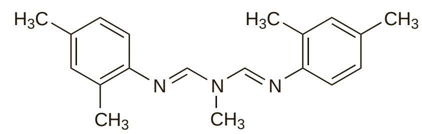
Amitratsi; Amitrazum; U-36059. *N,N′*-[(Methylimino)dimethylidyne]di-2,4-xylidine.

Амитраз

$C_{19}H_{23}N_3 = 293.4$.

CAS — 33089-61-1.

ATC Vet — QP53AD01.



Pharmacopoeias. In *BP(Vet)*. Also in *US* for veterinary use only.

BP(Vet) 2008 (Amitraz). A white to buff powder. Practically insoluble in water; decomposes slowly in alcohol; freely soluble in acetone.

Profile

Amitraz is used as a topical ectoparasiticide in veterinary practice. It is effective against various lice, mites, and ticks.

◊ References to poisoning with amitraz.

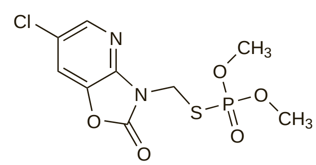
Azamethiphos *(BAN)*

Azametifós; CGA-18809; OMS-1825. *S*-[(6-Chloro-2,3-dihydro-2-oxo-1,3-oxazolo[4,5-*b*]pyridin-3-yl)methyl] *O,O*-dimethyl phosphorothioate.

$C_9H_{10}ClN_2O_5PS = 324.7$.

CAS — 35575-96-3.

ATC Vet — QP53AF17.



Profile

Azamethiphos is an organophosphorus insecticide (p.2047) used in veterinary practice for the control of sea-lice infestation in salmon and for the control of ectoparasites in the environment.

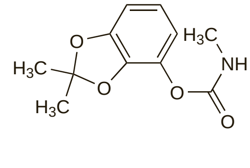
Bendiocarb

2,3-Isopropylidenedioxyphenyl methylcarbamate.

$C_{11}H_{13}NO_4 = 223.2$.

CAS — 22781-23-3.

ATC Vet — QP53AE03.



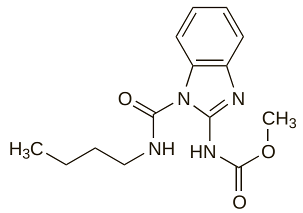
Profile

Bendiocarb is a carbamate insecticide (p.2037) for agricultural and household use.

Benomyl

Benomilo. Methyl 1-(butylcarbamoyl)benzimidazol-2-ylcarbamate.

$C_{14}H_{18}N_4O_3$ = 290.3.
CAS — 17804-35-2.



Profile

Benomyl is a fungicide used for the treatment and control of fungal plant diseases.

◊ References.

1. WHO. Benomyl. *Environmental Health Criteria 148*. Geneva: WHO, 1993. Available at: http://www.inchem.org/documents/ehc/ehc/ehc148.htm (accessed 23/04/04)

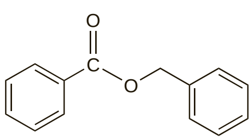
Benzyl Benzoate

Bencilo, benzoato de; Bensylbensoat; Bentsyylibentsoaatti; Benzil Benzoat; Benzil-benzoát; Benzilbenzoatas; Benzoato de bencilo; Benzoato de Benzilo; Benzoesäurebenzylester; Benzyl Benz.; Benzyl-benzoát; Benzyle, benzoate de; Benzylis benzoas; Benzylu benzoesan.

$C_6H_5.CO.O.CH_2.C_6H_5$ = 212.2.
CAS — 120-51-4.
ATC — P03AX01.
ATC Vet — QP53AX11.



Pharmacopoeias. In *Eur.* (see p.vii), *Int.*, *Jpn*, and *US.*

Ph. Eur. 6.2 (Benzyl Benzoate). Colourless or almost colourless crystals, or a colourless or almost colourless oily liquid. F.p. is not below 17°. Practically insoluble in water; miscible with alcohol, with dichloromethane, and with fatty and essential oils. Store in well-filled airtight containers. Protect from light.

USP 31 (Benzyl Benzoate). A clear, colourless, oily liquid with a slight aromatic odour. Practically insoluble in water and in glycerol; miscible with alcohol, with chloroform, and with ether. Store at a temperature not exceeding 40° in well-filled airtight containers. Protect from light.

Adverse Effects and Treatment

Benzyl benzoate is irritant to the eyes and mucous membranes and it may be irritant to the skin. Hypersensitivity reactions have been reported. If ingested, benzyl benzoate may cause stimulation of the CNS and convulsions. Systemic symptoms have been reported on excessive topical use. For poisoning associated with topical use the skin should be washed. Appropriate symptomatic measures should also be instituted.

Uses and Administration

Benzyl benzoate is an acaricide used in the treatment of scabies (p.2035) although other treatments are generally preferred. A 25% emulsion is applied to the whole body, usually from the neck down (although the *BNF* considers that application should be extended to the scalp, neck, face, and ears). If the application is thorough, one treatment may suffice, although the possibility of failure is lessened by a second application within 5 days. Alternatively, three applications at 12-hour intervals, without bathing, may be made, followed by bathing 12 hours after the last application. The *BNF* recommends one application to the whole body, repeated, without bathing, on the next day, and washed off 24 hours later; a third application may sometimes be necessary. Benzyl benzoate is not generally recommended for infants and children, but if used the application should be diluted to minimise the risk of irritation, although this also reduces efficacy.

Benzyl benzoate has also been used as a pediculicide.

Benzyl benzoate is also used as a solubilising agent.

Preparations

BP 2008: Benzyl Benzoate Application;
USP 31: Benzyl Benzoate Lotion.

Proprietary Preparations (details are given in Part 3)

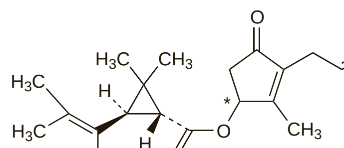
Bioallethrin *(BAN)*

Allethrin I; Bioaletrina; Depallethrin. (*RS*)-3-Allyl-2-methyl-4-oxocyclopent-2-enyl (1*R*,3*R*)-2,2-dimethyl-3-(2-methylprop-1-enyl)-cyclopropanecarboxylate.

$C_{19}H_{26}O_3$ = 302.4.
CAS — 584-79-2.
ATC — P03AC02.
ATC Vet — QP53AC02.



and epimer at c*

Profile

Bioallethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049). It is used topically, with the synergist piperonyl butoxide (p.2049), in the treatment of pediculosis (p.2034). It is also used in anti-mosquito devices and for the control of household insect pests.

◊ References.

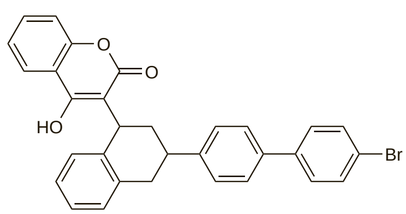
Brodifacoum

Brodifacum; WBA-8119. 3-[3-(4′-Bromobiphenyl-4-yl)-1,2,3,4-tetrahydro-1-naphthyl]-4-hydroxycoumarin.

$C_{31}H_{23}BrO_3$ = 523.4.
CAS — 56073-10-0.



Profile

Brodifacoum is an anticoagulant rodenticide. It is reported to be effective in warfarin-resistant strains of rodents.

◊ References.

1. WHO. Anticoagulant rodenticides. *Environmental Health Criteria 175*. Geneva: WHO, 1995. Available at: http://www.inchem.org/documents/ehc/ehc/ehc175.htm (accessed 23/04/04)
2. WHO. Brodifacoum health and safety guide. *IPCS Health and Safety Guide 93*. Geneva: WHO, 1995. Available at: http://www.inchem.org/documents/hsg/hsg/hsg093.htm (accessed 23/04/04)

Toxicity. Brodifacoum, a second-generation anticoagulant rodenticide, inhibits prothrombin synthesis to cause bleeding that may be occult.[1] It is absorbed from the gastrointestinal tract; dermal absorption is possible. Poisons containing 100 mg in each kg of bait are not hazardous to man; more concentrated forms are particularly hazardous and their availability should be restricted. Baits, which should be prepared only by trained personnel, should contain a suitable marker-dye.

There have been reports of poisoning with brodifacoum.[2-10]

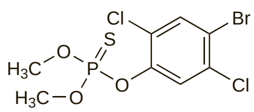
Bromophos

Bromofós; Bromofos; OMS-658. *O*-4-Bromo-2,5-dichlorophenyl *O,O*-dimethyl phosphorothioate.

$C_8H_8BrCl_2O_3PS$ = 366.0.

CAS — 2104-96-3.

ATC Vet — QP53AF11.



Profile

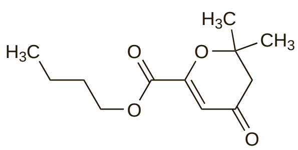
Bromophos is an organophosphorus insecticide (p.2047) used in veterinary practice for the control of ectoparasites in the environment. It has also been used as an agricultural insecticide.

Butopyronoxyl

Butopiroxinilo; Indalone. Butyl 3,4-dihydro-2,2-dimethyl-4-oxo-2*H*-pyran-6-carboxylate.

$C_{12}H_{18}O_4$ = 226.3.

CAS — 532-34-3.



Profile

Butopyronoxyl has been used as an insect repellent.

Carbamate Insecticides

Insecticidas del grupo de los carbamatos.

Description. The carbamate insecticides are *N*-substituted esters of carbamic acid.

◊ References.

1. WHO. Carbamate pesticides: a general introduction. *Environmental Health Criteria 64*. Geneva: WHO, 1986. Available at: http://www.inchem.org/documents/ehc/ehc/ehc64.htm (accessed 24/07/08)

Adverse Effects

As for Organophosphorus Insecticides, p.2047.

The carbamates are cholinesterase inhibitors, differing from the organophosphorus insecticides in that the inhibition they produce is generally less intense and more rapidly reversible. In addition, they do not appear to enter the CNS as readily and severe central effects are therefore uncommon.

Treatment of Adverse Effects

If substantial amounts of carbamate insecticides have been ingested the use of gastric lavage should be considered if the patient presents within 1 hour. Contaminated clothing should be removed and the skin washed with soap and water. Treatment is largely symptomatic and supportive and includes atropine, but this may not always be necessary due to the rapidly reversible nature of the cholinesterase inhibition produced. Pralidoxime is thought to be generally unnecessary; some *animal* studies have suggested that it may increase the toxicity of carbamates.

Carbaryl *(BAN)*

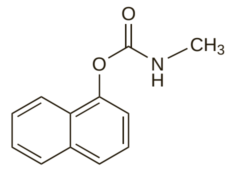
Carbaril *(pINN)*; Carbarilo; Carbarilum; Karbaril; OMS-29. 1-Naphthyl methylcarbamate.

Карбарил

$C_{12}H_{11}NO_2$ = 201.2.

CAS — 63-25-2.

ATC Vet — QP53AE01.



Pharmacopoeias. In *Br.*

BP 2008 (Carbaryl). A white to off-white or light grey powder which darkens on exposure to light. Very slightly soluble in water; soluble in alcohol and in acetone. Store at a temperature not exceeding 25°. Protect from light.

Adverse Effects and Treatment

As for Carbamate Insecticides, above. Carbaryl may be absorbed after ingestion, inhalation, or skin contamination.

Carbaryl has been reported to produce neoplasms in *mice* and *rats* and in late 1995 the UK DoH advised that it would be prudent to consider carbaryl as a potential human carcinogen; its medicinal use was limited to prescription only. However, the DoH emphasised that the risk was a theoretical one and that any risk from the intermittent use of head lice preparations was likely to be very small.

Uses and Administration

Carbaryl is a carbamate insecticide (above). It is used as a 0.5 or 1.0% lotion or shampoo in the treatment of head and pubic pediculosis (p.2034). Lotions are generally preferred to shampoos as the contact time is longer. Aqueous lotions are preferred to treat pubic lice because alcoholic lotions are irritant to excoriated skin and the genitalia; aqueous lotions may also be preferable in asthmatic subjects or children to avoid alcoholic fumes. Skin or hair treated with an alcohol-based preparation should be allowed to dry naturally.

Carbaryl is also used as a topical ectoparasiticide in veterinary practice and as an agricultural, horticultural, and household insecticide.

◊ References.

Preparations

BP 2008: Carbaryl Lotion.

Proprietary Preparations (details are given in Part 3)

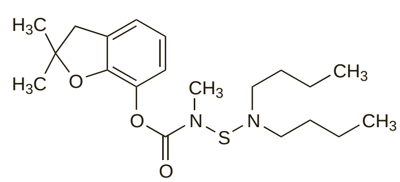
Israel: Hafif; ***UK:*** Carylderm.

Carbosulfan

Carbosulfán. 2,3-Dihydro-2,2-dimethylbenzofuran-7-yl (dibutylaminothio)methylcarbamate.

$C_{20}H_{32}N_2O_3S$ = 380.5.

CAS — 55285-14-8.



Profile

Carbosulfan is a carbamate insecticide (p.2037) used in agriculture and for the larvicidal treatment of rivers in the control of onchocerciasis (p.137).

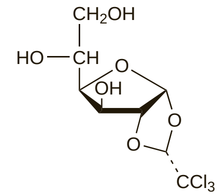
Chloralose *(rINN)*

Alphachloralose; Chloralosane; α-Chloralose; Chloralosum; Cloralosa; Glucochloral. (*R*)-1,2-*O*-(2,2,2-Trichloroethylidene)-α-D-glucofuranose.

Хлоралоза

$C_8H_{11}Cl_3O_6$ = 309.5.

CAS — 15879-93-3.



Profile

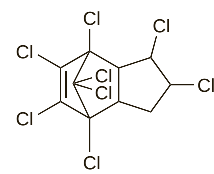
Chloralose has general properties similar to those of cloral hydrate (p.979), of which it is a derivative. It is used as a rodenticide. It was formerly used for its hypnotic properties.

Chlordane

Chlordan; Clordano. 1,2,4,5,6,7,8,8-Octachloro-2,3,3a,4,7,7a-hexahydro-4,7-methanoindene.

$C_{10}H_6Cl_8$ = 409.8.

CAS — 57-74-9.



Profile

Chlordane is a chlorinated insecticide (p.2037). Its use is limited, or even prohibited, in some countries because of toxicity due to its persistent nature.

◊ References.

1. Kutz FW, *et al.* A fatal chlordane poisoning. *J Toxicol Clin Toxicol* 1983; **20:** 167–74.

Chlorinated Insecticides

Insecticidas clorados.

Adverse Effects

Chlorinated or organochlorine insecticides form a very wide group and the toxicity of individual members varies considerably. In general these insecticides produce symptoms consistent with CNS stimulation. They may be absorbed through the respiratory and gastrointestinal tracts and through the skin.

Symptoms of acute poisoning include nausea and vomiting, paraesthesia, giddiness, tremors, convulsions, coma, and respiratory failure. Liver, kidney, and myocardial toxicity have been reported. Effects on the blood include agranulocytosis and aplastic anaemia. Symptoms may be complicated by the effects of the solvent.

Chlorinated insecticides have been reported to enhance microsomal hepatic enzyme activity. Skin reactions can occur after contact.

Polychlorinated biphenyl (PCB) and terphenyl compounds were formerly used as insecticides in many countries. They accumulate in body fat and are not readily excreted, although they are distributed into breast milk and possibly cross the placenta; because of this and because of accidental contamination they remain a cause for concern. The related polybrominated biphenyl compounds (PBB), which have no insecticidal uses, have also been absorbed by humans after accidental contamination of the food chain.

Some chlorinated insecticides have weak oestrogenic effects; it has been proposed that exposure may increase the risk of breast cancer.

Treatment of Adverse Effects

If chlorinated insecticides have been ingested gastric lavage or activated charcoal may be considered if the patient presents within 1 hour. Contaminated clothing should be removed and the skin washed with soap and water. Treatment is largely symptomatic and supportive with treatment of CNS stimulation such as hyperactivity and convulsions.

◊ References.

1. WHO. Safe use of pesticides: fourteenth report of the WHO expert committee on vector biology and control. *WHO Tech Rep Ser 813* 1991. Available at: http://libdoc.who.int/trs/WHO_TRS_813.pdf (accessed 24/07/08)
2. Proudfoot A, ed. Pesticide poisoning: notes for the guidance of medical practitioners. 2nd ed. London: DoH, The Stationery Office, 1996.

Uses

The chlorinated or organochlorine insecticides were widely used but, because of persistence in man, many have been banned or restricted.

◊ References.

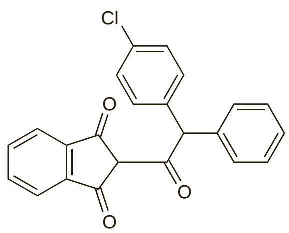
Chlorophacinone

Clorofacinona; LM-91. 2-[2-(4-Chlorophenyl)-2-phenylacetyl]indane-1,3-dione.

$C_{23}H_{15}ClO_3$ = 374.8.
CAS — 3691-35-8.



Profile

Chlorophacinone is an indanedione derivative used as an anticoagulant rodenticide. It is also reported to uncouple oxidative phosphorylation with consequent stimulation of cellular metabolism which may contribute to its toxicity.

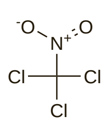
Chloropicrin

Cloropicrina; Nitrochloroform. Trichloronitromethane.

CCl_3NO_2 = 164.4.
CAS — 76-06-2.



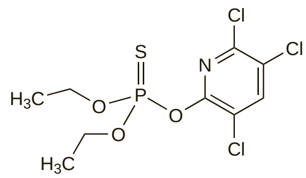
Profile

Chloropicrin is a lachrymatory agent with an intense odour. It is intensely irritating to the skin and mucous membranes. It is an insecticide and is used for fumigating stored grain and soil. Chloropicrin is also added to other fumigants as a warning gas.

Chlorpyrifos *(BAN)*

Clorpirifós. *O,O*-Diethyl *O*-3,5,6-trichloro-2-pyridyl phosphorothioate.

$C_9H_{11}Cl_3NO_3PS$ = 350.6.
CAS — 2921-88-2.



Profile

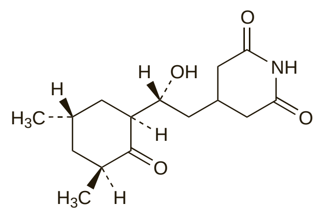
Chlorpyrifos is an organophosphorus insecticide (p.2047) used in agriculture.

Cicloheximide *(rINN)*

Cicloheximida; Cicloheximidum; Cycloheximide *(USAN)*; U-4527. 3-{(2*R*)-2-[(1*S*,3*S*,5*S*)-3,5-Dimethyl-2-oxocyclohexyl]-2-hydroxyethyl}glutarimide.

Циклогексимид

$C_{15}H_{23}NO_4$ = 281.3.
CAS — 66-81-9.



Profile

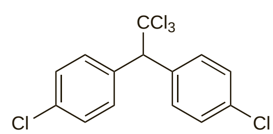
Cicloheximide is an antimicrobial substance produced by strains of *Streptomyces griseus*. It has antifungal properties and has been used for the treatment and control of certain mycotic plant diseases.

Clofenotane *(rINN)*

Chlorofenotano; Chlorophenothane; Chlorphenothanum; Clofénotane; Clofenotano; Clofenotanum; DDT; Dichlorodiphenyltrichloroethane; Dichophanum; Dicophane; Klofenotaani; Klofenotan. 1,1,1-Trichloro-2,2-bis(4-chlorophenyl)ethane.

Клофенотан

$C_{14}H_9Cl_5$ = 354.5.
CAS — 50-29-3.
ATC — P03AB01.
ATC Vet — QP53AB01.



Pharmacopoeias. In *It.*

Adverse Effects and Treatment

As for Chlorinated Insecticides, p.2037.

◊ References.

1. WHO. DDT and its derivatives. *Environmental Health Criteria 9*. Geneva: WHO, 1979. Available at: http://www.inchem.org/documents/ehc/ehc/ehc009.htm (accessed 28/05/04)
2. WHO. DDT and its derivatives—environmental aspects. *Environmental Health Criteria 83*. Geneva: WHO, 1989. Available at: http://www.inchem.org/documents/ehc/ehc/ehc83.htm (accessed 28/05/04)

Carcinogenicity. Some small epidemiological studies have suggested that certain organochlorines, namely 1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (DDE), a metabolite of clofenotane, and polychlorinated biphenyls (PCBs), might increase the risk of breast cancer in women. However, re-analysis[1,2] of the available data indicated that an association with breast cancer was unlikely for clofenotane; there was no evidence for an association with the PCBs. Any link between exposure to clofenotane and the development of testicular cancer in men was also refuted[3] after long-term monitoring of populations in Scandinavia.

1. Key T, Reeves G. Organochlorines in the environment and breast cancer. *BMJ* 1994; **308:** 1520–1.
2. van't Veer P, *et al.* DDT (dicophane) and postmenopausal breast cancer in Europe: case-control study. *BMJ* 1997; **315:** 81–5.
3. Ekbom A, *et al.* DDT and testicular cancer. *Lancet* 1996; **347:** 553–4.

Effects on fertility. A metabolite of clofenotane, 1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (DDE), was reported[1] to have anti-androgenic properties in *rats* and exposure to clofenotane might account for a previously reported decline in male fertility and an increase in male reproductive abnormalities.

1. Keke WR, *et al.* Persistent DDT metabolite p,p′-DDE is a potent androgen receptor antagonist. *Nature* 1995; **375:** 581–5.

Effects on the nervous system. A retrospective study[1] found that retired malaria workers exposed long-term to clofenotane did less well in neurobehavioural tests than a control group, and had an increase in neuropsychological and psychiatric symptoms.

1. van Wendel de Joode B, *et al.* Chronic nervous-system effects of long-term occupational exposure to DDT. *Lancet* 2001; **357:** 1014–16.

Pregnancy. In a large prospective study[1] of children born between 1959 and 1966, an association was found between preterm births and small-for-gestational-age babies, and maternal concentrations of a metabolite of clofenotane, 1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (DDE) measured in serum samples which had been stored during pregnancy.

1. Longnecker MP, *et al.* Association between maternal serum concentration of the DDT metabolite DDE and preterm and small-for-gestational-age babies at birth. *Lancet* 2001; **358:** 110–14.

Pharmacokinetics

Clofenotane may be absorbed after ingestion or inhalation or through the skin. Clofenotane is stored in the body, particularly in body fat, and is very slowly eliminated. It crosses the placenta and appears in breast milk. It is metabolised in the body to the ethylene derivative, 1,1-dichloro-2,2-bis(*p*-chlorophenyl)ethylene (DDE); the acetic acid derivative (DDA) also appears in the urine.

Uses

Clofenotane is a chlorinated insecticide (p.2037). It is a stomach and contact poison and retains its activity for long periods under a variety of conditions. It is effective against disease vectors such as fleas, lice, and mosquitoes and has been applied topically for pediculosis (p.2034) and scabies (p.2035), although more suitable alternatives exist.

Because of the extreme persistence of clofenotane, concern over its effect in the environment, and the problem of resistance, the widespread use of clofenotane is now generally discouraged. It is no longer used in some countries while in others its use is limited.

◊ Despite reservations regarding the use of clofenotane for vector control, many countries have relied on it for the control of both malaria and visceral leishmaniasis. WHO has concluded[1,2] that clofenotane might be used provided:

- that it was used only for indoor spraying
- that it was known to be effective
- that it was manufactured to WHO's specifications
- that the necessary safety precautions were taken in its use and disposal

However, they recommended further investigation of the effects of clofenotane in breast milk and of suspected carcinogenicity, as well as clarification of the significance of the reduced density of muscarinic receptors caused by clofenotane.

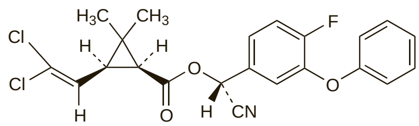
ATC Vet — QP53AC12.



(1S,3S-isomer)

Profile

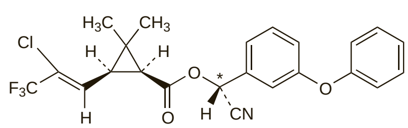
Cyfluthrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in agriculture and veterinary practice, and in the vector control of malaria (p.594).

Preparations

Proprietary Preparations (details are given in Part 3)
Ital.: Responsar†; Solfac.

Cyhalothrin *(BAN)*

Cihalotrina; Cyhalotryna; PP-563. (*RS*)-α-Cyano-3-phenoxybenzyl (*Z*)-(1*RS*,3*RS*)-3-(2-chloro-3,3,3-trifluoropropenyl)-2,2-dimethylcyclopropanecarboxylate.
$C_{23}H_{19}ClF_3NO_3$ = 449.9.
CAS — 68085-85-8.
ATC Vet — QP53AC06.



and enantioner plus epimer at c*

Profile

Cyhalothrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) that is used, particularly as a mixture of the (*Z*)-(1*R*,3*R*) *S* ester and the (*Z*)-(1*S*,3*S*) *R* ester (known as lambda-cyhalothrin), for the control of insect pests in public health. It has also been used in agriculture and in veterinary practice.

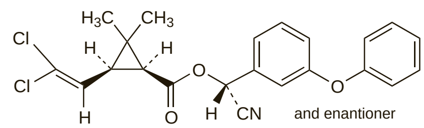
Alfacipermetrina. (*SR*)-α-Cyano-3-phenoxybenzyl (1*RS*,3*RS*)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate.
$C_{22}H_{19}Cl_2NO_3$ = 416.3.
CAS — 67375-30-8.



and enantioner

Profile

Cypermethrin, an isomeric mixture containing alpha-cypermethrin, is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in veterinary practice as a topical ectoparasiticide and to control sea-lice infestation in salmon. It is used in agriculture. Zeta-cypermethrin is also used. Alpha-cypermethrin is used in agriculture and for vector control in the management of malaria (p.594).

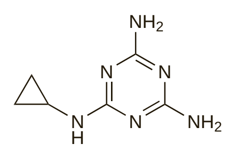
Cyromazine *(BAN, rINN)*

CGA-72662; Ciromazina; Cyromazinum. *N*-Cyclopropyl-1,3,5-triazine-2,4,6-triamine.
Циромазин
$C_6H_{10}N_6$ = 166.2.
CAS — 66215-27-8.



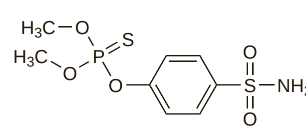
Pharmacopoeias. In *US* for veterinary use only.
USP 31 (Cyromazine). A white or off-white, odourless, crystalline powder. Slightly soluble in water and in methyl alcohol.

Profile

Cyromazine is used as a topical ectoparasiticide in veterinary practice.

Cythioate *(BAN)*

Citioato. *O,O*-Dimethyl *O*-(4-sulphamoylphenyl) phosphorothioate.
$C_8H_{12}NO_5PS_2$ = 297.3.
CAS — 115-93-5.
ATC Vet — QP53AF10; QP53BB01.



Profile

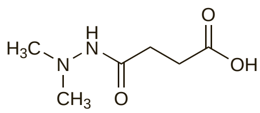
Cythioate is an organophosphorus insecticide (p.2047) used as a systemic ectoparasiticide in veterinary practice; it is given orally to the host animal.

Daminozide

Daminozida. *N*-Dimethylaminosuccinamic acid.

$C_6H_{12}N_2O_3$ = 160.2.

CAS — 1596-84-5.



Profile

Daminozide is a plant growth regulator that has been used in pesticides to improve fruit crops. There have been concerns about residues of the chemical in the fruit.

Deltamethrin (BAN)

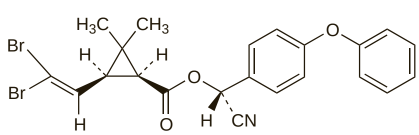
Decamethrin; Deltamethrinum; Deltametriini; Deltametrin; Deltametrina; Deltametryna; NRDC-161. (*S*)-α-Cyano-3-phenoxybenzyl (1*R*,3*R*)-3-(2,2-dibromovinyl)-2,2-dimethylcyclopropanecarboxylate.

$C_{22}H_{19}Br_2NO_3$ = 505.2.

CAS — 52918-63-5.

ATC — P03BA03.

ATC Vet — QP53AC11.



Pharmacopoeias. In *BP(Vet).*

BP(Vet) 2008 (Deltamethrin). A white to buff-coloured crystalline powder. Insoluble in water; soluble in alcohol and in acetone.

Profile

Deltamethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in the vector control of malaria (p.594). It is also used as a topical ectoparasiticide in veterinary practice and as an agricultural and household insecticide.

◊ References.

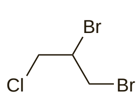
Dibromochloropropane

Dibromocloropropano. 1,2-Dibromo-3-chloropropane.

$C_3H_5Br_2Cl$ = 236.3.

CAS — 96-12-8.



Profile

Dibromochloropropane has been used as a pesticide. Low sperm counts and evidence of testicular damage have occurred in workers exposed to dibromochloropropane.

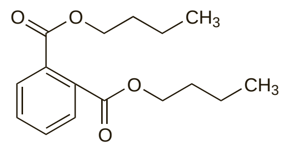
Dibutyl Phthalate

Butyl Phthalate; DBP; Dibutil-ftalát; Dibutilo ftalatas; Dibutilo, ftalato de; Dibutyle, phtalate de; Dibutylftalat; Dibutyl-ftalát; Dibutylis phthalas; Dibutylu ftalan; Dibutyyliftalaatti. Dibutyl benzene-1,2-dicarboxylate.

$C_{16}H_{22}O_4$ = 278.3.

CAS — 84-74-2.

ATC — P03BX03.



Pharmacopoeias. In *Eur.* (see p.vii). Also in *USNF.*

Ph. Eur. 6.2 (Dibutyl Phthalate). A clear, oily, colourless or very slightly yellow liquid. Practically insoluble in water; miscible with alcohol. Store in airtight containers.

USNF 26 (Dibutyl Phthalate). A clear, oily, colourless or very slightly yellow liquid. Practically insoluble in water; miscible with alcohol and with ether. Store in airtight containers.

Adverse Effects and Precautions

Dibutyl phthalate has occasionally caused hypersensitivity reactions. As with other phthalates contact with plastics should be avoided.

Uses and Administration

Dibutyl phthalate has been used as an insect repellent although it is slightly less effective than dimethyl phthalate (p.2041). It is less volatile and less easily removed by washing than dimethyl phthalate, and its chief use therefore has been for the impregnation of clothing.

Dibutyl phthalate has also been used as a plasticiser.

◊ References.

Preparations

Proprietary Preparations (details are given in Part 3)

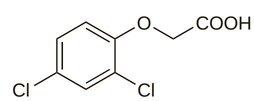
Multi-ingredient: ***S.Afr.:*** Mylol†.

Dichlorophenoxyacetic Acid

2,4-D; Diclorofenoxiacético, ácido. 2,4-Dichlorophenoxyacetic acid.

$C_8H_6Cl_2O_3$ = 221.0.

CAS — 94-75-7.



Adverse Effects, Treatment, and Precautions

Most cases of poisoning with dichlorophenoxyacetic acid have involved its ingestion with other herbicides; the solvent may also play a part in any toxicity. There is little pattern to the range of adverse effects that may occur after ingestion, inhalation, or topical exposure.

Adverse effects have involved the CNS and peripheral nervous system, muscles, and the cardiovascular system. Gastrointestinal effects are common with poisoning. Hepatotoxicity, nephrotoxicity, and pulmonary disorders have occurred but it is not clear that dichlorophenoxyacetic acid contributed to the toxicity. The role of phenoxyacetic acids in cancer is discussed under trichlorophenoxyacetic acid (p.2051).

Activated charcoal or possibly gastric lavage should be considered after ingestion of substantial amounts if the patient presents within 1 hour. Contaminated clothing should be removed and the skin washed with soap and water. Forced alkaline diuresis or haemodialysis have been reported to be effective in removing dichlorophenoxyacetic acid; the latter is considered more effective. Further treatment is symptomatic.

4. Bradberry SM, *et al.* Mechanisms of toxicology, clinical features, and management of acute chlorophenoxy herbicide poisoning: a review. *J Toxicol Clin Toxicol* 2000; **38:** 111–22.

Uses

Dichlorophenoxyacetic acid is a herbicide widely used for weed control in cereals and other crops. It is usually used as its salts or esters with other herbicides.

Dichlorvos (BAN, USAN, rINN)

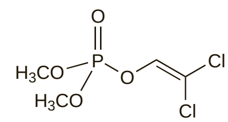
DDVP; Dichlorfos; Dichlorvosum; Diclorvós; NSC-6738; OMS-14; SD-1750. 2,2-Dichlorovinyl dimethyl phosphate.

Дихлорвос

$C_4H_7Cl_2O_4P$ = 221.0.

CAS — 62-73-7.

ATC Vet — QP52AB03; QP53AF04.



Pharmacopoeias. In *Fr.* for veterinary use.

Profile

Dichlorvos is an organophosphorus insecticide (p.2047) of short persistence, effective against a wide range of insects. It is sometimes used as a fumigant. It has been used for the extermination of insects in aircraft (disinsection). It is also used as a topical ectoparasiticide and as an anthelmintic in veterinary practice. Concern has been expressed over its possible carcinogenicity.

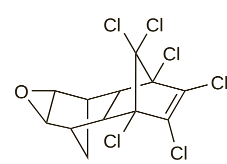
Dieldrin (BAN, pINN)

Dieldrina; Dieldrine; Dieldrinum; Dieldryna.

Диэлдрин

CAS — 60-57-1 (HEOD).



(HEOD)

Description. Dieldrin contains about 85% of (1*R*,4*S*,5*S*,8*R*)-1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4a,5,6,7,8,8a-octahydro-1,4:5,8-dimethanonaphthalene (HEOD), $C_{12}H_8Cl_6O$ = 380.9. The remaining 15% is mainly chlorinated organic compounds related to HEOD.

Adverse Effects and Treatment

As for Chlorinated Insecticides, p.2037.

Dieldrin is more toxic than clofenotane (p.2038) and is readily absorbed through the skin.

Uses

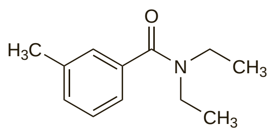
Dieldrin is a chlorinated insecticide (p.2037) formerly used as a sheepdip. Its use is now limited to a few specified purposes such as termite control.

Diethyltoluamide *(BAN, rINN)*

DEET; *N,N*-Diethyl-3-methylbenzamide; Diéthyltoluamide; Diethyltoluamidum; Dietiltoluamida; Dietiltoluamida. *NN*-Diethyl-*m*-toluamide.

Диэтилтолуамид

$C_{12}H_{17}NO$ = 191.3.
CAS — 134-62-3.
ATC — P03BX01.
ATC Vet — QP53GX01.



Pharmacopoeias. In *Int.* and *US.*

USP 31 (Diethyltoluamide). A colourless liquid with a faint pleasant odour. Practically insoluble in water and in glycerol; miscible with alcohol, with carbon disulfide, with chloroform, with ether, and with isopropyl alcohol. Store in airtight containers.

Adverse Effects and Precautions

Occasional hypersensitivity to diethyltoluamide has been reported. Diethyltoluamide should not be applied near the eyes, to mucous membranes, to broken skin, or to areas of skin flexion, as irritation or blistering may occur. Systemic toxicity has been reported after application of large topical doses, particularly in children.

◊ Hypersensitivity and anaphylaxis has been described in a patient after exposure to diethyltoluamide.[1] Toxic encephalopathy has been noted in children given liberal applications of this compound;[2] seizures have also been reported,[3] and there have been cases of manic psychosis[4] and cardiovascular toxicity (sinus bradycardia and orthostatic hypotension)[5] associated with topical application. An assessment[6] of both published and unpublished data concluded that there had been remarkably few problems considering the widespread use of diethyltoluamide and that the encephalopathy in children had not been substantiated by detailed surveillance; however, another case analysis[7] did find an association with encephalopathy in children.

Toxic reactions, including death, have been reported after the ingestion of large amounts of diethyltoluamide-containing insect repellents.[8]

8. Tenenbein M. Severe toxic reactions and death following the ingestion of diethyltoluamide-containing insect repellents. *JAMA* 1987; **258:** 1509–11.

Uses

Diethyltoluamide is an insect repellent that is effective against mosquitoes as well as blackflies, harvest-bugs or chiggers, midges, ticks, and fleas. It is considered to be of value for personal protection against malaria (p.594). It has also been used as a repellent against leeches. It may be applied to skin and clothing.

Preparations

USP 31: Diethyltoluamide Topical Solution.

Proprietary Preparations (details are given in Part 3)

Toxicity. Difenacoum, a second-generation anticoagulant rodenticide inhibits prothrombin synthesis to cause bleeding that may be occult.[1] It is absorbed from the gastrointestinal tract; dermal absorption is possible. Poisons containing 100 mg in each kg of bait are not hazardous to man; more concentrated forms are particularly hazardous and their availability should be restricted. Baits, which should be prepared only by trained personnel, should contain a suitable marker-dye.

There have been reports of poisoning with difenacoum.[2-4]

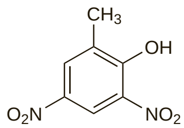
CAS — 534-52-1.



Profile

Dinitro-*o*-cresol is a dinitrophenol formerly used as an insecticide and herbicide. It increases metabolism by uncoupling oxidative phosphorylation and was also formerly used in obesity. Fatal poisoning has occurred.

◊ References.

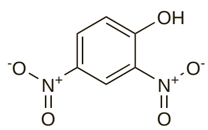
1. WHO. Dinitro-ortho-cresol. *Environmental Health Criteria 220.* Geneva: WHO, 2000. Available at: http://www.inchem.org/documents/ehc/ehc/ehc220.htm (accessed 26/04/04)

Dinitrophenol

Dinitrofenol. 2,4-Dinitrophenol.

$C_6H_4N_2O_5$ = 184.1.

CAS — 51-28-5.



Profile

Dinitrophenol has been used as a herbicide. Since dinitrophenol increases metabolism by uncoupling oxidative phosphorylation it was formerly used in the treatment of obesity. Fatal poisoning has occurred.

Dioctyl Adipate

DEHA; Di-(2-ethylhexyl)adipate; Dioctilo, adipato de.

$C_{22}H_{42}O_4$ = 370.6.

Profile

Dioctyl adipate is used as an insect repellent. It is also used as a plasticiser by the plastics industry; concern about the migration of this and other plasticisers into foodstuffs from polythene films used to wrap them ('cling film') have led to its use at lower concentrations.

Preparations

Proprietary Preparations (details are given in Part 3)
UK: Protec.

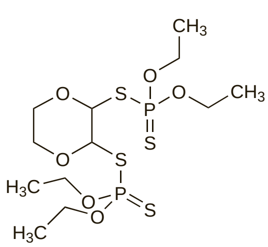
Dioxation *(BAN, rINN)*

Dioxathion; Dioxatión; Dioxationum. It consists mainly of *cis* and *trans* isomers of *S,S*′-1,4-dioxan-2,3-diyl bis(*O,O*-diethyl phosphorodithioate).

Диоксатион

$C_{12}H_{26}O_6P_2S_4$ = 456.5.

CAS — 78-34-2.



Profile

Dioxation is an organophosphorus insecticide (p.2047) that has been used in agriculture and as a topical ectoparasiticide in veterinary practice.

Diphenadione *(BAN, pINN)*

Difenadiona; Diphacinone; Diphénadione; Diphenadionum. 2-(Diphenylacetyl)indan-1,3-dione.

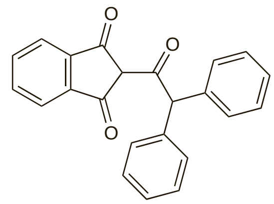
Дифенадион

$C_{23}H_{16}O_3$ = 340.4.

CAS — 82-66-6.

ATC — B01AA10.

ATC Vet — QB01AA10.



Profile

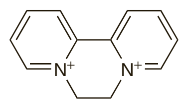
Diphenadione is used as an anticoagulant rodenticide.

Diquat Dibromide

Diquat, dibromuro de. 9,10-Dihydro-8a,10a-diazoniaphenanthrene dibromide; 1,1′-Ethylene-2,2′-bipyridyldiylium dibromide.

$C_{12}H_{12}Br_2N_2$ = 344.0.

CAS — 2764-72-9 (diquat); 85-00-7 (diquat dibromide).



(diquat)

Profile

Diquat dibromide is a contact herbicide used in agriculture and horticulture. It has similar adverse effects to those of paraquat (p.2047).

◊ References.

Emamectin

Emamectina. A mixture of (4″-*R*)-5-*O*-Demethyl-4″-deoxy-4″-(methylamino)avermectin A_{1a} and (4″-*R*)-5-*O*-Demethyl-25-de(1-methylpropyl)-4″-deoxy-4″-(methylamino)-25-(1-methylethyl)avermectin A_{1a} in the ratio of 9:1.

CAS — 121124-29-6 (major component); 121424-52-0 (minor component); 137335-79-6.

ATC Vet — QP54AA06.

Profile

Emamectin is an avermectin insecticide used for the control of sea-lice infestation in salmon.

Endod

Profile

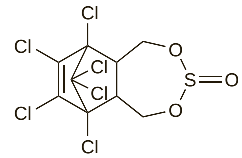
Endod is obtained from the dried fruits of *Phytolacca dodecandra* (Phytolaccaceae) and has molluscicidal properties. It has been investigated for the control of the snail vector of schistosomiasis.

Endosulfan

Endosulfán. 1,4,5,6,7,7-Hexachloro-8,9,10-trinorborn-5-en-2,3-ylenebismethylene sulphite.

$C_9H_6Cl_6O_3S$ = 406.9.

CAS — 115-29-7.



Profile

Endosulfan is a chlorinated insecticide (p.2037) used in agriculture.

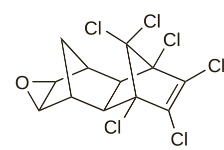
Endrin

Endrín; Endryna. (1*R*,4*S*,4a*S*,5*S*,6*S*,7*R*,8*R*,8a*R*)-1,2,3,4,10,10-Hexachloro-1,4,4a,5,6,7,8,8a-octahydro-6,7-epoxy-1,4:5,8-dimethanonaphthalene.

$C_{12}H_8Cl_6O$ = 380.9.

CAS — 72-20-8.



Profile

Endrin is a chlorinated insecticide (p.2037), but its use was prohibited, at least in some countries, because of toxicity and persistence in the environment.

◊ General references to endrin,[1-4] including reports of poisoning.[2,3]

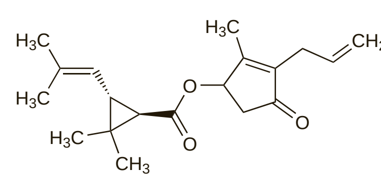
Esdepallethrine

Esdepaletrina. (*S*)-3-Allyl-2-methyl-4-oxocyclopent-2-enyl (1*R*,3*R*)-2,2-dimethyl-3-(2-methylprop-1-enyl)-cyclopropanecarboxylate.

$C_{19}H_{26}O_3$ = 302.4.

CAS — 28434-00-6.



Profile

Esdepallethrine is a pyrethroid insecticide (see Pyrethrum Flower, p.2049). It is used as an acaricide with piperonyl butoxide (p.2049) in the topical treatment of scabies (p.2035).

Esdepallethrine is also used in devices and sprays to control insects, including mosquitoes.

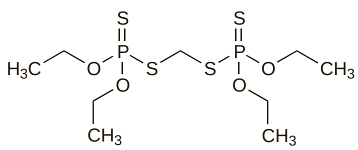
Preparations

Proprietary Preparations (details are given in Part 3)
Fr.: Cinq sur Cinq; Mousticologne.

Multi-ingredient: ***Arg.:*** Acardust†; ***Canad.:*** Scabene†; ***Fr.:*** A-Par; Acardust; Cinq sur Cinq; Spregal; ***Gr.:*** Spregal; ***Israel:*** Acardust; ***Neth.:*** Spregal; ***Rus.:*** Spregal (Спрегаль); ***S.Afr.:*** Spregal.

Ethion

Diethion; Etión; Etion. *O,O,O′,O′*-Tetraethyl *S,S′*-methylenediphosphorodithioate.
$C_9H_{22}O_4P_2S_4$ = 384.5.
CAS — 563-12-2.

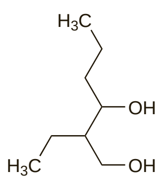


Profile

Ethion is an organophosphorus insecticide used as a topical ectoparasiticide in veterinary practice.

Ethohexadiol

Ethylhexanediol; Etohexadiol. 2-Ethylhexane-1,3-diol.
$C_8H_{18}O_2$ = 146.2.
CAS — 94-96-2.
ATC — P03BX06.
ATC Vet — QP53GX04.



Profile

Ethohexadiol is an insect repellent. It may be applied topically to the skin and to clothing. It has been used with dimethyl phthalate.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Fr.:*** Moustidose Adult et Enfant.

Ethyl Butylacetylaminopropionate

EBAAP; IR-3535; Merck-3535; Repellent 3535. (*N*-Butyl-*N*-acetyl)-3-ethylaminopropionate; *N*-Acetyl-*N*-butyl-beta-alanine ethyl ester; .
$C_{11}H_{21}NO_3$ = 215.3.
CAS — 52304-36-6.

Profile

Ethyl butylacetylaminopropionate is used as an insect repellent; it may be applied to the skin.

Preparations

Proprietary Preparations (details are given in Part 3)
Belg.: Mouskito; Shampoux Repel; ***Braz.:*** Johnson's Baby Locao Anti-Mosquito; ***Fr.:*** Cinq sur Cinq; Prebutix; ***Thai.:*** Johnson's Baby Clear†; ***UK:*** Mijex Extra.

Multi-ingredient: ***Arg.:*** Standard XXI; ***Austral.:*** Apex Repel Super; Apex Repel Ultra; ***Belg.:*** Mouskito Sun; ***Fr.:*** Guep'Away†; Mousticologne; Moustidose Bebe-Nourrisson; Prebutix; ***NZ:*** Apex Repel Super; Apex Repel Ultra.

Ethylene Dibromide

EDB; Etileno, dibromuro de. 1,2-Dibromoethane.
$C_2H_4Br_2$ = 187.9.
CAS — 106-93-4.

Profile

Ethylene dibromide is an insecticidal fumigant and a lead scavenger used in the petroleum industry. Its use has been restricted in certain areas because of carcinogenicity in *animals* and because of evidence of persistence in fruit and cereals that have undergone fumigation.

Ethylene dibromide is more toxic than carbon tetrachloride or ethylene dichloride. It is irritant to the eyes, skin, and mucous membranes. Inhalation leads to drowsiness, CNS depression, and possibly pulmonary oedema. Contact with the skin causes blistering and it is readily absorbed. Kidney and liver damage may occur.

◊ Reports of poisoning due to ethylene dibromide.

1. Letz GA, *et al.* Two fatalities after acute occupational exposure to ethylene dibromide. *JAMA* 1984; **252:** 2428–31.
2. Singh S, *et al.* Non-fatal ethylene dibromide ingestion. *Hum Exp Toxicol* 2000; **19:** 152–3.
3. Mehrotra P, *et al.* Two cases of ethylene dibromide poisoning. *Vet Hum Toxicol* 2001; **43:** 91–2.
4. Singh N, *et al.* Outcome of sixty four cases of ethylene dibromide ingestion treated in tertiary care hospital. *J Assoc Physicians India* 2007; **55:** 842–5.

Ethylene Dichloride

Brocide; Dutch Liquid; Etileno, dicloruro de. 1,2-Dichloroethane.
$C_2H_4Cl_2$ = 98.96.
CAS — 107-06-2.

Profile

Ethylene dichloride is an insecticidal fumigant. It is also used in the petroleum industry and as an industrial solvent. Exposure to the vapour may cause lachrymation and corneal clouding, nasal irritation, and vertigo due to the depressant effect on the CNS. Contact with the skin may cause dermatitis. Kidney and liver damage, hypotension and cardiac impairment, gastrointestinal disturbances, haemorrhage, coma, and pulmonary oedema may follow absorption after inhalation, topical application, or ingestion.

Ethylene dichloride has been reported to be carcinogenic in *animals.*

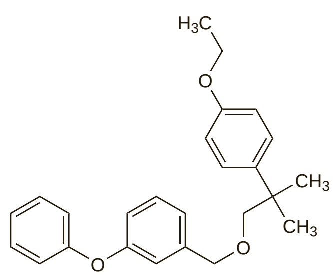
Etofenprox *(rINN)*

Étofenprox; Etofenproxum. α-[(*p*-Ethoxy-β,β-dimethylphenethyl)oxy]-*m*-phenoxytoluene.
Этофенпрокс
$C_{25}H_{28}O_3$ = 376.5.
CAS — 80844-07-1.

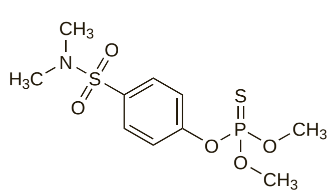


Profile

Etofenprox is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in the vector control of malaria (p.594).

Famphur

Famfur; Famophos.
$C_{10}H_{16}NO_5PS_2$ = 325.3.
CAS — 52-85-7.

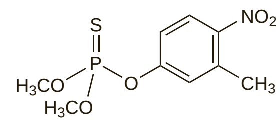


Profile

Famphur is an organophosphorus insecticide (p.2047) used as a systemic ectoparasiticide in veterinary practice; it is applied topically to the host animal.

Fenitrothion *(BAN)*

Fenitrotión. *O,O*-Dimethyl *O*-4-nitro-*m*-tolyl phosphorothioate.
$C_9H_{12}NO_5PS$ = 277.2.
CAS — 122-14-5.



Profile

Fenitrothion is an organophosphorus insecticide (p.2047) used as a topical ectoparasiticide in veterinary practice. It is also used as an agricultural insecticide.

◊ References.

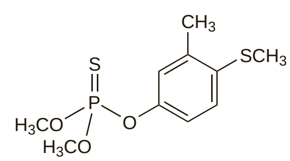
Fenthion *(BAN)*

Bayer-29493; Fentión; S-752. *O,O*-Dimethyl *O*-4-methylthio-*m*-tolyl phosphorothioate.
$C_{10}H_{15}O_3PS_2$ = 278.3.
CAS — 55-38-9.
ATC Vet — QP53BB02.



Pharmacopoeias. In *BP(Vet).*

BP(Vet) 2008 (Fenthion). A yellowish-brown oily substance. Immiscible with water; miscible with alcohol and with chloroform.

Profile

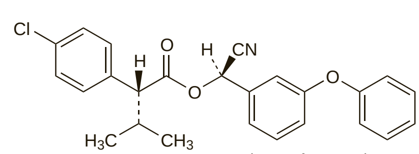
Fenthion is an organophosphorus insecticide (p.2047) used as a systemic ectoparasiticide in veterinary practice; it is applied topically to the host animal. Fenthion has also been used in agriculture.

Toxicity. Macular changes have been detected in the eyes of workers regularly exposed to fenthion.[1] It was considered that there was a need for long-term studies on subjects exposed to different organophosphorus compounds to assess their role in producing macular changes.

1. Misra UK, *et al.* Some observations on the macula of pesticide workers. *Hum Toxicol* 1985; **4:** 135–45.

Fenvalerate *(BAN)*

Fenvalerato; Fenwalerianian; OMS-2000; Pydrin; S-5602; SD-43775; WL-43775. (*RS*)-α-Cyano-3-phenoxybenzyl (*RS*)-2-(4-chlorophenyl)-3-methylbutyrate.
$C_{25}H_{22}ClNO_3$ = 419.9.
CAS — 51630-58-1.
ATC Vet — QP53AC14; QP53AX02.



mixture of 4 stereoisomers

Profile

Fenvalerate is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used as a topical ectoparasiticide in veterinary practice. It has also been used as an insecticide in agriculture and horticulture.

Esfenvalerate, one of the stereoisomers of fenvalerate, is also used as an agricultural insecticide.

◊ References.

1. WHO. Fenvalerate health and safety guide. *IPCS Health and Safety Guide 34*. Geneva: WHO, 1989. Available at: http://www.inchem.org/documents/hsg/hsg/hsg034.htm (accessed 26/04/04)
2. WHO. Fenvalerate. *Environmental Health Criteria 95*. Geneva: WHO, 1990. Available at: http://www.inchem.org/documents/ehc/ehc/ehc95.htm (accessed 26/04/04)

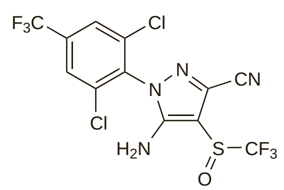
Fipronil *(BAN)*

Fiproniili; Fipronilo; MB-46030; RM-1601. (*RS*)-5-Amino-1-(2,6-dichloro-4-trifluoromethylphenyl)-4-(trifluoromethylsulfinyl)pyrazole-3-carbonitrile.

$C_{12}H_4Cl_2F_6N_4OS$ = 437.1.

CAS — 120068-37-3.

ATC Vet — QP53AX15.



Profile

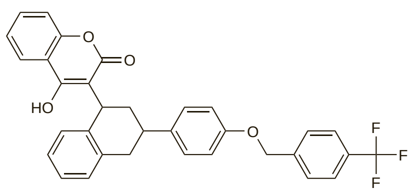
Fipronil is used as a topical ectoparasiticide in veterinary practice. It has also been investigated for the treatment of head lice.

Flocoumafen

Flocoumafene; Flocumafeno; OMS-3047. 4-Hydroxy-3-[1,2,3,4-tetrahydro-3-[4-(4-trifluoromethylbenzyloxy)phenyl]-1-naphthyl]coumarin.

$C_{33}H_{25}F_3O_4$ = 542.5.

CAS — 90035-08-8.



Profile

Flocoumafen is a coumarin derivative used as an anticoagulant rodenticide. It is said to be effective in rodents resistant to other anticoagulant rodenticides.

◊ References.

1. WHO. Anticoagulant rodenticides. *Environmental Health Criteria 175*. Geneva: WHO, 1995. Available at: http://www.inchem.org/documents/ehc/ehc/ehc175.htm (accessed 26/04/04)

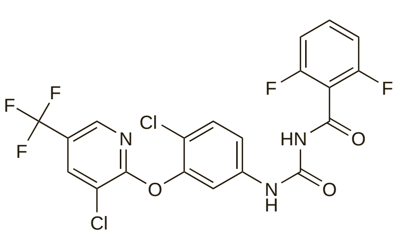
Fluazuron *(rINN)*

CGA-157419; Fluazurón; Fluazuronum. 1-(4-Chloro-3-{[3-chloro-5-(trifluoromethyl)-2-pyridyl]oxy}phenyl)-3-(2,6-difluorobenzoyl)urea.

Флуазурон

$C_{20}H_{10}Cl_2F_5N_3O_3$ = 506.2.

CAS — 86811-58-7.



Profile

Fluazuron is used as a topical ectoparasiticide in veterinary practice.

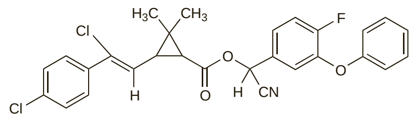
Flumethrin *(BAN)*

Flumethrinum; Flumetriini; Flumetrin; Flumetrina. α-Cyano-4-fluoro-3-phenoxybenzyl 3-(β,4-dichlorostyryl)-2,2-dimethylcyclopropanecarboxylate.

$C_{28}H_{22}Cl_2FNO_3$ = 510.4.

CAS — 69770-45-2.

ATC Vet — QP53AC05.



Profile

Flumethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used as a topical ectoparasiticide in veterinary practice.

◊ Reports of poisoning with flumethrin.

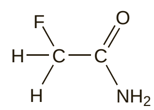
1. Box SA, Lee MR. A systemic reaction following exposure to a pyrethroid insecticide. *Hum Exp Toxicol* 1996; **15:** 389–90.

Fluoroacetamide

Compound 1081; Fluoroacetamida.

$FCH_2.CONH_2$ = 77.06.

CAS — 640-19-7.



Profile

Fluoroacetamide is a rodenticide and produces adverse effects similar to those of sodium fluoroacetate (p.2050).

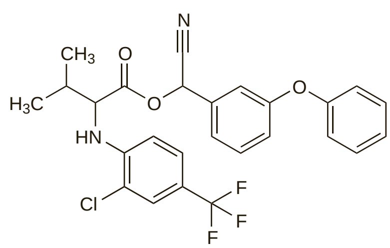
Fluvalinate

Fluvalinato; ZR-3210. Cyano(3-phenoxyphenyl)methyl ester of *N*-[2-chloro-4-(trifluoromethyl)phenyl]-DL-valine.

$C_{26}H_{22}ClF_3N_2O_3$ = 502.9.

CAS — 69409-94-5.

ATC Vet — QP53AC10.



Profile

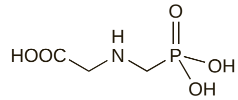
Fluvalinate is a pesticide used in beekeeping.

Glyphosate

Glifosato. *N*-(Phosphonomethyl)glycine.

$C_3H_8NO_5P$ = 169.1.

CAS — 1071-83-6.



Profile

Glyphosate is used as a herbicide.

◊ References.

1. WHO. Glyphosate. *Environmental Health Criteria 159*. Geneva: WHO, 1994. Available at: http://www.inchem.org/documents/ehc/ehc/ehc159.htm (accessed 26/04/04)

Toxicity. Reports[1-3] and reviews[4] of poisoning with glyphosate products, prognostic factors,[5] guidelines for treatment[6] have been published. The toxicity has been believed to be largely due to the inclusion of surfactants, particularly polyoxyethyleneamine, in the herbicide (Roundup) formulation but products vary considerably as to the surfactant contained and the concentration and salt of glyphosate used, and the evidence that surfactants potentiate glyphosate toxicity is unclear.[6]

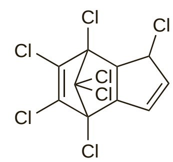
Heptachlor

Heptacloro. 1,4,5,6,7,8,8-Heptachloro-3a,4,7,7a-tetrahydro-4,7-methanoindene.

$C_{10}H_5Cl_7$ = 373.3.

CAS — 76-44-8.



Profile

Heptachlor is a chlorinated insecticide (p.2037), but its use was prohibited, at least in some countries, because of its persistent nature.

◊ References.

1. WHO. Heptachlor. *Environmental Health Criteria 38*. Geneva: WHO, 1984. Available at: http://www.inchem.org/documents/ehc/ehc/ehc38.htm (accessed 26/04/04)

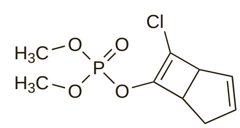
Heptenophos

Heptenofós; Hoe-02982. 7-Chlorobicyclo[3.2.0]hepta-2,6-dien-6-yl dimethyl phosphate.

$C_9H_{12}ClO_4P$ = 250.6.

CAS — 23560-59-0.



Profile

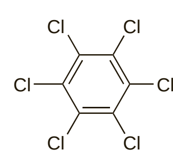
Heptenophos is an organophosphorus insecticide (p.2047) that has been used in veterinary practice for the control of ectoparasites. It is also used in agriculture.

Hexachlorobenzene

HCB; Heksachlorobenzen; Hexaclorobenceno.

C_6Cl_6 = 284.8.

CAS — 118-74-1.



NOTE. Hexachlorobenzene should not be confused with gamma benzene hexachloride (lindane).

Profile

Hexachlorobenzene has been used as an agricultural fungicide. It is not biodegradable to any significant extent and hexachlorobenzene residues in food have arisen as a result of its occurrence in industrial wastes as well as its use as a fungicide; its use is banned in some countries.

Hexachlorobenzene is reported to be distributed into breast milk.

◊ References.

1. WHO. Hexachlorobenzene. *Environmental Health Criteria 195*. Geneva: WHO, 1997. Available at: http://www.inchem.org/documents/ehc/ehc/ehc195.htm (accessed 26/04/04)

Hydrocyanic Acid

Cianhídrico, ácido; Prussic Acid.

CAS — 74-90-8.

Description. Hydrocyanic acid is an aqueous solution containing hydrogen cyanide, HCN = 27.03. A colourless liquid with a characteristic almond odour.

Adverse Effects and Precautions

Hydrocyanic acid and its vapour are intensely poisonous. Cyanides interfere with the oxygen uptake of cells by inhibition of cytochrome oxidase, an enzyme necessary for cellular oxygen transport.

Poisoning by cyanides may occur from inhalation of the vapour, ingestion, or absorption through the skin. Poisoning may arise from cyanide pesticides, industrial accidental exposure, or the inhalation of fumes from some burning plastics. Poisoning may also occur from cyanide-containing plants or fruits.

When large doses of hydrocyanic acid are taken, unconsciousness occurs within a few seconds and death within a few minutes. With smaller toxic doses the symptoms, which occur within a few minutes, may include constriction of the throat, nausea, vomiting, giddiness, headache, palpitation, hyperpnoea then dyspnoea, bradycardia (although initially there may be tachycardia), unconsciousness, and violent convulsions, followed by death. The characteristic smell of bitter almonds may not be obvious and not all individuals can detect it. Cyanosis is not prominent. Similar but usually slower effects occur with cyanide salts.

The fatal dose of hydrocyanic acid for man is considered to be about 50 mg and of the cyanides about 250 mg.

Treatment of Adverse Effects

Treatment must be given rapidly but should not involve the use of antidotes unless it is certain that cyanide has been absorbed and poisoning is severe.

Cyanide is absorbed very rapidly on inhalation and the poisoned patient should be removed from the area and given oxygen. Steps should be taken to ensure that the airway is adequate. Contaminated clothing should be removed and skin washed. If the patient is conscious, amyl nitrite may be inhaled for up to 30 seconds in every minute but the value of this practice is questionable. Should the patient be unconscious or nearly so, then in the UK and some other countries it is the practice to give dicobalt edetate (p.1443) by injection since it forms a stable complex with the cyanide ion. However, cyanide poisoning should be confirmed, as absence of cyanide puts the patient at risk from the adverse effects of dicobalt edetate. The recommended dose of dicobalt edetate is 300 mg given intravenously over about 1 to 5 minutes, depending on the severity of the poisoning, and repeated once or twice depending on the response. It is customary to give 50 mL of glucose 50% intravenously after each injection. In the USA cyanide antidote kits containing amyl nitrite, sodium nitrite, and sodium thiosulfate are available. After the use of inhaled amyl nitrite, 10 mL of sodium nitrite injection (3%) is given intravenously over 5 to 20 minutes, then, using the same needle and vein, an injection of 12.5 g of sodium thiosulfate (50 mL of a 25% solution or 25 mL of a 50% solution) is given over a period of about 10 minutes. The nitrite components from amyl nitrite and sodium nitrite convert haemoglobin to methaemoglobin which competes with cytochrome oxidase for cyanide, with the formation of cyanmethaemoglobin; sodium thiosulfate acts as a sulfur donor and aids the conversion or inactivation of cyanide from cyanmethaemoglobin to thiocyanate. If toxic symptoms recur, the injections of nitrite and thiosulfate may be repeated at half the initial doses. Appropriate measures should be instituted to correct hypotension and acidosis. The methaemoglobinaemia induced by the nitrites in the antidote kits can be dangerous and fatalities have been reported.

Hydroxocobalamin may be used for the management of cyanide toxicity. The usual dose is 70 mg/kg by intravenous infusion, repeated once or twice according to severity. Alternatively, hydroxocobalamin 5 g may be given by intravenous infusion over 15 minutes, followed if necessary by a second dose of 5 g intravenously, infused over 15 minutes to 2 hours.

If cyanide has been ingested, one of the above procedures should be used. Activated charcoal or gastric lavage may be considered if the patient presents within 1 hour.

◊ Some references concerning the management of cyanide poisoning.[1-4] The use of solutions A and B (15.8% ferrous sulfate in 0.3% citric acid, and 6% sodium carbonate respectively) as so called oral antidotes in persons exposed to cyanide has been condemned as ineffective and lacking scientific evidence.[2]

4. Geller RJ, *et al.* Pediatric cyanide poisoning: causes, manifestations, management, and unmet needs. *Pediatrics* 2006; **118:** 2146–58.

Uses

Cyanides have various industrial applications. Hydrocyanic acid and cyanide salts produce hydrogen cyanide, which has been used as a gas for the eradication of rabbits, rodents, and some other pests. Cyanide salts that might be encountered include calcium cyanide, mercuric cyanide, potassium cyanide, potassium ferricyanide, potassium sodium cyanide, and sodium cyanide.

Preparations

Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Spain:*** Oftalmol Ocular.

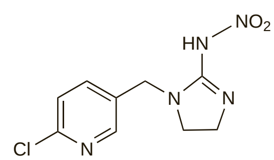
Imidacloprid

Bay-NTN-33893. 1-[(6-Chloro-3-pyridinyl)methyl]-4,5-dihydro-*N*-nitro-1*H*-imidazol-2-amine.

$C_9H_{10}ClN_5O_2$ = 255.7.

CAS — 105827-78-9; 138261-41-3.

ATC Vet — QP53AX17.



Profile

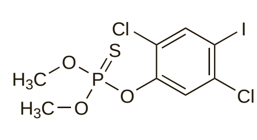
Imidacloprid is used as a topical ectoparasiticide in veterinary practice, and as an insecticide in agriculture. It has also been investigated for use in the treatment of head lice.

Iodofenphos *(BAN)*

Iodofenfós; Jodfenphos. *O*-2,5-Dichloro-4-iodophenyl *O,O*-dimethyl phosphorothioate.

$C_8H_8Cl_2IO_3PS$ = 413.0.

CAS — 18181-70-9.



Profile

Iodofenphos is an organophosphorus insecticide (p.2047) used in veterinary practice for the control of ectoparasites in the environment. It has also been used as an agricultural insecticide. It is an effective mosquito larvicide.

Iodopropynyl Butyl Carbamate

3-Iodo-2-propynyl-*N*-butyl carbamate.

$C_8H_{12}INO_2$ = 281.1.

CAS — 55406-53-6.

Profile

Iodopropynyl butyl carbamate is a carbamate pesticide (p.2037). It is used as a preservative in cosmetic preparations; contact sensitisation has been reported. It is also used as a wood preservative.

◊ References.

Preparations

Proprietary Preparations (details are given in Part 3)

Irl.: Saliker†.

Multi-ingredient: ***Arg.:*** Pityval†; Saliker†; ***Braz.:*** Effaclar; Pityval; Saliker; ***Fr.:*** Effaclar; Pityval; Saliker†; ***Irl.:*** Effaclar; Effaclar AI; Effaclar K.

Lindane *(BAN, USAN, rINN)*

666; Benhexachlor; Gamma Benzene Hexachloride; Gamma-BHC; Gamma-HCH; HCH; Hexicide; Lindaani; Lindán; Lindan; Lindanas; Lindano; Lindanum. 1α,2α,3β,4α,5α,6β-Hexachlorocyclohexane.

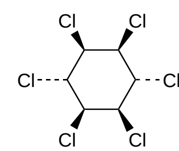
Линдан

$C_6H_6Cl_6$ = 290.8.

CAS — 58-89-9.

ATC — P03AB02.

ATC Vet — QP53AB02; QS02QA01.



Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int.*, and *US.*

Ph. Eur. 6.2 (Lindane). A white or almost white crystalline powder. Practically insoluble in water; soluble in dehydrated alcohol; freely soluble in acetone. Protect from light.

USP 31 (Lindane). A white, crystalline powder with a slight musty odour. Practically insoluble in water; soluble in dehydrated alcohol; freely soluble in chloroform; sparingly soluble in ether; slightly soluble in ethylene glycol.

Adverse Effects, Treatment, and Precautions

As for Chlorinated Insecticides, p.2037.

Serious adverse effects, including seizures and deaths, have been reported in patients who have used higher than recommended concentrations of lindane, or after a second application of lindane to the skin in the treatment of scabies and pediculosis: lindane should not be used as a first-line treatment in the management of the latter conditions. Babies, children, the elderly and people weighing less than 50 kg are considered to be particularly at risk. Lindane should not be used in patients who have a body-weight less than 50 kg, a history of epilepsy, have open or crusted sores on the skin around the head and neck or broken skin around the treatment areas, or skin conditions such as psoriasis or atopic dermatitis. Lindane is excreted into the breast milk but the amount excreted is not considered to be clinically significant; breastfeeding should, however, be avoided for at least 4 days after stopping treatment. There is limited human data on the use of lindane in pregnancy and *animal* data indicate a low risk for congenital defects, but because of its serious toxic potential safer alternative products are recommended.

◊ Seizures have been reported after the topical use of lindane.[1] In reply, one of the manufacturers stated that up to the end of 1983 they were aware of 21 cases of convulsive disorders apparently associated with the use of their product; it had been used by over 40 million people. Of the 21 cases, the seizures were definitely or probably caused by the product in 11, but in 9 the seizures were associated with ingestion or excessive use.[2] From 1998 to 2003, 870 cases of unintentional lindane ingestion were reported in the USA.[3] Signs and symptoms of illness after ingestion included abdominal cramps, confusion, cough, headache, nausea, oral irritation, seizures, and vomiting.

Isolated reports of adverse effects associated with lindane include disseminated intravascular coagulation and subsequent death after oral ingestion[4] and aplastic anaemia after prolonged topical exposure (twice daily application for 3 weeks).[5]

5. Rauch AE, *et al.* Lindane (Kwell)-induced aplastic anemia. *Arch Intern Med* 1990; **150:** 2393–5.

Uses and Administration

Lindane is a chlorinated insecticide (p.2037). It has been used topically in a concentration of 1% for scabies (p.2035) in selected patients and has also been used in pediculosis (p.2034), but use for head lice is restricted by resistance.

The symbol † denotes a preparation no longer actively marketed

Lindane has been used for the control of disease vectors including mosquitoes, lice, and fleas, but resistance has developed. It has also been used as an agricultural and a horticultural insecticide, but its use is prohibited or restricted in many countries.

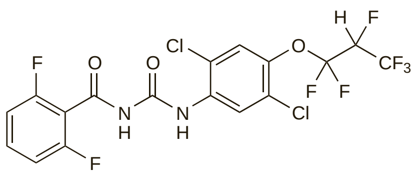
Lufenuron *(BAN, rINN)*

CGA-184699; Lufenurón; Lufénurone; Lufenuronum. 1-[2,5-Dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenyl]-3-(2,6-difluorobenzoyl)urea; (*RS*)-*N*-[2,5-Dichloro-4-(1,1,2,3,3,3-hexafluoropropoxy)phenylcarbamoyl]-2,6-difluorobenzamide.

Луфенурон

$C_{17}H_8Cl_2F_8N_2O_3$ = 511.2.
CAS — 103055-07-8.
ATC Vet — QP53BC01.



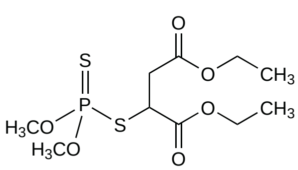
Profile

Lufenuron is used as a systemic ectoparasiticide in veterinary practice; it is given by mouth or injection to the host animal.

Malathion *(BAN)*

Carbofos; Compound 4047; Malathionum; Malatión; Malation; Malationas; Malationi; OMS-1. Diethyl 2-(dimethoxyphosphinothioylthio)succinate.

$C_{10}H_{19}O_6PS_2$ = 330.4.
CAS — 121-75-5.
ATC — P03AX03.
ATC Vet — QP53AF12.



Pharmacopoeias. In *Eur.* (see p.vii) and *US*.

Ph. Eur. 6.2 (Malathion). A clear, colourless or slightly yellowish liquid. It freezes at about 3°. Slightly soluble in water; miscible with alcohol, with acetone, with cyclohexane, and with vegetable oils. Store in airtight containers. Protect from light.

USP 31 (Malathion). A clear, colourless, or slightly yellowish liquid with a characteristic odour. Congeals at about 2.9°. Slightly soluble in water; miscible with alcohols, with ethers, with esters, with ketones, with aromatic and alkylated aromatic hydrocarbons, and with vegetable oils. Store in airtight containers. Protect from light.

Stability. The manufacturers have reported that malathion is sensitive to heat and is degraded at temperatures above 30°.

Adverse Effects and Treatment

As for Organophosphorus Insecticides, p.2047.

Malathion is one of the safer organophosphorus insecticides but its toxicity may be increased by the presence of impurities.

◊ Acute renal insufficiency has been described in a patient associated with excessive exposure to a malathion spray.[1] The condition resolved without specific treatment. Renal toxicity had not previously been associated with organophosphorus pesticides. In a second case of acute poisoning,[2] due to ingestion of malathion, mild transient renal insufficiency and proteinuria with several other late complications including cardiac arrhythmias, pulmonary oedema, diffuse interstitial fibrosis, and muscle weakness due to peripheral neuropathy, were seen subsequent to recovery from the initial cholinergic toxicity.

1. Albright RK, *et al*. Malathion exposure associated with acute renal failure. *JAMA* 1983; **250:** 2469.
2. Dive A, *et al*. Unusual manifestations after malathion poisoning. *Hum Exp Toxicol* 1994; **13:** 271–4.

Uses and Administration

Malathion is an organophosphorus insecticide (p.2047). It is used in the treatment of head and pubic pediculosis (p.2034) and in scabies (p.2035); lotions of 0.5% and shampoos of 1% are commonly available. Lotions are generally preferred to shampoos as the contact time is longer. Aqueous lotions are preferred to treat pubic lice and scabies because alcoholic lotions are irritant to excoriated skin and the genitalia; aqueous lotions may also be preferable in asthmatic subjects or children to avoid alcoholic fumes. Skin or hair treated with an alcohol-based preparation should be allowed to dry naturally.

Malathion is also used in veterinary practice, agriculture, and horticulture. It is widely used for adult and larval mosquito control although resistance occurs.

Preparations

USP 31: Malathion Lotion.

Proprietary Preparations (details are given in Part 3)
Austral.: Lice Rid†; ***Belg.:*** Prioderm; Radikal; ***Denm.:*** Prioderm; ***Fin.:*** Prioderm; ***Fr.:*** Prioderm; ***Gr.:*** Sicaril; Specifthir†; ***Irl.:*** Derbac-M; Prioderm; Quellada M; ***Israel:*** Prioderm; ***Ital.:*** Aftir Gel; ***Neth.:*** Noury Hoofdlotion; Prioderm; ***Norw.:*** Prioderm; ***NZ:*** A-Lices; Derbac-M; Prioderm; ***Port.:*** Olicide†; ***Rus.:*** Pedilin (Педилин); ***Singapore:*** A-Lices; Lice Care; ***Swed.:*** Prioderm; ***Switz.:*** Lusap†; Prioderm; ***UK:*** Derbac-M; Prioderm; Quellada M; Suleo-M†; ***USA:*** Ovide.

Metaldehyde

Metaldehído.

$(C_2H_4O)_x$.
CAS — 9002-91-9.

Description. Metaldehyde is a cyclic polymer of acetaldehyde.

Adverse Effects and Treatment

Symptoms of poisoning by metaldehyde, which may be delayed, include vomiting and diarrhoea, fever, drowsiness, convulsions, and coma. Death from respiratory failure may occur within 48 hours. Kidney and liver damage may occur.

Treatment is symptomatic, although activated charcoal may be considered if more than 50 mg/kg has been ingested within the preceding hour.

3. Bleakley C, *et al*. Self-poisoning with metaldehyde. *Emerg Med J* 2008; **25:** 381–2.

Uses

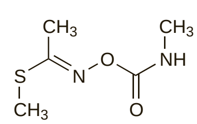
Metaldehyde is a molluscicide used in pellets against slugs and snails. It is an ingredient of some firelighters.

'Meta' is compressed metaldehyde which has been used as a solid fuel burning with a non-luminous carbon-free flame.

Methomyl

Metomilo. *S*-Methyl *N*-(methylcarbamoyloxy)thioacetimidate.

$C_5H_{10}N_2O_2S$ = 162.2.
CAS — 16752-77-5.



Profile

Methomyl is a carbamate insecticide (p.2037) that has been used in agriculture.

◊ References.

1. WHO. Methomyl health and safety guide. *IPCS Health and Safety Guide 97*. Geneva: WHO, 1995. Available at: http://www.inchem.org/documents/hsg/hsg/hsg097.htm (accessed 26/04/04)

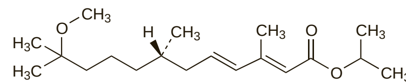
Methoprene *(rINN)*

Méthoprène; Methoprenum; Metopreno; ZR-515. Isopropyl 11-methoxy-3,7,11-trimethyldodeca-2(*E*),4(*E*)-dienoate.

Метопрен

$C_{19}H_{34}O_3$ = 310.5.
CAS — 40596-69-8.
ATC Vet — QP53BD01.



Profile

Methoprene is an insect growth regulator which mimics the action of insect juvenile hormones and, if it is applied at the appropriate period of sensitivity, it causes death by preventing the transformation of larva to pupa. It is used against a variety of insects including fleas and mosquitoes. It is used in veterinary practice for the control of ectoparasites in the environment, rather than being applied to the animals themselves. It is also used in agriculture.

Preparations

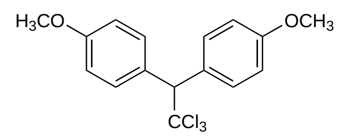
Proprietary Preparations (details are given in Part 3)

Multi-ingredient: ***Fr.:*** Aspipur.

Methoxychlor

Methoxy-DDT; Metoksychlor; Metoxicloro. 1,1,1-Trichloro-2-2-bis(*p*-methoxyphenyl)-ethane.

$C_{16}H_{15}Cl_3O_2$ = 345.6.
CAS — 72-43-5.



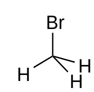
Profile

Methoxychlor is a chlorinated insecticide (p.2037) used in agriculture, horticulture, and veterinary practice.

Methyl Bromide

Metilo, bromuro de. Bromomethane; Monobromomethane.

CH_3Br = 94.94.
CAS — 74-83-9.



Adverse Effects, Treatment, and Precautions

Methyl bromide is a vesicant. Toxic effects after inhalation or percutaneous absorption are mainly due to neurotoxicity and include dizziness, headache, vomiting, blurred vision, weakness, ataxia, confusion, mania, hallucinations, mental depression, convulsions, pulmonary oedema, and coma. Renal and hepatic toxicity may also occur and death may be due to circulatory collapse or respiratory failure. Onset of symptoms may be preceded by a latent period. Concentrations of 1% or more are irritant to the eyes. Treatment is symptomatic although dimercaprol or acetylcysteine therapy has been tried.

Rubber absorbs and retains methyl bromide and should not therefore be used in protective clothing.

9. Geyer HL, *et al.* Methyl bromide intoxication causes reversible symmetric brainstem and cerebellar MRI lesions. *Neurology* 2005; **64:** 1279–81.

Uses

Methyl bromide has been used as an insecticidal fumigant for soil and some foodstuffs.

When supplied for fumigation it usually contains chloropicrin as a lachrymatory warning agent.

Methyl bromide has been used as a gaseous disinfectant; it has low antimicrobial activity but good penetrating power.

Methyl bromide was formerly used with carbon tetrachloride in some fire extinguishers. It has also been used as a refrigerant.

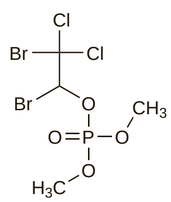
Naled

Bromchlophos. Dimethyl 1,2-dibromo-2,2-dichloroethyl phosphate.

$C_4H_7Br_2Cl_2O_4P$ = 380.8.

CAS — 300-76-5.



Profile

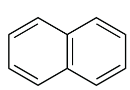
Naled is an organophosphorus insecticide used as a topical ectoparasiticide in veterinary practice.

Naphthalene

Naftalen; Naftaleno; Naphthalin.

$C_{10}H_8$ = 128.2.

CAS — 91-20-3.



Adverse Effects, Treatment, and Precautions

Ingestion of naphthalene can produce headache, nausea and vomiting, diarrhoea, profuse sweating, dysuria, coma, and convulsions. Less than one naphthalene mothball (200 to 500 mg) may cause haemolysis. Ingestion of 5 to 15 g is considered lethal for adults and a dose as low as 74 mg/kg has proved fatal. In children ingestion of 100 mg/kg is lethal. Doses as low as 2 g and 80 mg/kg ingested over 2 days have proved fatal in young children. Treatment is symptomatic; lavage may be considered if the patient presents within 1 hour of ingestion. The vapour is irritating to the eyes; chronic exposure has led to cataract formation. Haemolytic anaemia and haematuria leading to acute renal failure may occur particularly in persons with G6PD deficiency. Blood transfusions may be required.

Pregnancy. Haemolytic anaemia in a neonate has been attributed to inhalation of naphthalene by the mother during the twenty-eighth week of pregnancy.[1]

1. Athanasion M, *et al.* Hemolytic anemia in a female newborn infant whose mother inhaled naphthalene before delivery. *J Pediatr* 1997; **130:** 680–1.

Uses

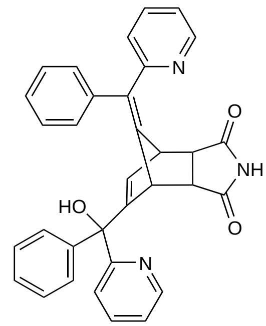
Naphthalene has been used in lavatory deodorant discs and in mothballs. It has also been used as a soil fumigant.

Norbormide

McN-1025; Norbormida. 5-[α-Hydroxy-α-(2-pyridyl)benzyl]-7-[α-(2-pyridyl)benzylidene]-8,9,10-trinorborn-5-ene-2,3-dicarboximide.

$C_{33}H_{25}N_3O_3$ = 511.6.

CAS — 991-42-4.



Profile

Norbormide is a selective rodenticide effective against most species of *rats*, in which it produces extreme irreversible peripheral vasoconstriction. It is not very toxic to other rodents.

Organophosphorus Insecticides

Insecticidas organofosforados; Organofosforlu İnsektisitler.

Description. The organophosphorus or organophosphate insecticides may be esters, amides, or thiol derivatives of phosphoric, phosphonic, phosphorothioic, or phosphonothioic acids.

◊ References.

1. WHO. Organophosphorus insecticides: a general introduction. *Environmental Health Criteria 63*. Geneva: WHO, 1986. Available at: http://www.inchem.org/documents/ehc/ehc/ehc63.htm (accessed 19/07/04)

Adverse Effects

Organophosphorus insecticides are potent cholinesterase inhibitors and can be very toxic. This inhibition results in both muscarinic and nicotinic effects with some central involvement.

Toxic effects may include abdominal cramps, nausea, vomiting, diarrhoea, pancreatitis, urinary incontinence, miosis or mydriasis, weakness, respiratory disturbances, lachrymation, increased salivation and sweating, bradycardia or tachycardia, hypotension or hypertension, cyanosis, muscular twitching, and convulsions. Some organophosphorus compounds cause delayed neuropathy. CNS symptoms include restlessness, anxiety, dizziness, confusion, coma, and depression of the respiratory or cardiovascular system. Patients may experience mental disturbances. Inhalation or external contact can cause local as well as systemic effects.

Repeated exposure may have a cumulative effect though the organophosphorus insecticides are, in contrast to the chlorinated insecticides, rapidly metabolised and excreted and are not appreciably stored in body tissues.

Treatment of Adverse Effects

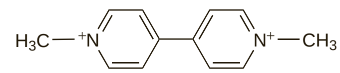
Rapid treatment for poisoning with organophosphorus insecticides is essential. Use of gastric lavage may be considered if a substantial amount has been ingested within 1 to 2 hours of presentation, unless the product is formulated in a hydrocarbon solvent (as there is a high risk of fatal aspiration pneumonia). Contaminated clothing should be removed and the skin, including any areas contaminated by vomiting or hypersecretion, should receive copious and prolonged washing with soap and water. Contamination of the eye is treated by washing of the conjunctiva. The patient should be treated with atropine (see Poisoning, p.1221) and either pralidoxime (p.1460) or obidoxime (p.1456) and symptomatic treatment should be instituted. Diazepam is sometimes given; it may be necessary to give it parenterally in moderate to severe poisoning to control muscle fasciculations and convulsions; oral dosage in mild poisoning may be helpful in relieving anxiety. The patient should be observed for signs of deterioration due to delayed absorption.

Paraquat

Parakuat. 1,1′-Dimethyl-4,4′-bipyridyldiylium ion.

$C_{12}H_{14}N_2$ = 186.3.

CAS — 4685-14-7.



Paraquat Dichloride

Paraquat, dicloruro de.

$C_{12}H_{14}Cl_2N_2$ = 257.2.

CAS — 1910-42-5.

Adverse Effects

Concentrated solutions of paraquat may cause irritation, inflammation, and possibly blistering of the skin, cracking and shedding of the nails, and delayed healing of cuts and wounds. It is not significantly absorbed from undamaged skin. A few fatalities have occurred after skin contact, but these appear to have been associated with prolonged contact and concentrated solutions.

Splashes in the eye cause severe inflammation, which may be delayed for 12 to 24 hours, corneal oedema, reduced visual acuity, and extensive superficial stripping of the corneal and conjunctival epithelium, which usually slowly heals. Inhalation of dust or spray may cause nasal bleeding.

Paraquat weedkillers available for use in domestic gardens contain 2.5% w/v paraquat, sometimes with other herbicides such as diquat. While this strength of paraquat can cause nausea and vomiting as well as some respiratory changes when ingested, it is not considered to be a lethal form.

Most of the cases of severe poisoning follow the ingestion or sometimes injection of the concentrated forms of paraquat herbicide (20% w/v), the distribution of which is restricted to agriculturalists and horticulturalists. Ingestion of, or dermal exposure to small amounts of concentrated paraquat may result in severe pulmonary fibrosis and death within 24 hours. A dose of 10 to 15 mL of the concentrate (20% w/v) is considered to be lethal. Most, but not all patients who ingest 20 to 40 mg of paraquat ion/kg (7.5 to 15 mL of the concentrate) die within 2 or 3 weeks after ingestion. Ingestion of doses of more than 40 mg of paraquat ion/kg (more than 15 mL of concentrate) usually results in death within 1 to 7 days after ingestion. The irritant effects of paraquat are reflected in oesophageal ulceration and gastrointestinal effects. There is widespread organ damage, most notably involving the kidneys and lungs. In such poisoning death is virtually certain and occurs rapidly.

Preparations of paraquat may contain an emetic or a laxative and some contain a malodorous agent to deter ingestion.

Treatment of Adverse Effects

After contact with paraquat, contaminated clothing should be removed and the skin washed with soap and water. The eyes, if splashed, should be irrigated; later topical therapy may involve the symptomatic use of antibacterials or corticosteroids.

There is no specific treatment for paraquat poisoning and the immediate aim is to remove or inactivate the paraquat. Although the benefit of gastric decontamination is uncertain, if the patient presents less than 6 hours after ingestion the initial management involves giving an oral adsorbent, preferably activated charcoal in a dose of 100 g and followed by 50 g every 2 hours for up to 6 hours post ingestion. Fuller's earth (often as a 15% suspension) and bentonite (as a 7% suspension) are alternative oral adsorbents and are given in similar doses to those of charcoal. When none of these adsorbents is available, a suspension of clay or of uncontaminated soil should be considered if medical attention is likely to be delayed. An osmotic laxative may be used with the first dose of the adsorbent in order to hasten bowel evacuation and prevent obstruction due to the adsorbent. Patients may require intensive supportive therapy, but oxygen should not be given initially as it appears to enhance the pulmonary toxicity of paraquat; however, it may be needed in later stages as part of palliative care.

Methods aimed at hastening elimination such as forced diuresis, peritoneal dialysis, haemodialysis, and haemoperfusion have been tried but the first three appear to be ineffective and results with the last method have varied; no method is of proven value.

◊ For some general references concerning the treatment of paraquat toxicity, see under Adverse Effects, above.

Once paraquat has been absorbed, moderate to severe poisoning may result in acute renal failure, hepatitis, and pulmonary fibrosis; death may occur after 2 to 3 weeks. Pulse therapy with cyclophosphamide and methylprednisolone might be of benefit in such patients but not in those with fulminant poisoning.[1,2]

Uses

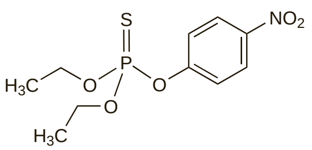
Paraquat is a contact herbicide widely used as the dichloride in agriculture and horticulture. Liquid concentrates are supplied in the UK only to approved users.

Parathion

Paratión. *O,O*-Diethyl *O*-4-nitrophenyl phosphorothioate.

$C_{10}H_{14}NO_5PS$ = 291.3.

CAS — 56-38-2.



Profile

Parathion is an organophosphorus insecticide (p.2047) that has been used in agriculture and horticulture. Its metabolite diethyl nitrophenyl phosphate (paraoxon, p.1883) contributes to its toxicity.

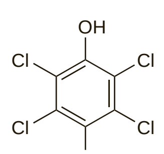
Pentachlorophenol

PCP; Penta; Pentaclorofenol.

C_6HCl_5O = 266.3.

CAS — 87-86-5.



NOTE. The name PCP has also been used as a synonym for phencyclidine hydrochloride.

Adverse Effects, Treatment, and Precautions

Pentachlorophenol may be absorbed in toxic amounts through the skin or by inhalation, as well as by ingestion. Pentachlorophenol and its aqueous solutions are irritant to the eyes, mucous membranes, and to the skin, and may produce caustic burns. The systemic effects are due to uncoupling of oxidative phosphorylation with consequent stimulation of cellular metabolism. Acute poisoning with pentachlorophenol increases metabolic rate, leading to raised temperature with copious sweating and thirst, restlessness, fatigue, increased rate and depth of respiration, and tachycardia. There may be abdominal pain and nausea, and death has occurred from respiratory failure. Symptoms of subacute or chronic poisoning include hyperpyrexia and CNS, haematological, renal, reproductive, respiratory, and skin disorders.

Treatment is symptomatic. Raised body temperature should be treated by physical means; the use of antipyretics is not recommended since they can increase toxicity.

6. Kentor PM. Urticaria from contact with pentachlorophenate. *JAMA* 1986; **256:** 3350.

Pharmacokinetics

Pentachlorophenol may be absorbed after ingestion or inhalation or through the skin. After ingestion, the majority of a dose is eliminated in the urine as unchanged pentachlorophenol and its glucuronide, with small amounts appearing in the faeces.

Uses

Pentachlorophenol has been used mainly as the sodium salt (C_6Cl_5NaO = 288.3), as a preservative for a wide range of industrial and agricultural products, including wood and other building materials, textiles, glues, and starch. It has also been used for the control of slime and algae, and as a molluscicide, fungicide, and herbicide.

Permethrin *(BAN, USAN, rINN)*

Perméthrine; Permethrinum; Permetriini; Permetrin; Permetrina; Permetryna. 3-Phenoxybenzyl (1*RS*,3*RS*)-(1*RS*,3*SR*)-3-(2,2-dichlorovinyl)-2,2-dimethylcyclopropanecarboxylate.

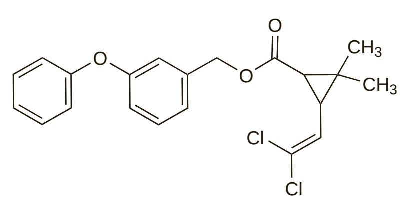
Перметрин

$C_{21}H_{20}Cl_2O_3$ = 391.3.

CAS — 52645-53-1.

ATC — P03AC04.

ATC Vet — QP53AC04.



Profile

Permethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049). It is used in the treatment of head pediculosis (p.2034) as a 1% application; there have been signs of resistance. It is also used as a 5% cream for pubic pediculosis and as an acaricide in the treatment of scabies (p.2035).

Permethrin is also used as a topical ectoparasiticide in veterinary practice and as an agricultural, horticultural, and household insecticide.

Permethrin is active against mosquitoes and is widely used for the impregnation of bednets and curtains in the control of malaria (p.594). It is also active against blackflies in the adult and larval stages and is used for the larvicidal treatment of rivers in the control of onchocerciasis (p.137). It is also active against tsetse flies.

Permethrin is suitable for aircraft disinsection.

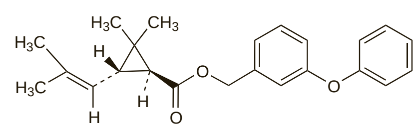
$C_{23}H_{26}O_3$ = 350.5.

CAS — 26002-80-2.

ATC — P03AC03.

ATC Vet — QP53AC03.



Profile

Phenothrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049). It is used for the treatment of head and pubic pediculosis (p.2034) as a 0.2% alcoholic or 0.5% aqueous lotion, or as a 0.5% alcoholic foam; as with permethrin there have been signs of resistance.

Phenothrin is also used in veterinary practice as a topical ectoparasiticide, as a household insecticide, and for the disinsection of public areas and aircraft.

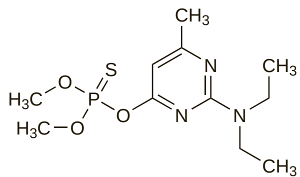
Metilpirimifós. *O*-2-Diethylamino-6-methylpyrimidin-4-yl *O,O*-dimethyl phosphorothioate.
$C_{11}H_{20}N_3O_3PS$ = 305.3.
CAS — 29232-93-7.



Profile

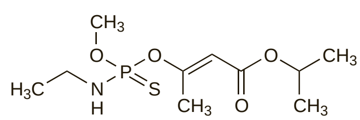
Pirimiphos-methyl is an organophosphorus insecticide (p.2047). It is used in agriculture and domestically.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Fr.:*** Anti-Ac†.

Propetamphos *(BAN)*

Propetamfós; Propetamfos. Isopropyl (*E*)-3-[(ethylamino)(methoxy)phosphinothio-oxy]but-2-enoate.
$C_{10}H_{20}NO_4PS$ = 281.3.
CAS — 31218-83-4.
ATC Vet — QP53AF09.

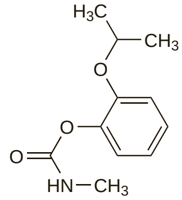


Profile

Propetamphos is an organophosphorus insecticide (p.2047) used as a topical ectoparasiticide in veterinary practice.

Propoxur *(BAN)*

2-Isopropoxyphenyl methylcarbamate.
$C_{11}H_{15}NO_3$ = 209.2.
CAS — 114-26-1.
ATC Vet — QP53AE02.



Profile

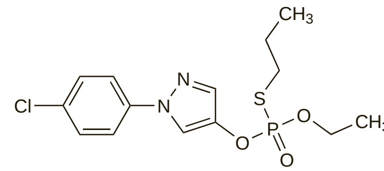
Propoxur is a carbamate insecticide (p.2037) used as a topical ectoparasiticide in veterinary practice. It is also used as a fumigant in agriculture.

Preparations

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: ***Ital.:*** Baygon.

Pyraclofos

Piraclofós. (*RS*)-[*O*-1-(4-Chlorophenyl)pyrazol-4-yl *O*-ethyl *S*-propyl phosphorothioate].
$C_{14}H_{18}ClN_2O_3PS$ = 360.8.
CAS — 77458-01-6.



Profile

Pyraclofos is an organophosphorus insecticide (p.2047) used for the larvicidal treatment of rivers in the control of onchocerciasis (p.137).

Pyrethrum Flower

Chrysanthème Insecticide; Dalmatian Insect Flowers; Flor del pelitre; Insect Flowers; Insektenblüten; Piretro; Pyrethri Flos.
CAS — 8003-34-7 (pyrethrum); 121-21-1 (pyrethrin I); 121-29-9 (pyrethrin II); 25402-06-6 (cinerin I); 121-20-0 (cinerin II).
ATC — P03AC01.
ATC Vet — QP53AC01.

	R^1	R^2
Pyrethrin-I	CH_3	$CH{=}CH_2$
Pyrethrin-II	$COOCH_3$	$CH{=}CH_2$
Cinerin-I	CH_3	CH_3
Cinerin-II	$COOCH_3$	CH_3

Pharmacopoeias. In *BP(Vet)*, which also includes the extract. *US* includes only the extract.
BP(Vet) 2008 (Pyrethrum Flower). The dried flowerheads of *Chrysanthemum cinerariaefolium* containing not less than 1% of pyrethrins of which not less than one-half consists of pyrethrin I. It has a faint but characteristic odour.
BP(Vet) 2008 (Pyrethrum Extract). An extract prepared from Pyrethrum Flower. It contains 24.5 to 25.5% of pyrethrins, of which not less than half consists of pyrethrin I. A dark olive green or brown viscous liquid or, if decolourised, a pale amber liquid. Store in a well-filled container. Protect from light. It should be thoroughly stirred before use.
USP 31 (Pyrethrum Extract). A mixture of three naturally occurring, closely related insecticidal esters of chrysanthemic acid (pyrethrins I: jasmolin I, cinerin I, and pyrethrin I) and three closely related esters of pyrethric acid (pyrethrins II: jasmolin II, cinerin II, and pyrethrin II). The ratio of pyrethrins I to pyrethrins II is not less than 0.8 and not more than 2.8. It may contain pigments characteristic of chrysanthemum species, triglyceride oils, terpenoids, and carotenoid. It may also contain suitable solvents and antioxidants. It contains no other added substances. It is a pale yellow liquid having a bland, flowery odour. Insoluble in water; soluble in liquid paraffin and in most organic solvents. Store in airtight containers. Protect from light.

Adverse Effects and Precautions

Pyrethrum is irritant to the eyes and mucosa. Hypersensitivity reactions have been reported.

◊ References to the potential for toxicity of pyrethrin and pyrethroid insecticides.

4. Proudfoot AT. Poisoning due to pyrethrins. *Toxicol Rev* 2005; **24:** 107–13.
5. Ray DE, Fry JR. A reassessment of the neurotoxicity of pyrethroid insecticides. *Pharmacol Ther* 2006; **111:** 174–93.

Uses

Pyrethrum flower is mainly used for the preparation of pyrethrum extracts containing a mixture of chrysanthemic acid and pyrethric acid esters (pyrethrins I and II).

Pyrethrins in the form of pyrethrum extract have a long history of use as insecticides. Pyrethrum is rapidly toxic to many insects. It has a much quicker knock-down effect than clofenotane or lindane, but it is less persistent and less stable. Its action can be enhanced by certain substances such as piperonyl butoxide (p.2049), and pyrethrins with piperonyl butoxide are used clinically in the treatment of pediculosis (p.2034).

Pyrethroid insecticides (synthetic analogues of pyrethrins), such as permethrin and phenothrin, are also used clinically; deltamethrin and permethrin are among those used for the vector control of malaria.

Pyrethrum, pyrethrins, and pyrethroids are also used as topical ectoparasiticides in veterinary practice and as agricultural, horticultural, and household insecticides.

Preparations

Proprietary Preparations (details are given in Part 3)

Ital.: Pearsol; SH3.

Multi-ingredient: *Arg.:* Quitoso†; ***Austral.:*** Banlice; ***Canad.:*** Licetrol†; Pronto; R & C; ***Fr.:*** Spray-Pax; ***Ger.:*** Goldgeist; ***Israel:*** A-200†; Kin Soff; ***Ital.:*** Milice; Sinezan; ***Port.:*** Para-Pio†; ***Rus.:*** Bubil (Бубил); Spray-Pax (Спрей-пакс); ***Turk.:*** Kwell-P; ***UK:*** Fortefog; Prevent; ***USA:*** Blue; Licide; Pronto; Pyrinyl II; Pyrinyl Plus; RID; Tisit.

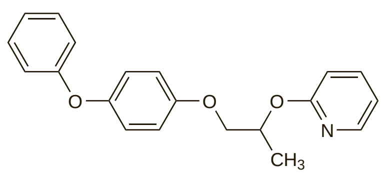
Pyriproxyfen

Piriproxifeno; Pyriproksifeeni; Pyriproxifen; Pyriproxifène; Pyriproxifenum; Pyriproxyfenum; S-9318; S-31183. 2-[1-Methyl-2-(4-phenoxyphenoxy)ethoxy]pyridine.

$C_{20}H_{19}NO_3$ = 321.4.

CAS — 95737-68-1.

ATC Vet — QP53AX23.



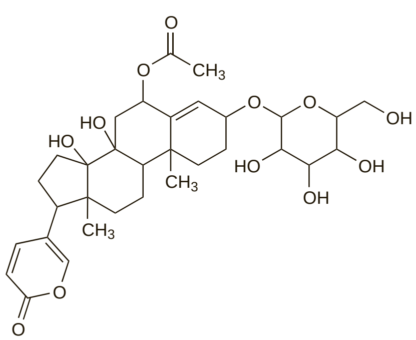
Profile

Pyriproxyfen is used as a topical ectoparasiticide in veterinary practice.

Red Squill

Esquila.

CAS — 507-60-8 (scilliroside).



(scilliroside)

Profile

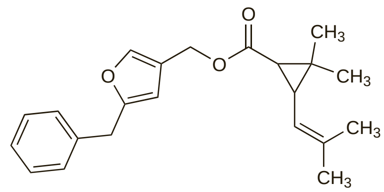
Red squill is a red variety of *Urginea maritima*, which contains, in addition to cardiac glycosides, an active principle, scilliroside. It is very toxic to *rats* and has been incorporated in rat poisons; it has neurotoxic and cardiotoxic properties.

Resmethrin

Resmetrina. 5-Benzyl-3-furylmethyl (1*RS*,3*RS*)-(1*RS*,3*SR*)-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylate.

$C_{22}H_{26}O_3$ = 338.4.

CAS — 10453-86-8.



Profile

Resmethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in veterinary practice for the control of ectoparasites in the environment. Resmethrin is also used as an agricultural, horticultural, and household insecticide, but is not synergised by pyrethrum synergists such as piperonyl butoxide (p.2049).

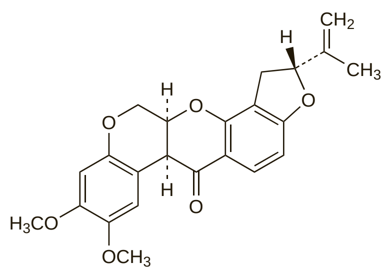
Rotenone

Rotenona; Rotenonum. (2*R*,6a*S*,12a*S*)-1,2,6,6a,12,12a-Hexahydro-2-isopropenyl-8,9-dimethoxychromeno[3,4-*b*]furo[2,3-*h*]-chromen-6-one.

$C_{23}H_{22}O_6$ = 394.4.

CAS — 83-79-4.



Profile

Rotenone is a non-systemic insecticide used in agriculture and in horticulture.

Rotenone is the active ingredient of derris (the dried rhizome and roots of *Derris elliptica*; also known as tuba root or aker-tuba) and of lonchocarpus (the dried root of *Lonchocarpus utilis*; also known as cube root, timbo, or barbusco). Powdered forms of derris and of lonchocarpus have been used as insecticides and fish poisons.

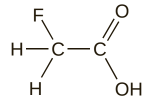
Sodium Fluoroacetate

Compound 1080; Fluoroacetato sódico; Sodium Monofluoroacetate.

$FCH_2.CO_2Na$ = 100.0.

CAS — 62-74-8.



(fluoroacetic acid)

Adverse Effects, Treatment, and Precautions

Sodium fluoroacetate is highly toxic, the lethal dose if ingested being about 1 to 5 mg/kg. Toxic effects may be delayed for several hours after absorption by mouth or inhalation, and include nausea and vomiting, apprehension, muscle twitching, cardiac irregularities, convulsions, respiratory failure, coma, and death usually due to ventricular fibrillation.

Treatment is generally supportive and symptomatic.

4. Proudfoot AT, *et al*. Sodium fluoroacetate poisoning. *Toxicol Rev* 2006; **25:** 213–19.

Uses

Sodium fluoroacetate is a highly effective rodenticide but must be used with great caution because of its toxicity to other animals and to man.

Sulfiram *(BAN, rINN)*

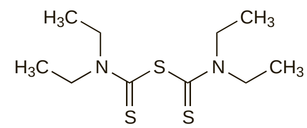
Monosulfiram; Sulfiramum. Tetraethylthiuram monosulphide.

Сульфирам

$C_{10}H_{20}N_2S_3$ = 264.5.

CAS — 95-05-6.

ATC Vet — QS02QA02.



Adverse Effects and Precautions

An erythematous rash has occasionally been reported. Sulfiram produces effects similar to those of disulfiram (p.2296) if ingested with alcohol. As there may be a risk of absorption after application of sulfiram to the whole body, patients are advised to abstain from alcohol for at least 48 hours.

◊ The reactions to alcohol occasionally reported in patients who have applied sulfiram solution[1,2] resemble those seen with disulfiram. Analysis has shown that sulfiram solutions exposed to room light undergo photochemical conversion to disulfiram, and that the concentration of disulfiram, and the ability of the solution to inhibit aldehyde dehydrogenase and hence the metabolism of alcohol, increases with the duration of such storage.[3,4] Whether patients who have applied sulfiram solution should avoid direct light immediately afterwards has not been elucidated.[4]

4. Lipsky JJ, *et al*. Monosulfiram, disulfiram, and light. *Lancet* 1994; **343:** 304.

Uses and Administration

Sulfiram is a pesticide that has been used as an acaricide, either alone or with benzyl benzoate, in the treatment of scabies (p.2035), although other treatments are now preferred.

Sulfiram has also been used as a pesticide in veterinary practice.

Preparations

Proprietary Preparations (details are given in Part 3)

Braz.: Sarfiram; Sulfitrat†; Tetmosol; Valfiran; ***India:*** Tetmosol; ***Mex.:*** Tetmosol†; ***Port.:*** Thiosan†; ***S.Afr.:*** Tetmosol; ***Singapore:*** Tetmosol†.

Multi-ingredient: *Fr.:* Ascabiol.

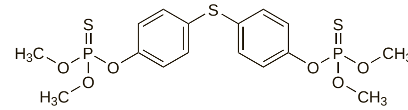
Temefos *(USAN, rINN)*

27165; Téméfos; Temefós; Temefosum; Temephos. *O,O′*-(Thiodi-*p*-phenylene) *O,O,O′,O′*-tetramethyl bis(phosphorothioate).

Темефос

$C_{16}H_{20}O_6P_2S_3$ = 466.5.

CAS — 3383-96-8.



Profile

Temefos is an organophosphorus insecticide (p.2047). It is effective against the larvae of mosquitoes, blackflies, and other insects, and is used for the larvicidal treatment of rivers in the control of onchocerciasis (p.137). It is also effective against the crustacean host to the larvae of the guinea worm and is used in the control of dracunculiasis (p.136); treatment of drinking water is both effective and acceptable.

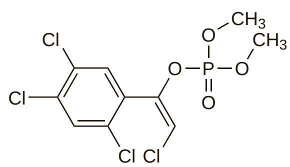
Tetrachlorvinphos

ENT-25841; SD-8447; Tetrachlorowinfos; Tetraclorvinfós. 2-Chloro-1-(2,4,5-trichlorophenyl)vinyl dimethyl phosphate.

$C_{10}H_9Cl_4O_4P$ = 366.0.

CAS — 961-11-5; 22248-79-9 (Z-tetrachlorvinphos); 22350-76-1 (E-tetrachlorvinphos).

ATC Vet — QP53AF14.



Profile

Tetrachlorvinphos is an organophosphorus insecticide (p.2047) used as an ectoparasiticide in veterinary practice.

Tetramethrin *(rINN)*

Tétraméthrine; Tetramethrinum; Tetrametrina. Cyclohex-1-ene-1,2-dicarboximidomethyl (1*RS*,3*RS*)-(1*RS*,3*SR*)-2,2-dimethyl-3-(2-methylprop-1-enyl)cyclopropanecarboxylate.

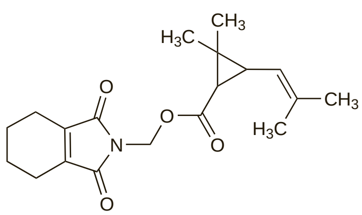
Тетраметрин

$C_{19}H_{25}NO_4$ = 331.4.

CAS — 7696-12-0.

ATC — P03BA04.

ATC Vet — QP53AC13.



Profile

Tetramethrin is a pyrethroid insecticide (see Pyrethrum Flower, p.2049) used in the treatment of pediculosis (p.2034). It is also used in veterinary practice for the control of ectoparasites in the environment and as a household insecticide.

◊ References.

Preparations

Proprietary Preparations (details are given in Part 3)

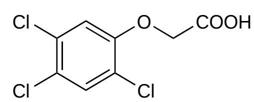
Multi-ingredient: ***Fr.:*** Aspipur; ***Gr.:*** Cif Candioli; Runde; ***Ital.:*** Baygon; Mom Piretro Emulsione†; Mom Shampoo Antiparassitario; Neo Mom; ***Rus.:*** Pedilin Ko (Педилин Ко).

Trichlorophenoxyacetic Acid

2,4,5-T; Triclorofenoxiacético, ácido. 2,4,5-Trichlorophenoxyacetic acid.

$C_8H_5Cl_3O_3$ = 255.5.

CAS — 35915-18-5.



Profile

Trichlorophenoxyacetic acid is a selective herbicide with similar actions to dichlorophenoxyacetic acid (p.2040). It is usually used in ester formulations. It was used with dichlorophenoxyacetic acid as a defoliating agent in the Vietnam war.

Toxicity. The phenoxy herbicides were used for defoliation in Vietnam as Agent Orange, which consisted of a mixture of dichlorophenoxyacetic acid, trichlorophenoxyacetic acid, and the impurity TCDD (dioxin), and concern has been expressed that they may have contributed to an increased incidence of cancer among exposed subjects as well as an adverse effect on the offspring of those subjects. This has been a matter of considerable debate,[1] prompting a series of biennial reassessments of the health effects of Agent Orange by the US National Academy of Sciences' Institute of Medicine.[2] To date the Institute has concluded[3] that there is evidence of increased incidence of chronic lymphocytic leukaemia, soft tissue sarcoma, Hodgkin's disease, non-Hodgkin's lymphoma, and chloracne, with phenoxy herbicides.

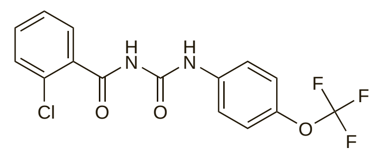
Triflumuron

Triflumurón; Trifluron. 2-Chloro-*N*-([{4-(trifluoromethoxy)phenyl}amino]carbonyl)benzamide.

$C_{15}H_{10}ClF_3N_2O_3$ = 358.7.

CAS — 64628-44-0.



Profile

Triflumuron is an insecticide used in agriculture and as a topical ectoparasiticide in veterinary practice.

Preparations

Proprietary Preparations (details are given in Part 3)

Ital.: Baycidal†.

Radiopharmaceuticals

Radioactive compounds are used in medicine as sources of radiation for radiotherapy and for diagnostic purposes. They have numerous uses in research and industry.

Sealed radioactive sources are bonded or encapsulated to prevent the escape of the radioactive material and are used as supplied. Unsealed sources, on the other hand, are radioactive materials usually in liquid, particulate, or gaseous form that are removed from their containers for application. Radiopharmaceuticals come within this category.

The aim of this chapter is to provide background information on the radionuclides that are used as radiopharmaceuticals. Care is required in the preparation, handling, use, and disposal of these compounds; they are thus best dealt with by those with suitable experience and training.

Atomic Structure

An atom may be viewed as a central positively charged nucleus around which negatively charged electrons revolve in orbits. The electrons are arranged round the atomic nucleus in a series of 'shells' in each of which is a limited number of orbits.

The nucleus consists of 2 main kinds of particles known as protons, each of unit positive charge, and neutrons, which are uncharged; the total number of these particles in the nucleus is known as the *mass number.*

Each electron carries a negative charge which is of the same size as the positive charge of the proton, so that in the neutral atom the number of electrons is equal to the number of protons in the nucleus.

The number of protons in the nucleus is known as the *atomic number*, and this determines the number of electrons in the extranuclear structure. All the atoms of a particular chemical element have the same atomic number, but while the number of protons is constant, the number of neutrons in the atoms, and thus their masses (mass numbers), may vary. These different forms of the same element are known as isotopes of the element and these isotopes differ in some of their physical properties.

Some isotopes may be stable, the differences between them arising solely from their difference in mass; others may be radioactive (*radioisotopes*), their nuclei changing spontaneously and emitting particles or electromagnetic waves, or both.

Most of the naturally occurring isotopes are stable, though there are a number which are unstable and therefore radioactive, for example, uranium-235. In addition, artificial radionuclides are prepared by converting stable nuclei into unstable forms or naturally occurring radionuclides may be prepared by artificial means.

The symbol used for a nuclide is a development of the chemical symbol for the atom, with the mass number as a superscript and the atomic number as a subscript; thus the symbols for the 3 hydrogen isotopes—common hydrogen, deuterium, and tritium—are ${}^{1}_{1}H$, ${}^{2}_{1}H$, and ${}^{3}_{1}H$, and the symbols for the 3 naturally occurring uranium isotopes are ${}^{234}_{92}U$, ${}^{235}_{92}U$, and ${}^{238}_{92}U$; as the atomic number can be inferred from the chemical symbol it is the usual practice to omit the subscript. It is also common practice to write out the full name of the element followed by the mass number, e.g. chromium-51 for ${}^{51}Cr$.

Emissions from Radioisotopes

The 3 main types of emission from radioactive substances are *alpha particles, beta particles,* and *gamma-rays.* Most sources emit more than one type of radiation.

Alpha particles are positively charged particles (helium nuclei), each consisting of 2 protons and 2 neutrons.

Beta particles (β^- or β^+) are identical to electrons or positrons but arise from the nucleus. They are emitted with great velocity and their energies are spread over a spectrum. Positrons are similar to electrons, having a similar mass but a positive charge.

Gamma-rays are electromagnetic radiations or *photons* with wavelengths much shorter than those of light.

In certain cases, e.g. chromium-51, *electron capture* (EC) occurs, an electron from an inner shell being absorbed by the nucleus with the production of an *X-ray* characteristic of the daughter atom or emission of an *Auger electron.*

The type of emission from a radionuclide largely determines its usefulness in medicine. Those emitting alpha particles are very little used partly because detection and measurement are difficult. Positron-emitters, such as carbon-11, fluorine-18, nitrogen-13, and oxygen-15, have become more popular in recent years and are used in positron-emission tomography (PET) where the radiation is measured from within the body, as opposed to computed tomography (CT) where the energy is supplied from an external source. Single photon emission tomography (SPECT) is another technique like positron-emission tomography that provides views of slices through the body and this technique uses gamma-ray emitting radionuclides which are the most accessible and the most common radiation source in radiopharmaceuticals.

Decay of Radionuclides

A radionuclide will consist of atoms in several forms, including: unstable atoms, which will at some time undergo an energy change with the emission of ionising radiation; those that are actually undergoing this change; and those that have undergone the change. In quantitative terms this transition occurs at a rate that is characteristic of the radionuclide and it is expressed as its half-life—the time required for the activity to fall by one-half. Many radionuclides have complex decay characteristics with several possible energies of emitted particles and radiation. Some radionuclides may be in an excited or metastable state denoted by the suffix m attached to the mass number (e.g. technetium-99m) and undergo *isomeric transition* (IT) with the release of gamma-rays.

The activity of radionuclides is measured in terms of the rate of transformation or disintegration. The unit is the becquerel (Bq) = 1 transformation/second; the curie (Ci) was formerly used as the unit of activity; $1\ Ci = 3.7 \times 10^{10}\ Bq$.

Supply, Preparation, and Control

A wide range of radionuclides and specially formulated radiopharmaceuticals is available from specialised manufacturers. However, there are national controls on the use, transport, storage, and disposal of such compounds. Authority and guidance should be sought from the relevant bodies and authorities before using such compounds.

Generators are special features in the supply of radionuclides. They are receptacles containing a parent and daughter nuclide in equilibrium and from which the daughter nuclide, which usually has a short half-life, may be eluted. Generators are available for the production of indium-113m, krypton-81m, and technetium-99m. Generators are also available for some positron-emitters.

Storage conditions for radiopharmaceuticals should be such as to prevent the inadvertent emission of radioactivity as well as to meet the storage requirements for the pharmaceutical that has been labelled. Thus due account still has to be paid, for instance, to the effects of temperature and light. Radiopharmaceuticals are liable to decomposition by self-irradiation effects which may cause degradation of solvent, preservative, or other compounds. There can also be a continuous formation of oxidising and reducing chemical species arising from the effect of the radioactivity on any chemical substances present in the radiopharmaceutical, even in minute amounts.

Adverse Effects

The internal irradiation of tissues after the use of radionuclides carries similar dangers to exposure to ionising radiation from an external source, and locally high radiation doses may arise if these nuclides are concentrated in a tissue. The most serious danger is genetic damage prior to and during the reproductive period. Tissues whose cells are in a continuous state of multiplication are particularly sensitive to the effects of radiation.

Untoward effects of exposure to the larger doses of irradiation include leucopenia, anaemia, inflammation of the skin, radiation sickness, and neoplasms.

In considering the effect of a given radionuclide it is usual to calculate the dose to the organ most critically affected, and also the dose to the whole body.

In considering the adverse effects of radiopharmaceuticals one should not forget the effects that might arise from the carrier or from contaminants.

General Uses

Radiopharmaceuticals are used widely in many branches of medicine and surgery, mainly for the diagnosis and sometimes for the treatment of disease. They can provide information not available using other diagnostic techniques such as contrast media, ultrasound, and computed tomography or other external irradiation. Highly specific information may be derived using monoclonal antibodies tagged with radionuclides.

Many investigations involve oral or parenteral doses of radionuclides or labelled compounds followed usually by an imaging procedure. Some investigations involve the measurement of radioactive concentrations in organs, tissues, blood, urine, or faeces. The quantities used are always the smallest that will give the desired accuracy of image or of measurement.

Radiological Terms

- Alpha particles–nuclei of helium atoms emitted by radioactive atomic nuclei
- annihilation–the interaction and disappearance of a positive and a negative electron with the conversion of their energy into electromagnetic radiation
- atomic number (Z)–the number of protons in the atomic nucleus
- Auger effect–the emission of an electron from an atom due to the filling of a vacancy in an inner electron shell
- becquerel (Bq)–the SI unit of activity, defined as 1 transformation/second. The curie was formerly used as the unit of activity. $1\ Bq = 2.7 \times 10^{-11}\ Ci$
- beta particles–electrons or positrons emitted by radioactive atomic nuclei
- carrier-free–a preparation in which substantially all the atoms of the activated element present are radioactive. Material of high specific activity is often loosely referred to as 'carrier-free'
- curie (Ci)–now superseded as a unit of activity by the becquerel. A curie (Ci) represented 3.7×10^{10} transformations/second. $1\ Ci = 3.7 \times 10^{10}\ Bq$
- daughter–of a given nuclide, any nuclide that originates from it by radioactive decay

- electron capture (EC)–a mode of radioactivity decay involving the capture of an orbital electron by its nucleus
- gamma-radiation–electromagnetic radiation emitted in the process of a change in configuration of a nucleus or particle annihilation and having wavelengths shorter than those of X-rays
- gray (Gy)–the SI unit of absorbed dose, defined as 1 J/kg. The rad was formerly used as the unit of absorbed dose. 1 Gy = 100 rads
- isomeric transition (IT)–the decay of one isomer to another having a lower energy state. The transition is accompanied by the emission of gamma-radiation
- isomers–nuclides with the same mass number and atomic number but with nuclei having different energy states
- isotopes–nuclides with the same atomic number but different mass numbers
- nuclide–a species of atom having a specific mass number, atomic number, and nuclear energy state
- photon–a quantum of electromagnetic radiation
- positron–a positive beta particle
- rad (radiation absorbed dose)–now superseded as a unit of absorbed dose by the gray. A rad is equal to 10^{-2} J/kg. The röntgen and the rad in soft tissue are approximately equivalent in magnitude for moderate energies. 1 rad = 10^{-2} Gy
- radioactive decay–the spontaneous change of a nucleus resulting in the emission of a particle or a photon
- radioactivity–the property of certain nuclides of spontaneously emitting particles or photons or of undergoing spontaneous fission
- radioisotope–an isotope that is radioactive
- radionuclide–a nuclide that is radioactive
- rem (röntgen-equivalent-man)–now superseded as a unit of dose equivalent by the sievert (Sv). A rem is numerically equal to the absorbed dose in rads multiplied by the appropriate quality factor defining the biological effect and by any other modifying factors. The sievert is the joule/kg (J kg^{-1}) equal to 100 rem
- röntgen (R)–a unit of exposure of X- or gamma-radiation, equal to 2.58×10^{-4} coulombs/kg in air; superseded by the SI unit of exposure, the coulomb/kg (C kg^{-1}). 1 C kg^{-1} = 3.876×10^3 R
- sievert (Sv)–the SI unit of dose equivalent numerically equal to the absorbed dose in grays multiplied by the appropriate quality factor defining the biological effect and by any other modifying factors expressed in J/kg
- specific activity–the activity per unit mass of a material containing a radioactive substance
- X-rays–electromagnetic radiation other than annihilation radiation originating in the extranuclear part of the atom and having wavelengths much shorter than those of visible light

Carbon-11

Carbono 11.

CAS — 14333-33-6.

HALF-LIFE. 20.4 minutes.

Profile

Carbon-11 is a positron-emitter that is used in positron-emission tomography (see Emissions from Radioisotopes, p.2052). Compounds that have been labelled with carbon-11 include L-methionine for the detection of malignant neoplasms, acetic and palmitic acids for the study of myocardial metabolism, raclopride and mespiperone for the study of CNS dopaminergic D_2 receptors, and flumazenil for the study of GABA receptors. Labelled carbon monoxide may be used to assess blood volume.

Preparations

Ph. Eur.: -Methionine ((C)Methyl) Injection; Flumazenil (N-(C)Methyl) Injection; Raclopride ((C)Methoxy) Injection; Sodium Acetate ((1- C)) Injection;
USP 31: Carbon Monoxide C 11; Flumazenil C 11 Injection; Mespiperone C 11 Injection; Methionine C 11 Injection; Raclopride C 11 Injection; Sodium Acetate C 11 Injection.

Carbon-14

Carbono 14.

CAS — 14762-75-5.

HALF-LIFE. 5730 years.

Profile

Carbon-14 has been used to label many organic compounds that may be employed in breath tests.

Urea (p.1620) labelled with carbon-14 is used in a breath test to detect *Helicobacter pylori* as an aid in the diagnosis of peptic ulcer disease (p.1702).

Preparations

USP 31: Urea C 14 Capsules.

Proprietary Preparations (details are given in Part 3)
Cz.: HeliCap; ***Neth.:*** HeliCap; ***Port.:*** HeliCap; ***USA:*** Pytest.

Chromium-51

Cromo 51.

CAS — 14392-02-0.
ATC — V09CX04 (chromium edetate (^{51}Cr)).
ATC Vet — QV09CX04 (chromium edetate (^{51}Cr)); QV09GX03 (chromate labelled cells (^{51}Cr)).

HALF-LIFE. 27.7 days.

Profile

Chromium-51, as sodium chromate (^{51}Cr), is used to label red blood cells so that red cell survival and red cell volume can be measured. Chromium-51 activity in the faeces can be used to estimate gastrointestinal blood losses. Red blood cells labelled with chromium-51 and damaged by heat before re-injection have been used for spleen scanning.

As chromium edetate (^{51}Cr) given intravenously, chromium-51 is used in the determination of the glomerular filtration rate.

As chromic chloride (^{51}Cr), chromium-51 has been given intravenously for the determination of loss of serum protein into the gastrointestinal tract.

Preparations

Ph. Eur.: Chromium(Cr) Edetate Injection; Sodium Chromate(Cr) Sterile Solution;
USP 31: Chromium Cr 51 Edetate Injection; Sodium Chromate Cr 51 Injection.

Cobalt-57

Cobalto 57.

CAS — 13981-50-5.
ATC — V09XX01 (cobalt cyanocobalamin (^{57}Co)).
ATC Vet — QV09XX01 (cobalt cyanocobalamin (^{57}Co)).

HALF-LIFE. 271 days.

Profile

Cobalt-57, in the form of an aqueous solution or capsules of cyanocobalamin (^{57}Co), is given orally for the measurement of absorption of vitamin B_{12} in the diagnosis of pernicious anaemia and other malabsorption syndromes. It is also used with cyanocobalamin (^{58}Co), see below.

Preparations

Ph. Eur.: Cyanocobalamin(Co) Capsules; Cyanocobalamin(Co) Solution;
USP 31: Cyanocobalamin Co 57 Capsules; Cyanocobalamin Co 57 Oral Solution.

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: *Cz.:* Dicopac†; ***UK:*** Dicopac.

Cobalt-58

Cobalto 58.

CAS — 13981-38-9.
ATC — V09XX02 (cobalt cyanocobalamin (^{58}Co)).
ATC Vet — QV09XX02 (cobalt cyanocobalamin (^{58}Co)).

HALF-LIFE. 70.8 days.

Profile

Cobalt-58, in the form of an aqueous solution or capsules of cyanocobalamin (^{58}Co), is given orally for the measurement of absorption of vitamin B_{12} in the diagnosis of pernicious anaemia and other malabsorption syndromes.

The different emissions of cobalt-57 and cobalt-58 allow the isotopes to be distinguished. This can be used to differentiate between failure of absorption due to lack of intrinsic factor (pernicious anaemia) and that due to ileal malabsorption, by giving both free cyanocobalamin (^{58}Co) and cyanocobalamin (^{57}Co) bound to intrinsic factor. A dual isotope kit has been used for this purpose.

Preparations

Ph. Eur.: Cyanocobalamin(Co) Capsules; Cyanocobalamin(Co) Solution;
USP 31: Cyanocobalamin Co 58 Capsules.

Proprietary Preparations (details are given in Part 3)
Multi-ingredient: *Cz.:* Dicopac†; ***UK:*** Dicopac.

Erbium-169

CAS — 15840-13-8.
ATC — V10AX04 (erbium citrate colloid (^{169}Er)).
ATC Vet — QV10AX04 (erbium citrate colloid (^{169}Er)).

HALF-LIFE. 9.4 days.

Profile

Erbium-169 is a radionuclide that has been used in the treatment of arthritic conditions particularly of the small joints.

Preparations

Proprietary Preparations (details are given in Part 3)
Cz.: Ermm-1.

Fluorine-18

Flúor 18.

CAS — 13981-56-1.
ATC — V09IX04 (fludeoxyglucose (^{18}F)).
ATC Vet — QV09IX04 (fludeoxyglucose (^{18}F)).

HALF-LIFE. 110 minutes.

Profile

Fluorine-18 is a positron-emitting radionuclide that is used in positron-emission tomography (see Emissions from Radioisotopes, p.2052).

Fludeoxyglucose (^{18}F) (2-deoxy-2-fluoro-^{18}F-α-D-glucopyranose; ^{18}F-fluorodeoxyglucose) is given by intravenous injection for the assessment of cerebral and myocardial glucose metabolism in various physiological or pathological states including stroke and myocardial ischaemia. It is also used for the detection of malignant tumours including those of the brain, liver, lung, and thyroid gland. Fluorodopa (^{18}F) is also used in cerebral imaging. Sodium fluoride (^{18}F) is used in bone scanning.

Preparations

Ph. Eur.: Fludeoxyglucose (F) Injection; Sodium Fluoride (F) Injection;
USP 31: Fludeoxyglucose F 18 Injection; Fluorodopa F 18 Injection; Sodium Fluoride F 18 Injection.

Proprietary Preparations (details are given in Part 3)
Austria: 18F-FDG; Efdege; Flucis; ***Cz.:*** Efdege; FDG Scan; ***Hung.:*** Pozitron-Scan-FDG; ***Neth.:*** Efdege; Flucis; Glucotrace; ***Port.:*** Contracer; Flucis; Steripet; ***Spain:*** Farna FDG; FDG Scan; Fluodos; Fluorscan; Fluotracer.

Gallium-67

Galio 67.

CAS — 14119-09-6.
ATC — V09HX01 (gallium citrate (^{67}Ga)).
ATC Vet — QV09HX01 (gallium citrate (^{67}Ga)).

HALF-LIFE. 3.26 days.

Profile

Gallium-67 is used in the form of an intravenous injection of gallium citrate (^{67}Ga).

Gallium citrate (^{67}Ga) is concentrated in some malignant tumours of the lymphatic system, as well as in some other tissues, and is used for tumour visualisation. Concentration also occurs in inflammatory lesions and the injection is therefore used for the localisation of focal inflammatory sites, such as may occur in abscesses, osteomyelitis, or sarcoidosis. Gallium scans have proved useful for the detection of the various infections and malignancies that may be encountered in patients with AIDS.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to gallium-67 since radioactivity has been reported to be present in breast milk for 2 weeks.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 01/07/04)

Preparations

Ph. Eur.: Gallium(Ga) Citrate Injection;
USP 31: Gallium Citrate Ga 67 Injection.

Gold-198

Oro 198.

CAS — 10043-49-9.
ATC — V10AX06 (colloidal gold (^{198}Au)).
ATC Vet — QV10AX06 (colloidal gold (^{198}Au)).

HALF-LIFE. 65 hours (2.7 days).

Profile

Gold-198, as colloidal gold (^{198}Au) with most of the activity associated with particles of diameter 5 to 20 nm, has been used by intrapleural or intraperitoneal injection in the treatment of malignant ascites and malignant pleural effusion, and by intravenous injection for the measurement of liver blood flow, in liver scanning, and for general investigations of the reticuloendothelial system. Since the gamma-ray energies are not particularly good for scanning and the radiation dose to the patient is relatively high, it has generally been superseded by more suitable agents such as technetium-99m-labelled compounds.

Indium-111

Indio 111.

CAS — 15750-15-9.

ATC — V09AX01 (indium pentetate (^{111}In)); V09GX02 (indium imciromab (^{111}In)); V09HB01 (indium oxinate labelled cells (^{111}In)); V09HB02 (indium tropolonate labelled cells (^{111}In)); V09IB01 (indium pentetreotide (^{111}In)); V09IB02 (indium satumomab pendetide (^{111}In)); V09IB03 (indium antiovariumcarcinoma antibody (^{111}In)); V09IB04 (indium capromab pendetide (^{111}In)).

ATC Vet — QV09AX01 (indium pentetate (^{111}In)); QV09GX02 (indium imciromab (^{111}In)); QV09HB01 (indium oxinate labelled cells (^{111}In)); QV09HB02 (indium tropolonate labelled cells (^{111}In)); QV09IB01 (indium pentetreotide (^{111}In)); QV09IB02 (indium satumomab pendetide (^{111}In)); QV09IB03 (indium antiovariumcarcinoma antibody (^{111}In)); QV09IB04 (indium capromab pendetide (^{111}In)).

HALF-LIFE. 67 hours (2.8 days).

Profile

Indium-111 as indium (^{111}In) complexed with pentetic acid (pentetate) is used diagnostically in CSF studies.

Leucocytes labelled with indium (^{111}In) hydroxyquinoline are used for the location of inflammatory lesions; applications have been the detection or localisation of abscesses, infections (including those occurring in patients with AIDS), inflammatory bowel diseases such as Crohn's disease or ulcerative colitis, and transplant rejection. Platelets have been similarly labelled and used for the detection of thrombi and for the investigation of thrombocytopenia. Labelled erythrocytes have been used to investigate gastrointestinal haemorrhage.

Colloids have been prepared using indium chloride (^{111}In) and have been used for investigation of the lymphatic system. Indium (^{111}In) bleomycin has been given by intravenous injection for the detection of tumours. Indium (^{111}In) pentetreotide is used for the detection and localisation of tumours originating from neuroendocrine cells.

Several different monoclonal antibodies, such as altumomab pentetate, capromab pendetide, ibritumomab tiuxetan, imciromab pentetate, and satumomab pendetide, have been labelled with indium-111. Uses include the detection, diagnosis, and evaluation of malignant neoplasms of the colon, rectum, prostate, and ovaries as well as the detection and localisation of myocardial infarction.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to indium-111 since a very small amount of radioactivity has been reported to be present in breast milk for 20 hours.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 01/07/04)

Preparations

Ph. Eur.: Indium(In) Chloride Solution; Indium(In) Oxine Solution; Indium(In) Pentetate Injection;
USP 31: Indium In 111 Capromab Pentetide Injection; Indium In 111 Chloride Solution; Indium In 111 Ibritumomab Tiuxetan Injection; Indium In 111 Oxyquinoline Solution; Indium In 111 Pentetate Injection; Indium In 111 Pentetreotide Injection; Indium In 111 Satumomab Pendetide Injection.

Austria: Octreoscan; ***Cz.:*** Myoscint†; Octreoscan; OncoScint†; ***Israel:*** Prostascint Kit; ***Ital.:*** Octreoscan; ***Neth.:*** OctreoScan; ***Port.:*** Octreoscan; ***Spain:*** OncoScint CR 103†; ***USA:*** Octreoscan; OncoScint CR/OV†.

Indium-113m

Indio 113m.

CAS — 14885-78-0 (indium-113).

HALF-LIFE. 99.5 minutes.

Profile

Indium-113m is a daughter of tin-113 (^{113}Sn, half-life 115 days) and because of its short half-life is normally prepared just before use by elution from a sterile generator consisting of tin-113 adsorbed on an ion-exchange material contained in a column.

Indium-113m may be used for labelling a variety of materials with differing physical properties including particles and colloids suited to scanning procedures for various organs and tissues. Chelates with pentetic acid have also been used. The short half-life of indium-113m and its lack of beta-emission have allowed large doses to be given with a small radiation dose to the patient. High count rates for scanning are therefore achieved.

Iodine-123

Iodo 123.

CAS — 15715-08-9.

ATC — V09AB01 (iodine iofetamine (^{123}I)); V09AB02 (iodine iolopride (^{123}I)); V09AB03 (iodine ioflupane (^{123}I)); V09CX01 (sodium iodohippurate (^{123}I)); V09FX02 (sodium iodide (^{123}I)); V09IX01 (iobenguane (^{123}I)).

ATC Vet — QV09AB01 (iodine iofetamine (^{123}I)); QV09AB02 (iodine iolopride (^{123}I)); QV09AB03 (iodine ioflupane (^{123}I)); QV09CX01 (sodium iodohippurate (^{123}I)); QV09FX02 (sodium iodide (^{123}I)); QV09IX01 (iobenguane (^{123}I)).

HALF-LIFE. 13.2 hours.

Profile

Iodine-123 has similar adverse effects and precautions to those of iodine-131 (see below).

Its principal use is in thyroid uptake tests and thyroid imaging when it is given orally or by intravenous injection as sodium iodide (^{123}I).

Sodium iodohippurate (^{123}I) is given intravenously in tests of renal function and in renal imaging.

Iobenguane (^{123}I) (*m*-iodobenzylguanidine (^{123}I)) is given intravenously for the localisation of certain tumours, for example phaeochromocytomas, and for the evaluation of neuroblastoma. It is also used for functional studies of the adrenal medulla and myocardium.

Ioflupane (^{123}I) is given intravenously to detect loss of functioning dopaminergic neurones in the differential diagnosis of tremor and parkinsonism.

Various monoclonal antibodies have been labelled with iodine-123; potential applications include the detection of malignant neoplasms.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to iodine-123 since radioactivity has been reported to be present in breast milk for up to 36 hours.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 01/07/04)

Preparations

Ph. Eur.: Sodium Iodide(I) Injection; Sodium Iodide(I) Solution for Radiolabelling; Sodium Iodohippurate(I) Injection;
USP 31: Iobenguane I 123 Injection; Iodohippurate Sodium I 123 Injection; Sodium Iodide I 123 Capsules; Sodium Iodide I 123 Solution.

Iodine-125

Iodo 125.

CAS — 14158-31-7.

ATC — V09CX03 (sodium iotalamate (^{125}I)); V09GB01 (fibrinogen (^{125}I)); V09GB02 (iodinated human albumin (^{125}I)); V09IX03 (iodine CC49 monoclonal antibody (^{125}I)).

ATC Vet — QV09CX03 (sodium iotalamate (^{125}I)); QV09GB01 (fibrinogen (^{125}I)); QV09GB02 (iodinated human albumin (^{125}I)); QV09IX03 (iodine CC49 monoclonal antibody (^{125}I)).

HALF-LIFE. 60.1 days.

Profile

Iodine-125 has similar adverse effects and precautions to those of iodine-131 (see below).

Iodine-125 is not very suitable for the external counting of radioactivity in the thyroid gland because its gamma-energy is weak and tissue absorption is high. However, it is very suitable for radio-immunoassays *in vitro* and because it has a long half-life it is preferred as a label for many compounds to detect and estimate drugs and hormones in body fluids.

Iodine-125 has been used orally as sodium iodide (^{125}I) in the diagnosis of thyroid disorders.

Sodium iotalamate (^{125}I) has been used intravenously in the determination of glomerular filtration rate and sodium iodohippurate (^{125}I) intravenously for the measurement of effective renal plasma flow.

Iodine-125, as iodinated (^{125}I) human fibrinogen, has been used intravenously to demonstrate and locate deep-vein thrombosis of the leg. Iodinated (^{125}I) fibrinogen has also been used in the measurement of fibrinogen metabolism in certain disturbances of blood coagulation.

Human albumin iodinated with iodine-125 has been used for the determination of blood or plasma volume.

Iodine-125 implants have been used for the local treatment of cancers (brachytherapy). Titanium capsules containing iodine-125 adsorbed onto a silver rod have been used in the treatment of cancers of the head and neck, lung, pancreas, and prostate. Brain tumours have been treated with titanium capsules containing iodine-125 adsorbed onto anion exchange resin spheres.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to iodine-125 since radioactivity has been reported to be present in breast milk for 12 days.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 01/07/04)

Preparations

Ph. Eur.: Human Albumin Injection, Iodinated (I);
USP 31: Iodinated I 125 Albumin Injection; Iothalamate Sodium I 125 Injection.

Proprietary Preparations (details are given in Part 3)
Austral.: OncoSeeds; Rapid Strand; ***USA:*** Glofil.

Iodine-131

Iodo 131.

CAS — 10043-66-0.

ATC — V09CX02 (sodium iodohippurate (^{131}I)); V09FX03 (sodium iodide (^{131}I)); V09IX02 (iobenguane (^{131}I)); V09XA01 (iodine norcholesterol (^{131}I)); V09XA02 (iodocholesterol (^{131}I)); V09XA03 (iodinated human albumin (^{131}I)); V10XA01 (sodium iodide (^{131}I)); V10XA02 (iobenguane (^{131}I)); V10XA53 (iodine tositumomab (^{131}I)).

ATC Vet — QV09CX02 (sodium iodohippurate (^{131}I)); QV09FX03 (sodium iodide (^{131}I)); QV09IX02 (iobenguane (^{131}I)); QV09XA01 (iodine norcholesterol (^{131}I)); QV09XA02 (iodocholesterol (^{131}I)); QV09XA03 (iodinated human albumin (^{131}I)); QV10XA01 (sodium iodide (^{131}I)); QV10XA02 (iobenguane (^{131}I)); QV10XA53 (iodine tositumomab (^{131}I)).

HALF-LIFE. 8.04 days.

Adverse Effects

A percentage of patients treated with iodine-131 for hyperthyroidism become hypothyroid each year, depending on the dose given, and eventually most patients will require thyroid replacement therapy. Hypoparathyroidism has also been reported. Radiation thyroiditis with soreness may develop shortly after treatment. There may be severe and potentially dangerous swelling of the thyroid especially in patients with large goitres and this has on rare occasions produced asphyxiation. Leukaemia and carcinoma of the thyroid have occasionally been reported, particularly in young patients. Retrospective studies have shown an increased incidence of thyroid cancer in adults after iodine-131 treatment for hyperthyroidism. However, the absolute risk of thyroid cancer is small and the underlying thyroid disease may play a role.

In the treatment of thyroid carcinoma, the larger doses of radioactive iodine sometimes cause nausea and vomiting a few days after ingestion, which may be due to gastritis as iodine-131 is also concentrated in gastric mucosa. Salivary gland toxicity may also occur. Large doses depress the bone marrow.

2. Franklyn JA, *et al.* Cancer incidence and mortality after radioiodine treatment for hyperthyroidism: a population-based cohort study. *Lancet* 1999; **353:** 2111–15.
3. Rivkees SA, Cornelius EA. Influence of iodine-131 dose on the outcome of hyperthyroidism in children. *Pediatrics* 2003; **111:** 745–9.

Precautions

The use of sodium iodide (^{131}I) is contra-indicated, even in diagnostic doses, during pregnancy. Sodium iodide (^{131}I) should not be given to patients with large toxic nodular goitres or to patients with severe thyrotoxic heart disease. There is some controversy as to whether radio-iodine therapy exacerbates Graves' ophthalmopathy (see Hyperthyroidism, p.2165).

Many drugs have been reported to interfere with thyroid- or other organ-function studies and checks should be made on any treatment the patient might be receiving before any estimations are carried out.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to iodine-131 since radioactivity has been reported to be present in breast milk for 2 to 14 days; high doses used for the treatment of thyroid cancer may prolong exposure to the infant.

1. American Academy of Pediatrics. The transfer of drugs and other chemicals into human milk. *Pediatrics* 2001; **108:** 776–89. Correction. *ibid.*; 1029. Also available at: http://aappolicy.aappublications.org/cgi/content/full/pediatrics%3b108/3/776 (accessed 01/07/04)

Uses and Administration

Iodine radioisotopes are mainly used in studies of thyroid function and in the treatment of hyperthyroidism (p.2165) and some forms of thyroid carcinoma (p.674).

Iodine radioisotopes can be incorporated into many compounds including liothyronine and levothyroxine, triglycerides and fatty acids, such as glyceryl trioleate and oleic acid, and proteins, such as iodinated human albumin, with varying degrees of stability and with little or no change in the biological activity of the labelled molecule. It is common practice to saturate the thyroid with non-radioactive iodine when uptake of radiation by the gland is not desired (see Radiation Protection, p.2171).

Sodium iodide (^{131}I) is given orally and by intravenous injection in studies of thyroid function, particularly in measurements of the uptake of iodine by the thyroid, and in thyroid scanning. It is also used in the treatment of hyperthyroidism and in the treatment of malignant neoplasms of the thyroid.

Injections containing iobenguane (^{131}I) (*m*-iodobenzylguanidine (^{131}I)) may be used for the localisation and treatment of phaeochromocytoma (p.1179) and neuroblastoma (p.674).

Human albumin iodinated with iodine-131 is used in the determination of the blood or plasma volume.

Sodium iodohippurate (^{131}I) is used intravenously for renal-function tests and for renal imaging.

Rose bengal sodium (^{131}I) has been given intravenously in tests of liver function.

Iodinated (^{131}I) norcholesterol (6β-iodomethyl-19-norcholest-5(10)-en-3β-ol (^{131}I)) has been used for adrenal scintigraphy by slow intravenous injection.

Various monoclonal antibodies labelled with iodine-131 are used for the detection of malignant neoplasms and some are used for therapeutic purposes, such as iodine (^{131}I) tositumomab for non-Hodgkin's lymphoma.

Preparations

Ph. Eur.: Iobenguane(I) Injection for Diagnostic Use; Iobenguane(I) Injection for Therapeutic Use; Iodinated(I) Norcholesterol Injection; Sodium Iodide(I) Capsules for Diagnostic Use; Sodium Iodide(I) Capsules for Therapeutic Use; Sodium Iodide(I) Solution; Sodium Iodide(I) Solution for Radiolabelling; Sodium Iodohippurate(I) Injection;

Iron-59

Hierro 59.
CAS — 14596-12-4.
ATC — V09XX04 (ferric citrate (^{59}Fe)).
ATC Vet — QV09XX04 (ferric citrate (^{59}Fe)).

HALF-LIFE. 44.6 days.

Profile

Iron-59, in the form of ferrous citrate (^{59}Fe) or ferric citrate (^{59}Fe), has been used by intravenous injection in the measurement of iron absorption and utilisation. Ferric chloride (^{59}Fe) has been given for the same purpose.

Krypton-81m

Criptón 81m.
CAS — 15678-91-8.
ATC — V09EX01 (krypton gas (^{81m}Kr)).
ATC Vet — QV09EX01 (krypton gas (^{81m}Kr)).

HALF-LIFE. 13.1 seconds.

Profile

Krypton-81m is a daughter of rubidium-81 (^{81}Rb, half-life 4.58 hours), and is prepared immediately before use by elution from a generator containing rubidium-81 adsorbed on a suitable ion-exchange column using air or oxygen as the eluent. Krypton-81m is used as a gas in lung ventilation studies. Such ventilation studies can be combined with lung perfusion studies to diagnose pulmonary embolism.

Preparations

Ph. Eur.: Krypton(Kr) Inhalation Gas;
USP 31: Krypton Kr 81m.

Proprietary Preparations (details are given in Part 3)
Cz.: KryptoScan; ***Neth.:*** KryptoScan.

Nitrogen-13

Nitrógeno 13.
CAS — 13981-22-1.

HALF-LIFE. 9.96 minutes.

Profile

Nitrogen-13 is a positron-emitting radionuclide that is used in positron-emission tomography (see Emissions from Radioisotopes, p.2052). In the form of ammonia (^{13}N) it is given intravenously for imaging blood flow in organs such as the heart, brain, and liver. Nitrogen gas (^{13}N) may be used for pulmonary ventilation studies.

Preparations

Ph. Eur.: Ammonia(N) Injection;
USP 31: Ammonia N 13 Injection.

Oxygen-15

Oxígeno 15.
CAS — 13982-43-9.

HALF-LIFE. 2 minutes.

Profile

Oxygen-15 is a positron-emitting radionuclide used in positron-emission tomography (see Emissions from Radioisotopes, p.2052). It is used in the form of water (^{15}O) and is given intravenously to study cerebral and myocardial perfusion.

Oxygen gas, carbon dioxide, and carbon monoxide have also been labelled with oxygen-15.

Preparations

Ph. Eur.: Carbon Monoxide(O); Oxygen(O); Water(O) Injection;
USP 31: Water O 15 Injection.

Phosphorus-32

Fósforo 32.
CAS — 14596-37-3.
ATC — V10AX01 (phosphorus chromic phosphate colloid (^{32}P)); V10XX01 (sodium phosphate (^{32}P)).
ATC Vet — QV10AX01 (phosphorus chromic phosphate colloid (^{32}P)); QV10XX01 (sodium phosphate (^{32}P)).

HALF-LIFE. 14.3 days.

Profile

Phosphorus-32, given as sodium phosphate (^{32}P), is used intravenously in the treatment of polycythaemia vera (p.654). Phosphorus-32 is taken up by the rapidly proliferating haematopoietic cells sufficiently to reduce their reproduction. Sodium phosphate (^{32}P) has also been used intravenously in the treatment of chronic myeloid (p.653) and chronic lymphocytic leukaemia (p.653) and in the palliative treatment of bone metastases.

Chromic phosphate (^{32}P) is given intraperitoneally or intrapleurally in the treatment of malignant effusions (p.659); it may also be given by interstitial injection for the treatment of ovarian (p.670) or prostatic carcinoma (p.671).

Preparations

Ph. Eur.: Sodium Phosphate(P) Injection;
USP 31: Chromic Phosphate P 32 Suspension; Sodium Phosphate P 32 Solution.

Proprietary Preparations (details are given in Part 3)
USA: Phosphocol.

Rhenium-186

Renio 186.
CAS — 14998-63-1.
ATC — V10AX05 (rhenium sulfide colloid (^{186}Re)); V10BX03 (rhenium etidronate (^{186}Re)).
ATC Vet — QV10AX05 (rhenium sulfide colloid (^{186}Re)); QV10BX03 (rhenium etidronate (^{186}Re)).

HALF-LIFE. 90.6 hours.

Profile

Rhenium-186 has been used in colloidal form for the treatment of arthritic joint conditions. Rhenium (^{186}Re) etidronate is used for the palliation of painful bone metastases of prostate cancer. Etidronate labelled with another isotope, rhenium-188, has also been used. Monoclonal antibodies labelled with rhenium-186 have been investigated for the treatment of various malignant neoplasms.

Preparations

Proprietary Preparations (details are given in Part 3)
Cz.: Nanocis; RE-186-MM-1; Re-Bone.

Rubidium-82

Rubidio 82.
CAS — 14391-63-0.

HALF-LIFE. 75 seconds.

Profile

Rubidium-82 is a positron-emitting radionuclide that is used in positron-emission tomography (see Emissions from Radioisotopes, p.2052). Rubidium chloride (^{82}Rb) is given intravenously for cardiac imaging.

Preparations

USP 31: Rubidium Chloride Rb 82 Injection.

Samarium-153

Samario 153.
CAS — 15766-00-4.
ATC — V10AX02 (samarium hydroxyapatite colloid (^{153}Sm)); V10BX02 (samarium lexidronam (^{153}Sm)).
ATC Vet — QV10AX02 (samarium hydroxyapatite colloid (^{153}Sm)); QV10BX02 (samarium lexidronam (^{153}Sm)).

HALF-LIFE. 47 hours.

Profile

Samarium-153, in the form of samarium (^{153}Sm) lexidronam (samarium (^{153}Sm) EDTMP) is used for the palliative treatment of painful bone metastases (p.660). It is given by intravenous injection.

Selenium-75

Selenio 75.
CAS — 14265-71-5.
ATC — V09DX01 (selenium tauroselcholic acid (^{75}Se)); V09XX03 (selenium norcholesterol (^{75}Se)).
ATC Vet — QV09DX01 (selenium tauroselcholic acid (^{75}Se)); QV09XX03 (selenium norcholesterol (^{75}Se)).

HALF-LIFE. 118.5 days.

Profile

Selenium-75 in the form of tauroselcholic acid (^{75}Se) (^{75}SeHCAT) is used orally in the measurement of bile acid absorption for the assessment of ileal function.

Selenium-75 in the form of 6β-[(methyl[^{75}Se]seleno)methyl]-19-norcholest-5(10)-en-3β-ol (selenonorcholestenol (^{75}Se)) has been used intravenously in adrenal scintigraphy.

Preparations

Proprietary Preparations (details are given in Part 3)
Neth.: SeHCAT; ***UK:*** Scintadren.

Strontium-89

Estroncio 89.
CAS — 14158-27-1.
ATC — V10BX01 (strontium chloride (^{89}Sr)).
ATC Vet — QV10BX01 (strontium chloride (^{89}Sr)).

HALF-LIFE. 50.5 days.

Profile

Strontium-89, in the form of strontium chloride (^{89}Sr), is used for the palliation of pain in patients with bone metastases (p.660); it is given intravenously.

HALF-LIFE. 6.02 hours.

Adverse Effects and Precautions

Hypersensitivity reactions have been reported with technetium-99m preparations.

Breast feeding. The American Academy of Pediatrics has stated[1] that temporary cessation of breast feeding is required after exposure to technetium-99m since radioactivity has been reported to be present in breast milk for 15 to 72 hours.

Uses and Administration

Technetium-99m is a daughter of molybdenum-99 (^{99}Mo, half-life 66.2 hours) and because of its short half-life is normally prepared just before use by elution from a sterile generator consisting of molybdenum-99 adsorbed onto alumina in a glass column. Technetium-99m as pertechnetate ($^{99m}TcO_4^-$) is obtained by elution with a sterile solution of sodium chloride 0.9%. Radiopharmaceuticals of technetium-99m are prepared shortly after elution to reduce loss by decay.

Because it has a short half-life and can be given in relatively large doses, and because the energy of its gamma-emission is readily detected, technetium-99m is very widely used, either as the pertechnetate or in the form of various labelled compounds, particles, and colloids for scanning bone and organs such as the brain, heart, kidney, liver, lung, spleen, and thyroid.

Sodium pertechnetate (^{99m}Tc) is used intravenously for angiography and for imaging blood pools, brain, salivary glands, and thyroid gland; the oral route may also be used for brain and thyroid imaging. Topical application to the eye is used for studying nasolachrymal drainage and the intraurethral route for imaging the urinary tract. Potassium perchlorate may be given before the pertechnetate to prevent uptake in the thyroid or choroid plexus and thus enhance visualisation in other organs.

Macroaggregates of human albumin labelled with technetium-99m [macrosalb (^{99m}Tc)] are used in lung scanning for the detection of abnormal lung perfusion patterns; after intravenous injection of a suspension of suitable particle size, usually 10 to 100 micrometres, the particles become trapped in the lung capillaries enabling ischaemic areas to be defined. Labelled albumin microspheres of particle size 10 to 50 micrometres are used similarly. Labelled macroaggregates of albumin have also been used in venography for the detection of deep-vein thrombosis of the legs. Technetium (^{99m}Tc) apcitide is a labelled peptide that binds to the glycoprotein IIb/IIIa receptor of activated platelets, and is also used for imaging of deep-vein thrombosis.

When technetium-99m bound to human serum albumin is given intravenously it becomes evenly distributed in the circulation and highly vascular organs or pools of blood may be readily located. Such a preparation is used in the examination of the heart.

Technetium-99m in the form of a colloid, such as albumin, sulfur, antimony sulfide, or tin, is used intravenously for the examination of the liver, spleen, and bone marrow. Sulfur colloid (^{99m}Tc) may be given orally for oesophageal and gastrointestinal imaging. Albumin colloid (^{99m}Tc) may be given subcutaneously for scanning of the lymphatic system. Colloidal rhenium sulfide (^{99m}Tc) has been used for sentinel lymph node detection in patients with malignancies.

Technetium-99m complexes of iminodiacetic acid derivatives, such as disofenin, etifenin, lidofenin, and mebrofenin are used intravenously in the investigation of hepatic function and in the imaging of the hepatobiliary system.

Agents used intravenously in both brain and renal imaging are technetium-99m-labelled gluconate, gluceptate, and pentetate. Other technetium-99m-labelled compounds are used in brain and kidney scanning; for instance, labelled bicisate and exametazime have been used in brain imaging and betiatide, mertiatide, and succimer have been used in kidney studies. The pentetate is also given by inhalation for lung ventilation imaging, and orally for studies of gastro-oesophageal reflux and gastric emptying.

For bone scanning various labelled phosphate compounds may be used and include medronate, oxidronate, and pyrophosphate, all given intravenously. Technetium-99m as the pyrophosphate is also used in cardiac scintigraphy. Technetium-99m as the medronate and pyrophosphate are also used to label red blood cells for use in blood pool scintigraphy, cardiac scintigraphy, detection of gastrointestinal bleeding, and testicular scintigraphy.

Compounds used intravenously in cardiac imaging include technetium-99m-labelled sestamibi, teboroxime, and tetrofosmin. Technetium (^{99m}Tc) sestamibi is also used for breast imaging.

Technetium-99m-labelled leucocytes (prepared using exametazime) are used for localisation of sites of inflammation or infection.

Monoclonal antibodies labelled with technetium-99m, such as arcitumomab and nofetumomab merpentan, are used for the detection and localisation of malignant neoplasms. Labelled sulesomab is used in the detection of osteomyelitis. Labelled fanolesomab was used in the diagnosis of appendicitis but was withdrawn from the market due to severe adverse effects. Technetium (^{99m}Tc) depreotide is a labelled peptide used intravenously for imaging of pulmonary malignancy.

Many other technetium-99m-labelled compounds have been prepared and used in different clinical studies for the examination of different organs or systems. Use with other radionuclides includes subtraction scanning with thallium-201 to detect parathyroid tumours.

Thallium-201

Talio 201.

CAS — 15064-65-0.
ATC — V09GX01 (thallium chloride (^{201}Tl)).
ATC Vet — QV09GX01 (thallium chloride (^{201}Tl)).

HALF-LIFE. 73.1 hours.

Profile

Thallium-201, in the form of thallous chloride (^{201}Tl), is given by intravenous injection for scanning the myocardium in the investigation of acute myocardial infarction. It is also used for myocardial perfusion imaging in cardiac stress testing of patients with ischaemic heart disease. Adenosine (see Ischaemic Heart Disease, p.1203), dipyridamole (see Myocardial Imaging, p.1268), or dobutamine (see Diagnosis and Testing, p.1272) may be used to induce pharmacological stress in those patients unable to tolerate exercise.

Other uses include muscle perfusion scintigraphy in peripheral vascular disorders, visualisation of brain and thyroid tumours and metastases, and the localisation of parathyroid adenomas and hyperplasia by thallium-201 and technetium-99m subtraction scanning.

Preparations

Ph. Eur.: Thallous(Tl) Chloride Injection;
USP 31: Thallous Chloride Tl 201 Injection.

Proprietary Preparations (details are given in Part 3)
Austria: DRN 8103.

Tritium

Hydrogen-3; Tritio.

CAS — 10028-17-8.

HALF-LIFE. 12.3 years.

Profile

Tritium, in the form of tritiated water, has been used to determine the total body water by a dilution technique.

Preparations

Ph. Eur.: Tritiated(H) Water Injection.

Xenon-127

Xenón 127.

CAS — 13994-19-9.
ATC — V09EX02 (xenon gas (^{127}Xe)).
ATC Vet — QV09EX02 (xenon gas (^{127}Xe)).

HALF-LIFE. 36.41 days.

Profile

Xenon-127 has similar physical properties to those of xenon-133 (see below) and is also used by inhalation for pulmonary function studies and lung imaging.

Preparations

USP 31: Xenon Xe 127.

Xenon-133

Xenón 133.

CAS — 14932-42-4.
ATC — V09EX03 (xenon gas (^{133}Xe)).
ATC Vet — QV09EX03 (xenon gas (^{133}Xe)).

HALF-LIFE. 5.25 days.

Profile

Xenon-133 is an inert gas with relatively low solubility in plasma. In the gaseous form, it is mixed with air or oxygen in a bag or in a closed or open circuit spirometer. When the gas is stopped, xenon-133 is excreted promptly and completely through the lungs. It is used by inhalation in pulmonary function studies and lung imaging as well as in cerebral blood flow studies. It has also been used for these purposes in the form of an injection in sodium chloride 0.9%.

Preparations

Ph. Eur.: Xenon(Xe) Injection;
USP 31: Xenon Xe 133; Xenon Xe 133 Injection.

Yttrium-90

Itrio 90.

CAS — 10098-91-6.

ATC — V10AA01 (yttrium citrate colloid (^{90}Y)); V10AA02 (yttrium ferrihydroxide colloid (^{90}Y)); V10AA03 (yttrium silicate colloid (^{90}Y)); V10XX02 (ibritumomab tiuxetan (^{90}Y)).

ATC Vet — QV10AA01 (yttrium citrate colloid (^{90}Y)); QV10AA02 (yttrium ferrihydroxide colloid (^{90}Y)); QV10AA03 (yttrium silicate colloid (^{90}Y)); QV10XX02 (ibritumomab tiuxetan (^{90}Y)).

HALF-LIFE. 64.1 hours.

Yttrium-90 conjugated to ibritumomab tiuxetan (p.730) is used in the treatment of non-Hodgkin's lymphoma. Conjugates with various other monoclonal antibodies and compounds are also under investigation for malignant neoplasms.

Yttrium-90, in the form of a colloidal suspension of yttrium silicate (^{90}Y) has been used for instillation into pleural or peritoneal cavities in the treatment of malignant pleural effusion (p.659) or malignant ascites.

Yttrium-90, as either yttrium citrate (^{90}Y) or yttrium silicate (^{90}Y), has also been used in the treatment of arthritic conditions of joints.

Yttrium-90 enclosed in glass microspheres has been used for the local treatment of malignant neoplasms of the liver.

Preparations

USP 31: Yttrium Y 90 Ibritumomab Tiuxetan Injection.

Proprietary Preparations (details are given in Part 3)

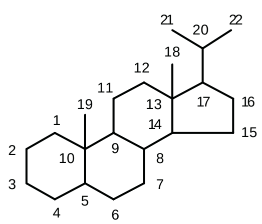
Sex Hormones and their Modulators

The male and female sex organs, the adrenal cortex, and the placenta produce steroidal hormones that influence the development and maintenance of structures directly and indirectly associated with reproduction. The secretion of these sex hormones is controlled by gonadotrophic hormones of the anterior lobe of the pituitary gland (and in pregnancy, from the placenta); the secretion of pituitary gonadotrophic hormones is in turn influenced by the hypothalamus and also by the concentration of circulating sex hormones. There are 3 groups of endogenous sex hormones, androgens, oestrogens, and progestogens, all of which are derived from the same steroidal precursors. The progestogenic hormone, progesterone, is formed from pregnenolone, and both of these compounds may be converted to androgen precursors such as androstenedione. Androstenedione is converted to the androgenic hormone testosterone by hydroxysteroid dehydrogenases. Oestrogenic hormones are synthesised from androstenedione (and also from testosterone) by the action of aromatase.



steroidal skeleton

Testosterone is the main androgenic hormone formed in the interstitial (Leydig) cells of the testes. A small proportion of circulating testosterone is also derived from the metabolism of less potent androgens secreted by the adrenal cortex and ovaries. In many target tissues testosterone is then converted to the more active dihydrotestosterone by 5α-reductase. Some testosterone also undergoes peripheral conversion to oestradiol.

Testosterone controls the development and maintenance of the male sex organs and the male secondary sex characteristics. It also produces systemic anabolic effects, such as increased retention of nitrogen, calcium, sodium, potassium, chloride, and phosphate. This leads to an increase in water retention and bone growth. The skin becomes more vascular and less fatty and erythropoiesis is increased.

Numerous derivatives of testosterone have been developed. Alkylation at the 17α position results in derivatives that are orally active, but associated with a risk of hepatotoxicity (see Table 1, below). Esterification of the 17β-hydroxyl group increases lipid solubility and is used to prepare long-acting intramuscular preparations (e.g. testosterone enantate). Removal of the 19-methyl group is reported to improve the anabolic to androgenic ratio (e.g. nandrolone). The derivatives also vary in their plasma protein binding affinity, and degree of conversion to dihydrotestosterone and aromatic conversion to oestrogen. Numerous other structural modifications have been made.

Oestradiol is the most active of the naturally occurring oestrogens formed from androgen precursors in the ovarian follicles of premenopausal women. In men and postmenopausal women (and to an insignificant extent in premenopausal women) oestrogens are also formed in adipose tissue from adrenal androgens.

Table 1. 17α-Alkylated testosterone derivatives

Danazol	Norethandrolone
Ethylestrenol	Oxandrolone
Fluoxymesterone	Oxymetholone
Methandienone	Stanozolol
Methyltestosterone	

Oestrogens control the development and maintenance of the female sex organs, secondary sex characteristics, and mammary glands as well as certain functions of the uterus and its accessory organs (particularly the proliferation of the endometrium, the development of the decidua, and the cyclic changes in the cervix and vagina). Large amounts of oestradiol are also formed in the placenta; in late pregnancy, this increases the spontaneous activity of the uterine muscle and its response to oxytocic drugs. The additional activity of progesterone is essential for the complete biological function of the female sex organs. Oestrogens also have some direct effects on metabolic processes, including those affecting bone mass, lipids, carbohydrates, and proteins.

A number of oestrogens are used therapeutically. Ethinyl substitution at the C17 position has led to the development of synthetic oestrogens such as ethinylestradiol and mestranol, which have greatly improved potency and oral activity. Oral activity of natural oestrogens is improved by esterification (e.g. estradiol valerate) or by conjugation (e.g. estrone sulfate). Esterification also increases solubility in lipid vehicles and is used to prepare long-acting intramuscular preparations.

A number of nonsteroidal oestrogens, including chlorotrianisene, dienestrol, and diethylstilbestrol, have also been used.

Progesterone is the main hormone secreted by the corpus luteum. It acts on the endometrium by converting the proliferative phase induced by oestrogen to a secretory phase thereby preparing the uterus to receive the fertilised ovum. Progesterone has a catabolic action and causes a slight rise in basal body temperature during the secretory phase of menstruation. During pregnancy the placenta produces large quantities of progesterone, which suppresses uterine motility and is responsible for the further development of the breasts.

Progestogens (gestagens, progestagens, progestins) are synthetic compounds with actions similar to those of progesterone. They are either progesterone derivatives or 19-nortestosterone analogues. The 19-nortestosterone analogues (such as norethisterone and norgestrel) possess some androgenic activity, but some newer norgestrel derivatives (desogestrel, gestodene, and norgestimate) have little androgenic activity. The progesterone derivatives dydrogesterone, hydroxyprogesterone, and medroxyprogesterone are less androgenic than the 19-nortestosterone analogues. The progesterone derivatives chlormadinone, and particularly cyproterone, have anti-androgenic activity.

The principal natural and synthetic sex hormones covered in this chapter are thus:

- **androgens and anabolic steroids**, typified by testosterone (p.2129)
- **oestrogens**, typified by estradiol (p.2097)
- **progestogens**, typified by progesterone (p.2125)

Other related substances also described in this chapter are:

- drugs with mainly **weak androgenic** properties such as danazol and gestrinone
- drugs that combine **oestrogenic and progestogenic** properties such as tibolone
- drugs with mainly **anti-androgenic** properties including the progesterone derivative cyproterone acetate. Those anti-androgens used principally in the hormonal treatment of prostate cancer are covered in the Antineoplastics chapter; they include the nonsteroidal drugs bicalutamide (p.686), flutamide (p.725), and nilutamide (p.756). The nonsteroidal 5α-reductase inhibitors finasteride (p.2188) and dutasteride (p.2188) and the plant extract saw palmetto (p.2192), used in the treatment of benign prostatic hyperplasia, are covered in the Urological Drugs chapter
- drugs with mainly **anti-oestrogenic** properties. These include the nonsteroidal anti-oestrogens clomifene, cyclofenil, and the more selective nonsteroidal anti-oestrogens ormeloxifene and raloxifene. Those anti-oestrogens used principally in the hormonal treatment of breast cancer are covered in the Antineoplastics chapter; they include the oestrogen receptor antagonists tamoxifen (p.772) and toremifene (p.781), and various aromatase inhibitors such as formestane (p.726) and anastrozole (p.681)
- **gonad-regulating hormones** (see below for more detail) include endogenous and recombinant forms of luteinising and follicle-stimulating hormones, and their releasing hormone gonadorelin and its analogues.

The therapeutic applications of sex hormones and related substances are broad and cover many circumstances where hormonal manipulation is desirable. Major applications are the use of oestrogens and progestogens for **contraception** (p.2070) and for the alleviation of **menopausal symptoms** (p.2077). A physiological application is the use of sex hormones or gonad-regulating hormones in the management of **delayed puberty** (p.2079) and **hypogonadism** (p.2079). Other clinical applications include the management of **benign prostatic hyperplasia** (p.2178), **endometriosis** (p.2091), **gynaecomastia** (p.2092), **hirsutism** (p.2089), **infertility** (p.2080), **mastalgia** (p.2092), **menorrhagia** (p.2126), and **premenstrual syndrome** (p.2099). Hormonal manipulation also has an important role in the treatment of **malignant neoplasms** of the breast (p.661), prostate (p.671), and endometrium (p.663).

Hormonal Contraceptives

Anticonceptivos hormonales; Contraceptifs Hormonaux; Hormonale Kontrazeptiva.

Гормональный Контрацептивы

Types of Contraceptive

Hormonal contraceptives are currently only available for women although preparations for men are being evaluated. Oral hormonal contraceptives for women are divided into 2 main types: 'combined' (containing an oestrogen and a progestogen) and 'progestogen-only'. Parenteral preparations have also been developed and include subcutaneous implants and depot intramuscular injections. Progestogen-releasing intra-uterine devices and a combined hormonal contraceptive vaginal ring are available. A combined hormonal transdermal patch has also been developed.

Parenteral progestogen-only contraceptives provide reliable suppression of ovulation by suppressing the necessary mid-cycle surge of luteinising hormone. However, the low doses in progestogen-only oral contraceptives do not suppress it reliably in all cycles. Contraceptive efficacy is instead achieved by thickening the cervical mucus so that it is not readily penetrated by sperm, and by preventing proliferation of the endometrium so that it remains unfavourable for implantation of any fertilised ova. Intra-uterine progestogen-only devices act similarly; the physical presence of the system in the uterus may also contribute to overall contraceptive efficacy.

Oestrogens inhibit ovulation by suppressing the mid-cycle release of follicle-stimulating hormone. They act synergistically with progestogens in combined oral contraceptives to provide regular and consistent suppression of ovulation.

Oral preparations are also available for *emergency contraception* after unprotected coitus; they prevent implantation of any fertilised ova.

Adverse Effects

Many reports have been published of adverse effects associated with the use of **combined oral contraceptives**. The data have mostly been gained retrospectively and often involve older preparations containing higher doses of oestrogen and progestogen than are used currently.

There may be gastrointestinal adverse effects such as nausea or vomiting, chloasma (melasma) and other skin or hair changes, headache, water retention, weight gain, breast tenderness, and changes in libido.

Menstrual irregularities such as spotting, breakthrough bleeding, or amenorrhoea can occur during treatment. These effects may result from the relative balance of oestrogenic and progestogenic effects of particular products and their incidence may be reduced by changing to a different product. For example, early or mid-cycle spotting or absence of withdrawal bleeding may require a preparation with a greater oestrogen to progestogen ratio or less progestogen as in multiphasic preparations.

Intolerance to contact lenses has been reported and vision may deteriorate in myopic patients. Some patients may experience depression and other mental changes. Preparations containing a progestogen with androgenic properties such as levonorgestrel or norgestrel may be associated with increased oiliness of the skin and acne. Conversely, acne may be improved with progestogens such as norgestimate or desogestrel.

There is an increased risk of cardiovascular disease and associated mortality related, at least in part, to the oestrogen content of combined oral contraceptives. The incidence of cardiovascular adverse effects is probably less with the newer lower-dose preparations than with the older higher-dose preparations. Increased mortality from myocardial infarction is much greater with increased age and in cigarette smokers, although some evidence suggests that healthy women aged over 35 years who do not smoke are not at increased risk. Other risk factors include a family history of arterial disease, diabetes mellitus, hypertension, obesity, and migraine. Thrombosis may be more common when factor V Leiden is present or in patients with blood groups A, B, or AB. Specific risk factors for venous thromboembolism include varicose veins, long-term immobilisation, obesity, and a family history of venous thromboembolism. Recent evidence has also indicated that the risk of venous thromboembolism varies according to the progestogen component of combined oral contraceptives; a higher incidence has been associated with desogestrel and gestodene than with levonorgestrel, norethisterone, and etynodiol. For further discussion see Venous Thromboembolism, below.

Combined oral contraceptives may cause hypertension and there may be reduced glucose tolerance and changes in lipid metabolism. Liver function can be impaired, although jaundice is rare. There appears to be a marked increase (though the incidence is still very low) in the relative risk of benign liver tumours. Malignant liver tumours have also been reported.

Combined oral contraceptives are reported to slightly increase the risk of cervical cancer (although other factors may be involved) and breast cancer, but to protect against ovarian cancer and endometrial cancer. For further discussion, see Carcinogenicity, below.

As with combined oral contraceptives, **progestogen-only contraceptives** may cause nausea, vomiting, headache, breast discomfort, depression, skin disorders, and weight gain. Menstrual irregularities such as amenorrhoea, breakthrough bleeding, spotting, and menorrhagia are more common with progestogen-only contraceptives, and are particularly common with parenteral preparations. Available progestogen-only contraceptives carry less risk of thromboembolic and cardiovascular disease than combined oral contraceptives.

Carcinogenicity. Concern has often been expressed as to whether the use of hormonal contraceptives by normally healthy women may either cause or increase the risk of developing malignant neoplasms. To investigate any possible link between such use and cancer, two main types of study have been used by epidemiologists, namely the prospective study and the case-control study. Many factors have made direct comparison of results difficult and such factors include the type and composition of oral contraceptive used (which has changed over the years), the age of the patient, the age at which use first began, and the sexual and obstetric history of the patient. Overall the evidence indicates that combined oral contraceptives in fact exert a protective effect against the development of endometrial and ovarian carcinoma. However, there is a small increase in risk of breast cancer during use and for 10 years after discontinuation. In addition, there does appear to be a slight risk of cervical cancer with the prolonged use of combined oral contraceptives and a negligible risk of liver cancer. For further details concerning the effects on individual organs, see the following sections. It should be noted that even where the relative risk has been shown to be substantially increased this will not translate into many new cases of a rare cancer, and this contributes to the difficulties of assessing clinical relevance.

In the long-term Oxford Family Planning Association contraceptive study, the beneficial effects of oral contraceptives on the uterus and ovary were calculated to outweigh the adverse effect on the cervix.[1] This large cohort study also found no increased risk of breast cancer although the data could not exclude a small increase in risk with current use that declined after stopping. Long-term follow-up of the prospective Royal College of General Practitioners' study has found no overall increased risk of cancer.[2] It is also worthy of note that two large prospective cohort studies (the Nurses' Health Study and the Royal College of General Practitioners' study) found no evidence of a difference in overall mortality between women who had used oral contraceptives and those who had not.[3,4] Some general reviews on hormonal contraceptives and cancer are cited below.[5-9]

BREAST. Numerous epidemiological studies have been published on the potential link between hormonal contraceptives and breast cancer. Most of these data relate to **combined oral contraceptives**, which are the most widely used form. The breast cancer risk from use of these contraceptives will require monitoring for some time to come as the first users of oral contraceptives continue to age, and because of the changing patterns of use.

Early studies from the 1980s variously failed to show any significant increase in risk of breast cancer in women who had ever used hormonal contraceptives compared with those who had never done so,[1-4] or showed an increase in risk,[5] or identified a risk in specific sub-groups of users.[6-12] Potential identified risk factors, for which much of the evidence was conflicting, included current use,[10] duration of use,[7,11] age at first use,[6] duration of use before a first full-term pregnancy,[7,8] nulliparity,[9] high-dose preparations,[11] and family history of breast cancer.[12] It was also reported that use of oral contraceptives might lead to an accelerated presentation of breast cancer,[13] or an increased risk of invasive cancer.[4]

In response to these studies, the UK CSM,[14] the FDA in the USA,[15] and the International Committee for Research in Reproduction[16] issued advice that the available evidence did not require a change in prescribing practice. This advice has not been subsequently changed, although patients should be informed of the possible small increase in risk of breast cancer, which has to be weighed against established benefits of therapy.[17]

A Collaborative Group on Hormonal Factors in Breast Cancer was set up to re-analyse all the worldwide epidemiological evidence on breast cancer risk and hormonal contraceptives. The group identified individual data on 53 297 women with breast cancer, and 100 239 controls (women without breast cancer) from 54 studies, and published a summary of their findings,[18] and a further detailed review.[19] They reported that women currently using oral contraceptives have a slight increase in the relative risk of breast cancer (1.24; 95% confidence intervals 1.15 to 1.33), and that this risk decreases after stopping use, and is no longer significant after 10 or more years. There was a weak trend towards an increase in risk with increasing duration of use. Thus, it appears that the risk of breast cancer

- increases soon after first exposure
- does not increase with duration of exposure
- returns to normal 10 years after cessation of exposure.[18]

Reviews[20,21] of major studies published between 1990 and 2000, including that of the Collaborative Group, have also indicated that, in general, there is some excess breast cancer risk in current or recent users of oral contraceptives, but that excess risk does not persist in the long term after cessation of oral contraceptive use, regardless of duration of use.

The Collaborative Group found that cancers diagnosed in those who had ever used hormonal contraceptives were clinically less advanced than in those who had never done so.[18] Further information is required on whether this is related to earlier diagnosis or a biological effect of the hormones. In addition, data on breast cancer mortality are required.

When analysed by *age at first use*, the risk was largest in those women who started use as teenagers. Because of the trend towards earlier use, further review of long-term data is required.[18] The most important risk factor is, however, the *age at which women discontinue* the contraceptive; the greater the age at stopping, the more breast cancers are diagnosed.[17]

Data from the collaborative group suggested that there was no difference in risk with *parity* when comparing nulliparous women, parous women who began use of oral contraceptives before their first child, and parous women who began use of oral contraceptives after the birth of their first child.[18] However, a later meta-analysis[22] reported higher risks in parous women, particularly those who used oral contraceptives for 4 or more years before first full-term pregnancy.

Low-dose oral contraceptives were not associated with a decreased risk of breast cancer.[18] When preparations were grouped according to oestrogen dose (< 50 micrograms, 50 micrograms, and >50 micrograms), there was, if anything, a decrease in breast cancer risk with increasing dose among women who had stopped use 10 or more years before, largely due to a reduction in breast cancer risk in those who had used the highest dose preparations.

The Collaborative Group's analysis did not note any difference in risk according to *family history.*[18] However, a subsequent cohort study found an increased risk of breast cancer among women with a strong family history of the disease who used earlier formulations of oral contraceptives.[23] Another cohort study[24] provided support for the Collaborative Group's findings, reporting no statistical difference in the risk with oral contraceptive use in women with a family history of breast cancer; there was actually a trend towards a reduction in risk of breast cancer with long-term use. Women carrying mutations in the BRCA1 or BRCA2 genes are at increased risk of developing breast cancer; any additional risk from oral contraceptives is of particular concern because these women may be encouraged to take them to reduce their risk of ovarian cancer (see Ovary, below). However, results from studies in known carriers of these mutations have been mixed. A modest increase in the risk of breast cancer in BRCA1 carriers has been reported with ever use of oral contraceptives,[25] but another study[26] found a reduced risk in carriers who used current preparations containing lower oestrogen doses than those available before 1975. Further study is needed in these women.

There are far fewer data on risk of breast cancer with **progestogen-only contraceptives**, which are less frequently used than combined preparations.

A WHO study published in 1991 indicated that, overall, depot medroxyprogesterone acetate did not increase the risk of breast cancer (relative risk compared with never users 1.21; 95% confidence intervals 0.96 to 1.53) and that risk did not increase with duration of use.[27] However, there appeared to be a slight increase in risk within the first 4 years of use, especially in women under 35 years of age. These findings agreed with those of a smaller study[28] in which women who had used depot medroxyprogesterone acetate for 2 years or longer before the age of 25 had a relative risk of 4.6. Pooled analysis of these 2 studies indicated that current or recent use was the key factor.[29] The relative risk of breast cancer in women who had used medroxyprogesterone acetate in the last 5 years was 2.0, and there was no increased risk in women who had ceased use more than 5 years previously, regardless of their duration of use. Another small study[30] reported no increase in risk overall in women who had ever used medroxyprogesterone acetate; there was an increase for current use in the subgroup of women aged 35 to 44 (relative risk 2.3), but this was no longer the case 4 years after stopping.

The Collaborative Group on Hormonal Factors in Breast Cancer reported that there was some evidence of an increased risk of breast cancer for use of oral or injectable progestogens in the previous 5 years (relative risk 1.17), and no risk 10 or more years after stopping use.[18] These findings were broadly similar to those for combined preparations. As for combined preparations, the most important factor is the *age at discontinuation.* For women who stop by age 30 after 5 years use of a progestogen-only preparation there would be an estimated increase from 44 to 46 or 47 cases per 10 000 compared with those who have never used a hormonal contraceptive. For 5 years use stopping by age 40 there would be an estimated increase from 160 to 170 cases diagnosed in the following 10 years.[17]

CERVIX. It is often considered difficult to carry out satisfactory epidemiological studies on the relationship between hormonal contraceptives and cervical cancer because of the many known variables that can influence the development of this type of neoplasm. For example, sexual activity *per se,* and multiple sexual partners (both of the woman and her partner) increase the risk, while the use of other non-hormonal barrier methods of contraception may offer some protection against cervical neoplasia. Nevertheless, there have been some suggestions that the use of oral contraceptives may be associated with an increased risk.

Two UK cohort studies from the 1980s revealed an increased risk of cervical cancer in women receiving oral contraceptives that was shown to increase with increasing duration of use.[1,2]

In 1992, WHO reviewed[3] these cohort data, and data from 18 case-controlled studies carried out up to 1990. They concluded that use of oral contraceptives for more than 5 years was associated with a modest increase in the relative risk of cervical squamous cell carcinoma (in the order of 1.3 to 1.8). Additional potential risk factors included recent or current use and high oestrogen dose. Of known risk factors for cervical cancer, women with multiple sexual partners, genital infection, or high parity had enhanced risks associated with oral contraceptives.[3] Later reviews came to similar conclusions.[4,5]

Most cervical cancers are squamous cell carcinomas, but it has been proposed that oral contraceptive use might be a particular risk factor for the rarer adenocarcinoma of the cervix, the incidence of which has risen in younger women. Reviewing studies up to 1990, WHO concluded that data were insufficient to draw firm conclusions on links between oral contraceptives and the risk of cervical adenocarcinoma.[3] A case-controlled study from 1994 found an increased risk of adenocarcinoma of the cervix in users of oral contraceptives.[6] Any use of oral contraceptives was associated with an approximate doubling of risk, and use for more than 12 years was associated with a relative risk 4.4 times greater than that in women who never used an oral contraceptive. In 1996, a WHO study reported that the strength of the observed relationship for cervical adenocarcinomas and adenosquamous carcinomas and oral contraceptives was about the same as that for invasive squamous cell cervical carcinomas.[7]

Human papillomavirus (HPV) has a role in the aetiology of cervical cancer; women who are HPV positive and using oral contraceptives may be at increased risk of cervical neoplasm.[8,9] A pooled analysis of 8 case-control studies in women who tested positive for HPV DNA suggested risk of invasive squamous cervical cancer or carcinoma *in situ* was increased about threefold in those who used oral contraceptives for 5 years or more.[10]

Data on the risk of cervical cancer with **progestogen-only contraceptives** are limited. WHO have investigated any possible link between the use of medroxyprogesterone acetate as a long-acting injectable contraceptive and cervical neoplasia. Analysis showed a small non-significant elevated risk (1.11; 95% confidence interval 0.9 to 1.29), and no clear association with duration of use.[11] A later case-control study[12] found no significant association between injectable progestogen contraceptives and invasive cervical cancer risk.

ENDOMETRIUM. It has been shown that **combined oral contraceptives** decrease the risk of endometrial cancer. WHO analysed data from case-control and cohort studies published up to 1990,[1] including data from the large Cancer and Steroid Hormone Study (CASH) in the USA,[2] and reported that there was a highly significant trend of decreasing risk of endometrial cancer with increasing duration of use of combined oral contraceptives. The reduction in risk was estimated to be 20% after 1 year and 50% after 4 years of use.[1] The protective effect was observed for endometrial cancer with and without squamous elements,[1,2] and was found to persist for at least 15 years after cessation of use.[2] More recent studies with longer term follow-up have indicated that the protection persists for at least 20 years.[3,4] Further follow-up is required to determine the true duration of protection; data from one study[5] suggested that the reduction in risk was more pronounced in women who had stopped contraceptive use more than 25 years before, but another study[4] suggested that any protective effect may no longer be present 30 years after stopping combined oral contraceptive use.

The results of the WHO Collaborative Study on Neoplasia and Steroid Contraceptives suggested that protection may be greater with preparations containing high-dose progestogen.[6] However, another study found that risk of endometrial cancer was unrelated to progestogen potency of the oral contraceptive, although this study also reported no protective effect for less than 5 years of use.[7] Further analysis of the CASH study data[8] found that although preparations containing high and low doses of progestogen had a similar protective effect overall, it was greatest for high-dose progestogen preparations in women with a higher BMI.

Unopposed menopausal oestrogen replacement therapy is known to increase the risk of endometrial cancer (see p.2072), and there is some evidence[3,7] that it reduces the protective effect of previous oral contraception.

There are limited data on the effect of **progestogen-only contraceptives** on the risk of endometrial cancer, although they would be expected to be protective. Results from the WHO Collaborative Study[9] suggest that depot medroxyprogesterone acetate reduced the risk of endometrial cancer; the estimated relative risk in users was 0.21. However, many of the women in this study received supplemental oestrogen to control menstrual irregularity, and were therefore technically taking a form of combined therapy.[10] There was some evidence that the protective effect of medroxyprogesterone acetate was greater in women who had not received oestrogen,[10] although this remains to be proven.

GASTROINTESTINAL TRACT. A link between female sex hormones and the risk of colorectal cancer has been postulated. Epidemiological studies have variously shown a possible increased risk of rectal cancer,[1] a possible decreased risk of colorectal cancer[2] in women ever having used oral contraceptives, and no association between past oral contraceptive use and colorectal cancer.[3] A meta-analysis,[4] which included these 3 studies, found a reduction in the risk of colorectal cancer for women who had ever used oral contraceptives. Duration of use was not related to risk reduction, but the effect was apparently stronger for recent contraceptive use although this was based on limited data. Subsequent studies have produced similar results. A reduction in risk has been associated with ever use of oral contraceptives in one report,[5] while others have found no effect statistically but a trend towards protection with current or recent use.[6,7]. LIVER. The use of **combined oral contraceptives** has been rarely associated with liver tumours, both benign (hepatic adenomas and focal nodular hyperplasia)[1] and malignant (hepatocellular carcinoma).[1,2]

Early studies of *hepatic adenoma* found that risk increased with the duration of use of oral contraceptives, and appeared to be higher in women who had used preparations with a high oestrogen content.[1] There are also case reports of adenoma that has regressed after stopping oral contraceptive use.[3] However, a study[4] in the 1990s found no increase in risk associated with contraceptive use, and the authors considered that lower doses of oestrogens might explain the different findings. The association between oral contraceptive use and *focal nodular hyperplasia* has also been studied. One case-control study[4] found a slight increase in risk associated with use for 10 years or more. Another study[5] that followed a series of patients for about 2 years after diagnosis found no correlation between oral contraceptive use and lesion size or number, and no increase in lesion size in those patients who continued to use hormonal contraception.

Hepatocellular carcinomas are associated with hepatitis B, and are relatively common in countries where this is endemic but rare elsewhere. Case-control studies in populations at high risk for hepatocellular carcinoma suggest that the use of oral contraceptives does not significantly affect the risk, although long-term data are scanty.[6,7] However, survival after curative treatment is better in women than men, and a retrospective study from Hong Kong has suggested that this may be associated with a history of oral contraceptive use.[8] In contrast, case-control studies in countries where the prevalence of hepatitis B is low have shown an increased risk of hepatocellular carcinoma among users of oral contraceptives, particularly after long-term use (reviewed by WHO[1] and La Vecchia[2,9]). However, because the malignancy is so rare, this increased risk may be negligible.[2] For example, there has been no increase in mortality from liver cancer in young women in the UK since the introduction and use of oral contraceptives.[10] Similar findings have been reported for the USA and Sweden.[11]

There are limited data specifically on **progestogen-only contraceptives**. Results from a WHO study[12] provided no evidence that use of medroxyprogesterone acetate as a long-acting injectable contraceptive altered the risk of developing liver cancer but the power of the study to detect small alterations in risk was low.

OVARY. There is convincing evidence that **combined oral contraceptives** reduce the risk of ovarian cancer,[1,2] possibly as a function of their inhibition of ovulation. Relative risks for ovarian cancer have variously been reported as 0.4 to 0.8 in those who have ever used oral contraceptives, and decrease with increasing duration of use. There is evidence that there may be a delay of several years before the protective effect becomes apparent,[3] but that it persists for as long as 20 or 30 years after cessation of use.[3-5] The protective effect has been noted for both malignant and borderline malignant tumours[6] and for each of the major histological subtypes of epithelial ovarian cancer, although there have been conflicting data for mucinous tumours.[5]

It has been suggested that newer lower-dose oestrogen preparations may be slightly less protective than higher-dose preparations.[7] The relative risk for use of high-dose preparations was 0.68, and for low-dose preparations was 0.81, but it was noted that this difference could have occurred by chance. A later study[4] reported that risk reduction was not affected by oral contraceptive formulation. In contrast, another study[8] found a greater risk reduction associated with low-dose contraceptives than older high-dose preparations (odds ratio of 0.24 versus 0.70). The authors speculated that the accompanying changes in progestogen content might have played a role. This was examined using the data from the Cancer and Steroid Hormone (CASH) study, which suggested that higher progestogen potency provided greater risk reduction than lower progestogen potency, regardless of oestrogen dose.[9] Androgenicity of the progestogen does not appear to influence the protective effect of combined oral contraceptives.[10]

The protective effect against ovarian cancer may have significant implications for public health. There have been substantial declines in ovarian cancer incidence and mortality in younger women in countries where oral contraceptives have become widely used; it is estimated that 3000 to 5000 cases (and consequently 2000 to 3000 deaths) are avoided each year in Europe; similar numbers are quoted in North America.[11]

There are few data on the effects of **progestogen-only contraceptives** on the risk of ovarian cancer. WHO have investigated the effect of depot medroxyprogesterone acetate on ovarian cancer, and found that it was not associated with either a decrease or increase in risk (relative risk 1.07; 95% confidence interval 0.6 to 1.8).[12] This is perhaps surprising since the preparation, like combined oral contraceptives, inhibits ovulation.

Women carrying mutations in either the BRCA1 or BRCA2 gene are at increased risk of ovarian cancer, and the effect of oral contraceptives in these women has been evaluated. Although there was no protective effect in one study,[13] others have found a risk reduction with contraceptive use similar to that reported for noncarriers.[14-17] It has been suggested that oral contraceptives might be used prophylactically to protect against ovarian cancer in women with these mutations, but this must be considered in the context of their increased risk of breast cancer (see Breast, above). Women with endometriosis may also be at increased risk of ovarian cancer, and an analysis[18] of the pooled data from 4 studies suggested that long-term use of oral contraceptives may also be protective in this group.

SKIN. Although there have been some suggestions of a possible association between the use of oral contraceptives and the development of malignant melanoma[1-4] most studies, including analyses of relatively large numbers of women suffering from malignant melanoma, found no such association with either current or prior use of oral contraceptive preparations.[5-12] A meta-analysis of 18 case-control studies confirmed the lack of association.[13]

Ectopic pregnancy. All methods of contraception effectively reduce the risk of ectopic pregnancy overall by reducing the rate of pregnancy. However, when contraception fails the proportion of pregnancies that are ectopic is higher for users of oral and intra-uterine **progestogen-only contraceptives** and levonorgestrel implants than in the general population.[1] There is no increase in the proportion of ectopic pregnancies for methods that inhibit ovulation more reliably, such as combined oral contraceptives[1] and medroxyprogesterone acetate depot injection.[2]

A small number of cases of ectopic pregnancy after failure of **emergency contraception**, with both the Yuzpe regimen (oestrogen plus progestogen)[3] and progestogen-only contraception,[4] have been reported. However, data from clinical studies[5] and postmarketing surveillance[6] have shown that when levonorgestrel emergency contraception does rarely fail, there is no increase in the chance of ectopic pregnancy occurring.

Effects on body-weight. Weight gain has been reported as an adverse effect of combined oral contraceptives, but there is no strong evidence from clinical studies to confirm that they have a significant effect on weight.[1,2] However, there is some evidence that weight gain might be associated with medroxyprogesterone acetate when given as a long-acting injectable contraceptive. There have been reports of both weight gain[3] over 5 years, and no change in weight[4] over 10 years, in women using medroxyprogesterone compared with those using a copper IUD. Studies[5,6] in adolescents using medroxyprogesterone or an oral contraceptive for 12 or 18 months have reported more weight gain in those using medroxyprogesterone, and that significant weight gain was more likely in those who were overweight when contraception was started. The risk of weight gain, however, may be confounded by a number of factors including age, race, diet, exercise, and prior pregnancy.

For discussion of a possible association between obesity and oral contraceptive failure, see Obesity, under Precautions, below.

Effects on carbohydrate metabolism. The potential effects of oral contraceptives on carbohydrate metabolism are of concern because impaired glucose tolerance, hyperinsulinism, and insulin resistance contribute to atherogenesis and cardiovascular disease.[1] Early studies suggested that the prevalence of abnormal glucose tolerance in oral contraceptive users was increased from about 4 to 35%.[2] This decreased glucose tolerance was found to be related to oestrogen dose, particularly those greater than 75 micrograms daily, and to the type of progestogen. Marked hyperglycaemia has been associated with contraceptives containing high doses of oestrogen but is not seen with combined oral contraceptives used currently, which contain lower doses of oestrogen.[1] Progestogens have little effect on glucose tolerance, but are associated with hyperinsulinaemia. This effect is dose-dependent, and levonorgestrel has the most potent effect, with desogestrel, gestodene, and norethisterone reported to have less effect.[1] Combined oral contraceptives can also induce insulin resistance;[1] it is believed that the oestrogen is responsible and that the progestogen modifies this effect.[3]

Despite evidence of these effects, more recent studies of lower-dose preparations containing desogestrel, levonorgestrel, or norethisterone have found little or no effect on various measurements of carbohydrate metabolism;[4-6] this lack of effect has also been confirmed in a meta-analysis[7] of studies of hormonal contraceptive use in non-diabetic women although it was noted that no strong statement could be made since few studies compared the same types of contraceptives and some had large drop out rates. Also, data from the Nurses' Health Study indicate that oral contraceptive use does not appear to increase the risk of developing type 2 diabetes mellitus.[8,9] However, a study in the USA of breast-feeding women of Hispanic origin who had experienced recent gestational diabetes, suggested that the use of progestogen-only, but not combined, contraceptives was associated with an increased risk of developing type 2 diabetes mellitus in this group.[10]

Injectable progestogen-only contraceptives have been reported in epidemiological studies to be associated with an increase in the incidence of type 2 diabetes mellitus. However, metabolic studies in lean, non-diabetic women have generally found no effect on glucose concentrations, suggesting that obesity or weight gain associated with injectable progestogen-only contraceptive use may play a role.[11]

Effects on the cardiovascular system. Soon after their introduction in the 1960s it became apparent that **combined oral contraceptives** were associated with an increased risk of cardiovascular effects including *hypertension, venous thromboembolism, myocardial infarction*, and *stroke*. Consequently, there are a number of contra-indications and precautions relating to their use in women with risk factors for cardiovascular disease (see under Precautions, below).

Changing patterns of use, and a progressive reduction in doses, have meant a continued need to evaluate the risks associated with oral contraceptives.

Current use of lower-dose combined oral contraceptives (less than 50 micrograms oestrogen) increases blood pressure in many women, and also results in a small but significant increased risk of venous thromboembolism. Any increased risk of myocardial infarction and stroke is low in women aged less than 35 years who do not smoke and who do not have pre-existing hypertension. Further details of these adverse effects are covered in the sections below.

The effect of progestogens on the cardiovascular risk profile of oral contraceptives has not been established. Some of the newer progestogens have been reported to have more favourable effects on plasma lipids (see Effects on Lipids, below) and there is some suggestion that they may have a lower risk of myocardial infarction, but there are insufficient data to confirm or refute this. However, it has been reported that desogestrel and gestodene are associated with a higher risk of venous thromboembolism than older progestogens.

The Nurses' Health Study found no association between ever having used oral contraceptives and death from cardiovascular disease.[1] The Royal College of General Practitioners' study reported an increase in death from cerebrovascular disease with current or recent (within 10 years) use of oral contraceptives, but not for past use (greater than 10 years).[2]

HYPERTENSION. In a one-year prospective multicentre study[1] involving 704 women under the age of 35 using a **combined oral contraceptive** containing levonorgestrel 250 micrograms and ethinylestradiol 50 micrograms and 703 women using a non-hormonal intra-uterine contraceptive device, those using the oral contraceptive developed higher systolic and diastolic blood pressures (systolic pressures were 3.6 to 5.0 mmHg higher, diastolic pressures were 1.9 to 2.7 mmHg higher). Only 4 women receiving oral contraceptives developed hypertension. A similar increase in blood pressure was noted in a study[2] involving 222 users of combined oral contraceptives containing 30 micrograms ethinylestradiol. There was a greater increase in blood pressure for those preparations containing 250 micrograms levonorgestrel than those containing 150 micrograms levonorgestrel.

More recently, data from the Nurses' Health Study[3] showed an increased risk (relative risk 1.8) for the development of hypertension in women taking lower-dose combined oral contraceptives. Increasing doses of progestogen were positively associated with hypertension, and the lowest risk occurred in women receiving triphasic preparations, which have the lowest total dose of progestogen. A UK study[4] found a small increase in blood pressure of 2.3/1.6 mmHg associated with the use of combined oral contraceptives. In this study, oral **progestogen-only contraceptives** were not associated with an increase in blood pressure. A more recent review[5] also found no evidence that use of progestogen-only contraception for up to 2 to 3 years was associated with high blood pressure. Similarly, depot medroxyprogesterone acetate does not raise blood pressure.[6]

MYOCARDIAL INFARCTION. Case-control studies from the 1970s and early 1980s revealed an increased risk of acute myocardial infarction in users of oral contraceptives (generally of the high-dose type) relative to those never having used them.[1,2] Several large cohort studies have provided similar findings.[3-6] Among current users the reported[1-3,5,6] relative risk of myocardial infarction has varied between about 1.8 and 6.4, whereas in women having used oral contraceptives in the past the reported[2-5] relative risk has varied between about 0.8 and 2.5. Women who *smoke* while using oral contraceptives are at a greatly increased risk,[1,5,7] those smoking more than 15 to 25 cigarettes daily having at least a twentyfold increased risk of myocardial infarction compared with non-smoking non-oral contraceptive users.[1,5]

These studies have principally been from the USA or the UK. The WHO Collaborative Study of Cardiovascular Disease and Steroid Hormone Contraception has reported the findings of an international multicentre case-control study.[8] The overall odds ratio for acute myocardial infarction in current users of combined oral contraceptives was 5.01 in Europe and 4.78 in Africa, Asia, and Latin America. This increase in risk reflected use in women who had coexistent risk factors such as smoking, and who had not had their blood pressure checked before use. Thus, when the background incidence of acute myocardial infarction is taken into account, use of combined oral contraceptives in non-smoking women aged less than 35 years is associated with an excess of 3 per million women-years, and this is likely to be lower in those women who have their blood pressure screened before and during use. However, in older women who smoke, the excess risk associated with the use of combined oral contraceptives is substantial (400 per million women-years). There was no increase in risk associated with past use of oral contraceptives irrespective of duration of use.

There has been interest in the effect of different progestogen components on the risk of myocardial infarction. Limited data from the WHO study[8] and from the USA[9] and the UK[10] suggested no difference in risk between desogestrel or gestodene compared with levonorgestrel. Analysis of European data[11] suggested a reduction in risk with gestodene- and desogestrel-containing products compared with other progestogens (0.28; 95% confidence intervals 0.09 to 0.86). A WHO Scientific Group meeting concluded that available data did not allow the conclusion that risk of myocardial infarction was related to progestogen type.[12]

More recently, data on combined oral contraceptives that have lower oestrogen doses have revealed at most small and non-significant increases in risk of acute myocardial infarction associated with oral contraceptive use,[10,13-15] although case-control studies have suggested that again, there may be a greatly increased risk in women who smoke more than 20 to 25 cigarettes daily.[10,16] However, subsequent meta-analyses including these and other studies have concluded that, overall, there was an increased risk of myocardial infarction with current use of low-dose combined oral contraceptives (oestrogen less than 50 micrograms). Subgroup analyses of progestogen type found that there was an increased risk in users of second generation contraceptives (generally containing levonorgestrel) compared with non-users; calculated odds ratios were 2.18 (1.62 to 2.94),[17] 2.17 (1.76 to 2.69),[18] and 1.85 (1.03 to 3.32).[19] However, the risk was not increased in users of third generation contraceptives (generally containing desogestrel or gestodene) compared with non-users.[17-19] Clinically, although the risk of myocardial infarction may be increased, the absolute risk is very low in healthy young women who do not smoke and do not have cardiovascular risk factors. Despite reassuring data for these newer progestogens regarding the risk of myocardial infarction, there is probably a small increased risk of venous thromboembolism associated with desogestrel or gestodene (see below).

STROKE. Current use of **combined oral contraceptives** has been associated with an increased risk of stroke, with most data relating to older high-dose oestrogen preparations. In general this association has been strongest for ischaemic stroke, and relatively weak for haemorrhagic stroke.[1] A Danish study found that low-dose oral contraceptives (30 to 40 micrograms of oestrogen) were associated with a lower risk of cerebral thromboembolism than preparations containing 50 micrograms oestrogen.[2]

Data on 2198 cases of stroke (haemorrhagic, ischaemic, and unclassified) and 6086 controls have been reported from the WHO Collaborative Study of Cardiovascular Disease and Steroid Hormone Contraception.[3,4] For all strokes combined, odds ratios for the current use of lower-dose (less than 50 micrograms oestrogen) and higher-dose preparations were, respectively, 1.41 (95% confidence intervals 0.90 to 2.20) and 2.71 (1.70 to 4.32) in Europe, and 1.86 (1.49 to 2.33) and 1.92 (1.48 to 2.50) in Africa, Asia, and Latin America. In Europe, it was estimated that the incidence rate of stroke in women aged 20 to 44 years was 4.8 per 100 000 women-years, and that this was increased to 6.7 per 100 000 in users of lower-dose preparations and 12.9 per 100 000 in users of higher-dose preparations.[3]

The risk of haemorrhagic stroke was significant only in women aged greater than 35 years, those who had a history of hypertension, and those who were current smokers.[3]

The overall odds ratio for ischaemic stroke was 2.99 (1.65 to 5.40) in Europe and 2.93 (2.15 to 4.00) in Africa, Asia, and Latin America.[4] Odds ratios were lower in women aged less than 35 years, those who did not smoke, those with no history of hypertension, and those who reported that their blood pressure had been checked before use. Duration of current use and past use were unrelated to risk.[4] A similar overall odds ratio of 2.3 (1.15 to 4.59) has been reported from the UK.[5] Similar findings have also been published from the USA.[6] Low-dose preparations (less than 50 micrograms oestrogen) were associated with a non-significant increase in ischaemic stroke; the odds ratio was 1.18 (0.54 to 2.59); a later meta-analysis considered the association between low-dose combined oral contraceptives and stroke to be tenuous at best, and possibly non-existent.[7]

A meta-analysis[8] of studies of ischaemic stroke found that there was an overall increased risk associated with the current use of oral contraceptives. However, the risk was less elevated with lower oestrogen doses, and in studies that controlled for smoking and hypertension.

As regards the effect of the type of progestogen on risk of stroke, one case-control study[9] reported that there was no significant difference in risk of ischaemic stroke between low-dose oral contraceptives containing second generation progestogens and those containing desogestrel, gestodene, or norgestimate. However, another study[10,11] found that levonorgestrel- or norgestimate-containing preparations were associated with a higher risk of cerebral thrombosis than preparations containing desogestrel or gestodene. A re-analysis of the WHO data led to the cautious conclusion that the risk for stroke between second and third generation progestogens was similar,[12] and this was also supported by analysis of the General Practice Research Database[13] and a Dutch case-control study.[14] Meta-analyses[8,15] also found no significant difference between progestogen generations in the risk of ischaemic stroke.

Data for **progestogen-only contraceptives** are limited. The Danish study reported no increase in cerebral thromboembolic attacks in users of oral progestogen-only contraceptives; the odds ratio was 0.9 (0.4 to 2.4).[2]

Venous thromboembolism. Use of **combined oral contraceptives** has long been known to be associated with an increased risk of venous thromboembolic events, particularly deep-vein thrombosis and pulmonary embolism. This increased risk applies both to idiopathic events and events associated with surgery or trauma, is limited to current users and is probably highest in the first year of use. Most early data relate to high-dose combined preparations, and it has been suggested by some studies,[1] but not others,[2,3] that preparations containing lower doses of oestrogen may be associated with a lower risk. More recently, reports have identified an increased risk of cerebral-vein thrombosis with oral contraceptives.[4]

The WHO Collaborative Study of Cardiovascular Disease and Steroid Hormone Contraception reported data from over 10 times more cases than any previous study.[5] The increased risk of idiopathic deep-vein thrombosis and/or pulmonary embolism associated with current use of combined oral contraceptives was 4.15 (95% confidence intervals 3.09 to 5.57) in Europe and 3.25 (2.59 to 4.08) in Africa, Asia, and Latin America. The increased risk was apparent within 4 months of starting use, was unaffected by duration of use, and had disappeared within 3 months of stopping use. Risk was unaffected by age, hypertension, or smoking (in contrast to myocardial infarction, see above), but was increased in those with a body-mass index greater than 25 kg/m^2 and in those with a history of hypertension of pregnancy. Of preparations containing progestogens of the norethisterone or norgestrel type, risk was non-significantly less with lower-dose oestrogen than with high-dose oestrogen.

The progestogen component has generally been considered to be unrelated to thromboembolic events; therefore, it came as a surprise when WHO found a higher risk in combined oral contraceptives containing *desogestrel* or *gestodene* than in those containing older progestogens.[5] These risk data were the subject of a separate report,[6] and were subsequently confirmed by 3 further case-control studies.[7-9] The increased risk varied from 4.8 to 9.1 compared with non-users, and was found to be 1.5 to 2.6 times higher than for preparations containing levonorgestrel or other progestogens. The incidence of venous thromboembolic disease has been estimated to be 25 per 100 000 users per year for desogestrel- and gestodene-containing products and 15 per 100 000 users per year for products containing low-dose oestrogen with other progestogens, compared with 5 per 100 000 per year for non-users. The risk was especially high in women with the factor V Leiden mutation,[8] who are at increased risk of thrombosis, but screening to exclude these women from using oral contraceptives was not considered necessary.[10,11] Despite much debate about possible bias and confounding in these results,[12,13] and the ambiguous or contradictory results of subsequent studies,[14-16] many sources seem now to agree with the 1997 conclusion of a WHO scientific group meeting[17] that there is a modestly increased risk of venous thromboembolism associated with the use of products containing desogestrel or gestodene, compared with levonorgestrel. The extent of any risk associated with combined products containing *drospirenone* has also been questioned. Data from a prescription event monitoring study suggested that it was associated with a high incidence of deep-vein thrombosis and pulmonary embolism,[18] but the authors acknowledged potential bias that may have affected the result. Subsequent large cohort studies[19,20] reported that the risk of venous thromboembolism was similar to that for users of other combined oral contraceptives, including levonorgestrel-containing preparations. It is unclear to what extent products containing *cyproterone* are associated with increased risk (see Effects on the Cardiovascular System, under Cyproterone Acetate, p.2088).

Regulatory agencies have reacted in different ways to these data. The UK CSM has advised caution in prescribing of these products (see Cardiovascular Disease under Precautions, below), as have some other European authorities.

The mechanism behind differences in thrombotic potential is not known, but there is evidence that oral contraceptives may increase concentrations of prothrombin and factor VIII, and induce a resistance to the blood's natural anticoagulation system.[11] These effects may be greater with products containing desogestrel and gestodene compared with older progestogens.[11] Thrombophilias, including factor V Leiden, further increase the risk of thromboembolism from hormonal contraceptives.[21]

There has also been some concern about a possible increase in cardiovascular risk with a **transdermal patch** that releases ethinylestradiol and norelgestromin, because users are exposed to about 60% more total oestrogen than users of an oral contraceptive containing ethinylestradiol 35 micrograms (peak serum concentrations are lower but steady-state concentrations are higher). However, 2 studies comparing the patch with a combined oral contraceptive (ethinylestradiol plus norgestimate) came to different conclusions; one found the risk of venous thromboembolism to be similar,[22] while the other found a twofold increase in risk with the patch.[23] Further study is needed to explain this discrepancy, and to determine whether there is any effect on the risks of myocardial infarction and stroke.

Effects on the ears. In the Royal College of General Practitioners' study of oral contraception in the UK,[1] by 1981 there had been 13 cases of newly occurring otosclerosis in each of the groups of oral contraceptive users (101 985 woman-years) and controls (146 534 woman-years); this showed a non-significant relative risk of 1.29. Although, by analogy with pregnancy, it may be prudent to suppose that oral contraceptives could exacerbate pre-existing otosclerosis, the data do not support the view that the condition is associated with their use. Similarly, the Oxford Family Planning Association contraceptive study[2] of 17 032 women followed for up to 26 years found no association between oral contraceptive use and the development of a range of ear diseases, including otosclerosis.

Effects on the eyes. Analysis of data from 2 large UK cohort studies suggested that oral contraceptive use does not increase the risk of eye disease, with the possible exception of retinal vascular lesions.[1] Retinal vein thrombosis has also been reported after the use of emergency contraception.[2] The patient presented with a 10-day history of blurred vision that started the day after taking a regimen of ethinylestradiol with norgestrel; the condition resolved after 2 months of treatment with low-dose aspirin.

Effects on fertility. After stopping hormonal contraceptives some patients may experience amenorrhoea, anovulation, and infertility. This infertility, however, has been shown by most studies to be only temporary.

Data from the Oxford Family Planning Association study[1] have indicated that impairment of fertility after oral contraceptives was only very slight and short-lived in women who had previously had a baby. In nulliparous women aged 25 to 29 years impairment of fertility was more pronounced but the effect had almost entirely disappeared after 48 months. In nulliparous women aged 30 to 34 years the duration of impairment was longer but, again, this was not permanent as by 72 months after stopping oral contraceptive use the numbers of women who had not conceived were similar to a group who had previously used non-hormonal methods of contraception. In contrast to women using intra-uterine devices, in whom long-term use was associated with greater impairment of fertility than short-term (less than 42 months) use, there appears to be no association between fertility and duration of oral contraceptive use.[2] However, a later survey,[3] although concurring that the effects were transient, did find a relationship between duration of use of combined oral contraceptives and subsequent time to pregnancy.

Oral progestogen-only preparations do not appear to have a significant effect on fertility.[3] Smaller studies have also indicated that injectable progestogen-only contraceptives have no long-lasting effects on fertility;[3,4] but it has been suggested that a return to ovulation occurs significantly earlier in prior norethisterone enantate users than in medroxyprogesterone users.[5]

Infertility may also be related to the presence of pelvic inflammatory disease; for further details concerning the role of oral contraceptives in this disorder, see Pelvic Inflammatory Disease, below.

Effects on the gallbladder. Data from the Royal College of General Practitioners' (RCGP) oral contraception study accumulated up to December 1979 revealed no overall increased risk of gallbladder disease in the long-term, despite the indications of earlier data and other studies relating to short-term use.[1] Further studies[2,3] have identified an increased risk of gallbladder disease in oral contraceptive users under the age of 30 or 20, respectively. A systematic review[4] also found that oral contraceptives were associated with a slightly and transiently increased risk of gallbladder disease. However, the results of separate studies varied considerably and the reviewers highlighted a number of possible confounding factors and biases, nonetheless, it was concluded that newer low-dose contraceptives (less than 50 micrograms of oestrogen) were less likely to cause problems than older formulations. Later data from the RCGP study showed an increase in risk of mild hepatitis during the first 4 years of oral contraceptive use, possibly reflecting gallstone-associated cholestasis.[5] This risk then decreased to less than that seen in women who had never used oral contraceptives.

Effects on the gastrointestinal tract. Several studies,[1-3] epidemiological data,[4] and a meta-analysis,[5] have shown a weak association between oral contraceptive use and the onset of Crohn's disease or ulcerative colitis. However, the suggestion that oral contraceptives have an aetiological role in chronic inflammatory bowel disease cannot be regarded as established.

The rate of relapse of Crohn's disease in women taking oral contraceptives has also been studied. Although one study[6] reported an increased risk of relapse in women who had taken oral contraceptives in the past, both this study and another prospective cohort study[7] found no increase in risk in current users. These results may have been influenced by smoking, or changes in oestrogen dose and progestogen content.

Women with inflammatory bowel disease may be offered the same contraceptive choices as other women, although oral contraceptive absorption, and hence efficacy, may be reduced when there is small bowel involvement or malabsorption.[8]

Effects on lipids. Combined oral contraceptives have been reported to be associated with an excess risk of various adverse cardiovascular events (see above). Because other epidemiological evidence suggests that the composition of blood lipids may be one of several factors involved in the aetiology of some of these disorders, many workers have investigated the biochemical profiles of women taking various formulations of oral contraceptives. Results have often been conflicting as the net effect is the result of opposing actions of the oestrogen and the progestogen components, and depends on the ratio between these. In general, the oestrogen component increases triglycerides, but decreases low-density lipoproteins, whereas the progestogen component tends to decrease high-density lipoproteins and increase low-density lipoproteins, particularly if it is androgenic (19-nortestosterone-derived progestogens). Newer non-androgenic progestogens such as desogestrel and gestodene appear to have a less detrimental effect on serum lipids. However, the contribution of these lipid changes to the incidence of cardiovascular disease in oral contraceptive users is uncertain. In particular, contrary to expectations, desogestrel and gestodene appear to be associated with a higher risk of venous thromboembolism than older progestogens (see above).

Some references to the effects of various oral contraceptives on serum lipid profiles are given below.[1-4]

For further details concerning the proposed role of the various serum lipids and subfractions in the aetiology of cardiovascular disease, see Hyperlipidaemias, p.1169.

For reports of pancreatitis secondary to hyperlipidaemia associated with the use of combined oral contraceptives, see below.

Effects on the liver. The use of combined oral contraceptives has been rarely associated with the benign liver tumours, hepatic adenoma and focal nodular hyperplasia (see under Carcinogenicity, above).

Hepatitis possibly associated with gallstones has also been reported (see Effects on the Gallbladder, above).

Effects on mental state. Changes in mood and affect have been reported with oral contraceptives, and the onset of depression is a common reason given for stopping use. Nonetheless, a review[1] concluded that most women taking oral contraceptives actually experienced beneficial effects, with less variability in affect across the menstrual cycle and less negative affect during the menstrual phase compared with non-users. However, there may be a subgroup of women predisposed to negative changes in mood and affect because of factors such as a history of depression, premenstrual mood symptoms before oral contraceptive use, a history of mood symptoms related to pregnancy, or a family history of mood complaints related to oral contraceptives. A lower ratio of progestogen to oestrogen was associated with more negative mood changes in women with a history of premenstrual emotional symptoms, while a higher ratio was associated with negative changes in women without such a history. In addition, monophasic regimens appeared to have a greater stabilising effect than triphasic preparations. A number of possible mechanisms have been suggested to explain how combined hormonal contraceptives might influence mood.[2]

Cohort studies of injectable[3] and implantable[4] progestogen-only contraceptives found no overall change in depressive symptom score. A small increase in depressive score noted at the 2-year follow-up of implant users was found to occur in women who also had a decrease in relationship satisfaction, which the authors concluded was independent of contraceptive use. Another study[5] found an association between injectable medroxyprogesterone acetate and depressive symptoms, but other factors that might have influenced this result were also identified and another explanation could not be ruled out.

Effects on the musculoskeletal system. ***BONE DENSITY.*** Combined oral contraceptives are generally considered not to have a detrimental effect on bone mineral density but study results have been inconsistent and any clinical significance unclear. However, overall, combined oral contraceptives appear not to affect bone mineral density or biochemical markers of bone turnover.[1]

Reviews of studies in different age groups have found that bone mineral density in healthy premenopausal women does not appear to be significantly affected.[2,3] However, there is limited evidence that adolescents and young women (less than 23 years of age) using oral combined contraceptives have a lower bone mineral density than non-users; it is unclear whether contraceptives might prevent young women from reaching their peak bone mass and put them at increased risk of osteoporosis later in life.[3] There is some evidence of a positive effect on bone mineral density in perimenopausal[2,3] and postmenopausal women[3] taking combined oral contraceptives, but past use in postmenopausal women appeared to have no effect. Although bone mineral density is used as an indicator of fracture risk, the true effects of combined oral contraceptives on this clinical outcome are unclear;[1] there is a particular lack of data in older women, in whom osteoporotic fractures are most common.[3]

There is stronger evidence that bone mineral density is reduced in current users of the depot progestogen-only contraceptive, medroxyprogesterone acetate. Recovery occurs after stopping treatment,[4,5] but it is still unclear whether adult women can regain baseline bone mineral density levels, and whether adolescents can reach peak bone mass.[4] There is also a lack of data on the clinical outcome of fracture in both current and former users of all ages.[1,4]

As adolescence is an age at which bone mineral density is normally increasing there is some concern about the possible long-term effects of medroxyprogesterone. The UK CSM has advised that in adolescents it should only be used if other methods of contraception are unsuitable or unacceptable, and that there should be a re-evaluation of risks and benefits for women of all ages who wish to continue use beyond 2 years.[6] The FDA has also advised[7] that, for all women, medroxyprogesterone should only be used as a long-term contraceptive, giving an example of more than 2 years, if other contraceptive methods are inadequate. In contrast, however, WHO[8] advises that there should be no restriction, including duration of use, on the use of medroxyprogesterone in women aged 18 to 45 who are otherwise eligible to use it; in adolescents and women over 45, the advantages generally outweigh the theoretical risks of fracture, but because of limited data on long-term use the overall risks and benefits should be reconsidered over time with the individual user. Others[9] offer similar recommendations in support, pointing out that further research is needed.

There is some evidence that oestrogen supplementation may reduce or prevent the reduction in bone mineral density caused by medroxyprogesterone acetate.[10,11] Although such supplementation could be considered in medroxyprogesterone users who have osteopenia or are at high risk, the optimal dose, route, and extent of benefit has not been established.[9]

RHEUMATOID ARTHRITIS. There have been rare reports of arthritis or arthropathies attributed to oral contraceptives, and some large studies have investigated the incidence of rheumatoid arthritis in oral contraceptive users. A negative association between the use of oral contraceptives and the development of rheumatoid arthritis has been reported in some studies thus giving rise to the suggestion that oral contraceptive use may, in fact, have some sort of protective role. These findings were not, however, substantiated by a recent, large, long-term cohort study[1] which found no association, either beneficial or detrimental, between the use of oral contraceptives and the later development of rheumatoid arthritis. An earlier meta-analysis also found no conclusive evidence of a protective effect of oral contraceptives on rheumatoid arthritis risk.[2] There is limited information about the effect of oral contraceptives on pre-existing rheumatoid arthritis. One study[3] found that there was no significant influence on the progression of the disease, but there was a trend towards less radiographic joint damage and disability with long-term oral contraceptive use.

Effects on the nervous system. *Headache* is reported as a common adverse effect and frequent reason for stopping combined oral contraceptives. However, a systematic review[1] found that although study results could not be pooled, there was no strong evidence associating combined oral contraceptive use with headache. There may have been an increase in headache in the early cycles, but this tended to improve with continued use; for most women there was no effect on headache activity and some actually reported improvement. Headache also appeared to be associated with oestrogen withdrawal during the tablet-free week of the cycle, but there was no evidence that headache was improved by changing to a preparation with a lower dose of oestrogen. However, some women appeared to be at higher risk, such as those with a strong personal or family history of troublesome headaches, particularly migraine. Combined oral contraceptives are not contra-indicated in women with non-migrainous headache, but they should be used with caution or avoided in women with migraine because of the increased risk of stroke (see Migraine, under Precautions, below).

Chorea has been reported in women using combined oral contraceptives. Reviews of the literature have reported the onset of chorea to range from 1 week to 11 months,[2] with an average of 3 months,[3] and resolution of symptoms after stopping the contraceptive to occur after 1 week to 5 months[2] or an average of 5 weeks.[3] The mechanism of this effect is unclear. Some cases occurred in patients with no history of neurological disease,[2,3] but others had a history of rheumatic fever, often with Sydenham chorea, or chorea gravidarum, chorea secondary to other conditions, or congenital heart disease.[3] There is some evidence that chorea could be mediated by the production of antiphospholipid antibodies, as either a primary antiphospholipid syndrome or secondary to SLE.[4,5] It has been suggested that the production of these antibodies could be aggravated by the oestrogen component of combined oral contraceptives.[4] In another case report[6] it was suggested that the presence of anti-basal ganglia antibodies might have played a role in the development of chorea by making the basal ganglia more susceptible to the effects of the oestrogen component of an oral contraceptive.

It is generally advised that combined oral contraceptives should be used with caution or avoided in women with antiphospholipid antibodies because they are at increased risk of venous thromboembolism, see Cardiovascular Disease, under Precautions, below.

Effects on the skin. Oral contraceptives may cause chloasma, and those containing androgenic progestogens may cause or aggravate acne and hirsutism. More rarely, oral contraceptives have been implicated in photosensitivity reactions[1] and photosensitivity associated with drug-induced lupus erythematosus.[2] A survey of people using UVA sunbeds at commercial premises in the UK revealed that the prevalence of pruritus, nausea, and skin rashes as adverse reactions to sunbed use was higher in women taking oral contraceptives than in women receiving no medication.[3] There has been a report of hidradenitis suppurativa, a condition resulting in the recurrence of boils at the axillary apocrine sweat glands, anogenital region, and breasts, occurring in 7 women using oral contraceptives.[4] Sweet's syndrome (acute febrile neutrophilic dermatosis) has been described very rarely with hormonal contraceptives. In one case,[5] the reaction started 10 days after beginning a combined oral contraceptive and resolved after stopping the contraceptive and treating with oral and topical corticosteroids. The woman reported that a similar reaction had occurred 6 months earlier with a different combined oral contraceptive. Sweet's syndrome has also occurred 1 month after insertion of a levonorgestrel IUD; the condition was controlled with corticosteroids, but only resolved completely after removal of the IUD.[6]

For mention of the refuted association between oral contraceptives and malignant melanoma, see Skin under Carcinogenicity above. Auto-immune progesterone dermatitis has been reported in women with a history of oral contraceptive use (see p.2125).

Effects on the uterus. The Oxford Family Planning Association study found that the risk of developing uterine leiomyomas (uterine fibroids) was reduced by the use of oral contraceptives[1] by about 17% with each 5 years of oral contraceptive use. This was not thought to be due to selective prescribing.[2,3] The authors hypothesised that unopposed oestrogen may be a risk factor for uterine fibroids, and that the reduced risk with oral contraceptives might be analogous to the reduction in endometrial carcinoma seen with these drugs (see above).[1] Other studies[4,5] have also reported a reduced risk of uterine leiomyomas in current users of oral contraceptives, while past users have a risk similar to that in women who have never used oral contraceptives. However, one study[4] did suggest that in women who had first used oral contraceptives at an early age (13 to 16 years) there was a modestly elevated risk. Another case-control study involving 390 women with leiomyomas failed to find a protective (or detrimental) effect with oral contraceptive use.[6] A further cohort study[7] also found no association between oral contraceptive use and leiomyoma formation, but did report a reduced risk with current use of medroxyprogesterone acetate depot injection.

Pelvic inflammatory disease. It has been suggested that oral contraceptives protect against pelvic inflammatory disease. However, although oral contraceptives are thought to reduce the risk of developing acute pelvic inflammatory disease, higher rates of infection of the lower genital tract by *Chlamydia trachomatis*,[1] and, more tentatively, *Neisseria gonorrhoeae*,[2] have been reported. Other studies[3,4] have suggested that oral contraceptive use is associated with reduced symptom severity, but absence of symptoms is not the same as absence of disease: oral contraceptives might reduce the inflammatory reaction to infection, resulting in unrecognised disease and subsequent complications such as tubal infertility and ectopic pregnancy.[5] There is evidence that users of older oral contraceptives containing more than 50 micrograms of oestrogen may have been at increased risk of tubal infertility, particularly if first used before 20 years of age.[6] No increased risk, or an active decrease in risk (depending on age at first use) was reported for formulations containing 50 micrograms or less of oestrogen, which are now favoured.

The possible effects of depot medroxyprogesterone acetate have also been examined and one study[7] suggested that it was associated with an increase in cervical chlamydial and gonococcal infections. However, confounding factors in this study such as sexual practices, a history of infection, and the background pool of infectivity in sexual partners, have been highlighted[8,9] and cast doubt on a true causal relationship between medroxyprogesterone acetate and risk of infection.

Precautions

Before hormonal contraceptives are given, the woman should undergo an appropriate medical examination and her medical history should be carefully evaluated. Regular examination is recommended during use. The contraceptive effectiveness of combined and progestogen-only preparations may be reduced during episodes of vomiting or diarrhoea and extra contraceptive measures may be necessary during and for 7 days after recovery. For precautions to be taken if a 'pill' is missed, see Uses and Administration, below.

Combined oral contraceptives are *contra-indicated* in women with markedly impaired liver function or cholestasis, the Dubin-Johnson or Rotor syndromes, hepatic adenoma, oestrogen-dependent neoplasms such as breast or endometrial cancer, cardiovascular disease (see also below) including previous or current thromboembolic disorders or high risk of them, and arterial disease or multiple risk factors for it, disorders of lipid metabolism, undiagnosed vaginal bleeding, possible pregnancy, or a history during pregnancy of pruritus or cholestatic jaundice, chorea, herpes gestationis, pemphigoid gestationis, or deteriorating otosclerosis. They are also contra-indicated in severe or focal migraine (or where there are other risk factors for cardiovascular disease) and should be used with caution in other forms of migraine (for further details, see below). They should be *given with caution* to women with a history of clinical depression, gallbladder disease, sickle-cell disease, or conditions influenced by fluid retention. Oral contraceptive absorption, and hence efficacy, may be reduced in women with inflammatory bowel disease when there is small bowel involvement or malabsorption. They should also be used with caution in those with varicose veins (and should be avoided where the restrictions outlined under Venous Thromboembolism apply, see Cardiovascular Disease, below). Where not actually contra-indicated, they should also be used with caution in those with a risk factor for cardiovascular disease such as diabetes mellitus, smoking, obesity, hypertension, or a family history of cardiovascular disorders (see also below). Current opinion is that low-dose combined oral contraceptives may be used in women over the age of 35 years provided they do not smoke and have no other risk factors for cardiovascular disease, but that they should be avoided over the age of 50 years. Use by those undergoing surgery or prolonged bed rest may increase the risk of thromboembolic episodes and it is generally recommended that combined oral contraceptives should be stopped 4 weeks before major elective surgery (but see also below). Combined oral contraceptives should not be used after recent evacuation of a hydatidiform mole until urine and plasma gonadotrophin concentrations have returned to normal. Contact lenses may irritate. The use of combined oral contraceptives may influence the results of certain laboratory tests including liver, thyroid, adrenal, and renal-function tests, plasma concentrations of binding proteins and lipid/lipoprotein fractions, and fibrinolysis and coagulation parameters.

Combined oral contraceptives should be *stopped immediately*, and appropriate investigations and treatment carried out, if any of the following occur:

- sudden severe chest pain, sudden breathlessness, or severe pain/swelling in calf of one leg (possibly indicative of thromboembolic complications)
- unusual, severe, prolonged headache, sudden disturbances of vision or hearing or other perceptual disorders, collapse, marked numbness or weakness affecting one side of the body, or other signs or symptoms suggestive of cerebrovascular accident
- a first unexplained epileptic seizure
- hepatitis, jaundice, generalised itching, liver enlargement, severe upper abdominal pain
- significant rise in blood pressure (above 160 mmHg systolic or 100 mmHg diastolic)
- clear exacerbation of other conditions known to be capable of deteriorating during oral contraception or pregnancy.

Progestogen-only contraceptives, whether oral or injectable, may be used when oestrogen-containing preparations are contra-indicated but certain contra-indications and precautions must still be observed. They are contra-indicated in women with undiagnosed vaginal bleeding, possible pregnancy, severe arterial disease, hormone-dependent neoplasms, and severe liver disease such as hepatic adenoma.

Like combined oral contraceptives they should not be used after recent evacuation of a hydatidiform mole. Progestogen-only contraceptives should be used with caution in women with heart disease, malabsorption syndromes, liver dysfunction including recurrent cholestatic jaundice, or a history of jaundice in pregnancy. Oral progestogen-only contraceptives should also be used with caution in past ectopic pregnancy (see above) or functional ovarian cysts. Despite unsatisfactory evidence of hazard, other suggested cautions for progestogen-only contraceptives include diabetes mellitus, hypertension, migraine, and thromboembolic disorders.

Breast feeding. Progestogen-only contraceptives are the hormonal contraceptives of choice for breast-feeding women because they do not affect lactation,[1] but recommendations vary about when they can or should be started, and may not match licensed product information. Some guidelines[2] recommend that all progestogen-only methods can be started 6 weeks after birth. Others[3] suggest that oral preparations can be started any time in breast-feeding women, although they are not needed before 3 weeks postpartum; the *BNF* also warns that there is an increased risk of breakthrough bleeding if progestogen-only oral contraceptives are started before 3 weeks postpartum. Progestogen-only parenteral contraceptives, such as medroxyprogesterone acetate, are usually not given until 6 weeks postpartum;[1-3] troublesome bleeding can occur before this time.[3] The etonogestrel implant may be used 3 weeks postpartum and the levonorgestrel IUD may be inserted 4 weeks postpartum.[3]

Combined oral contraceptives can reduce the volume of breast milk and are therefore avoided in breast-feeding women for the first 6 weeks after birth.[1,3] In general, they are not recommended for 6 months or until weaning,[2,3] but some suggest[3] that they may be considered between 6 weeks and 6 months postpartum if breast feeding is established and other contraceptive methods are unacceptable.

Very small amounts of oestrogens and progestogens from hormonal contraceptives are distributed into breast milk, but there is no indication that this adversely affects development of the breast-fed infant.[3,4] The American Academy of Pediatrics[5] has also reviewed the use of hormonal contraceptives during lactation, commenting that early information was based on the use of high-dose contraceptives. It was noted that there might be a decrease in milk production, but that there was insufficient information to confirm that there was any alteration in the composition of breast milk, and that although there had been rare cases of gynaecomastia in breast-fed infants of mothers who received high-dose contraceptives, there was no consistent evidence of long-term adverse effects on the infant. A later study[6] of 48 children whose mothers had received high-dose combined oral contraceptives during breast feeding found no effect on these children compared with controls, up to 8 years of age. The Academy therefore considers[7] that combined oral contraceptives are usually compatible with breast feeding.

Breast feeding itself suppresses ovulation and can be used, if started immediately postpartum, as the lactational amenorrhoea method of contraception; for further details, see Contraception, p.2070.

Cardiovascular disease. Combined oral contraceptives are associated with a number of arterial and venous risks. Progestogen-only contraceptives are associated with fewer risks, although they still need to be avoided when arterial disease is severe.

Arterial disease. In the UK the *BNF* has recommended that combined oral contraceptives may be used with **caution** if any **one** of the following factors are present, but should be **avoided** if **two or more** factors are present:

- *family history of arterial disease* in first-degree relative aged under 45 years (avoid if there is also an atherogenic lipid profile)
- *diabetes mellitus* (avoid if diabetic complications are present)
- *hypertension* (avoid if blood pressure is above 160/100 mmHg)
- *smoking* (avoid if 40 or more cigarettes are smoked daily)
- *age over 35 years* (avoid if over 50 years)
- *obesity*—body-mass index above 30 kg/m^2 (avoid if body-mass index exceeds 39 kg/m^2)
- *migraine,* see under Migraine, below.

Venous thromboembolism. Combined oral contraceptives increase the risk of venous thromboembolism and should not be used in women with a personal history of venous or arterial thrombosis. In addition they should be used with **caution** if any **one** of the following risk factors are present, but should be **avoided** if **two or more** factors are present:

- *family history of venous thromboembolism* in first-degree relative aged under 45 years (avoid if there is a known prothrombotic coagulation abnormality such as antiphospholipid antibodies, which may occur in patients with SLE, or factor V Leiden)
- *long-term immobilisation* such as wheelchair use (avoid if confined to bed or with a leg in plaster)
- *varicose veins* (avoid during sclerosing treatment)
- *obesity*—body-mass index above 30 kg/m^2 (avoid if body-mass index greater than 39 kg/m^2).

The *BNF* also advises that women taking combined oral contraceptives may be at an increased risk of deep-vein thrombosis during *travel* involving prolonged periods of immobility (over 5 hours). The risk may be reduced by appropriate exercise during the journey, and possibly by wearing graduated compression hosiery.

In the light of evidence indicating an increased risk of venous thromboembolism with combined oral contraceptives containing *desogestrel* or *gestodene* (see Venous Thromboembolism, under Effects on the Cardiovascular System, above), the UK CSM advised additional precautions for these products. As well as the usual precautions, it was initially advised they should not be used by obese women (body-mass index greater than 30 kg/m^2), those with varicose veins, or those with a history of thrombosis of any cause. Moreover, it was also recommended that they should be used only by women who were intolerant of other combined oral contraceptives and who were prepared to accept an increased risk of venous thromboembolism. Subsequently the CSM[1] modified its advice as follows: they recommended that these products should be avoided in women with known risk factors for venous thromboembolism. However, in women without contra-indications, the type of combined contraceptive was considered a matter of clinical judgement and personal choice, as long as the woman was fully informed of the small excess risk associated with desogestrel- and gestodene-containing products.

Available at: http://www.mhra.gov.uk/home/idcplg?IdcService=GET_FILE&dDocName=CON2023234&RevisionSelectionMethod=LatestReleased (accessed 14/01/08)

Lupus erythematosus. SLE is an auto-immune disease that is far more common in women than in men, and usually has a peak onset for women in their 20s and 30s. There is some evidence to suggest that oral contraceptive use may be associated with a slightly increased risk in the onset of SLE.[1-3] There are also reports and studies of the effect of contraceptives on disease exacerbation, although there has been an apparent reduction in reports which has coincided with the lowering of oestrogen content in contraceptive preparations.[2] More recently, controlled studies[4,5] have found that disease activity and flares over 12 months in women with stable SLE were similar whether they were given a combined oral contraceptive (containing ethinylestradiol 30 or 35 micrograms), a progestogen-only oral preparation, placebo, or copper IUD. However, patients with major disease, such as lupus nephritis, could be at greater risk of exacerbation. It is also generally advised that combined oral contraceptives should be avoided in women with antiphospholipid antibodies (which includes about a third of all patients with SLE) because they are at increased risk of venous thromboembolism.[1,2]

Migraine. Both migraine and the use of combined oral contraceptives have been identified as risk factors for ischaemic stroke. A systematic review[1] concluded that in women with a history of migraine, users of combined oral contraceptives were 2 to 4 times more likely to have an ischaemic stroke than non-users. It was unclear, however, whether this increase in relative risk was due to independent effects of contraceptives and migraine, or whether contraceptive use had a greater effect in women with a history of migraine than in those without.

In the UK the *BNF* has recommended that combined oral contraceptives be **contra-indicated** in:

- migraine with typical focal aura
- severe migraine regularly lasting longer than 72 hours despite treatment
- migraine treated with an ergot derivative

It also recommends **caution** in migraine without focal aura and migraine controlled with a serotonin (5-HT$_1$) agonist. A woman receiving a combined oral contraceptive should report any increase in headache frequency or the onset of focal symptoms. If focal neurological symptoms not typical of aura persist for longer than one hour the combined oral contraceptive should be discontinued and the woman referred urgently to a neurologist.

Other risk factors for arterial disease should also be considered in women with a history of migraine (see Cardiovascular Disease, above).

1. Curtis KM, *et al.* Use of combined oral contraceptives among women with migraine and nonmigrainous headaches: a systematic review. *Contraception* 2006; **73:** 189–94.

Obesity. It has been suggested that higher body-weight or BMI might be associated with a greater risk of oral contraceptive failure. A number of cohort and case-control studies have evaluated this association, with mixed results that may have been confounded by recall bias, inaccuracy of reported body-weight, non-compliance, and change in oestrogen dose over time. Some studies have suggested that there is an increased risk of contraceptive failure,[1,2] while others have found no association.[3] In addition, some have found a weak association that was no longer statistically significant when results were adjusted for confounders such as education, income, and ethnicity.[4,5] It is therefore unclear whether an association exists, but obesity is a risk factor for cardiovascular disease and combined oral contraceptives should be used with caution, or avoided, in these women (see Cardiovascular Disease, above).

Porphyria. Oral contraceptives have been associated with acute attacks of porphyria and are considered unsafe in porphyric patients. The progestogen content is considered more hazardous than the oestrogen content. A progestogen-only contraceptive may be used with extreme caution if non-hormonal contraception is inappropriate and potential benefit outweighs the risk. The risk of an acute attack is greatest in women who have had a previous attack or are under 30 years of age. Long-acting progestogen preparations should never be used in those at risk.

Pregnancy. In contrast to the numerous cases of congenital malformations reported after the use of high doses of sex hormones for hormonal pregnancy tests, there have been only a few suggestions that continued use of oral contraceptives during early pregnancy may result in congenital limb reduction deformities,[1-3] and one case of neonatal choreoathetosis after prenatal exposure to oral contraceptives.[4]

Many studies, conversely, have shown no evidence that the use of oral contraceptives is associated with congenital malformations or teratogenic effects, whether past use (stopped before conception), use after the last menstrual period, or known use in early pregnancy. A meta-analysis[5] confirmed this; the relative risk for all malformations with use of oral contraceptives was estimated to be 0.99 (95% confidence intervals 0.83 to 1.19). The use of oral contraceptives in early pregnancy also appears unlikely to increase the risk of hypospadia in male fetuses[6,7] (see also under Precautions of Estradiol, p.2098).

Depot intramuscular medroxyprogesterone acetate is a highly effective contraceptive, but failures do occur rarely. A review[8] of such failures had limited data on birth outcome in 100 women who continued the pregnancy, but no abnormalities or fetal anomalies were reported.

In 25 pregnancies that were continued after the failure of levonorgestrel-based emergency contraception,[9] there was 1 case of gastro-oesophageal reflux requiring medical treatment and 1 case of nasolachrymal duct obstruction that was surgically drained, but compared with a control group and expected baseline risk there was no increased risk of congenital or genital abnormalities.

For a discussion of the ectopic pregnancy risk in users of hormonal contraceptives, see above.

Sickle-cell disease. *Sickle-cell disease* and oral contraceptive use are both associated with an increased risk of thrombosis but it is by no means certain that the two risks are additive. Study of a small number of women with sickle-cell disease found that combined and progestogen-only contraceptives had no effect on red cell deformability.[1] Licensed product information for some preparations has specifically warned against the use of combined oral contraceptives in sickle-cell disease. However, there is a lack of strong clinical evidence to support such a contra-indication,[2,3] and there is some suggestion that progestogen-only contraception may be associated with improvements in clinical symptoms and sickle-cell crises.[4] WHO considers[5] that in women with sickle-cell disease the benefits generally outweigh the risks for low-dose combined oral contraceptives (35 micrograms or less of ethinylestradiol) and other forms of combined hormonal contraceptives (injectable, transdermal patch, and vaginal ring), and that there is no restriction for the use of progestogen-only contraceptives (oral, depot injection, implant, and intra-uterine device).

For *sickle-cell trait* there is no increased risk of thrombosis and no contra-indication to the use of a combined or progestogen-only preparation. Many women with sickle-cell trait have, unnecessarily, been denied the use of oral contraceptives in the mistaken belief that advice for sickle-cell disease applies to the trait.[6]

Surgery. Case reports and epidemiological studies showing an increased risk of idiopathic deep-vein thrombosis and pulmonary embolism in young women taking **combined oral contraceptives** (see above) led to the widespread belief that oral contraceptives may predispose to deep-vein thrombosis postoperatively. In consequence, the advice commonly given in the UK has been that, if possible, combined oral contraceptives should be stopped 4 weeks before major elective surgery and all surgery of the legs, and that prophylactic heparin should be considered where this was not possible.[1] They can normally be started again at the first menses occurring at least 2 weeks after full mobilisation. However, estimates of the size of the risk are variable;[2-5] one report[2] found that the incidence of deep-vein thrombosis postoperatively in young women taking combined oral contraceptives was about twice that of women not taking contraceptives but the difference was not statistically significant. Some have considered[6] that the risk to young women of becoming pregnant after stopping oral contraceptives, or of developing adverse effects from heparin prophylaxis, may be greater than the risk of developing postoperative deep-vein thrombosis. This is in line with the views of the Thromboembolic Risk Factors (THRIFT) Consensus Group.[7] They suggested that unless there were other risk factors there was insufficient evidence to support a policy of routinely stopping combined oral contraceptives before major surgery. Additionally, there was insufficient evidence to support routine specific thromboembolic prophylaxis in women without additional risk factors. A review[8] has subsequently recommended that women for whom major elective surgery was planned should continue taking the combined oral contraceptive but should receive thromboprophylaxis in the perioperative period. It has also been pointed out[9,10] that for patients awaiting surgery who require contraception, a progestogen-only oral contraceptive or an injection of medroxyprogesterone acetate may be suitable since neither preparation increases the risk of thrombosis.

Travel. For a warning that women taking oral contraceptives may be at increased risk of deep-vein thrombosis from travel involving prolonged immobility see Cardiovascular Disease, above.

Interactions

Enzyme-inducing drugs can cause combined oral contraceptives to fail by increasing their metabolism and clearance. This effect is well established for a number of *antiepileptics*, *griseofulvin*, and *rifamycin antibacterials*, and has also been suggested for some *antivirals* and for *modafinil*. Although less well documented, these interactions would also be expected to apply to progestogen-only contraceptives. The *BNF* has provided recommendations for contraception in women taking enzyme-inducing drugs.

- When a short course of an enzyme-inducing drug is taken, the dose of a combined oral contraceptive should be adjusted to provide ethinylestradiol 50 micrograms or more daily. Additional non-hormonal contraceptive methods should be used during the course and for 4 weeks after stopping it.
- For women requiring long-term treatment with an enzyme-inducing drug, an alternative method of contraception that is unaffected by the enzyme-inducing drug should be considered. However, if a combined oral contraceptive is used, a regimen that provides ethinylestradiol 50 micrograms or more daily should be used. 'Tricycling' has also been recommended where 3 or 4 cycles of monophasic tablets are taken without any breaks, followed by a short tablet-free interval of 4 days; the efficacy of this regimen is uncertain however. Enzyme activity may not return to normal for several weeks after stopping long-term treatment, and appropriate contraceptive measures should be continued for 4 to 8 weeks. These measures are not sufficient for long-term use of rifamycins, and an alternative method such as an IUD is always recommended.
- For women using a contraceptive transdermal patch, additional non-hormonal contraceptive methods should be used during a short-term course of an enzyme-inducing drug and for 4 weeks after stopping. If concomitant use runs beyond the 3 weeks of patch treatment, a new treatment cycle should be started immediately without a patch-free interval. For women taking an enzyme-inducing drug long-term, another form of contraception should be considered.
- Progestogen-only oral contraceptives and injectable preparations containing norethisterone or etonogestrel (but not medroxyprogesterone) may be affected by enzyme-inducing drugs, and an additional or alternative method of contraception is recommended during treatment and for at least 4 weeks after stopping. An alternative method of contraception should be considered if long-term treatment with an enzyme-inducing drug is required. Intra-uterine progestogen-only contraceptives are unlikely to be affected by enzyme-inducing drugs.
- An increased dose of postcoital (emergency) contraception, as a single oral dose of levonorgestrel 3 mg, has been suggested for women receiving enzyme-inducing drugs. Alternatively, a copper IUD may be used.

Rarely, *broad-spectrum antibacterials* have been associated with combined oral contraceptive failure, possibly by reducing enterohepatic recycling of the oestrogen component. As the doses of oestrogen and progestogen in oral contraceptives have decreased, reports of menstrual irregularities and unintended pregnancies attributed to these drug interactions have increased.

Further details of drugs affecting hormonal contraceptives are given below under specific headings.

Oral contraceptives may also *affect other drugs*. Compounds undergoing oxidative metabolism can have their plasma concentration raised by oral contraceptives through an inhibitory action. Conversely, oral contraceptives appear to induce glucuronidation of some drugs thus reducing their plasma concentration. Oral contraceptives can also antagonise the actions of a number of drugs. Drugs affected include:

- some analgesics (increased clearance of paracetamol and morphine)
- anticoagulants (increased and decreased effects reported; see p.1431)
- some antidepressants (reduced effectiveness, but also increased toxicity; see p.380)
- antidiabetics (antagonism of effect)
- the antiepileptic lamotrigine (decreased plasma concentrations; see p.486)
- antihypertensives (antagonism of effect)
- benzodiazepines (increased or decreased clearance; see p.991)
- ciclosporin (increased toxicity; see p.1828)
- clofibrate (increased clearance and antagonism of effect)
- corticosteroids (enhanced effect; see p.1495)
- levothyroxine (reduced free fraction due to increased binding globulin concentration; see p.2173)
- lidocaine (increased free fraction due to altered protein binding; see Protein Binding, under Pharmacokinetics, p.1864)
- selegiline (decreased clearance; see p.817)
- xanthines (decreased clearance; see p.1145)

Antibacterials. An interaction between the *rifamycins (rifampicin* and *rifabutin)* and oral contraceptives is well established and alternative contraceptive measures are necessary (see Rifamycins, below).

A variety of *broad-spectrum antibacterials* have also been reported to decrease oral contraceptive efficacy. Some studies have pointed to interference with intestinal flora involved in enterohepatic circulation of oestrogens as being a likely mechanism for this interaction. Although up until 1985 there had been 32 reports[1] of unintended pregnancies in women receiving *penicillins* (25 of them with *ampicillin*) the ability of antibacterials to inhibit oral contraceptive efficacy remains unproven. The data are consistent, however, with the supposition that efficacy is occasionally impaired.[2] Several cases of unintended pregnancies have been reported after the use of *tetracyclines*. It is recommended that additional contraceptive precautions should be used while taking, and for 7 days after stopping, a short course of any broad-spectrum antibacterial. If these 7 days run into the last 7 days of the cycle, then the tablet-free interval (or the 7 inert tablets) should be omitted and the next cycle of tablets started immediately. If the course of antibacterial exceeds 3 weeks the intestinal flora develop resistance and additional precautions become unnecessary.

With regard to other antibacterials, in theory any one with significant effects on intestinal flora could affect contraceptive efficacy. Isolated cases of pregnancy have been reported following the use of *cephalosporins, chloramphenicol, dapsone, isoniazid, nitrofurantoin, sulfonamides,* and *co-trimoxazole* but it is impossible to determine which, if any, of these interactions is real.

2. Dickinson BD, *et al.* Drug interactions between oral contraceptives and antibiotics. *Obstet Gynecol* 2001; **98:** 853–60.

RIFAMYCINS. *Rifampicin* regularly results in menstrual irregularities and occasionally in unintended pregnancies in women receiving oral contraceptives. It is a potent enzyme inducer and considerably enhances the metabolism of oral contraceptives. For short courses of rifampicin, additional contraceptive precautions should be taken during the course and for 4 weeks after stopping. A non-hormonal method of contraception such as an IUD is recommended during, and for 4 to 8 weeks after stopping, long-term rifampicin therapy.

Similar precautions are recommended during *rifabutin* therapy.

Contraceptive failure, resulting in an ectopic pregnancy, has also been reported in a woman who started rifampicin therapy 3 months after placement of an etonogestrel implant.[1]

1. Patni S, *et al.* Ectopic pregnancy with Implanon . *J Fam Plann Reprod Health Care* 2006; **32:** 115.

TROLEANDOMYCIN. Severe pruritus and jaundice may occur if oral contraceptives and troleandomycin are given together.[1] It has been suggested that their hepatic effects may be additive or synergistic, and that concurrent use should be avoided.

1. Miguet J-P, *et al.* Jaundice from troleandomycin and oral contraceptives. *Ann Intern Med* 1980; **92:** 434.

Antidepressants. *St John's wort* may decrease blood concentrations of oral contraceptives by enzyme induction.[1-3] There have been reports of intermenstrual bleeding and altered menstrual bleeding in women on long-term oral contraceptives who started taking St John's wort.[4] Several pregnancies have also been reported.[5,6]

For general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see above.

Antidiabetics. *Troglitazone* is an enzyme inducer and increases the clearance of oestrogens and progestogens. A high-dose oral contraceptive, or an alternative method of contraception should be considered in women receiving troglitazone and requiring contraception.[1] However, *rosiglitazone* is not an enzyme inducer and is not expected to affect the efficacy of oral contraceptives.[2]

For general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see above.

2. Inglis AML, *et al.* Lack of effect of rosiglitazone on the pharmacokinetics of oral contraceptives in healthy female volunteers. *J Clin Pharmacol* 2001; **41:** 683–90.

Antiepileptics. Oral contraceptive failure and breakthrough bleeding have been reported in numerous cases during antiepileptic therapy.[1,2] *Phenytoin*, barbiturates such as *phenobarbital* and *primidone*, and *carbamazepine* have been most frequently implicated, and *oxcarbazepine*, *felbamate*, and *topiramate* may interact similarly.[3] These drugs increase the clearance of both oestrogens and progestogens by enzyme induction, so diminishing their effects. Contraceptive methods that are not affected by enzyme induction include a copper or levonorgestrel IUD, or intramuscular depot medroxyprogesterone acetate.[4,5] If these are unsuitable, a combined oral contraceptive with an increased oestrogen content equivalent to ethinylestradiol 50 micrograms or more, and a corresponding increase in progestogen, is generally recommended. In addition, the use of a monophasic preparation given for 3 cycles without a break followed by a tablet-free interval of 4 days (tricycling) has also been suggested.[4] The importance of the progestogen in suppressing ovulation has also been discussed, with the suggestion that ethinylestradiol doses of less than 50 micrograms could be used provided the dose of progestogen is at least 1 mg of norethisterone, 150 micrograms of levonorgestrel, or 300 micrograms of norgestrel.[5] Biphasic, triphasic, and progestogen-only oral contraceptives are not recommended.[5]

Lamotrigine may also reduce contraceptive efficacy, and is markedly affected in turn by the contraceptive (see p.486).

For the effects of oral contraceptives on *valproate*, see p.511.

The efficacy of postcoital hormonal contraception (emergency contraception) is also reduced by enzyme-inducing antiepileptic drugs,[4] and an increased dose has been suggested (see above).

Antiepileptics that are reported not to interact with hormonal contraceptives include *ethosuximide*, *gabapentin*, *levetiracetam*, *tiagabine*, *valproate*, and *vigabatrin*.[4,5]

Antifungals. Menstrual irregularities and pregnancies have been reported in women receiving oral contraceptives and *griseofulvin*,[1,2] which is known to be an inducer of hepatic enzymes and may increase the metabolism of hormonal contraceptives. Additional contraceptive measures should be considered during concomitant use and after stopping griseofulvin; for general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see above. There have also been anecdotal reports[3-5] of menstrual irregularities and contraceptive failure with *fluconazole*, *itraconazole*, and *ketoconazole*, and similar advice applies to these if pregnancy is to be avoided with certainty.

Antivirals. A number of antivirals are likely to accelerate the metabolism of oestrogens and progestogens; theoretically therefore, they may decrease the efficacy of hormonal contraceptives. This has been suggested for HIV-protease inhibitors such as *nelfinavir*,[1] *ritonavir*,[2] and ritonavir-boosted HIV-protease inhibitors, and for the NNRTI *nevirapine*.[3] An alternative form of contraception should be considered. For general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see above.

Conversely, the area under the plasma-concentration-time curve for ethinylestradiol is reported to be increased by HIV-protease inhibitors such as *amprenavir*, *atazanavir*, and *indinavir*, and the NNRTIs *delavirdine* and *efavirenz*. Although the clinical implications are unknown, the licensed product information recommends alternative or additional contraception.

The *BNF* suggests that the use of condoms with a long-acting method, such as an injectable contraceptive, may be more suitable for patients with HIV infection or at risk of infection.

3. Mildvan D, *et al.* Pharmacokinetic interaction between nevirapine and ethinyl estradiol/norethindrone when administered concurrently to HIV-infected women. *J Acquir Immune Defic Syndr* 2002; **29:** 471–7.

Endothelin receptor antagonists. In a pharmacokinetic study of healthy women[1] the area under the concentration-time curve (AUC) of both ethinylestradiol and norethisterone were reduced by *bosentan*, probably by enzyme induction. The possibility of contraceptive failure should be considered, and licensed product information for bosentan suggests that an additional or alternative method of contraception should be used during bosentan therapy. For general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see above.

In contrast, *sitaxentan* is an inhibitor of some cytochrome P450 isoenzymes, and it has increased exposure to ethinylestradiol and norethisterone in women taking a combined oral contraceptive. An increase in oestrogen exposure may possibly increase the risk of thromboembolism.

1. van Giersbergen PLM, *et al.* Pharmacokinetic interaction between bosentan and the oral contraceptives norethisterone and ethinyl estradiol. *Int J Clin Pharmacol Ther* 2006; **44:** 113–18.

Retinoids. One woman taking an oral progestogen-only contraceptive (levonorgestrel 30 micrograms daily) showed a significant increase in plasma-progestogen while receiving *acitretin*, which indicated ovulation had occurred.[1] However, progestogen-only contraceptives do not suppress ovulation in all cycles, and this is not thought to be their primary mechanism of contraceptive efficacy (see Types of Contraceptive, p.2058). Nevertheless, because it is imperative that women receiving retinoids do not conceive, some have concluded that oral progestogen-only contraceptives are not suitable for use with retinoids.[2]

The anti-ovulatory efficacy of combined oral contraceptives was not affected by acitretin in 8 women in the study above,[1] or by *etretinate* in a study[3] in 12 women. Other studies have reported that *isotretinoin* did not significantly change plasma concentrations or adversely affect contraceptive efficacy of ethinylestradiol and levonorgestrel in 9 women,[4] or ethinylestradiol and norethisterone in 26 women.[5] It has been concluded that, unless otherwise contra-indicated, oral combined contraceptives are the contraceptive method of choice for women undergoing retinoid treatment.[2] Licensed product information for retinoids, including isotretinoin, reminds prescribers that two effective forms of contraception such as a combined oral contraceptive with a barrier method should be used during and after retinoid treatment (see also Pregnancy, under Isotretinoin, p.1601).

Both isotretinoin and combined oral contraceptives can have adverse effects on plasma lipids;[6] it has therefore been recommended that plasma lipids should be monitored during concurrent retinoid and oral contraceptive therapy, and that an oral contraceptive containing a non-androgenic progestogen is preferred,[2] since these have less detrimental effects on lipids (p.2064).

6. Chen Y, *et al.* Elevation of serum triglyceride and cholesterol levels from isotretinoin therapy with concomitant oral contraceptives. *Pharmacoepidemiol Drug Safety* 1995; **4:** 91–6.

Stimulants. *Modafinil* induces hepatic enzymes and may reduce the efficacy of oral contraceptives.[1] Licensed product information for modafinil suggests that alternative or additional methods of contraception are needed; US information recommends that this is also continued for 1 month after stopping modafinil, but in the UK it is recommended for 2 months.

For general recommendations on the use of hormonal contraceptives with enzyme-inducing drugs, see Interactions, above.

Pharmacokinetics

For a discussion of the pharmacokinetics of oestrogens and progestogens, see Estradiol, p.2098 and Progesterone, p.2126, respectively. The extent of binding of progestogens to serum sex-hormone binding globulin may be altered when they are given with an oestrogen. Oestrogens increase serum concentrations of sex-hormone binding globulin, and progestogens differ in their ability to suppress this effect.

Uses and Administration

The main use of hormonal contraceptives is for contraception, but combined oral contraceptives are also commonly used in menstrual disorders such as dysmenorrhoea (p.6), premenstrual syndrome (p.2099), and menorrhagia (p.2126), particularly where contraception is also required. Combined oral contraceptives are also used in polycystic ovary syndrome (p.2080) and Turner's syndrome (p.2081), and may be used in endometriosis (p.2091); those containing non-androgenic progestogens may be used in acne (p.2070) and hirsutism (p.2089).

Combined oral contraceptives containing both an oestrogen and a progestogen are the most effective type of oral contraceptive for general use. The synthetic ethinyl derivatives ethinylestradiol and mestranol are the oestrogens typically used in such preparations. The progestogenic component is usually a 19-nortestosterone derivative such as desogestrel, etynodiol diacetate, gestodene, levonorgestrel, lynestrenol, norethisterone, norethisterone acetate, norgestimate, or norgestrel. Preparations may be *monophasic* (containing a fixed dose of oestrogen and progestogen), or *biphasic* or *triphasic* (when the dose of progestogen, or both the progestogen and oestrogen, are varied through the cycle). Phased preparations are designed to mimic more closely the pattern of endogenous hormone secretion and may provide better cycle control than monophasic preparations. More rarely, *sequential* preparations are used, which contain an oestrogen alone for part of the cycle. Most combined oral contraceptives are taken for 21 days followed by an interval of 7 days when menstrual bleeding will occur. Some preparations include 21 active tablets plus 7 inert tablets to remove the need for counting days ('every day' preparations). Variations on this 28-day cycle include 22 days of active tablets followed by a 6-day interval for bleeding, and 24 days of active tablets followed by a 4-day interval. Long- or extended-cycle preparations are also available: some preparations may be taken continuously for 84 days, followed by 7 days of inert tablets or a lower dose of oestrogen alone (such as ethinylestradiol 10 micrograms). More recently, a preparation containing active tablets to be taken every day without any tablet-free interval has been introduced. The oestrogen content of most preparations is currently ethinylestradiol 20 to 40 micrograms daily; in some preparations a lower dose of 15 micrograms is used and in others up to 50 micrograms is available (even higher doses were often formerly used). A formulation containing the lowest dose of oestrogen compatible with good cycle control should be chosen, considering the following:

- *low-strength* preparations (ethinylestradiol 20 micrograms) are most appropriate for women with risk factors for cardiovascular disease (see under Precautions, above), provided a combined oral contraceptive is considered otherwise suitable
- *standard-strength* preparations (ethinylestradiol 30 or 35 micrograms or mestranol 50 micrograms if monophasic, or ethinylestradiol 30 to 40 micrograms if phased) are appropriate for most other women
- *high-strength* preparations (ethinylestradiol 50 micrograms) are generally used only in circumstances where bioavailability of the oestrogen is reduced, such as concomitant use of some enzyme-inducing drugs (see Interactions, above)

When first **starting** combined oral contraceptives, if the first tablet is taken on the first day of the menstrual cycle (the first day of bleeding) additional contraceptive precautions are unnecessary. If the first tablet is taken on the fourth day of the cycle or later, additional contraceptive precautions should be undertaken for 7 days (or 14 days for 'every day' preparations in case the inert tablets are inadvertently taken first). If amenorrhoea is present and pregnancy has been excluded, combined oral contraceptives may be started on any day, but additional precautions should be used for the first 7 days. In the case of abortion or miscarriage combined oral contraceptives should be started on the same day. In women not breast feeding, they may be started 3 weeks postpartum, but additional contraceptive precautions should be taken for the first 7 days if the combined oral contraceptive is started later than 3 weeks postpartum; progestogen-only contraceptives are preferred in breast-feeding women (see under Precautions, above).

When **changing** to a combined preparation containing a different progestogen, the new preparation should be started on the day after the last active tablet of the old preparation. If a tablet-free interval is taken then extra contraceptive precautions are necessary for the first 7 days of the new preparation. In the case of 'every day' preparations, to allow for the fact that the inert tablets may inadvertently be taken first, extra contraceptive precautions are necessary during the first 14 days. Meticulous regularity of dosage is essential and contraceptive protection may be lost if a dose is not taken at the proper time or is missed, especially if the missed dose is at the beginning or end of a cycle.

If a tablet is **missed** the risk of pregnancy is greatest when this happens at the beginning or at the end of a cycle, which lengthens the tablet-free interval. Over time, advice for dealing with missed tablets has changed and varies between countries and preparations. In 2004, WHO issued recommendations based on how many combined oral contraceptive tablets have been missed and when.

- If 1 or 2 tablets containing 30 or 35 micrograms of ethinylestradiol (or 1 tablet of 20 micrograms) have been missed at any time, the most recent missed tablet should be taken as soon as possible, and the rest of the course should be taken as normal; no additional contraceptive protection or emergency contraception is needed. This advice also applies if a new course of tablets has been started 1 or 2 days late for 30- or 35-microgram tablets, or 1 day late for 20-microgram tablets.
- If 3 or more tablets containing 30 or 35 micrograms of ethinylestradiol (or 2 or more tablets of 20 micrograms) have been missed at any time, the most recent missed tablet should be taken as soon as possible, and the rest of the course should be taken as normal; the woman should also use condoms or abstain from intercourse until she has taken active tablets for 7 days in a row. This advice also applies if a new course of tablets has been started 3 or more days late for 30- or 35-microgram tablets, or 2 or more days late for 20-microgram tablets. In addition, emergency contraception should be considered if the tablets were missed in the first week of the course and she had unprotected intercourse during the tablet-free interval or in the first week. If the tablets were missed in the third week of the course, then the tablet-free interval (or the 7 inert tablets) should be omitted and the next course of tablets started immediately after the last.

If the woman has missed more than 1 tablet, she can take the first missed tablet and then either continue taking the rest of the missed tablets or discard them to stay on schedule. Depending on when she realises that she has missed a tablet, she may take 2 tablets on the same day or even at the same time.

For extended-cycle preparations, licensed product information gives similar advice regarding missed tablets (or starting a course late), in that the course should be resumed as soon as possible. If 1 tablet has been missed, additional contraception is not needed, but if 2 or more tablets have been missed, additional contraception should be used until 7 days of active tablets have been taken.

Similarly, extra contraceptive measures may be needed during, and after recovery from, vomiting or diarrhoea. WHO recommends that if the woman vomits within 2 hours after taking a tablet, she should take another tablet. If there is severe vomiting or diarrhoea for more than 24 hours she should continue taking the course if she can, and if it continues for 2 or more days she should follow the advice for missed tablets.

Progestogen-only oral contraceptives are suitable for women when an oestrogen component is contra-indicated. They are taken continuously, usually **starting** on day one of the menstrual cycle, with no interval during menstrual bleeding. They are associated with a higher failure rate than the combined preparations. Regularity in taking the doses is even more important with this type of preparation; contraceptive efficacy is reduced if a dose is delayed by more than 3 hours (a delay of up to 12 hours is acceptable for desogestrel). Commonly used progestogens include the 19-nortestosterone derivatives etynodiol diacetate, levonorgestrel or norgestrel, and norethisterone.

When **changing** from a combined oral contraceptive preparation to an oral progestogen-only contraceptive, the new tablets should be started immediately with no tablet-free interval (or, in the case of 'every day' preparations, omitting the inert tablets).

If a **missed tablet** is delayed by more than 3 hours (or 12 hours for desogestrel), it should be taken as soon as possible and the next tablet taken at the correct time. Although some UK licensed product information suggests that additional contraceptive methods should be used for the next 7 or 14 days, depending on the product, WHO suggests that extra contraception is only required for the next 2 days. Postcoital hormonal contraception (emergency contraception) should be considered if unprotected intercourse has occurred before 2 further tablets have been taken correctly. Additional contraceptive methods may also be needed during, and after recovery from, vomiting or diarrhoea, and WHO gives the same advice as that for combined oral contraceptives described above.

Progestogens are also used alone as **parenteral contraceptives** and provide a very high level of contraceptive efficacy. They are usually given within the first 5 days of the menstrual cycle. Injectable contraceptives are usually used to provide short-term protection for several months or are used in women unable to use other methods. Medroxyprogesterone acetate is given by intramuscular or subcutaneous injection as a long-acting depot preparation to provide contraception for at least 12 weeks. Norethisterone enantate is used similarly by intramuscular injection to provide protection for up to 8 weeks. Levonorgestrel is used in the form of a subcutaneous implant providing contraception for up to 5 years. A contraceptive implant containing etonogestrel, effective for 3 years, is also available. A combined parenteral contraceptive containing the oestrogen estradiol cipionate with medroxyprogesterone acetate, and given monthly by intramuscular injection, has been developed.

Hormonal **intra-uterine contraceptive devices** are also available. One such device releases progesterone to provide contraception for 1 year; another releases levonorgestrel for 5 years. These are usually inserted within 7 days of the onset of menstruation. A contraceptive **vaginal ring**, which releases ethinylestradiol and etonogestrel, is retained in the vagina for 3 weeks; it is then removed for a one-week interval after which a new ring is inserted.

A contraceptive **transdermal patch**, which releases ethinylestradiol and norelgestromin, has been developed. A new patch is applied each week for 3 weeks, followed by a one-week patch-free interval. If the patch becomes partly or completely detached, or there is a delay in its application, contraceptive efficacy can be reduced or lost.

- If the patch has been detached for less than 24 hours, it should be re-applied if it is still sufficiently adhesive, or replaced with a new patch; no additional contraceptive method is needed and the following patch should be applied on the usual day. If it has been detached for 24 hours or more, a new 4-week cycle should be started and a new patch applied; additional contraceptive precautions should be taken for the first 7 days.
- If application of the first patch of a new cycle is delayed after the patch-free interval, it should be applied as soon as remembered and this day used as the first day of the new cycle; additional contraceptive precautions should be used for 7 days, and if unprotected intercourse has occurred during the patch-free interval then the possibility of fertilisation should be considered.
- When the patch is changed in the middle of the cycle (week 2 and 3), if there is a delay of up to 48 hours the new patch should be applied immediately, with the next patch applied on the usual day; no additional contraceptive precaution is needed. If the delay is more than 48 hours, the new patch should be applied and a new 4-week cycle started; additional contraceptive precautions should be taken for 7 days.
- If there is a delay in removing the third patch, before the patch-free interval, it should be removed as soon as possible and the next cycle started on the usual day; no additional contraception is required.

Postcoital hormonal contraceptives (emergency contraception) should be taken within 72 hours after unprotected intercourse to be most effective (for details see Emergency Contraception, below). A single oral dose of levonorgestrel 1.5 mg may be given within 72 hours of intercourse, or it may be given as a dose of 750 micrograms within 72 hours of intercourse followed by a second dose 12 hours later. An alternative preparation available for such use consists of tablets each containing ethinylestradiol 50 micrograms and norgestrel 500 micrograms or levonorgestrel 250 micrograms. Two tablets should be taken within 72 hours and a further 2 tablets 12 hours later. UK licensed product information for levonorgestrel-only preparations suggests that if vomiting occurs within 3 hours of any dose it can be repeated. However, WHO considers that 2 hours is probably sufficient for hormone absorption and that no action is needed if vomiting occurs after this time. WHO also considers that combined hormonal preparations are more likely to cause nausea and vomiting, and that the use of an antiemetic may be considered before repeating a dose. The efficacy of postcoital hormonal contraception may be reduced in women who are being treated with enzyme-inducing drugs, and a higher dose of levonorgestrel has been suggested (see Interactions, above).

Acne. Oral contraceptives have been shown to be effective[1,2] in reducing inflammatory and non-inflammatory lesions in women with acne (p.1577) who require contraception, probably by a multifactorial action on circulating androgens. Studies have used combinations of ethinylestradiol with various progestogens; a systematic review[2] considered that combinations with chlormadinone or cyproterone acetate were more effective than those with levonorgestrel, but noted that this was based on limited evidence. Combination preparations based on cyproterone acetate, that also have a contraceptive effect, have traditionally been favoured for acne management (see also p.2089).

Contraception. Contraception is used for fertility control, and some methods have additional non-contraceptive health benefits. There are a wide variety of regular methods including periodic abstinence (natural family planning), male and female barrier methods, intra-uterine devices (IUDs), female hormonal contraceptives, and female or male sterilisation. In addition, female hormonal contraceptives and copper IUDs are available for emergency (postcoital) contraception. The methods used for contraceptive purposes can be grouped into three categories: those that prevent ovulation, those that prevent fertilisation of the ovum, and those that prevent implantation of the fertilised ovum. None of the available contraceptive methods are effective once implantation of a fertilised ovum has occurred, i.e. they are not abortifacients.

A large number of factors will influence the choice of contraceptive method. Those relating to the woman include age (and therefore likely fertility), parity, medical disorders, risk of sexually transmitted diseases, smoking status, breast feeding, and cultural and religious considerations. Those relating to the method include its failure rate, reversibility, ease of use, mechanism of action, adverse effects, and non-contraceptive benefits.

The most reliable reversible methods for contraception are those for which there can be no 'user' failure such as *progestogen injections* and *implants*, and progestogen or copper *intra-uterine devices* (IUDs). When used perfectly, these methods have reported failure rates of between 0.05 and 0.6% during the first year of use; higher rates had been reported with older IUDs. The duration of action of the various progestogen injections is up to 2 or 3 months, whereas progestogen implants and progestogen IUDs can be effective for 1 to 5 years, depending on the preparation. These long-acting progestogen preparations thicken cervical mucus, so preventing sperm penetration, and suppress the endometrium, so preventing implantation. In addition, they suppress ovulation; the degree of suppression is complete for injectable preparations, about 50% for implants, and low for the progestogen IUDs. Copper IUDs were traditionally thought to act by preventing implantation, but it is now thought that the biochemical changes which they produce in the uterus also prevent fertilisation. They are effective and have a prolonged action (up to 5 or 10 years). There is an increased risk of pelvic infection in the 20 days after insertion of an IUD, but the risk is the same as non-IUD users thereafter. An IUD must not be used in women with a current sexually transmitted infection or pelvic inflammatory disease, but it may be considered in those who are no longer at risk after an infection has been treated. For women at increased risk of infection, prophylactic antibacterial therapy may be given before IUD insertion if screening test results are not yet available. In the past, it was recommended that IUDs were not suitable for nulliparous women because of a risk of impaired fertility after removal. However, this may have been biased by other factors such as the increased risk of sexually transmitted infection associated with sexual behaviour in younger women. Nulliparity alone is therefore no longer considered a contra-indication to IUD use, and indeed some IUDs have been designed specifically for this group of women. Although IUDs are effective at preventing pregnancy, in the uncommon event of IUD failure, the risk of ectopic pregnancy is increased and can occur in 6 to 8% of these pregnancies.

Of methods subject to 'user' failure, *combined oral contraceptives* are the most effective. They have a reported failure rate during the first year of 0.3% if used perfectly, but 8% in typical practice. Their principal mechanism of action is to prevent ovulation, and they also decrease the chances of fertilisation and implantation. Combined oral contraceptives offer the non-contraceptive advantages of avoidance of dysmenorrhoea, premenstrual tension, and iron-deficiency anaemia, and in the long-term they protect against endometrial and ovarian cancer. However, they do not protect against sexually transmitted diseases, they are unsuitable for older women who smoke, and long-term use carries a slight increased risk of breast cancer. Other forms of combined contraceptive which have been developed recently include *monthly injection*, *vaginal ring*, and *transdermal patch*.

Progestogen-only oral contraceptives are considered to have a slightly higher failure rate than that for combined preparations because of the need for more accurate dosage timing. A 0.9% failure rate has been given for the first year of use if taken correctly, but in practice failure rates of up to 10% have been reported. Failure rates are lower in women taking these contraceptives during breast feeding, as breast feeding itself provides additional contraception (see also Natural Family Planning Methods, below). Regularity in taking them is essential; a dose should not be delayed for more than 3 hours (up to 12 hours for desogestrel). They act primarily to decrease the chance of fertilisation and implantation since they prevent ovulation in only 14 to 50% of cycles, although desogestrel is said to reliably inhibit ovulation. They are useful for women who are breast feeding, for those who smoke and are more than 35 years of age, and if medical conditions contra-indicate the use of oestrogens.

Barrier methods, including both male and female condoms, vaginal sponges containing spermicide, and diaphragms and cervical caps used with spermicide, act as a mechanical barrier to prevent fertilisation, and inactivate sperm. Barrier methods decrease the risk of sexually transmitted diseases and a shift towards their use has occurred since the emergence of HIV infection in particular. However, barrier methods are not as effective in preventing conception as hormonal contraception and IUDs. Even when used correctly, failure rates in the first year of use vary from 2% for the male condom, to 6% for the diaphragm with spermicide, to 20% for the vaginal sponge in parous women. Spermicides, such as nonoxinol 9, may be used as foam, cream, jelly, dissolvable vaginal tablets or pessaries, or as a spermicide-containing polyvinyl alcohol film placed over the cervix. However, they are generally considered relatively ineffective when used as the sole method of contraception, and such use is not recommended.

Natural family planning methods such as periodic abstinence using the calendar, temperature, cervical mucus ('Billings') or sympto-thermal methods require high motivation to learn and practice effectively. However, they may be the only acceptable method to some people. More recently, daily measurement of urine hormone concentrations has been used as a predictor of the timing of ovulation and hence the risk of becoming pregnant; on 'unsafe' days abstinence or barrier methods are required. Traditional methods such as withdrawal (coitus interruptus) are widely used in some areas, but are considered relatively ineffective. The lactational amenorrhoea method of contraception can be used during breast feeding for up to 6 months after childbirth. For it to be an effective contraceptive method, breast feeding must start immediately after birth, the infant must be fully or nearly fully breast-fed, feedings must be no more than 4 to 6 hours apart, and menstruation must not have restarted. When carried out consistently and correctly, this method has a failure rate of 0.9% in the first 6 months.

Various other methods of contraception are under investigation including the use of the antiprogestogen mifepristone, selective sex-hormone receptor modulators, and contraceptive vaccines. There has also been some investigation of **male contraception**. Weekly intramuscular injection of high-dose testosterone or nandrolone to produce azoospermia has been investigated with some success, but development of an oral contraceptive dosage form for males has been slow. Use of a progestogen with testosterone is being studied, as is the use of implants of synthetic androgens such as trestolone (7-α-methyl-19-nortestosterone; MENT).

The available irreversible methods of contraception are surgical male or female *sterilisation*. The use of mepacrine for non-surgical female sterilisation has been attempted but has proved extremely controversial.

Emergency contraception. Emergency contraception (postcoital contraception) can be used after unprotected intercourse but before a fertilised ovum has been implanted. Methods that act after implantation are considered abortifacients. The two most commonly used emergency contraceptives are *oral contraceptives* and *copper IUDs*.

Oral contraceptive regimens (the so-called ‘morning after pill’) have historically used a preparation containing high-dose oestrogen with a progestogen, taken within 72 hours of intercourse, and repeated 12 hours later (the Yuzpe regimen). This preparation is thought to act by a variety of mechanisms, which may depend on when in the menstrual cycle it is used. It may prevent implantation, prevent or delay ovulation, disrupt ovum transport, and alter corpus luteum function. However, levonorgestrel alone (without an oestrogen) is now widely recommended as an emergency contraceptive. A large WHO multicentre study found that levonorgestrel 750 micrograms alone within 72 hours of intercourse and repeated after 12 hours was more effective than the Yuzpe regimen and better tolerated.[1] Both regimens were most effective when given within 24 hours of intercourse.[1,2] A small observational study[3] of the Yuzpe method used between 72 and 120 hours after unprotected intercourse reported a trend towards decrease in effectiveness. A further large study[4] by WHO found that for up to 120 hours after intercourse, a single dose of levonorgestrel 1.5 mg was as effective as two doses of 750 micrograms given 12 hours apart, with a pregnancy rate of about 1.5%.

Efficacy rates vary between studies, but the Yuzpe method has been shown to reduce the risk of pregnancy by about 75% and levonorgestrel by about 89%.[5] Based on its greater efficacy and better tolerability, levonorgestrel is now generally recommended as the hormonal emergency contraceptive of choice that can be offered up to 120 hours after intercourse.[5-9]

Copper, but not progestogen, IUDs can be inserted up to 120 hours after unprotected intercourse for postcoital contraception. They have a failure rate of no more than 1% when used for emergency contraception.[9] Thus, when efficacy is a priority the IUD is the emergency contraceptive method of choice.

Mifepristone is under investigation as an emergency contraceptive. Its action appears to depend on inhibiting ovulation or, if ovulation has occurred, preventing implantation. Early studies used a single dose of 600 mg, but later studies have found 10 mg to be equally effective. Mifepristone also appears to be at least as effective as levonorgestrel but it can delay the onset of subsequent menstruation, which might cause anxiety in some women.[10,11]

Гормонозаместительная Терапия

The Menopause

The menopause is defined as the permanent cessation of cyclical menstruation due to loss of ovarian follicular activity. It is therefore determined in retrospect, conventionally after 1 year without menstruation. In the few years before the menopause (the menopausal transition), ovarian oestradiol secretion declines, sometimes in a fluctuating manner, and there is a resultant increase in pituitary follicle-stimulating hormone (FSH) secretion. The menopausal transition may be characterised by irregular menstrual cycles and dysfunctional uterine bleeding, and fertility is much reduced compared with the early reproductive years. The term perimenopause is used to cover the menopausal transition and the first year after the menopause, and may last 6 years or more. It has sometimes been referred to as the climacteric. Oestrogen concentrations reach their minimum and FSH concentrations their maximum about 4 years after the menopause. After the menopause the ovaries may continue to produce some androgens; adrenal and ovarian androgens are aromatised to oestrogens (predominantly oestrone) in the periphery, but oestrogen concentrations are much lower than in premenopausal women. The median age for the natural menopause is about 51 years. If the menopause occurs in women aged 40 years or less, it is considered premature. The menopause may be induced by surgical removal of both ovaries, or sometimes by antineoplastic drugs or radiotherapy.

The decline in oestrogen concentrations during the perimenopause may be associated with both acute and long-term effects. However, some of these may be difficult to differentiate from the effects of ageing, and the incidence varies geographically. Established *acute symptoms* can include vasomotor instability, manifesting as hot flushes and night sweats, and vaginal atrophy and dyspareunia. Non-specific symptoms include palpitations, headache, backache, and psychological symptoms such as tiredness, lack of concentration, loss of libido, irritability, insomnia, and depression. Insomnia may occur secondary to night sweats. There is little evidence that depressive illness is disproportionately increased at the menopause. Urinary problems are common in ageing women, and may occur in the perimenopause, but the extent that these are due to lack of oestrogens has not been determined. An established *long-term consequence* of the decline in oestrogen concentrations is an increased risk of bone fractures resulting from an increase in the rate of bone resorption. In addition, decline in oestrogen concentrations is associated with adverse effects on blood lipoproteins, and this may be a risk factor for cardiovascular disease.

Acute and longer-term effects of the menopause may be managed by using hormone replacement therapy (HRT) with oestrogens, with or without progestogens, and nonhormonal therapies (see Menopausal Disorders, p.2077).

Adverse Effects of HRT

When oestrogens are used for menopausal HRT, adverse effects include nausea and vomiting, abdominal cramps and bloating, weight changes, breast enlargement and tenderness, premenstrual-like syndrome, sodium and fluid retention, altered blood lipids, cholestatic jaundice, glucose intolerance, rashes and chloasma (melasma), changes in libido, migraine, dizziness, depression, mood changes, headache, leg cramps, vaginal candidiasis, and decreased tolerance of contact lenses. Transdermal delivery systems may cause contact sensitisation (possibly severe hypersensitivity reactions on continued exposure), and nasal sprays may cause local irritation, rhinorrhoea, and epistaxis. Headache has been reported on vigorous exercise. Use of oestrogen without a progestogen results in endometrial hyperplasia and an increased risk of endometrial carcinoma (see below). The addition of a progestogen for 10 to 14 days of a 28-day cycle reduces this risk but results in regular withdrawal bleeding towards the end of the progestogen. Use of continuous progestogen and oestrogen avoids withdrawal bleeding, but may result in irregular breakthrough bleeding, particularly in the early stages of therapy, or if used within 12 months of the last menstrual period. Current use of menopausal HRT is associated with an increased risk of venous thromboembolism and breast cancer (see below).

Carcinogenicity. Use of unopposed oestrogen as menopausal HRT in women with a uterus increases the risk of endometrial cancer, irrespective of the route of administration. This risk is reduced, although possibly not eliminated completely, by the concomitant use of a progestogen. There is also evidence that use of HRT, as oestrogen alone or with a progestogen, increases the risk of breast cancer.

Because of continuing modifications in regimens for HRT there is a continuing need to monitor the incidence of various cancers in users of this therapy.

The carcinogenicity of combined menopausal HRT has been reviewed.[1]

BREAST. Early age at menarche and late age at menopause increase the risk of breast cancer, and surgical oophorectomy at an early age decreases the risk of breast cancer. In addition, higher concentrations of unbound endogenous oestrogens in postmenopausal women appear to increase the risk of developing breast cancer.[1] Such risk factors have prompted concerns that menopausal HRT might be associated with an increased risk of breast cancer.

Reviews and analyses[2-4] of studies published during the 1970s and/or 1980s on the use of **unopposed oestrogen** replacement therapy in postmenopausal women have generally shown that there is an associated moderate increase in the risk of breast cancer; figures for overall relative risk compared with non-oestrogen users ranged from under 1 to up to 2. One of these,[3] a meta-analysis of studies from 1976 to 1989, further showed that although the relative risk of breast cancer rose to 1.3 after 15 years of oestrogen use, it did not appear to rise at all until after 5 years of use. A similar meta-analysis[4] differentiated between low-dose oestrogens and high-dose oestrogens; those taking 625 micrograms daily of conjugated oestrogens had a risk of breast cancer 1.08 times higher than non-oestrogen users, whereas the relative risk in those taking 1.25 mg daily or more was up to 2.0. A subsequent meta-analysis[5] differentiated between current use of HRT, duration of use, and use at any time. The highest relative risk of breast cancer was associated with current use (1.4); use for 10 years or more was associated with a relative risk of about 1.2, and having ever used HRT was not associated with an increased risk. In 1997 the Collaborative Group on Hormonal Factors in Breast Cancer reanalysed about 90% of the worldwide evidence on breast cancer and the use of HRT.[6] They reported that the relative risk of having breast cancer diagnosed was increased by a factor of 1.023 for each year of use, being 1.35 for 5 or more years of use. However, this effect was reduced on cessation of use, and had largely disappeared after about 5 years. In women who started therapy at age 50, the cumulative excess number of breast cancers diagnosed per 1000 women between age 50 and 70 were estimated to be 2, 6, and 12 for 5, 10, and 15 years of use, respectively, from a baseline of 45 per 1000 in never-users.[6] In contrast, the arm of the Women’s Health Initiative[7] that compared conjugated oestrogens with placebo over an average of about 7 years found a trend towards a reduction in breast cancer risk with HRT. A Finnish cohort study[8] also found no increase in risk with less than 5 years of oral estradiol or estriol therapy. For women taking unopposed oestrogen in the Nurses’ Health Study[9] cohort the linear increase in risk with increasing duration of use did not become statistically significant until current use exceeded 20 years.

Most data relate to the use of unopposed oestrogen. There has been speculation both that the concomitant use of progestogen in HRT could reduce the risk of breast cancer and that it might increase it. Bergkvist *et al.*[10] suggested an increased relative risk of

4.4 in the small subgroup using long-term **combined therapy**, but because of the large confidence intervals they considered these results inconclusive. Analysis of the Nurses' Health Study cohort has provided evidence that current use of oestrogen and progestogen is associated with a similar increased relative risk of breast cancer to that of unopposed oestrogen (1.4 versus 1.3).[11] The Collaborative Group on Hormonal Factors in Breast Cancer[6] found no evidence of marked differences between preparations containing oestrogens alone and those containing oestrogens and progestogens. However, in a randomised study, oestrogen plus progestogen was associated with greater increases in radiographic breast density than unopposed oestrogen.[12] The results of further cohort studies[13,14] and case-control studies[15,16] also suggest that the risk of breast cancer may be higher for current or recent use of combined HRT compared with oestrogen alone, and a cohort study[17] of over 1 million women (the Million Women Study) found relative risks of 1.3 for users of oestrogen alone, and 2.0 for combined HRT, compared with never-users. After an average follow-up of about 5 years the Women's Health Initiative,[18] comparing combined HRT with placebo in more than 16 000 women, was stopped early because of an increased rate of invasive breast cancer in women given HRT.

The public health perspective on the **implications** of any increased risk of breast cancer will depend on the background risk. This is high in western countries, so a small increased relative risk would equate to a large absolute increase in number of cases.[19]

If menopausal oestrogen therapy increases the risk of breast cancer, there is a need to ascertain whether these cancers can be detected early, how aggressive they are, and what the mortality rate from them is. Currently, there are limited data on these points.

- There is evidence[20,21] that the use of HRT decreases the sensitivity and specificity of screening mammography (resulting in more false positives and more false negatives), apparently because it increases radiographic breast density[22,23] or slows the natural change from dense patterns to fatty patterns,[24] so decreasing the ability to interpret the mammogram. This is of concern for the success of screening programmes, and has been suggested as a factor in the increased detection of interval cancers (those detected between screening appointments).[25] In addition, HRT-associated increases in radiographic breast density could actually be a marker for risk of breast cancer.[12,26]
- Some data suggest that breast cancers in women on HRT may be of better prognostic grade.[27,28] The Collaborative Group on Hormonal Factors in Breast Cancer reported that breast cancers were more likely to be localised in current or recent users of HRT, but that there was evidence of an increased risk of metastasis with increasing duration of use.[6] However, the Women's Health Initiative[26] did not confirm previous findings of favourable prognosis, and found breast cancers in combined HRT users to be larger, more likely to be node positive, and at a more advanced stage at diagnosis. The likelihood of good prognostic grade in women on HRT may depend on the histological type of any lesion that develops: invasive lobular and tubular cancers are more strongly associated with current use of HRT than invasive ductal cancer.[29]
- Follow-up of most studies is currently insufficient to give a clear indication of mortality risk with long-term use. Early data from a UK cohort study[30] suggested a decreased risk of breast cancer mortality, but after further follow-up the risk was no longer reduced.[31] Similarly, a study in 2614 women with breast cancer followed up for up to 22 years found that the use of HRT at the time of diagnosis was associated with a reduction in mortality, but the effect waned over time.[32] In contrast, data[11] from the Nurses' Health Study cohort suggest an increase in risk of death from breast cancer in women who have currently used HRT for 5 years or more (1.45). Similarly, although mortality was lower overall, a trend towards an increased risk of death from breast cancer (1.9; 95% confidence interval 0.4 to 8.4) was seen in a study of long-term use (mean of 17 years).[33]

The risk of breast cancer may be increased further by the use of HRT in women who are already at an increased risk. Although a study found a modest increase in risk in these women, it was not significantly higher, and there was a reduced total mortality rate.[34] It is unclear whether use of HRT in breast cancer survivors increases the risk of subsequent recurrence and associated mortality (see also Malignant Neoplasms under Precautions, below).

CERVIX. Studies of the effect of HRT on cervical cancer risk are likely to be subject to the potential confounding of other risk factors such as sexual activity. There are few data on this risk; one study[1] suggested oestrogens do not increase, and may decrease, the risk of cervical cancer, but another[2] suggested that unopposed oestrogen might increase the risk of adenocarcinoma. Therapy with combined HRT did not significantly affect the incidence of cytological abnormalities found in annual cervical smears in women in the Heart and Estrogen/progestin Replacement Study (HERS).[3] In the Women's Health Initiative study,[4] however, there was an overall increase in the incidence of new abnormalities in women given combined HRT, compared with placebo, although the incidence of high-grade squamous intra-epithelial lesion and cervical cancer was not affected.

ENDOMETRIUM. The increased incidence of endometrial hyperplasia and risk of cancer in women receiving unopposed oestrogen replacement therapy is well established. An analysis of case control studies published during the 1970s and 1980s revealed a relative risk of developing endometrial cancer of 1.4 to 7.6 in women who had ever used oestrogen, and a relative risk of 3.1 to 15 in long-term users, compared with nonusers.[1] Risk was also increased with higher doses of oestrogens. In general, endometrial cancer in oestrogen users was of a better prognostic stage, and survival rates were better, than in nonusers.[1] An elevated risk of endometrial cancer persists for a number of years after stopping unopposed oestrogen therapy.[2]

Addition of a progestogen to oestrogen replacement therapy reduces the incidence of endometrial hyperplasia[3] and cancer. However, the extent to which this alters the risks and benefits of oestrogen replacement therapy, and the optimum progestogen type, and dose and duration, have not been fully elucidated.

As regards risk of endometrial cancer, preliminary data from a cohort study revealed that the addition of cyclical progestogen to oestrogen therapy reduced this risk compared with oestrogen therapy alone.[4] A further case-control study confirmed that progestogens decreased the relative risk, and that the reduction in risk was greater when progestogens were used for 10 or more days per month than when they were used for less than 10 days per month.[5] Two much larger case-control studies have confirmed these findings.[6,7] However, 1 of these studies[6] reported that in long-term users the addition of a progestogen did not reduce the risk of endometrial cancer to that seen in nonusers—after 5 years of use, the relative risk of endometrial cancer with HRT containing 10 or more days of progestogen per month was 2.5 (95% confidence intervals 1.1 to 5.5). This finding remains to be confirmed.

Use of progestogens for 10 days of an 84-day cycle (long cycle) has been suggested to improve acceptability of combined HRT. However, one study of a long-cycle regimen was stopped because of an increased risk of endometrial hyperplasia and atypia compared with a conventional monthly cycle regimen.[8]

Some newer regimens of HRT use continuous low doses of progestogen with oestrogen, which avoid withdrawal bleeding. Data on the incidence of endometrial hyperplasia from randomised trials of these regimens have been reassuring.[3,9,10] Continuous norethisterone plus ethinylestradiol,[9] and continuous medroxyprogesterone plus conjugated oestrogens,[10] protected the endometrium against the hyperplasia seen with the oestrogen alone. Continuous therapy was as effective as cyclical therapy containing 12 days of progestogen,[10] and there is a suggestion from meta-analysis[3] that continuous therapy may even be more effective than sequential when given over a prolonged period, although this remains to be confirmed. The first data on endometrial cancer risk from continuous combined HRT suggest that it is as protective as sequential therapy with the progestogen given for 10 or more days per month (odds ratio 1.07 per 5 years of use for both regimens).[7] The Women's Health Initiative reported[11] that although the rate of endometrial cancer for continuous combined HRT was reduced, it was not significantly different to placebo over 5 years. However, in the analysis of endometrial cancer in the Million Women cohort study,[12] in which 55% of the 716 738 women had not used HRT, there was a lower risk of endometrial cancer with continuous combined HRT, whereas it was not altered for cyclic combined HRT, and was higher for oestrogen-only HRT and tibolone. The beneficial effects of combined HRT were also found to be greatest in obese women.

It is unclear whether use of HRT in endometrial cancer survivors increases the risk of subsequent recurrence and associated mortality (see also Malignant Neoplasms under Precautions, below).

Gastrointestinal tract. Evidence of an effect of oestrogen replacement therapy on colorectal cancer is ambiguous, since studies have reported both an increased and a decreased incidence; a meta-analysis in 1995 suggested no overall effect.[1] However, subsequent cohort studies did suggest a lower incidence of colon cancer in those who had received oestrogens.[2,3] This was most pronounced in current users in whom the relative risk was about one-third to one-half of that for women who had never taken oestrogen. Similarly, a large case-control study also reported a significant reduction in colon cancer, but not rectal cancer.[4] A later meta-analysis[5] concluded that the risk of colon cancer might be decreased among women who have recently used HRT, and that the risk of death from colon cancer might also be reduced. The Women's Health Initiative,[6] a placebo-controlled study of combined HRT in more than 16 000 women, found that those taking HRT had a decreased risk of developing colorectal cancer, but that at diagnosis there was greater lymph node involvement and it was at a more advanced stage.

There is less information on the effect of HRT on death from colorectal cancer. In the Nurses' Health Study cohort[7] there were decreased risks of death from colorectal cancer and death overall for women taking HRT when cancer was diagnosed, compared with those who had never taken HRT. However, this benefit was limited to women who had been taking HRT for no more than 5 years before diagnosis; longer duration of use and past use had no effect on survival.

Ovary. There was no clear evidence that the use of oestrogen replacement therapy altered the risk of invasive ovarian cancer in various case-control studies reviewed by the Collaborative Ovarian Cancer Group.[1] However, subsequent study of a large cohort has suggested that long-term oestrogen replacement therapy may increase the risk of fatal ovarian cancer.[2,3] Similarly, a meta-analysis indicated an increased risk for invasive epithelial ovarian cancer, especially after long-term use of HRT.[4] Another, later, cohort study[5] also reported that there was an increased risk of ovarian cancer with oestrogen replacement therapy, particularly when given for 10 years or more, but found no increase for combined HRT. A Swedish case-control study[6] looked at different types of HRT and also found that the risk was increased with oestrogen replacement therapy. For combined HRT, however, the risk was increased for women who had used sequential combined HRT (continuous oestrogen plus cyclical progestogen), but not for those who had used continuous combined HRT. Similarly, in the Women's Health Initiative,[7] a placebo-controlled study of continuous combined HRT in more than 16 000 women, the increased incidence of ovarian cancer was not significant during 5.6 years of follow-up. Further cohort data support an association with long-term current use of unopposed oestrogen replacement therapy,[8-10] but the role of progestogen remains less clear; the Million Women Study[10] also found increased risks with combined HRT, but the Nurses' Health Study[9] found no association. In the cohort NIH-AARP Diet and Health Study[8] the risk of ovarian cancer was also increased overall for 5 or more years of combined HRT use, and found to be higher for users of sequential compared with continuous combined HRT.

Effects on carbohydrate metabolism. Data from a survey of postmenopausal women showed that diabetic women who were currently taking HRT had better glycaemic control than those who had never taken HRT or were previous users.[1] In the Heart and Estrogen/Progestin Replacement study[2] in postmenopausal women with ischaemic heart disease, there was no significant change in fasting glucose concentrations after 4 years of combined HRT in women with or without diabetes compared with a rise in women given placebo. There was also a lower risk of developing diabetes in those given HRT (cumulative incidence 6.2%) compared with placebo (9.5%). The Women's Health Initiative study[3] reported changes in fasting glucose and insulin concentrations, indicating a fall in insulin resistance, in women treated with combined HRT. During an average 5.6 years of follow-up there was a lower incidence of diabetes in women given HRT (3.5%) compared with placebo (4.2%). This represented an absolute reduction of 15 cases of treated diabetes per 10 000 women per year of HRT treatment.

Although HRT may improve glycaemic control in diabetic postmenopausal women, it is generally used with caution in this group. Diabetic patients are already at increased risk of cardiovascular disease, and HRT may be associated with an increased risk of ischaemic heart disease (see below).

Effects on the cardiovascular system. Various facts support the theory that endogenous oestrogens may be cardioprotective. For example, mortality rates for cardiovascular disease in women are lower than those in men at all ages. In addition, women who have a surgically induced menopause at a young age are at increased risk of ischaemic heart disease compared with women who have a natural menopause.

Conversely, use of high doses of oestrogens for malignant disease is associated with an increased risk of cardiovascular events. Similarly, use of oestrogens in combined oral contraceptives carries a small increased risk of cardiovascular disease (see p.2062). Moreover, an early study in men surviving a myocardial infarction found that high doses of conjugated oestrogens (5 mg daily) were associated with a higher incidence of subsequent coronary events than placebo (see Effects on the Cardiovascular System, in Conjugated Oestrogens, p.2087).

In practice, a number of large observational studies found a decreased risk of ischaemic heart disease and mortality in women receiving menopausal HRT compared with those who have never received this therapy (see below). The reduction in risk was estimated as 30 to 50%, but biases such as the healthy user effect seem to play a part in this estimate; unfortunately, results from controlled studies have cast doubt on the extent of any reduction in risk. There is also evidence to show that HRT *increases* the risk of stroke (see below) and venous thromboembolism (see below).

The mechanisms by which oestrogen exerts its cardiovascular effects are not fully understood.[1] Oestrogen has beneficial effects on lipoproteins, but adverse effects on triglycerides (see below). Similarly, it has beneficial effects on some, and adverse effects on other, mediators of thrombosis. Oestrogen may also have a direct beneficial effect on the coronary vasculature. Progestogens may reduce the beneficial effects of oestrogens on some lipids, although observational data has suggested that this is not sufficient to reverse potential benefit.

1. Mendelsohn ME, Karas RH. The protective effects of estrogen on the cardiovascular system. *N Engl J Med* 1999; **340:** 1801–11.

Hypertension. Although high doses of oestrogens have been associated with increased blood pressure, use of menopausal HRT in normotensive and hypertensive women has little effect on blood pressure or may be associated with a small decrease.[1-4] An observational study[5] of normotensive postmenopausal women also found that, over time, the average increase in systolic blood pressure was significantly less in women who were taking HRT.

Ischaemic heart disease. In 1991, Stampfer and Colditz reviewed 31 case-control and cohort studies on the risk of ischaemic heart disease in women using menopausal HRT.[1] Four studies showed an adverse trend, 2 showed no effect on risk, and 25 showed a trend to **reduction in risk** or a significant reduction in risk. The summary relative risk was 0.56, with estimated 95% confidence intervals of 0.50 to 0.61. Other reviews have reported similar reductions in risk.[2,3] Much of the data relate to the use of unopposed oestrogen, which is no longer recommended in women with a uterus because of the risk of endometrial cancer (see above).

There was concern that the **addition of progestogen** might negate or reduce the cardiovascular benefits of oestrogens by reducing the oestrogen-induced rise in serum high-density-lipoprotein cholesterol concentrations. It was postulated that this might be particularly true for progestogens derived from nortestosterone rather than progesterone. Results from the Postmenopausal Estrogen/Progestin Interventions Trial (PEPI) indicated that the beneficial effects on blood lipoproteins and fibrinogen, although greatest with unopposed oestrogen, were still present when combined with medroxyprogesterone or micronised progesterone (micronised progesterone was preferable to medroxyprogesterone).[4] Moreover, the UK Medical Research Council Study reported a fairly even balance between possibly beneficial and adverse effects on lipid concentrations and coagulability when conjugated oestrogens alone were compared with conjugated oestrogens plus norgestrel (a nortestosterone derivative).[5] Similar results were reported in the CHART study for ethinylestradiol with or without norethisterone.[6] Although reassuring, these 3 studies provided information only on surrogate endpoints.

Data from the Nurses' Health Study cohort[7] showed a greater reduction in the risk of major ischaemic heart disease among women receiving an oestrogen plus a progestogen (relative risk 0.4) than those receiving an oestrogen alone (0.6), as compared with the risk in women not using hormones. *In-vitro* data suggest that progestogens may actually protect against atherosclerosis via inhibition of smooth muscle cell proliferation.[8]

As regards **duration of HRT use**, current use appeared to be the most important factor for cardiovascular risk reduction. Users with coronary risk factors appeared to derive greater benefit from HRT than those at low risk of coronary artery disease.[9] Of concern, the Nurses' Health Study reported that the apparent benefit from HRT decreased with increasing duration of use beyond 10 years because of an increase in mortality from breast cancer.[9]

However, a number of studies have now found **no beneficial effect** on risk of heart disease. In contrast to previous findings, a retrospective case-control study[10] did not find a decreased risk of myocardial infarction in women currently using combined HRT or oestrogens alone. The authors of this study suggested that the benefit of HRT may not be as large as has been estimated in some qualitative overviews, and emphasised the need for data from randomised studies.[10] This has been confirmed by results[11] of the Heart and Estrogen/Progestin Replacement Study, a randomised placebo-controlled study in women with established ischaemic heart disease. Combined HRT with conjugated oestrogens plus medroxyprogesterone produced no overall reduction in the occurrence of myocardial infarction or death due to ischaemic heart disease in these women. This overall lack of effect was due to an initial increase in cardiac events during the first year, with a later beneficial effect in years 3 to 5. During unblinded follow-up[12] of 2.7 years, these late beneficial effects did not persist and the risk of cardiovascular events was not reduced. Observational data from the Nurses' Health Study cohort[13] also noted a trend towards an initial increase in cardiac events followed by a decrease in risk with long-term use of HRT, in women with a history of ischaemic heart disease. Other studies found that HRT did not affect the progression of existing coronary atherosclerosis as measured by angiography.[14,15] Oestrogen therapy for 2 years also had no effect on the risk of further cardiac events in postmenopausal women who had survived a myocardial infarction.[16] There is also some evidence that the risks and benefits of HRT may vary according to the presence or absence of particular prothrombotic mutations.[17]

These worrying results have suggested that HRT should **not** be used for secondary prevention in women with heart disease, in contrast to some earlier suggestions (see also Cardiovascular Disorders under Uses and Administration, below).

In women without pre-existing heart disease, observational data from the Nurses' Health Study[18] showed a reduced risk of major coronary events in users of HRT, compared with never-users. However, there were increased rates of coronary events at an average follow-up of about 5 years in the Women's Health Initiative,[19] a primary prevention study comparing combined HRT with placebo in over 16 000 women. The risk was highest in the first year of HRT but decreased to a smaller non-significant excess risk in the following years.[20] The arm of the Women's Health Initiative that compared unopposed conjugated oestrogens with placebo in more than 10 000 women with prior hysterectomy found that over an average of 7 years there was no difference in the risk of ischaemic heart disease.[21,22] These results suggest that HRT should also **not** be used for primary prevention of ischaemic heart disease.

There is continuing debate about the effect of HRT on ischaemic heart disease, and how it might be influenced by age. The generalisability of some study results, such as in the Women's Health Initiative, has been questioned because the mean age of the study group has been much older than women who generally take HRT for vasomotor symptoms in their 50s. A meta-analysis[23] has compared data from younger and older women, and found that for younger women (less than 10 years since menopause or under 60 years of age) there was a reduced risk of myocardial infarction or cardiac death with HRT. In older women, however, events increased in the first year then decreased after 2 years, resulting in a neutral effect over time. Secondary analysis[24] of the Women's Health Initiative data found that for women who started HRT closer to menopause (aged 50 to 59 years or less than 10 years since menopause) there was a trend towards reduced risks of ischaemic heart disease and death, while risk increased with age and time since menopause. One factor might be the reduction by HRT of atherosclerotic calcification in the coronary arteries.[25] Further studies are underway to examine the effect of HRT, started soon after menopause, in the prevention of atherosclerosis.

STROKE. The Framingham Study suggested a more than twofold increased risk of stroke in women using menopausal HRT.[1] However, subsequent studies reporting risk of stroke separately from other cardiovascular events showed either no effect on risk[2] or a decreased risk in the order of 30 to 50%.[3,4]

Data from the Nurses' Health Study cohort[5] revealed little association between the risk of stroke of any type and current use of unopposed oestrogens or oestrogen plus progestogen. However, they reported a trend towards an increased risk of stroke in current users of high-dose oestrogen therapy (1.25 mg or higher). Similarly, a large Danish case-control study found that unopposed oestrogens or oestrogen plus progestogen had no effect on the risk of non-fatal haemorrhagic or thromboembolic stroke,[6] and data from the Heart and Estrogen/Progestin Replacement Study indicated that combined HRT in women with pre-existing ischaemic heart disease had no effect on risk of stroke.[7,8] In contrast to these results, the Women's Health Initiative, a placebo-controlled study of over 16 000 healthy women, found that combined HRT increased the risk of ischaemic stroke, and that the increase in risk became apparent after about 1 year of starting HRT.[9] Furthermore, the arm of the Women's Health Initiative that compared unopposed conjugated oestrogens with placebo in more than 10 000 women with prior hysterectomy also found an increased risk of stroke;[10] additional data and analysis also confirmed that the increased risk was for ischaemic stroke, and appeared after about 4 years.[11] Although the numbers of haemorrhagic strokes were small in both Women's Health Initiative studies, the combined data showed no significant effect of hormone therapy.[11] A systematic review,[12] which was dominated by the results of the Women's Health Initiative, found that HRT was associated with an increase in stroke. This was attributed largely to ischaemic stroke, whereas there was no significant change in the risks of haemorrhagic stroke, fatal stroke, or transient ischaemic attack. A poor outcome (death or dependency) was also found to be more likely with HRT. Secondary analysis[13] of the Women's Health Initiative data also found that the risk of stroke was increased regardless of years since menopause.

In a controlled study in postmenopausal women who had recently had a stroke or transient ischaemic attack, the use of unopposed oestrogen had no significant effect on mortality or the recurrence of stroke.[14]

VENOUS THROMBOEMBOLISM. Traditionally it has been assumed that, unlike combined oral contraceptives, menopausal HRT is not associated with an increased risk of venous thromboembolism.

However, observational studies have provided substantial evidence that there is an increased risk of deep-vein thrombosis and/or pulmonary embolism in women receiving HRT.[1-4] The relative risk of venous thromboembolism was found to be 2.1 to 3.6 in current users compared with past-users or those who had never received HRT. This equates to an excess of 16 to 23 cases per 100 000 women per year. One study found that the increase in risk was restricted to the first year of use.[4] Another reported an increased risk with increasing oestrogen dose.[2]

Evidence from later randomised placebo-controlled studies[5-8] supports the findings of the observational studies above. Results from the Women's Health Initiative also suggest that the risk is higher with combined HRT than oestrogen alone.[9] It has been suggested that transdermal HRT might be preferable in women with a history of thromboembolism (see Administration, below) and a case-control study[10] reported that unlike oral preparations, transdermal oestrogen was not associated with an increased risk of venous thromboembolism.

The UK CSM considers that the absolute risk of venous thromboembolism in all women using HRT is higher than was originally suggested, and that the risks are higher particularly in older women and in women with predisposing factors, such as a history of venous thromboembolism.[11] Women with the factor V Leiden thrombophilia are at high risk of developing venous thromboembolism when taking HRT. The pooled results of 2 studies showed[12] that in the presence of this thrombophilia alone the odds ratio of developing venous thromboembolism was 3.58, and for HRT alone was 3.16, but women who had both these risk factors had a much higher risk of 13.16.

Effects on the eyes. The risk of dry eye increases with age, when tear production normally decreases. The incidence is higher in women, but it is unclear whether sex hormone changes in perimenopausal and postmenopausal women play a role in ocular surface dysfunction.[1] The effects of HRT on the incidence and management of dry eye have been debated. Relief of symptoms has occurred in some women given HRT[1] and improvements in tests of tear function and conjunctival epithelium have been reported.[2] However, a large cohort study[3] found a higher prevalence of dry eye syndrome in women taking HRT, particularly oestrogen alone, than in those not taking HRT.

Effects on lipids. Oestrogens increase serum high-density-lipoprotein cholesterol and decrease low-density-lipoprotein cholesterol concentrations, effects that are considered favourable and may be a mechanism behind their apparent reduction in ischaemic heart disease in postmenopausal women, although controlled studies have not found combined HRT to reduce coronary events (see Effects on the Cardiovascular System, above). Oestrogens may also increase serum triglyceride concentrations, which is undesirable. Severe hypertriglyceridaemia and pancreatitis have occurred in women with hypertriglyceridaemia treated with oestrogens.[1,2] Use of concomitant progestogen reduces oestrogen-induced hypertriglyceridaemia.[2]

Effects on mental function. For results suggesting that HRT may increase the risk of developing dementia see under Uses and Administration, below.

Effects on the pancreas. Unopposed oestrogen has been associated with pancreatitis in women with hypertriglyceridaemia (see Effects on Lipids, above). There have also been a few cases of pancreatitis, attributed to HRT, in which triglyceride concentrations were within the normal range.[1,2]

Precautions

Before menopausal HRT is given the woman should undergo an appropriate medical examination and her medical history should be carefully evaluated. Regular examination is recommended during use.

HRT should be avoided in women with active thrombophlebitis or thromboembolic disease; it should not be given to those with a history of recurrent thromboembolism unless they are already receiving anticoagulant treatment.

HRT should not be given to those with undiagnosed abnormal vaginal bleeding, and abnormal vaginal bleeding during therapy should be investigated (see below). HRT is also contra-indicated in women with oestrogen-dependent neoplasms such as those of the breast or endometrium, and is usually considered contra-indicated in women with a history of these conditions although this has been debated (see below). Active liver disease and Dubin-Johnson or Rotor syndromes are also generally considered to be contra-indications.

Prolonged exposure to unopposed oestrogens increases the risk of endometrial cancer whatever the route of administration (see above). HRT should be used with caution in women with antiphospholipid antibodies or predisposing factors to thromboembolism (see also Venous Thromboembolism, above), and in migraine, a history of breast nodules or fibrocystic disease, uterine fibroids, or a history of endometriosis. HRT should also be used with caution in women with diabetes because of the increased risk of heart disease. Consideration should be given to temporarily stopping HRT 4 to 6 weeks before elective surgery (but see also below).

HRT should be stopped immediately, and appropriate investigations and treatment carried out, if any of the following occur:

- sudden severe chest pain, sudden breathlessness, or severe pain/swelling in calf of one leg (possibly indicative of thromboembolic complications)
- unusual, severe, prolonged headache, sudden disturbances of vision or hearing or other perceptual disorders, collapse, marked numbness or weakness affecting one side of the body, or other signs or symptoms suggestive of cerebrovascular accident
- a first unexplained epileptic seizure
- hepatitis, jaundice, generalised itching, liver enlargement, severe upper abdominal pain
- significant rise in blood pressure (above 160 mmHg systolic or 100 mmHg diastolic)
- clear exacerbation of other conditions known to be capable of deteriorating during HRT or pregnancy.

Although evidence is in many cases less well established, HRT should perhaps also be used with caution in diseases which may be exacerbated during pregnancy or oestrogen therapy including asthma, epilepsy, hypertension, renal disease, sickle-cell disease, melanoma, otosclerosis, multiple sclerosis, and SLE.

Doses of oestrogen in HRT are insufficient to provide contraception. HRT is contra-indicated in known or suspected pregnancy, and in women who are breast feeding.

Endometriosis. Women with endometriosis who are treated with hysterectomy and bilateral oophorectomy undergo a surgically-induced menopause and can experience acute menopausal symptoms; they are also at risk of conditions such as osteoporosis from long-term oestrogen deficiency. HRT until about 50 years of age has been recommended for women who undergo premature menopause, but disease reactivation and malignant transformation to adenocarcinoma in residual foci have been reported in women with a history of endometriosis, particularly with unopposed oestrogen. Although there are limited data to quantify the risks from HRT, they appear to be small. Nevertheless, recurrent disease may be more severe, with a greater chance of causing ureteric obstruction and consequent renal damage. To minimise the risks of reactivation and malignancy, women with a history of endometriosis should probably be given continuous combined HRT at the lowest effective dose. Although withholding HRT for a few months to wait for endometriosis to regress after surgery has been recommended, there is limited supporting evidence and others suggest that HRT may be started soon after surgery.[1]

1. Soliman NF, Hillard TC. Hormone replacement therapy in women with past history of endometriosis. *Climacteric* 2006; **9:** 325–35.

Lupus erythematosus. SLE is an auto-immune disease which is far more common in women than in men, and usually has a peak onset for women in their 20s and 30s. There is some evidence to suggest that menopausal HRT use may be associated with a slightly increased risk in the onset of SLE in older women.[1-3] In women with pre-existing SLE, small studies found no apparent effect of HRT on disease flares.[2] In a larger study of 351 women, who were given either combined HRT or placebo for 12 months, severe flares were rare in both groups but mild to moderate flares were increased in the HRT group.[4]

Women with SLE are at increased risk of thromboembolic disease, and it has been suggested that transdermal oestrogen HRT may have less of a thrombogenic effect than oral HRT.[5] Women with antiphospholipid antibodies (which includes about a third of all patients with SLE) are at the highest risk and some[5] suggest that HRT should be avoided altogether in patients with persistent antibodies.

Malignant neoplasms. HRT is usually avoided in women who have been treated for *breast cancer* because of the concern that oestrogen will stimulate cancer recurrence. A retrospective observational study[1] and a retrospective case-control study[2] among women diagnosed with breast cancer did not find any evidence of an adverse effect in those who began HRT after diagnosis. A systematic review[3] of studies of HRT in breast cancer survivors reached a similar conclusion, but also noted that these studies were small, not randomised, and many were uncontrolled. More recently, an open randomised study[4] was stopped early when it was found that 2 years of HRT increased the risk of breast cancer (local recurrence, contralateral cancer, or distant metastases); this has cast doubt on the safety of HRT in these patients. A similar study, however, found that about 4 years of HRT did not increase the risk of cancer recurrence.[5] Comparing these two results, the authors suggested that the increased risk may have been due to the use of combined HRT that included continuous progestogen, rather than cyclic or long-cycle regimens. A systematic review[6] of 20 studies, including these two, highlighted the many differences in design such as HRT regimens used, and concluded that in the absence of sufficient evidence of safety HRT should not be used in women with a history of breast cancer. Other reviewers[7] have also recommended a cautious approach, suggesting that HRT should not be used for first-line management of menopausal symptoms in these women, but may be justified when other treatments have failed. The safety of different HRT regimens requires further study,[6,7] and the use of tibolone is under investigation.[8]

Similarly, HRT is usually avoided in patients who have been treated for *endometrial cancer*, because of the theoretical risk of stimulating tumour recurrence.[9] There is a lack of well-designed studies on this subject, but some data suggest that HRT might not increase the rate of recurrence or death.[10,11]

Women who carry *mutations of the BRCA1 and BRCA2 genes* are at greatly increased risk of breast and ovarian cancers, and prophylactic oophorectomy after child-bearing may be considered as a means of reducing this risk. The use of HRT to manage the subsequent menopausal symptoms has been controversial because of concerns that it may adversely affect the risk of breast cancer. One study[12] that used a decision analytical model concluded that HRT did not negate the benefits of oophorectomy; the degree of life expectancy loss or gain was relatively small and influenced by length of HRT use, age at oophorectomy, and presence or absence of concurrent mastectomy. The authors suggested that the decision to use short-term HRT should be based on quality of life issues rather than life expectancy, and that HRT should be stopped at or before the expected age of natural menopause. A subsequent cohort study[13] also found that the use of HRT did not negate the protective effect of prophylactic oophorectomy against breast cancer in BRCA1/2 mutation carriers. Despite these reassuring results, data are limited and further studies are needed to determine appropriate formulations and the optimal timing and duration of HRT for these women.[14]

Porphyria. HRT should be used with caution in patients with porphyria.

Surgery. A review[1] recommended that women receiving HRT and due to have major elective surgery or leg surgery should continue taking the HRT and should routinely receive thromboprophylaxis (e.g. subcutaneous low-molecular-weight heparins and the use of graduated elastic compression stockings) in the perioperative period. Similar management was proposed when undergoing emergency surgery but prophylaxis was considered unnecessary with minor surgery. These conclusions were based on the advice of specialist groups but it was noted that there was some conflict with recommendations of manufacturers and those of the *BNF*. The *BNF* states that it may be prudent to stop HRT 4 to 6 weeks before major surgery; failing that, prophylaxis as above is recommended. HRT should only be restarted after full mobilisation.

Withdrawal. Although it is now generally recommended that menopausal HRT used to relieve vasomotor and vaginal symptoms should be given at the lowest effective dose for no longer than necessary (see Menopausal Disorders, p.2077), there has been little study of how to effectively withdraw HRT without a recurrence of menopausal symptoms. When the Women's Health Initiative (WHI) study was stopped prematurely, the effect of HRT withdrawal was assessed in 8405 of the women in this study who were receiving either combined HRT or placebo at the time.[1] A range of menopausal symptoms were reported in both groups. Moderate to severe vasomotor symptoms (hot flushes and night sweats) occurred in 21.2% of women who stopped HRT, compared with 4.8% stopping placebo; younger women were more likely to develop symptoms. Pain and stiffness was reported by about 37% who stopped HRT, with a similar incidence across age groups. Having these symptoms at study entry was the strongest factor for recurrence when treatment ended.

Once the WHI study was stopped, many other women were also advised, or independently chose, to stop HRT; retrospective studies in smaller groups have reported the recurrence of troublesome menopausal symptoms in 30% or more.[2-4] There also appeared to be no advantage to tapering the withdrawal of HRT, compared with stopping abruptly.[2,3] Women reported using various measures to manage recurrent menopausal symptoms,[1,3,4] including lifestyle management such as exercise and drinking more fluids, vaginal oestrogen therapy, antidepressants, and preparations such as cimicifuga (black cohosh), soya, or red clover; in some cases women restarted HRT.

Interactions

Drugs that increase the hepatic metabolism of oestrogens and progestogens have been associated with failure of the combined oral contraceptive (see p.2067). Important examples include rifamycins, some antiepileptics, and griseofulvin. It is not unreasonable to assume that these drugs would also be associated with decreased effectiveness of HRT, but there appears to be little information on this (for one report, see Antiepileptics, below).

Although oral contraceptives alter the effects of a number of drugs (see p.2067), the lower doses of oestrogens used in HRT are considered less likely to induce interactions, although the possibility remains.

◊ A study[1] in 12 healthy women aged 20 to 25 years, using bupropion as a probe reaction, found that HRT (estradiol valerate with levonorgestrel) was an inhibitor of the cytochrome P450 isoenzyme CYP2B6.

Alcohol. Acute ingestion of an alcoholic beverage led to a threefold increase in circulating estradiol in a study of women on menopausal HRT.[1] Another study[2] that included 309 women taking HRT found that about half had low serum-oestradiol concentrations, and that moderate alcohol consumption was one of the factors associated with achieving therapeutic concentrations.

Both alcohol consumption and HRT are risk factors for breast cancer, and cohort studies[3,4] have suggested that the risk from the combination may be higher than the individual risks alone.

Antiepileptics. *Phenytoin* was reported to reduce the effect of conjugated oestrogens in a menopausal woman.[1]

1. Notelovitz M, *et al.* Interaction between estrogen and Dilantin in a menopausal woman. *N Engl J Med* 1981; **304:** 788–9.

Levothyroxine. Increased doses of levothyroxine may be needed in hypothyroid women who receive oestrogens for postmenopausal HRT—see p.2173.

Tacrine. HRT may increase plasma concentrations of tacrine—see p.370.

Vitamins. The effect of oral *ascorbic acid* (500 mg twice daily) on plasma concentrations of oestradiol was studied in 25 postmenopausal women stabilised on transdermal estradiol gel.[1] After 1 month, oestradiol concentrations had risen for the group overall by about 21%. The greatest responses were in those who initially had low plasma concentrations of ascorbic acid or oestradiol. The authors suggested that the antioxidant effect of ascorbic acid might reverse the oxidation of oestrogens, but that these results did not support the general use of ascorbic acid as an adjuvant to HRT.

1. Vihtamäki T, *et al.* Oral ascorbic acid increases plasma oestradiol during postmenopausal hormone replacement therapy. *Maturitas* 2002; **42:** 129–35.

Pharmacokinetics

For a discussion of the pharmacokinetics of oestrogens and progestogens, see Estradiol, p.2098 and Progesterone, p.2126, respectively. The extent of binding of progestogens to serum sex-hormone binding globulin may be altered when they are given with an oestrogen. Oestrogens increase serum concentrations of sex-hormone binding globulin, and progestogens differ in their ability to suppress this effect.

Uses and Administration

The term *hormone replacement therapy* (HRT) is often used to represent the use of an oestrogen, with or without a progestogen, in peri- and postmenopausal women. HRT is used for the management of acute menopausal symptoms such as vasomotor symptoms and atrophic vaginitis, and can be used long-term in women with premature or surgically-induced menopause until the normal age of menopause. HRT may also be used for postmenopausal osteoporosis in selected women, when other preferred drugs cannot be used or have been ineffective. The most commonly used oestrogens in menopausal HRT are natural oestrogens such as estradiol, and conjugated oestrogens. Dosages of oestrogens used in HRT are generally lower than those used in combined oral contraceptives, and do not therefore provide contraception.

Oestrogens for HRT are available as oral tablets, intranasal sprays, subcutaneous implants, topical applications for vulvovaginal use, intravaginal rings, and transdermal patches and gels. Generally, if prolonged therapy (for more than 2 to 4 weeks) with an oestrogen by any route is envisaged in a woman with an intact uterus, a progestogen is required to prevent endometrial proliferation. This may be given by mouth cyclically for 10 to 14 days per cycle or continuously; transdermal preparations that supply both oestrogen and progestogen are now also available. Both progesterone derivatives such as medroxyprogesterone and dydrogesterone, and 19-nortestosterone analogues such as norethisterone, norgestrel, and levonorgestrel are used. Doses of progestogens for HRT are similar to those used in combined oral contraceptives.

Administration. In a discussion of the relative merits of oral and transdermal oestrogen therapy[1] it was suggested that there was circumstantial and theoretical evidence to suppose that transdermal therapy might be preferable in women who smoke, who suffer from migraine, hepatobiliary disease, or hypertriglyceridaemia, or who have a history of thromboembolism. In contrast, oral HRT might be preferable in patients with hypercholesterolaemia. However, studies to examine these suppositions were needed. Although there have been further studies comparing cardiovascular risk markers in women given oral or transdermal HRT, data on clinical outcome are scarce[2] (see also Venous Thromboembolism, under Adverse Effects, above). Various alternatives to oral oestrogen therapy have been reviewed.[3-5] For reviews of estradiol given as implants or transdermally, see p.2099.

Cardiovascular disorders. Observational studies have shown a decreased risk of ischaemic heart disease and consequent mortality in women receiving menopausal HRT and oestrogens are known to have some beneficial effects on the plasma lipid profile (see Effects on Lipids, above). However, results from randomised placebo-controlled studies of combined HRT for primary or secondary prevention of ischaemic heart disease have shown no overall benefit from HRT, and possibly an increased risk of coronary events (see Ischaemic Heart Disease, under Adverse Effects, above). It has therefore been recommended that HRT should not be used for prevention of cardiovascular disease.[1] Cardiovascular risk reduction, including management of blood lipids, is discussed on p.1164.

1. Mosca L, *et al.* Evidence-based guidelines for cardiovascular disease prevention in women. *Circulation* 2004; **109:** 672–93.

Dementia. Several observational studies[1-3] have suggested that oestrogens can reduce the risk and delay the onset of Alzheimer's disease (p.362) in postmenopausal women receiving HRT. However, subsequent meta-analyses[4,5] concluded that studies conducted so far had substantial methodological problems and that results were conflicting. A further observational study[6] has also reported improved global cognition, and a slower rate of decline over 3 years in women receiving HRT. This study also found[7] that previous HRT use reduced the risk of developing dementia, but that current HRT use had no effect unless it was taken for more than 10 years. In contrast, another observational study (a substudy of the Nurse's Health Study[8] including 13 807 women) found no association between HRT use and cognitive performance over 2 years, and a suggestion that long-term use or initiation at older ages may increase the risk of cognitive decline. Any apparent benefits of HRT have also been thrown into question by the results of two large controlled studies of women who received conjugated oestrogens with medroxyprogesterone, or placebo, for about 4 years. At the end of the Heart and Estrogen/Progestin Replacement Study of women with coronary disease, there was no difference in cognitive function tests between those receiving HRT or placebo.[9] In the Women's Health Initiative Memory Study of over 4000 women aged 65 years and older, HRT had no clinically significant effect on global cognitive function, but the risk of suffering a substantial decline was higher for the HRT group.[10] Also, HRT did not prevent the development of mild cognitive impairment, and actually doubled the risk of dementia.[11] The absolute risk of dementia is small, however, and this increase is equivalent to 45 cases of dementia per year for every 10 000 women taking HRT compared with 22 cases for placebo. Similar effects were found for conjugated oestrogens alone in women with a prior hysterectomy who were studied in a separate arm of the Women's Health Initiative.[12,13] Pooling of data from both the oestrogen alone and combined HRT arms of this study suggested that HRT had an adverse effect on cognition,[13] increased the risk for both dementia and mild cognitive impairment, and should not be used to prevent dementia or cognitive decline.[12] A substudy of the Women's Health Initiative examined changes in specific cognitive domains, particularly memory and affect, in 1416 women given combined HRT or placebo.[14] After an average of 4 to 5 years, combined HRT had a negative effect on verbal memory, but a trend to a positive effect on figural memory; there was no significant influence on other cognitive domains and affect.

It has been suggested that age might provide an explanation for the conflict between results of observational and controlled studies. A review that compared results from controlled studies in younger women (less than 65 years old) and older women (65 or older) found that younger women may not be at risk from oestrogen alone and may benefit in verbal memory and attention.[15] However, the reviewer noted that there were limited data available on oestrogen alone in younger women and a lack of studies of combined HRT. A case-control study[16] has also reported a reduced risk of Alzheimer's disease in younger women (50 to 63 years old), but not older women, given HRT.

Some reports[17-19] suggest that treatment with oestrogens may be of benefit in women who already have Alzheimer's disease. However, in a controlled trial in women with mild to moderate Alzheimer's disease, oestrogen replacement therapy for one year did not slow the progression of disease or improve global, cognitive, or functional outcomes.[20] Further analysis of the range of hormone concentrations measured in this study[21] found no association between plasma concentrations of estradiol and estrone, and cognitive function.

Hyperparathyroidism. The effects of HRT have been studied in postmenopausal women with mild primary hyperparathyroidism (p.1087). Oestrogens have been reported to reduce the rate of bone turnover and plasma concentrations of calcium in these patients, as well as increase bone mineral density.[1-4]

Menopausal disorders. The menopause (p.2071) is a natural process that occurs in women with normal ageing. For some, the only noticeable change during the perimenopause is irregular menstrual periods that eventually stop, but for others vasomotor symptoms and atrophic vaginitis can cause significant discomfort; effects vary not only between women, but also for the individual woman as she progresses through the menopausal transition. Menopausal effects can be more sudden and intense in women who have the abrupt loss of oestrogen associated with menopause induced by surgery, chemotherapy, or radiotherapy. Many reviews and guidelines have been published on management of the menopause including the use of HRT.

Acute menopausal symptoms. There are a number of strategies that may be tried for the management of acute menopausal symptoms.

- In postmenopausal women with only *vaginal symptoms*, non-hormonal vaginal lubricants and moisturisers can be tried first.[1] If these are inadequate, locally-acting vaginal oestrogen therapy may be effective;[1,2] improvement typically occurs within a few weeks, but may take 4 to 6 weeks. Oestrogen therapy may continue for as long as required for symptomatic relief, but data on the effects of long-term use are lacking.[1] Systemic exposure from vaginal preparations is believed to be limited, and the addition of a progestogen to protect against endometrial hyperplasia in women with a uterus is generally not indicated when low-dose local oestrogen therapy is used.[1] Nevertheless, studies have reported cases of endometrial hyperplasia and overstimulation; a systematic review found that there were insufficient data to confirm whether a progestogen should be given when vaginal oestrogens are used for more than 6 months.[2] Women using a cream may be at higher risk of systemic absorption since dosing relies on the amount of cream measured by the woman, which may be variable compared with vaginal tablets. (Some vaginal preparations are designed to deliver sufficient systemic oestrogen to treat vasomotor symptoms—see below.)
- Mild *vasomotor symptoms* may be adequately managed with lifestyle changes such as maintaining a lower core body temperature, physical activity, and relaxation techniques.[3] Moderate to severe symptoms can be controlled with HRT,[3-9] usually given orally or transdermally; some vaginal rings also deliver sufficient oestrogen to the circulation to treat vasomotor symptoms. The lowest dose that controls symptoms is given short term, generally for no more than 5 years. Women without a uterus, and who have not had endometriosis, may receive continuous oestrogen alone.[6,7] Women with a uterus should also receive a progestogen to reduce the risk of endometrial hyperplasia and cancer associated with unopposed oestrogen therapy[3,4,6,9] (for a discussion of the risks of endometrial cancer with HRT, see under Adverse Effects, above). In women who are postmenopausal (more than 12 months) continuous combined HRT may be used.[7] However, continuous combined HRT can cause irregular bleeding in perimenopausal women, so they are usually given a cyclical progestogen orally or transdermally, which will cause regular withdrawal bleeding; an alternative is the levonorgestrel intrauterine device. Vaginal progesterone or oral long-cycle regimens (progestogen for 12 to 14 days every 3 to 6 months) have been used to reduce adverse effects, but it is not clear that these provide adequate endometrial protection.[9]

  Perimenopausal women are still potentially fertile and HRT does not provide contraception. It is now considered that women free of all risk factors for venous and arterial disease may use a low-dose combined oral contraceptive (p.2069) to provide both relief of menopausal symptoms and contraception.[3] However, it is recommended that they should stop the oral contraceptive at the age of 50, so that the menstrual cycle and menopausal status can be assessed. Non-hormonal contraceptives or the progestogen-only oral contraceptive (see p.2070) may be used if contraception is required in perimenopausal women using HRT, and continued to the age of 55 when natural sterility can be assumed.[10]

  Alternative hormonal therapies for vasomotor symptoms include the progestogens megestrol and medroxyprogesterone.[3,6,11] Tibolone, which has oestrogenic, progestogenic, and androgenic properties, is another option for postmenopausal women.[4,7,12,13]

  Non-hormonal therapies have also been tried although evidence for the efficacy of these is less conclusive than that for HRT.[3,6,11,14] The antidepressants fluoxetine, paroxetine, and venlafaxine have shown some benefit in small trials, and low doses of gabapentin have been reported to be effective. Clonidine or veralipride may be considered when HRT is not suitable, but the use of these can be limited by adverse effects. Other therapies have been used to manage vasomotor symptoms based on anecdotal reports of benefit, but they have generally not been effective when studied in placebo-controlled trials. These include isoflavones from soya or red clover, evening primrose oil, cimicifuga (black cohosh), *Angelica sinensis* (dong quai), and vitamin E.
- *Non-specific symptoms* may also improve in women given HRT, but good evidence is somewhat scanty and HRT should not be used solely for these indications. Oestrogens might reduce recurrent urinary-tract infections in susceptible women,[7] but incontinence can worsen (see below). Many women report improved mood and well-being when given oestrogens, although it is unclear to what extent this is due to relief of other symptoms. Two large controlled studies[15,16] have found that combined HRT improved some quality of life measures in postmenopausal women with vasomotor symptoms, but that asymptomatic women in general received no benefit. There is insufficient evidence to support the use of oestrogen, alone or in combined HRT, for the treatment of depression.[9] Moreover, the addition of progestogens carries some risk of adverse effects on mood such as depression, anxiety, and irritability. Androgens such as testosterone are sometimes used as adjuncts to HRT to improve psychological well-being and libido,[17] particularly in women with surgically-induced menopause.[6]

Initiation of HRT. There is increasing discussion about when to start HRT, as the timing of treatment after menopause seems to relate to long-term health outcomes. There has been interest particularly in how the effect of HRT on ischaemic heart disease might be affected by age, considering that many women who took part in studies of HRT were older than those who generally take HRT for vasomotor symptoms in their 50s (see Ischaemic Heart Disease under Effects on the Cardiovascular System, above). The benefit-risk ratio is more likely to be acceptable for short-term symptomatic management in younger women around the age of typical natural menopause (about 51 years). It is also now generally advised that, unless there is a compelling indication, HRT should not be started in women older than 60 who have had a natural menopause at the typical age because they will usually have higher baseline risks of cardiovascular disease and breast cancer.[9] It is also generally agreed that all women who have had a *premature natural or induced menopause* should be offered HRT or a combined oral contraceptive until about 50 years of age, unless there are specific contra-indications to therapy. These women may need higher doses of HRT than those normally used to control vasomotor symptoms. Adjunctive androgen therapy may also be considered, particularly in oophorectomised women.[18] Considerations as to how long they need to continue HRT after the usual age for the menopause are probably the same as for other women.

Long-term use of HRT. There are extensive data from observational studies on the beneficial effects on fracture rates and cardiovascular disease, on the risks for development of breast cancer and endometrial cancer, and on the possible effects on overall mortality. However, the women receiving HRT in these studies may differ from women not receiving HRT, and the extent of any bias resulting from this is unclear.[19] Randomised prospective studies have confirmed the increased risk of breast cancer, venous thromboembolism, stroke, and dementia associated with combined HRT (see under Adverse Effects, above). Contrary to the anticipated benefits for preventing ischaemic heart disease, these studies also found an increase in coronary events, and such use is now not recommended (see Cardiovascular Disorders, above). These results have led to recommendations that HRT should not be used long term solely for the prevention of chronic disease in generally healthy postmenopausal women.[6,20,21] However, although other treatments are now preferred for the prevention and treatment of osteoporosis (p.1084), long-term HRT may be suitable for some women (see also below).

Osteoporosis. Oestrogens may be used in selected patients for the treatment and prevention of postmenopausal osteoporosis (p.1084). They have a direct antiresorptive effect on bone, and will increase bone mass density (BMD). However, data from the Heart and Estrogen/Progestin Replacement Study (HERS) have called into question the benefit of HRT in reducing the incidence of fractures.[1,2] A meta-analysis[3] including the initial HERS data,[1] most of which were from women without osteoporosis, consequently found only non-significant reduction in fracture risk in older women although overall the risk of fracture was reduced by between 20 and 30%. Subsequent results from the Women's Health Initiative[4] showed that, contrary to the results of this meta-analysis, combined HRT did reduce the risk of fracture in healthy postmenopausal women. Similarly, cohort data from 138 737 women in the Million Women Study[5] showed that current use of HRT reduced fracture risk, but that this protection wore off rapidly after stopping HRT. Other studies have also reported that protection against loss of bone mineral density[6] and fracture[7] is not retained after stopping HRT.

Despite the probable benefits, there is substantial evidence to show that HRT is associated with an increased risk of cancer, particularly breast cancer (see Breast under Carcinogenicity, above), and some cardiovascular diseases such as stroke and venous thromboembolism (see Effects on the Cardiovascular System, above). It is now generally recommended by authorities, such as the UK CSM,[8] that the risk to benefit ratio of HRT is unfavourable for the prevention of osteoporosis as first-line therapy, and that it should not be used in this way for women over 50 years of age. HRT does, however, remain an option when other osteoporosis prevention therapies are unsuitable. Younger women who have experienced premature menopause may be given HRT for menopausal symptoms and to prevent osteoporosis until the age of 50, after which its use should be reviewed and considered a second-line choice.

Suggested minimum daily doses are 625 micrograms of oral conjugated oestrogens, 2 mg of oral estradiol or 50 micrograms transdermally, and 15 micrograms of oral ethinylestradiol; lower doses may also be effective,[9-15] and a transdermal patch supplying 14 micrograms of estradiol daily is licensed for the prevention of osteoporosis in the USA. Addition of a progestogen (required to prevent endometrial hyperplasia in women with a uterus) does not impair the beneficial effect of oestrogens on BMD, whether given cyclically or continuously,[16,17] and may provide a further reduction in risk of fractures.[18] Although current, long-term use of HRT can increase BMD and reduce fracture risk, unresolved issues are the duration of therapy required to prevent fractures in old age, and the ideal age to start therapy to obtain the maximum benefits to the bone with the minimum risk of breast cancer.[18-20]

Oestrogens may also be used in women to reduce the risk of corticosteroid-induced osteoporosis (see Effects on Bones and Joints, p.1491).

Urinary incontinence. Urinary incontinence (p.2180) may be one of a number of acute symptoms associated with a decline in oestrogen levels at the menopause (see Menopausal Disorders, above). Studies[1,2] suggest that oestrogens used with alpha-adrenoceptor agonists are effective in the management of female stress incontinence and this combination has been advocated for use in postmenopausal patients with mild symptoms. Unfortunately addition of a progestogen to treatment to reduce the risk of endometrial carcinoma in women with an intact uterus might exacerbate the incontinence.[3] The value of oestrogens used without an alpha-adrenoceptor agonist in urinary incontinence is less clear. One study[4] reported that oestrogen therapy and pelvic floor exercises for 18 months was more effective than exercises alone in women with mild stress incontinence. However, a placebo-controlled study[5] found no improvement after 6 months of oestrogen therapy.

Some consider that oestrogens may be of use for symptoms of urgency, frequency, and nocturia in postmenopausal patients with urge incontinence, particularly if given locally;[6] it has been suggested that hypoestrogenism may reduce the sensory threshold of the bladder.[7] A meta-analysis of 23 studies concluded that oestrogen therapy subjectively improved urinary incontinence in postmenopausal women but many of the studies examined were considered to be deficient in some respect.[8] Later well-designed studies[9,10] of women with stress, urge, or mixed incontinence found that HRT did not improve, or even worsened, measures of incontinence, although there was the possibility that concomitant progestogen therapy might have affected efficacy. Furthermore, the placebo-controlled Women's Health Initiative[11] found that both oestrogen alone and combination HRT increased the overall risk of developing stress, urge, or mixed incontinence, and worsened incontinence in women who were symptomatic before starting HRT. Another placebo-controlled study[12] also found that combination HRT increased the risk of developing stress or urge incontinence, and the large Nurses' Health Study cohort reported[13] that the current use of HRT increased the risk of developing urinary incontinence.

Gonad-regulating Hormones

The Hypothalamic-Pituitary-Gonadal Axis

The regulation of sexual function involves the so-called hypothalamic-pituitary-gonadal axis.

The pituitary gland or hypophysis is composed in humans of 2 parts, the anterior lobe or adenohypophysis, and the posterior lobe (neurohypophysis) and neural stalk, above which lies the hypothalamus. Both parts of the pituitary secrete hormones: posterior pituitary hormones are synthesised in the hypothalamus and transported down nerve fibres to the pituitary where they are stored until required, whereas anterior pituitary hormones are synthesised *in situ* by specialised cells, but are subject to complex hormonal control by hypothalamic regulatory hormones and target organ hormones, as well as excitatory and inhibitory impulses from the brain. These interacting systems are collectively known as the hypothalamic-pituitary-endocrine axes.

The anterior pituitary hormones follicle-stimulating hormone (FSH) and luteinising hormone (LH) are collectively known as **gonadotrophic hormones** or gonadotrophins. They are glycoproteins secreted by specialised pituitary cells (gonadotropes) that stimulate gonadal function and sex hormone production. In men, LH stimulates the synthesis of testosterone and other androgens, while in women, FSH and LH regulate production of oestradiol and synthesis of progesterone in a complex and interacting manner. A third substance with gonadotrophic (primarily luteinising) actions, chorionic gonadotrophin, is secreted by the placenta.

The synthesis and secretion of pituitary gonadotrophic hormones is in turn stimulated by a hypothalamic releasing hormone, **gonadotrophin-releasing hormone** (GnRH). In post-pubertal subjects, GnRH is secreted from the hypothalamus at regular intervals determined by an internal 'clock' or neuronal pulse generator in the arcuate nucleus, and enters the blood of the portal vascular system that links the hypothalamus to the anterior pituitary. This results in pulsatile release of the gonadotrophic hormones, which is essential for normal gonadal function. More prolonged and continuous exposure to GnRH leads to desensitisation and downregulation of its receptors on pituitary gonadotropes, and hence, after an initial surge, to suppression of gonadotrophic hormone secretion.

The sex hormones themselves produce negative feedback effects at both hypothalamic and pituitary levels. In general, both oestrogen and progesterone reduce the amplitude (i.e. the amount) of gonadotrophic hormone released; progesterone also reduces the frequency of the pulses. Testosterone is thought to act by conversion to oestrogen via aromatase, although it also has some direct action. The gonads also produce a hormone, inhibin, that selectively inhibits FSH secretion from the pituitary without affecting LH, and its biological opposite, activin, which stimulates pituitary FSH secretion.

Types of Gonad-regulating Hormone

Gonad-regulating hormones in clinical use may be divided into 3 major groups.

- Endogenous follicle-stimulating and luteinising hormones are available from urinary sources as human menopausal gonadotrophins or menotrophin (p.2109) and as urofollitropin (p.2136), and in recombinant forms such as follitropins alfa and beta (p.2104) and lutropin alfa (p.2112). Chorionic gonadotrophin and its recombinant form choriogonadotropin alfa (p.2085) are also used.
- The hypothalamic releasing hormone gonadorelin (p.2106), and its longer-acting analogues such as buserelin (p.2083), deslorelin (p.2093), goserelin (p.2108), histrelin (p.2109), leuprorelin (p.2111), nafarelin (p.2117), and triptorelin (p.2135) are widely used to stimulate or inhibit the hypothalamic-pituitary-gonadal axis.
- More recently, direct gonadotrophin-releasing hormone antagonists have become available, such as abarelix (p.2081), cetrorelix (p.2084), and ganirelix (p.2105).

Use of Gonad-regulating Hormones

The gonad-regulating hormones play an important role in the management of a number of endocrine disorders, as discussed in the reviews below and elsewhere in this chapter. They also play an important role in the management of endocrine-sensitive malignant neoplasms (see p.643).

Amenorrhoea

Amenorrhoea is the absence of menstruation: a break in menstruation of 6 months or more is considered pathological in an adult woman who is not pregnant, lactating, or menopausal. Amenorrhoea occurring from the time of puberty is known as primary, while amenorrhoea developing later in life is referred to as secondary. Pathological amenorrhoea is usually associated with infertility (see also below). Hirsutism (p.2089) may also be present.

The causes of amenorrhoea (or oligomenorrhoea—infrequent and erratic periods) are most often ovarian or hypothalamic/pituitary in origin. Ovarian causes include failure of normal gonadal development, as in Turner's syndrome (below); premature ovarian failure including that due to trauma, drugs, radiotherapy, or autoimmunity; and conditions such as the polycystic ovary syndrome (below). Hypothalamic or pituitary causes include reduced production of gonadotrophins due to inadequate nutrition, excessive exercise, or pituitary trauma (see also Hypogonadism, below); or excess prolactin production (see Hyperprolactinaemia, below). Other causes, including adrenal disorders, thyroid disorders, abnormalities of the vagina or uterus, or testicular feminisation, may be found rarely.

The management of amenorrhoea essentially involves the identification of any underlying disorder and its correction, if possible. When the cause cannot be corrected, oestrogen replacement therapy, usually in the form of an oral contraceptive, is appropriate to minimise the consequences of long-term oestrogen deficiency.

Cryptorchidism

The testes are formed within the abdomen and subsequently descend the inguinal canal to the scrotum. Failure of the testes to descend (cryptorchidism) occurs in about 3 to 6% of newborn males but in many the testes descend during the first year of life decreasing the prevalence to about 1%. In children with cryptorchidism, pathological testicular damage has been noted by the age of 1 year, and may result in subsequent infertility; cryptorchidism also significantly increases the risk of testicular cancer. Abnormalities of the testes and anatomical abnormalities such as inguinal hernia may contribute to maldescent, and both primary testicular disease and gonadotrophin deficiency may be associated with cryptorchidism. For discussions of Hypogonadism and Infertility, see below. Cryptorchidism should be distinguished from retractile testes in which the testes develop normally and for which treatment is usually not required.

Although cryptorchidism is common, there is no consensus on the best treatment: surgery is commonly used in the USA whereas primary hormonal treatment is more popular in Europe.[1,2]

Surgery is successful in almost all cases, and is usually undertaken at around 1 year of age.[1,2] Primary hormonal therapy generally uses chorionic gonadotrophin or a gonadorelin analogue to stimulate androgen production. Success rates vary but reports are difficult to compare because of differences in patient age and treatment regimens, and the possible inclusion of retractile testes. Systematic reviews[3,4] suggest that gonadorelin and chorionic gonadotrophin are more effective than placebo with a success rate of about 20% overall, although this may be considerably lower if care is taken to exclude retractile testes. The lower the position of the undescended testis, the more likely benefit from hormonal therapy appears to be.[3,5] Treatment may also be less successful as boys grow older, and treatment before 12 to 18 months[6] or 2 years of age[4] has been recommended. Some reports suggest that results may be improved by combined therapy with gonadorelin and chorionic gonadotrophin,[7] but others have found no advantage over single drug therapy.[8,9] Surgery is used second-line when hormonal treatment is unsuccessful. There is some suggestion that medical treatment given either before or after surgery can improve the patient's fertility index, a predictor of future fertility.[6] Chorionic gonadotrophin may also be useful as an adjuvant before surgery, in order to cause a non-palpable testis to become palpable;[10] however, changes suggestive of inflammation in the testis have been reported after such treatment.[5]

Even after successful treatment, however, there may still be impaired fertility. Similarly, the risk of testicular cancer is not necessarily reduced, but orchidopexy does enable early detection and all patients should be monitored.[1,2]

Delayed puberty

The onset of puberty is associated with an increase in the secretion of luteinising hormone. There is a subsequent increase in concentrations of sex hormones, the development of secondary sexual characteristics, and an associated growth spurt. Delayed puberty is diagnosed when there is no breast development by 13.4 years of age in girls, and no testicular enlargement by 14 in boys. In addition to the various causes of hypogonadism (see below), some of which may be difficult to diagnose, severe systemic illness such as asthma or diabetes, or hypothyroidism, may cause delay in sexual maturation. Where no apparent cause can be found a family history of delayed maturation may suggest constitutional delayed puberty, in which normal pubertal development can eventually be expected.

Where pubertal delay is secondary to some other condition appropriate management of the precipitating cause is required. In constitutional delayed puberty small doses of oestrogens in girls, or androgens (such as oxandrolone or a testosterone ester) in boys, may be given to promote growth and sexual development if psychological problems are apparent. Care is required as overly aggressive therapy with sex hormones may lead to premature closure of the epiphyses and compromise final adult height. Treatment should be interrupted periodically to see if spontaneous pubertal development has begun. The use of chorionic gonadotrophin or a gonadorelin analogue has no advantage in such patients, although they have a role in hypogonadotrophic hypogonadism, which may be difficult to distinguish from constitutional delay.

Endometriosis

Gonadorelin analogues are used in the management of endometriosis (see p.2091) but the need for long-term therapy to prevent recurrence limits their value because of the risk of osteoporosis; 'add-back' therapy, with concomitant hormone replacement, can be used to prevent this.

Hyperprolactinaemia

Hyperprolactinaemia is a condition of elevated circulating prolactin concentrations. It occurs for physiological reasons in pregnancy or after mechanical stimulation of the nipple, as in suckling. However, hyperprolactinaemia may also be an adverse effect of drugs that inhibit dopaminergic function, such as antipsychotics and metoclopramide; other drugs causing hyperprolactinaemia include opioid analgesics, methyldopa, reserpine, oestrogens, SSRIs, and verapamil. Furthermore, pathological hyperprolactinaemia may be associated with prolactin-secreting pituitary adenomas (prolactinomas), damage to the pituitary stalk or hypothalamus (including that caused by non-secreting tumours), or trauma to the chest wall; it may also be associated with disorders such as Cushing's syndrome or hypothyroidism. Prolactinomas are amongst the commonest pathological causes, and so-called idiopathic hyperprolactinaemia, in which no apparent cause is found, may in fact represent undetected microadenoma.

The consequences of hyperprolactinaemia include suppression of ovarian function in women, leading to erratic cycles or amenorrhoea, and infertility (see also above and below respectively); in men, in whom the condition is less common, reduced gonadotrophin production leads to testosterone deficiency, diminished libido, and impotence. Both sexes may develop unwanted milk flow (galactorrhoea), although this also requires the presence of oestrogens; men may rarely develop gynaecomastia (p.2092) due to the change in oestrogen/androgen balance.

Management of hyperprolactinaemia depends on its cause. Pathological hyperprolactinaemia must be distinguished from physiological, and where it is secondary to another disease this should be managed appropriately; any drug thought likely to be causative should be withdrawn if possible. Some patients are asymptomatic, or are untroubled by their symptoms; whether such patients should be treated has been a matter of some controversy, although the risk of osteoporosis in women with prolonged suppression of ovarian function has been cited as a reason for such treatment.[1]

In many cases hyperprolactinaemia will be secondary to a prolactinoma. These are generally classified as microadenomas (less than 10 mm in size) or macroadenomas (over 10 mm in size); macroadenomas are often associated with prolactin concentrations more than 10 times the normal upper limit and their rapid expansion may result in visual defects and headache. Initially a course of treatment with a dopamine agonist such as bromocriptine, while rarely curative, is extremely effective in controlling hyperprolactinaemia and restoring gonadal function.[2,3] Surgical removal is now rarely indicated, although transsphenoidal decompression may be necessary for macroadenomas despite bromocriptine therapy, and ultimately radiotherapy may also be required.

The most extensively used dopamine agonist is bromocriptine; it decreases prolactin secretion and reduces tumour size in the majority of patients.[2] There are reports of maintained normoprolactinaemia and reduced tumour size when bromocriptine has been withdrawn after about 2 to 4 years of treatment.[4] However, this occurs in only a minority of patients, and macroadenomas in particular can re-expand, sometimes rapidly, when treatment is stopped.[2] It has been suggested[3] that when the prolactin concentration has been normal for 2 years and the tumour has decreased by at least 50%, the dose of bromocriptine can be gradually reduced, with close follow-up to detect tumour enlargement. The short half-life and the adverse effects of bromocriptine may pose problems, although depot formulations can minimise these. Giving oral prednisolone with intramuscular depot bromocriptine has been reported to reduce the incidence of adverse effects.[5]

Treatment of hyperprolactinaemia restores ovulation in the majority of female patients. In those who become pregnant it is generally advised that fetal exposure to the dopamine agonist should be as short as possible, and therefore stopped when pregnancy is confirmed. Bromocriptine is the drug of choice for patients who are planning pregnancy, because most experience exists with its use compared with other dopamine agonists. The hyperoestrogenic state of pregnancy itself can stimulate prolactinoma growth and patients must be carefully monitored throughout gestation. If symptomatic tumour growth occurs, bromocriptine may be restarted, which is probably less harmful to the mother and fetus than surgery. Surgical debulking before pregnancy has been advocated by some, but may not prevent symptomatic tumour enlargement during pregnancy.[2,6]

Alternative dopaminergic treatments include cabergoline and quinagolide.[2,7] Cabergoline appears to be more effective, and better tolerated, than bromocriptine, and can also be effective in patients who do not respond to bromocriptine. It is considered by some to be a first-line alternative, although bromocriptine is favoured in women who wish to become pregnant. Quinagolide appears to be of similar efficacy to bromocriptine, and may be useful in patients intolerant of or unresponsive to other drugs. Pergolide has also been tried, with similar efficacy to bromocriptine, but it is not licensed for such use.

Hypogonadism

Hypogonadism (decreased or absent gonadal function) may occur in both men and women, and may be either primary, due to some dysfunction of the gonads themselves, or secondary, due to hypopituitarism or some other cause of decreased gonadotrophic stimulation.

Primary ovarian dysfunction may be due to failure of the ovaries to form normally, as in Turner's syndrome (see below), or their degeneration before puberty; there may be premature failure, effectively an early menopause, due to low initial follicle numbers or to destruction of follicles by autoantibodies, chemotherapy, radiotherapy, infection, or trauma. Primary testicular dysfunction may be due to congenital disorders such as Klinefelter's syndrome (associated with an XXY chromosome constitution); the effects of chemotherapy, radiotherapy, infections (particularly mumps), or trauma; and a few other conditions such as testicular degeneration.

Secondary hypogonadism may be due to general hypopituitarism, or to a specific deficiency of gonadotrophin production, or gonadorelin production. Kallmann's syndrome is a congenital disorder of hypogonadotrophic hypogonadism due to gonadorelin deficiency associated with anosmia or hyposmia. The causes of pituitary or hypothalamic failure include neoplasms, radiotherapy to the head and neck, trauma, or infiltrative granulomatous diseases such as tuberculosis. Gonadotrophin production may also be suppressed by various drugs (notably exogenous sex steroids and continuous, rather than pulsatile, use of gonadorelin analogues), by weight loss or inadequate nutrition, by excessive exercise, by severe systemic illness, and by hyperprolactinaemia (see above).

The fundamental treatment for primary hypogonadism is replacement therapy with sex hormones to produce appropriate sexual development and activity and counteract effects such as osteoporosis, but fertility cannot usually be restored. In prepubertal children, the induction of secondary sexual characteristics must be balanced against a possible reduction in final height due to premature closure of the bone epiphyses. Women are generally given an oestrogen with a progestogen, and men are treated with androgens, often in the form of a long-acting testosterone ester such as the cipionate or enantate given intramuscularly. Transdermal testosterone is also effective.

The cause of secondary hypogonadism should be determined and managed appropriately if possible. In some cases this may be adequate to restore gonadal function but in other cases sex hormone replacement therapy as in primary hypogonadism will be required. Where there is no fundamental defect in gonadal function the possibility of using a gonadotrophic hormone or stimulating the release of gonadotrophins also exists. In general, however, such therapy is often reserved for attempts to restore fertility (see under Infertility, below), since it is inconvenient and expensive.

Infertility

Although about one couple in 6 may experience sufficient difficulty in conceiving children to seek medical help, most are subfertile rather than infertile, and may eventually conceive, with or without treatment. A number of possible treatments are available, but which is used depends upon the cause of the problem. Reduced fertility can have its origins in the male or the female partner or may be due to a combination of factors from both.

The most obvious cause of infertility is a failure of either ovulation in the female or spermatogenesis in the male. Such failures may be due to damage or abnormal formation of the gonads, a failure of hypothalamic/pituitary stimulation, abnormal feedback as in the polycystic ovary syndrome, or suppression of gonadal function as in hyperprolactinaemia. These conditions and their management are briefly discussed under Hypogonadism (above), Polycystic Ovary Syndrome (PCOS; below), and Hyperprolactinaemia (above).

Female factors. The primary problem in about 20% of infertile women is ovulatory dysfunction, and most of these women will have PCOS. *Clomifene* is often used first-line to stimulate ovulation in women with hypothalamic dysfunction, as in PCOS,[1-4] and has been reported to produce ovulation in about 70% of anovulatory women. Women with PCOS who do not respond to clomifene may be treated with ovarian drilling (laparoscopic diathermy).[2,4] Those who do ovulate with clomifene but have not become pregnant within 6 months may be offered intra-uterine insemination in addition to clomifene.[4] In overweight women with PCOS, metformin may be added when clomifene alone has not been effective.[1-4] The addition of a mid-cycle injection of chorionic gonadotrophin has also been tried for women who fail to ovulate with clomifene,[1] and to define the optimal time for intra-uterine insemination,[2] but such a regimen has not been proven to be better. Some women with clomifene-resistant anovulation may benefit from the sequential use of clomifene and a gonadotrophin that has follicle-stimulating activity.[2] In women with elevated dehydroepiandrosterone concentrations, the addition of a corticosteroid to clomifene may improve the ovulation rate.[1,2] Because of concerns about a possibly increased risk of ovarian cancer, opinion varies as to the maximum number of cycles for which clomifene should be used, but is usually either 6 or 12 cycles (see Carcinogenicity, p.2086). *Tamoxifen* is an alternative in those who cannot tolerate clomifene.[3,4] Aromatase inhibitors such as *letrozole* have also been tried, and seem to be at least as effective as clomifene in inducing ovulation,[5] although concerns about the potential for maternal or fetal toxicity remain to be assuaged.

Gonadotrophins with follicle-stimulating activity can be given directly to women with PCOS who have not ovulated with clomifene or tamoxifen; human menopausal gonadotrophin, urofollitropin, and recombinant follicle-stimulating hormone are considered to be equally effective.[4] Women with hypothalamic anovulation or hypogonadotrophic hypogonadism generally require gonadotrophins that also have luteinising hormone activity, because of low endogenous levels.[4,6] There is growing interest in the use of recombinant luteinising hormone in these patients.[6] Various regimens have been used but in general, follicle-stimulating hormone is given until a dominant follicle is suitably mature, and then chorionic gonadotrophin is given to trigger ovulation and provide luteal support.[6] The risks of ovarian hyperstimulation syndrome and multiple pregnancies are considerable however, particularly in PCOS, and close monitoring is mandatory using ovarian ultrasound to assess follicle development.[3,4]

Another method used for anovulation is pulsatile *gonadorelin*[4] (gonadotrophin-releasing hormone) or its analogues. It is primarily indicated in women with hypothalamic causes of anovulation; it is less effective in women with PCOS than in hypogonadotrophic patients.

Where anovulation is secondary to hyperprolactinaemia treatment with dopamine agonists such as bromocriptine can restore fertility (see Hyperprolactinaemia, above).

Where infertility is due to obstruction of the fallopian tubes or intra-uterine adhesions, surgery may be effective for some women.[4] Where infection is the cause, appropriate anti-infective agents may be useful. (See also under Pelvic Inflammatory Disease, p.184.)

Endometriosis (p.2091) is another important cause of infertility in women, although the reason for the association is not fully understood. Medical treatment of endometriosis does not enhance fertility, although conservative surgery may do so.[4]

In the absence of the above disorders and when infertility is otherwise unexplained the UK guidelines[4] indicate that treatment with clomifene should be offered.

Various other drugs have been used, on a more or less empirical basis. Growth hormone or one of its analogues has been used as an adjunct to ovarian stimulation with gonadotrophins but is not considered to improve pregnancy rates.[4]

Assisted reproduction may be considered when other methods fail. IVF is the most commonly used technique, in which oocytes are retrieved from the ovaries, fertilised *in vitro*, and resulting embryos are selected for transfer to the uterus. Less common techniques include transfer into a fallopian tube of gametes (an unfertilised egg and sperm) or a zygote (fertilised egg). Unlike ovulation induction described above, assisted reproduction techniques intentionally use ovarian hyperstimulation regimens to produce multiple oocytes for retrieval; women are therefore at risk of the ovarian hyperstimulation syndrome and should be monitored appropriately. Women with risk factors for ovarian hyperstimulation syndrome, such as those with PCOS, should not be given chorionic gonadotrophin for oocyte maturation or luteal support.[4] The most commonly used regimens are the 'long protocols' in which a gonadorelin agonist is started in the midluteal phase of the menstrual cycle to desensitise the pituitary and prevent a premature surge of luteinising hormone. When pituitary and ovulation suppression has been achieved, gonadotrophins (human menopausal gonadotrophins or follicle-stimulating hormone) are given to stimulate follicle production. At the appropriate stage of follicular development, a single dose of chorionic gonadotrophin is given to trigger ovulation. These 'long protocols' appear to give better results than short ('flare-up') or ultrashort regimens, in which gonadorelin agonists are given for less time, although short regimens may be useful in poor responders.[6] Meta-analysis indicates that recombinant follicle-stimulating hormone, urofollitropin, and human menopausal gonadotrophins are equally effective.[4] *Gonadorelin antagonists*, such as cetrorelix and ganirelix, have been used as an alternative to gonadorelin agonists. Pituitary desensitisation occurs more rapidly and shorter treatment regimens are used, but they may be associated with reduced pregnancy rates.[4,6,7] *Progesterone* is the preferred drug for luteal support for IVF procedures because of the increased likelihood of ovarian hyperstimulation syndrome with chorionic gonadotrophin.[4]

Male factors. Impaired male fertility may result from urogenital abnormalities, infections of the genital tract, increased scrotal temperature associated with varicocele, endocrine disturbances, genetic abnormalities, and immunological factors, but around 70% of cases may be idiopathic, where no causal factor is found.[8] Some forms of obstructive azoospermia can be corrected surgically. Varicocele repair with surgery or percutaneous embolisation may be considered in some men but the effects on fertility outcome are unclear.[8-10]

In men with hypogonadotrophic hypogonadism, replacement therapy with a gonadotrophin that has luteinising hormone activity, such as chorionic gonadotrophin, is given to stimulate testosterone production. Menopausal gonadotrophins, or the more specific follicle-stimulating hormone, are then added to stimulate spermatogenesis.[8,9] Spermatozoa may appear in the ejaculate after about 6 to 9 months of treatment, but may take considerably longer in some men.[9] Pulsatile gonadorelin may restore gonadotrophin secretion and correct infertility in men with hypogonadotrophic hypogonadism of hypothalamic origin, such as those with Kallmann's syndrome;[8,9] therapy for 1 to 2 years may be necessary to achieve adequate sperm production in some patients who have not previously received gonadotrophins or gonadorelin.[8]

In idiopathic oligospermia, results of drug therapy have been disappointing. Studies of gonadorelin have produced contradictory results and gonadotrophins have not been effective.[8] The antioestrogens, clomifene and tamoxifen, have been used in subfertile men,[9] but there is limited convincing evidence of benefit.[4,8] Corticosteroids have been used in men with autoantibodies to spermatozoa, but efficacy is unproven and corticosteroids are generally not recommended[4,8,9] although they might be considered in men with autoantibodies who have failed assisted reproduction techniques.[9] However, corticosteroids may have a beneficial effect on infertility associated with auto-immune orchitis.[9] Various other drugs have been used on an empirical basis for idiopathic male infertility but evidence for their efficacy is either limited or lacking.[8,9]

When other methods fail, assisted reproduction may be considered. Techniques for male infertility include intra-uterine insemination and intracytoplasmic sperm injection.[4,8-10]

Polycystic ovary syndrome

The polycystic ovary syndrome comprises enlargement of the ovaries with multiple follicular cysts and a thickened, whitish, capsule; there is persistent elevation of serum luteinising hormone concentrations, with a tendency to increased androgen concentrations. Women typically present with erratic menstruation, hirsutism, and obesity, although not all these features may be present; fertility is often impaired. Associated metabolic changes include hyperinsulinaemia with insulin resistance, and increased risk of developing hyperlipidaemia, hypertension, and ischaemic heart disease. The risk of endometrial cancer is also increased.

Management is essentially symptomatic. Patients should be encouraged to modify their lifestyle, to correct lipid abnormalities, and to lose weight if obese;[1,2] weight loss alone may be sufficient to improve menstrual regularity, hirsutism, and fertility. Symptoms of hyperandrogenism can be treated with an anti-androgen, such as cyproterone acetate or spironolactone, with an oestrogen or a combined contraceptive pill.[1-5] Flutamide and finasteride have also been used in these patients (see also the discussion of the management of hirsutism, p.2089).[5] In women who do not desire pregnancy, an oral contraceptive is also the recommended treatment for amenorrhoea or oligomenorrhoea.[2,5-7] Alternatively a progestogen that lacks androgenic properties may be given cyclically, in order to induce withdrawal bleeding (anovular women who do not receive hormonal treatment may be at increased risk of endometrial cancer).[3,6,7] Metformin may also improve metabolic abnormalities and menstrual regularity (see also below), and endocrinologists in the USA have suggested that it may be considered particularly for women who are overweight or obese.[1] However, other practitioners have argued that weight reduction is more effective and should be the initial management for obese women with polycystic ovary syndrome.[2]

In patients who wish to conceive, clomifene citrate is used to induce ovulation. In patients who do not respond, gonadotrophins or laparoscopic ovarian diathermy may be tried. The effects of metformin on ovulation induction are also under investigation (see below).[2,3,6,7] Patients must be monitored carefully during any therapy to induce ovulation, as women with polycystic ovaries are more prone to multiple follicle development and ovarian hyperstimulation. For further details on ovulation induction and assisted reproduction, see Infertility, above.

Insulin resistance is a feature of polycystic ovary syndrome, particularly in obese women. Small non-randomised studies of metformin have reported improvements in insulin metabolism, a reduction in circulating androgen concentrations, small reductions in body-mass index or waist/hip ratio, and improvements in menstrual cycles.[8] Previous controlled studies have found that metformin alone improved ovulation rates and menstrual cycles, and that rates could be improved further when given with clomifene citrate.[8,9] However, more recently, 2 large, placebo-controlled studies have found that metformin, either alone or with clomifene, did not improve the rate of ovulation, pregnancy, or live births in women with polycystic ovary syndrome.[2] Metformin may also improve responses to ovulation induction using follicle-stimulating hormone.[8] Long-term effects of metformin in polycystic ovary syndrome have not been studied, however, and any reduction in cardiovascular risks is yet to be established.[10] There has also been some interest in the use of thiazolidinediones, such as rosiglitazone, but these drugs can increase body-mass, which is undesirable in women who are already overweight.[5,8] Their use is considered investigational.[1]

Bromocriptine[4] may be useful in women with polycystic ovary syndrome and associated hyperprolactinaemia (see above).

Precocious puberty

Precocious puberty is commonly understood to mean the development of secondary sexual characteristics before the age of 8 years in girls or 9 years in boys; it is four to five times more common in girls. However, the age limit used to define precocious puberty in girls has been questioned.[1] Recent data from the United States suggests that puberty is occurring earlier in girls, at age 7 years for white girls, and 6 years for African-American girls. Precocious puberty is either central, due to premature activation of the hypothalamic-pituitary-gonadal axis, or peripheral, due to secretion of extrapituitary gonadotrophins or gonadal steroids independent of gonadorelin secretion from the hypothalamus or pituitary gonadotrophins. In many cases the cause is not apparent, and they are classified as idiopathic. A small proportion of cases are due to tumours. Central precocious puberty may be caused by CNS lesions secondary to diseases such as encephalitis, meningitis, or granuloma, or due to head trauma. Peripheral precocious puberty can be associated with congenital or familial syndromes such as McCune-Albright syndrome or familial testotoxicosis (familial male precocious puberty). Congenital adrenal hyperplasia (see p.1502) can also produce premature sexual development in boys and virilisation in girls.

Apart from early sexual maturation and the associated emotional distress, the chief clinical consequence of precocious puberty is short stature as an adult, due to premature closure of the epiphyses under the influence of sex steroids.[2,3] Age, emotional impact and final height potential should be considered in deciding when to begin and end treatment.[2]

Gonadorelin analogues are the treatment of choice in central precocious puberty.[2,3] The use of continuous rather than pulsatile gonadorelin can paradoxically suppress gonadotrophin secretion by desensitisation and down regulation of pituitary receptors. Cyproterone acetate has been given at the beginning of treatment to prevent the initial stimulatory effect of the gonadorelin analogue.[2] Although originally given daily, by subcutaneous injection or nasal insufflation, intramuscular and subcutaneous depot preparations of gonadorelin analogues are more convenient, and are now more widely used.[2,3] Treatment suppresses sexual development and skeletal maturation, and most studies have reported an improvement in final height.[3,4] However, the treatment of girls with borderline early puberty (between 6 and 8 years of age) has been questioned, as studies suggest that most will reach adult height within the normal range without treatment.[1] Such girls with idiopathic slowly progressing puberty, and no evidence of advanced bone age, may not require gonadorelin therapy, but should be monitored for an onset of rapid pubertal development.[1,5] Children with concomitant growth hormone deficiency (for example after cranial irradiation) may need additional therapy with somatropin or its analogues for maximum benefit.[6] Somatropin has also been used in children who do not have growth hormone deficiency but who have a poor response to gonadorelin analogue therapy; evidence for a beneficial effect is limited.[7]

In the peripheral forms of precocious puberty the gonadorelin analogues are ineffective. Any underlying condition such as a gonadal or adrenal neoplasm should be sought and treated appropriately. Otherwise, therapy is aimed at suppressing premature sexual maturation, and drugs such as cyproterone and medroxyprogesterone have been used.[8] In girls with precocious puberty associated with the McCune-Albright syndrome, the aromatase inhibitor testolactone has been used with some success to block oestrogen biosynthesis,[9,10] ketoconazole has been used in 2 cases,[11] and tamoxifen has been reported to be beneficial.[12] Although ineffective when given alone, testolactone was reported to be of benefit when used with the anti-androgen, spironolactone, in boys with testotoxicosis;[13] a reduction in the rate of bone maturation was reported. Response diminished with long-term treatment, but could be restored by the addition of a gonadorelin analogue, deslorelin, to therapy.[14] This regimen has also been reported[15] to improve predicted adult height. Ketoconazole, which has anti-androgenic properties, has also been tried in boys with familial male precocious puberty; it had beneficial effects on testosterone concentrations and adult height reported in a series of 5 patients.[16]

Premenstrual syndrome

Gonadorelin analogues have been used to treat patients with severe symptoms attributable to the premenstrual syndrome (p.2099), with 'add-back' therapy with oestrogen plus progestogen to prevent the symptoms of oestrogen deficiency.

Turner's syndrome

Turner's syndrome is a congenital disorder associated with the absence of an X or Y chromosome, resulting in an individual with only a single X chromosome who is female in phenotype but in whom the ovaries do not develop. In addition to this gonadal dysgenesis, which results in infertility and primary amenorrhoea, various physical abnormalities may be present including short stature, a short webbed neck and characteristic facial appearance, shield-like chest, multiple naevi, and certain renal and cardiovascular abnormalities. Hypothyroidism and glucose intolerance may occur.

As with other forms of ovarian failure, HRT with oestrogen and intermittent progestogen is indicated in women with Turner's syndrome, in order to produce sexual maturation and the development of secondary sexual characteristics as well as to avoid complications such as osteoporosis. Clinical opinion has generally been that therapy should begin with low doses of oestrogen in girls of prepubertal age, gradually increasing the dose to promote slow development of secondary sexual characteristics and eventual breakthrough bleeding, at which point a cyclic progestogen should be added to oestrogen maintenance to minimise the risk of endometrial hyperplasia and cancer. In general, therapy is started around 14 to 15 years of age, but may be started as early as 12 years of age in girls who have reached a satisfactory height, especially those who have been treated with growth hormone.[1-3] There is no consensus on which oestrogen is preferred for these patients; conjugated oestrogens, ethinylestradiol, and estradiol have all been used. An oral contraceptive may be used for maintenance therapy.[3]

A minority of patients with Turner's syndrome have some residual ovarian function, and there are a few reports of pregnancy in such patients. In women without ovaries it may be possible to maintain pregnancy by appropriate endocrine replacement after implantation of a fertilised donor egg.[1]

Short stature is the most common clinical manifestation of Turner's syndrome. Growth hormone therapy has been widely used and may be considered from as early as 2 years of age,[2] but there is considerable debate about the extent of the benefit in terms of final height. Results from 622 girls enrolled in the National Cooperative Growth Study[4] suggested a mean height gain of 6.4 ± 4.9 cm, and another cohort database[5] of 485 girls found that when treatment was started before puberty a mean increase in final height of 5 cm or more would be expected. A systematic review[6] of 4 controlled studies found that growth hormone increased short-term growth, but that there was limited controlled data on final height. It has been suggested[1] that a final height of 150 cm is an achievable goal for most patients. Growth hormone therapy during childhood and adolescence may also be important in maximising bone mass and reducing the risk of osteoporosis.[7] Although it is generally recommended that oestrogen replacement be delayed where growth promotion is a priority,[1,2] optimal oestrogen replacement therapy may also be important in maximising final height. In a comparison[8] of the introduction of conjugated oestrogen therapy at 12 or 15 years of age, the combination of growth hormone and oestrogen initially stimulated growth velocity and bone maturation more than growth hormone alone, but subsequently declined after about 2 years. Patients who received growth hormone for a longer period before starting oestrogen therapy attained greater adult height, a finding also noted in another study;[9] it was suggested that early use of growth hormone could allow oestrogen therapy to be begun at a more appropriate, younger age without compromising final height. However, the use of low-dose oestrogen from an even earlier age (as young as 8 years) to stimulate linear growth does not add to the effect of growth hormone therapy and may even reduce final height.[10] Combination of growth hormone with a non-aromatisable anabolic steroid such as oxandrolone is recommended as an option in girls aged 8 to 12 years if therapy is begun late,[1] or if response to growth hormone is inadequate.[2]

Adult women with Turner's syndrome require multidisciplinary management including cardiovascular monitoring, psychological support, and a programme of prevention for diabetes, osteoporosis, and hypertension.[1,2]

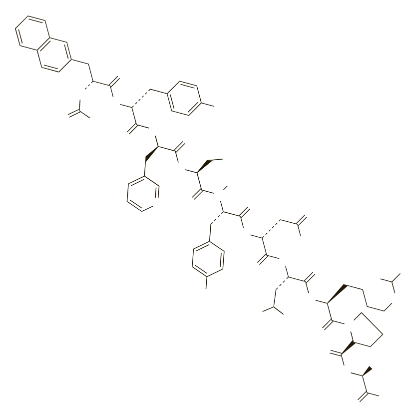
Abarelix *(USAN, rINN)*

Abarélix; Abarelixum; PPI-149; R-3827. *N*-Acetyl-3-(2-naphthyl)-D-alanyl-4-chloro-D-phenylalanyl-3-(3-pyridyl)-D-alanyl-L-seryl-*N*-methyl-L-tyrosyl-D-asparaginyl-L-leucyl-N^6-isopropyl-L-lysyl-L-prolyl-D-alaninamide.

Абареликс

$C_{72}H_{95}ClN_{14}O_{14}$ = 1416.1.
CAS — 183552-38-7.
ATC — L02BX01.
ATC Vet — QL02BX01.



Adverse Effects and Precautions

Immediate hypersensitivity reactions, including urticaria, pruritus, hypotension, and syncope, can occur with abarelix, and the cumulative risk of such a reaction increases with repeated doses. Patients should be monitored for at least 30 minutes after each injection. Hot flushes, sleep disturbance, breast enlargement and tenderness may result from testosterone reduction. Prolongation of the QT interval has occurred in patients receiving abarelix.

Elevations in transaminase concentrations have occurred, and liver function should be monitored before starting treatment, and periodically during treatment. The effectiveness of abarelix in the management of prostate cancer decreases with duration of therapy, and may be further reduced in patients weighing more than about 100 kg (225 pounds). The serum concentration of testosterone should be measured on day 29 of therapy and then every 8 weeks, to monitor for treatment failure.

Pharmacokinetics

Abarelix is absorbed slowly after intramuscular injection, with a peak concentration in serum reached after about 3 days. It is metabolised by hydrolysis and has an elimination half-life of about 13 days with intramuscular use.

◊ References.

1. Wong SL, *et al.* Pharmacokinetics and pharmacodynamics of a novel depot formulation of abarelix, a gonadotropin-releasing hormone (GnRH) antagonist, in healthy men ages 50 to 75. *J Clin Pharmacol* 2004; **44:** 495–502.

Uses and Administration

Like cetrorelix (p.2084), abarelix is a gonadorelin (gonadotrophin-releasing hormone) antagonist. It is used to reduce testosterone concentrations in the palliative hormonal therapy of prostate cancer (p.671). A dose of abarelix 100 mg is given intramuscularly on days 1, 15, and 29, and then every 4 weeks thereafter.

Abarelix has been investigated for the treatment of endometriosis.

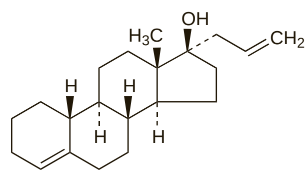
$C_{21}H_{32}O$ = 300.5.
CAS — 432-60-0.
ATC — G03DC01.
ATC Vet — QG03DC01.



Profile

Allylestrenol is a progestogen (see Progesterone, p.2125) structurally related to progesterone that has been given in threatened and recurrent miscarriage, and to prevent premature labour. However, with the exception of proven progesterone deficiency, such use is no longer recommended. In threatened miscarriage in progesterone-deficient women a suggested oral dose is 5 mg three times daily for 5 to 7 days.

Pregnancy. A case-control study of allylestrenol use in pregnancy during 1980 to 1984 in Hungary indicated that it was not teratogenic.[1]

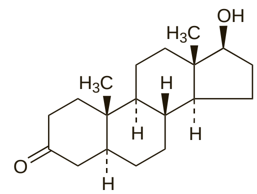
CAS — 521-18-6.
ATC — A14AA01; G03BB02.
ATC Vet — QA14AA01; QG03BB02.



Profile

Androstanolone is formed naturally in the body from testosterone (p.2129) by the action of 5α-reductase, and is more active than the parent compound. It has anabolic and androgenic properties and is applied topically in the form of a 2.5% gel for male hypogonadism and gynaecomastia, and for lichen sclerosus in both men and women.

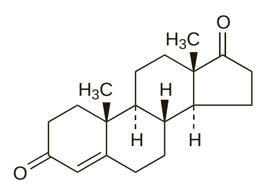
Androstenedione ⊗

Androstenodiona. Androst-4-ene-3,17-dione.

Андростендион

$C_{19}H_{26}O_2$ = 286.4.
CAS — 63-05-8.



NOTE. The following terms have been used as 'street names' (see p.vi) or slang names for various forms of androstenedione:
Andro.

Profile

Androstenedione is a naturally occurring adrenal androgen that is a precursor of androgens and oestrogens (see p.2058). It has been used in an attempt to enhance athletic performance and as hormone replacement for men. In March 2004 the FDA banned the distribution of dietary supplements containing androstenedione, considering them to be adulterated and warning that they did not meet safety requirements.

Action. The effects of androstenedione have been studied in groups of young (under 40 years of age) and older (up to 65 years) men with normal serum testosterone concentrations.[1-4] Testosterone concentrations were reported to remain unchanged[1,4] as well as increase,[2,3] although they returned to baseline in the longer study of 12 weeks.[3] In 3 of the studies, oestrogens (oestradiol and oestrone) increased.[1-3] Changes in lipid profiles were also noted, particularly a decrease in high-density lipoprotein (HDL) cholesterol.[1,3] Androstenedione did not enhance the effects of resistance training.[1,3]

There has been a report of impotence and severe oligospermia associated with ingestion of androstenedione by a bodybuilder.[5] Priapism has also been reported.[6]

ATC Vet — QL02AE01.

Adverse Effects and Precautions

As for Gonadorelin, p.2106.

Interactions

As for Gonadorelin, p.2107.

Pharmacokinetics

Buserelin is completely absorbed after subcutaneous injection, with peak plasma concentrations occurring about 1 hour after a dose. It accumulates in liver and kidneys as well as in the anterior pituitary. It is metabolised by tissue peptidases and is excreted in urine and bile as unchanged drug and metabolites. The half-life after injection is stated to be about 80 minutes.

Uses and Administration

Buserelin is an analogue of gonadorelin (p.2107) with similar properties. It is used for the suppression of testosterone in the treatment of malignant neoplasms of the prostate; it is also used in the treatment of endometriosis and as an adjunct to ovulation induction with gonadotrophins in the treatment of infertility. It has been used in precocious puberty and tried in the treatment of uterine fibroids (see below). Buserelin is usually given as the acetate but doses are expressed in terms of the base; 105 micrograms of buserelin acetate is equivalent to about 100 micrograms of buserelin.

In advanced **prostatic carcinoma** doses of 500 micrograms are injected subcutaneously every 8 hours for 7 days. On the eighth day treatment is changed to the nasal route; 100 micrograms is sprayed into each nostril 6 times daily (usually before and after meals). An acceptable response should be achieved within 4 to 6 weeks. Since there is an initial increase in circulating testosterone, an anti-androgen such as cyproterone acetate may be given for at least 3 days before beginning buserelin therapy, and continued for at least 3 weeks, to avoid the risk of a disease flare. Long-acting subcutaneous depot preparations that release buserelin over a 2- or 3-month period are also available.

In **endometriosis** a dose of 150 micrograms is sprayed into each nostril three times daily. The usual duration of therapy is 6 months, which should not be exceeded.

In **infertility**, pituitary desensitisation before ovulation induction with gonadotrophins is achieved by giving 150 micrograms intranasally four times daily, beginning either in the early follicular phase (day 1) or midluteal phase (day 21) of the menstrual cycle. Alternatively, 200 to 500 micrograms may be given daily as a subcutaneous injection. Therapy should be continued until pituitary downregulation occurs, which normally takes 1 to 3 weeks; if necessary 300 micrograms four times daily intranasally, or 500 micrograms twice daily subcutaneously may be given. Gonadotrophin treatment is then added to buserelin therapy until an appropriate stage of follicular development, when both are withdrawn and chorionic gonadotrophin is given to induce ovulation.

◊ General reviews.

1. Brogden RN, *et al.* Buserelin: a review of its pharmacodynamic and pharmacokinetic properties, and clinical profile. *Drugs* 1990; **39:** 399–437.

Endometriosis. Gonadorelin analogues such as buserelin have a role in the management of endometriosis (p.2091), but the need for long-term therapy limits their value because of the risk of osteoporosis; 'add-back' therapy (hormone replacement) can be used to prevent this.

Infertility. Buserelin is given with gonadotrophic hormone therapy for induction of ovulation and as an aid to improving IVF procedures. Buserelin with gonadotrophic hormones has been found to result in pregnancies in women previously unresponsive to clomifene citrate,[1,2] although there may be a greater risk of multiple births.[3]

The regimens used in IVF may be characterised according to how long the gonadorelin analogue is given for:

- long, 2 weeks or more
- short, 8 to 10 days
- ultrashort, 3 days

A comparative study of such regimens found that the best results in all age groups were consistently associated with the long buserelin protocol.[4] The timing of buserelin dosage may also be important. Starting buserelin in the midluteal phase of the cycle has been reported to produce more rapid pituitary down regulation and higher pregnancy rates from IVF than when buserelin was begun in the early follicular phase.[5]

For a general discussion of the management of infertility, see p.2080.

Malignant neoplasms. The long-term use of buserelin in men decreases the testicular concentration of testosterone. For this reason it is used in the treatment of prostatic cancer (p.671), which is androgen-dependent.[1] Gonadorelin analogues are an effective alternative to orchidectomy, sometimes combined with an anti-androgen for enhanced effect, and play a major role in the management of advanced, incurable disease.

Other reports of malignant neoplasms treated with buserelin include its use in metastatic breast cancer[2,3] (p.661).

1. de Voogt HJ, *et al.* The use of the LHRH-analogue buserelin in the treatment of prostatic cancer: a 10-year review on 1522 patients treated in 119 centers on 4 continents. *Scand J Urol Nephrol Suppl* 1991; **138:** 131–6.

3. Klijn JG, *et al.* Combined treatment with buserelin and tamoxifen in premenopausal metastatic breast cancer: a randomized study. *J Natl Cancer Inst* 2000; **92:** 903–11.

Porphyria. Buserelin given with medroxyprogesterone acetate suppressed cyclic and premenstrual exacerbations of porphyria (p.1448) in 2 patients. Doses used were 300 micrograms buserelin intranasally in the evenings of days 1 to 21 of the menstrual cycle and 10 mg medroxyprogesterone acetate daily by mouth from day 12 to 21. Both patients were free from porphyric attacks during the reported 11 months of treatment.[1] Intranasal buserelin has also been used in 1 patient to prevent premenstrual exacerbation of coproporphyria.[2] The initial dose of 900 micrograms daily could be tapered to 150 micrograms daily, with only 1 minor attack in 5 years of treatment. The authors of this report also noted a number of case reports of buserelin used in acute intermittent porphyria.

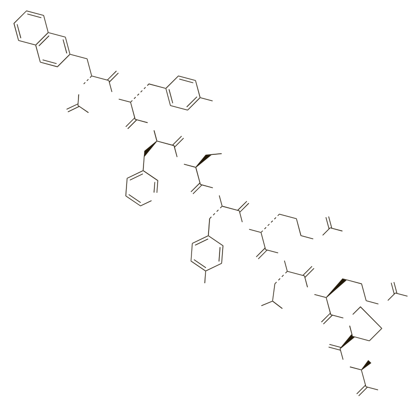
Cetrorelix Acetate *(BANM, USAN, rINNM)*

Acetato de cetrorelix; Cétrorélix, Acétate de; Cetrorelixi Acetas; D-20761; NS-75A; SB-75 (cetrorelix); SB-075 (cetrorelix). *N*-Acetyl-3-(2-naphthyl)-D-alanyl-*p*-chloro-D-phenylalanyl-3-(3-pyridyl)-D-alanyl-L-seryl-L-tyrosyl-N^5-carbamoyl-D-ornithyl-L-leucyl-L-arginyl-L-prolyl-D-alaninamide acetate.

Цетрореликса Ацетат

$C_{70}H_{92}ClN_{17}O_{14},xC_2H_4O_2$ = 1431.0 (cetrorelix).
CAS — 120287-85-6 (cetrorelix); 145672-81-7 (cetrorelix acetate).
ATC — H01CC02.
ATC Vet — QH01CC02.



(cetrorelix)

Adverse Effects and Precautions

Transient reactions at the injection site, including erythema, pruritus, and swelling, may occur. Nausea and headache have been reported occasionally. Systemic hypersensitivity reactions have been reported rarely.

Cetrorelix should not be used in patients with moderate to severe renal or hepatic impairment.

Pharmacokinetics

The bioavailability of cetrorelix after subcutaneous injection is about 85%. The mean terminal half-life after a subcutaneous injection of 3 mg is about 60 hours; it is less with lower doses (about 5 and 20 hours respectively after single and multiple doses of 250 micrograms).

◊ References.

2. Nagaraja NV, *et al.* Pharmacokinetic and pharmacodynamic modeling of cetrorelix, an LH-RH antagonist, after subcutaneous administration in healthy premenopausal women. *Clin Pharmacol Ther* 2000; **68:** 617–25.

Uses and Administration

Cetrorelix is a gonadorelin (gonadotrophin-releasing hormone) antagonist used as a component of ovarian stimulation regimens for assisted reproduction in infertility (p.2080); it is used to prevent luteinising hormone surges and premature ovulation. It has also been tried in benign prostatic hyperplasia, malignant neoplasms of the prostate, endometriosis, and for uterine fibroids. Cetrorelix is given by subcutaneous injection as the acetate; an intramuscular depot formulation containing cetrorelix embonate is reported to be under development. For assisted reproduction, doses of cetrorelix acetate equivalent to cetrorelix 250 micrograms daily may be given either in the morning beginning on day 5 or 6 of ovarian stimulation or in the evening beginning on day 5, and continued until ovulation induction. Alternatively a single dose equivalent to 3 mg of cetrorelix may be given on day 7; if follicle growth does not allow ovulation induction within 4 days, additional doses of cetrorelix 250 micrograms once daily may be given until the day of ovulation induction.

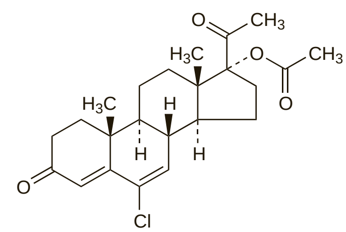
Chlormadinone Acetate *(BANM, USAN, rINNM)*

Acetato de clormadinona; Chlormadinone, Acétate de; Chlormadinoni Acetas; NSC-92338. 6-Chloro-17-hydroxypregna-4,6-diene-3,20-dione acetate.

Хлормадинона Ацетат

$C_{23}H_{29}ClO_4$ = 404.9.
CAS — 1961-77-9 (chlormadinone); 302-22-7 (chlormadinone acetate).
ATC — G03DB06.
ATC Vet — QG03DB06.



Pharmacopoeias. In *Chin., Fr.,* and *Jpn.*

Adverse Effects and Precautions

As for progestogens in general (see Progesterone, p.2125). See also under Hormonal Contraceptives, p.2059.

Effects on the skin. A report of auto-immune dermatitis in a patient associated with chlormadinone acetate.[1]

1. Katayama I, Nishioka K. Autoimmune progesterone dermatitis with persistent amenorrhoea. *Br J Dermatol* 1985; **112:** 487–91.

Interactions

As for progestogens in general (see Progesterone, p.2126). See also under Hormonal Contraceptives, p.2067.

Uses and Administration

Chlormadinone acetate is a progestogen structurally related to progesterone (p.2126) that has anti-androgenic activity. It is given either alone or with an oestrogen in the treatment of menstrual disorders such as menorrhagia (p.2126) and endometriosis (p.2091) in oral doses of 2 to 10 mg daily either cyclically or continuously. It may also be used as the progestogen component of combined oral contraceptives (see p.2069) at a dose of 1 to 2 mg daily, particularly in women with androgen-dependent conditions such as acne and hirsutism. Chlormadinone acetate has been used in some countries in the management of prostatic hyperplasia and prostate cancer; oral doses of 25 or 50 mg, respectively have been given twice daily.

Гонадотропин Хорионический

CAS — 9002-61-3.
ATC — G03GA01.
ATC Vet — QG03GA01.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Jpn*, and *US.*

Ph. Eur. 6.2 (Gonadotrophin, Chorionic). A dry preparation of placental glycoproteins extracted from the urine of pregnant women. The potency is not less than 2500 units/mg. A white to yellowish-white, amorphous powder. Soluble in water. Store at 2° to 8° in airtight containers. Protect from light.

USP 31 (Chorionic Gonadotropin). A gonad-stimulating polypeptide hormone obtained from the urine of pregnant women. It has a potency of not less than 1500 USP units/mg. A white or practically white, amorphous powder. Freely soluble in water. Store in airtight containers at 2° to 8°.

Choriogonadotropin Alfa *(BAN, USAN, rINN)* ⊗

Choriogonadotropine Alfa; Choriogonadotropinum Alfa; Coriogonadotropina alfa.

Хориогонадотропин Альфа

CAS — 177073-44-8 (choriogonadotropin alfa); 56832-30-5 (α subunit); 56832-34-9 (β subunit).
ATC — G03GA08.
ATC Vet — QG03GA08.

Adverse Effects and Precautions

Adverse effects that have been reported with chorionic gonadotrophin include headache, tiredness, changes in mood, depression, restlessness, oedema (especially in males), and pain on injection. Treatment for cryptorchidism may produce premature epiphyseal closure or precocious puberty. Gynaecomastia has been reported. Ovarian hyperstimulation may occur, with marked ovarian enlargement or cyst formation, acute abdominal pain, ascites, pleural effusion, hypovolaemia, shock, and thromboembolic disorders in severe cases.

Chorionic gonadotrophin should be given with care to patients in whom androgen-induced fluid retention might be a hazard as in asthma, epilepsy, migraine, or cardiovascular disorders, including hypertension, or renal disorders. Hypersensitivity reactions may occur and it is recommended that patients suspected to be susceptible should be given skin tests before treatment. It should not be given to patients with disorders that might be exacerbated by androgen release such as carcinoma of the prostate or precocious puberty. Use should also be avoided in the presence of breast, uterine, ovarian, and testicular tumours, as well as tumours of the hypothalamus, pituitary, thyroid, and adrenal glands.

Pharmacokinetics

Peak concentrations of chorionic gonadotrophin occur about 6 hours after an intramuscular dose and 16 to 20 hours after a subcutaneous injection. It is distributed primarily to the gonads. Blood concentrations decline in a biphasic manner, with half-lives of about 6 to 11 hours and 23 to 38 hours, respectively. Chorionic gonadotrophin is metabolised mainly in the kidneys. About 10 to 12% of an intramuscular dose is excreted in urine within 24 hours.

After subcutaneous doses, choriogonadotropin alfa has a bioavailability of about 40%. It is metabolised and excreted similarly to chorionic gonadotrophin.

Uses and Administration

Chorionic gonadotrophin is a hormone produced by the placenta and obtained from the urine of pregnant women. Its effects are mainly those of the gonadotrophin, luteinising hormone (p.2112), which is responsible for triggering ovulation and formation of the corpus luteum in women, and stimulates the production of testosterone by the testes in men. It is usually given by intramuscular injection although the subcutaneous route has also been used. Choriogonadotropin alfa is a recombinant form of chorionic gonadotrophin.

In *women* with **anovulatory infertility** due to absent or low concentrations of gonadotrophins, chorionic gonadotrophin is given to induce ovulation after follicular development has been stimulated with follicle-stimulating hormone or human menopausal gonadotrophins. A single dose of 5000 to 10 000 units of chorionic gonadotrophin is given by intramuscular injection to mimic the midcycle peak of luteinising hormone which normally stimulates ovulation. Up to 3 repeat injections of up to 5000 units each may be given within the next 9 days to prevent insufficiency of the corpus luteum. Chorionic gonadotrophin is also given with menotrophin as an adjunct to IVF procedures and other assisted conception techniques involving superovulation and oocyte collection.

Choriogonadotropin alfa is used similarly to induce ovulation in the treatment of anovulatory infertility, or as an adjunct to IVF procedures and other assisted conception techniques. A single dose of 250 micrograms is given, by subcutaneous injection, when optimal stimulation of follicular growth is achieved.

In *males*, chorionic gonadotrophin has been used in the treatment of prepubertal **cryptorchidism**. Regimens vary widely, but doses usually range from 500 to 4000 units three times weekly by intramuscular injection. Treatment should continue for 1 to 2 months after testicular descent.

Chorionic gonadotrophin is also given for male infertility associated with hypogonadotrophic **hypogonadism**. Again, there is considerable variation in the dosage regimen, and doses have varied from 500 to 4000 units two or three times weekly by intramuscular injection. A drug with follicle-stimulating activity such as menotrophin is often added to enable normal spermatogenesis.

In the treatment of **delayed puberty** associated with hypogonadism in males, an initial dose of chorionic gonadotrophin 500 to 1500 units is given twice weekly by intramuscular injection; the dose should be titrated against plasma-testosterone concentration.

Cryptorchidism. Although surgery remains the treatment with the best success rate, primary hormonal therapy with chorionic gonadotrophin is widely used for cryptorchidism (p.2079). Systematic reviews[1,2] suggest a success rate of about 20% overall, although this may be reduced when care is taken to exclude retractile testes. There is some suggestion that medical treatment given either before or after surgery can improve the patient's fertility index, a predictor of future fertility.[3] Chorionic gonadotrophin may also be used as an adjuvant before surgery, to render the testes palpable,[4] but changes suggestive of inflammation in the testis have been reported following such treatment.[5]

5. Kaleva M, *et al.* Treatment with human chorionic gonadotrophin for cryptorchidism: clinical and histological effects. *Int J Androl* 1996; **19:** 293–8.

Delayed puberty. Use of chorionic gonadotrophin may be appropriate in boys with delayed puberty due to hypogonadotrophic hypogonadism (p.2079).

Infertility. In women with anovulatory infertility chorionic gonadotrophin and choriogonadotropin alfa can be used to provoke ovulation and provide luteal support once maturation of a suitable number of follicles has been stimulated by other means. They are used similarly in the various protocols for assisted reproduction. However, use is not recommended for assisted reproduction in patients at risk of ovarian hyperstimulation, such as those with polycystic ovary syndrome. In men with hypogonadotrophic hypogonadism chorionic gonadotrophin is used to stimulate and maintain spermatogenesis. The management of male and female infertility, including the role of chorionic gonadotrophin, is discussed on p.2080.

Malignant neoplasms. Control of Kaposi's sarcoma (p.675) has been reported in a few patients given high-dose intramuscular chorionic gonadotrophin, but regrowth occurred when dosage was reduced or withdrawn.[1] Another study, using lower doses, was stopped due to toxicity and lack of benefit,[2] but others have confirmed benefit after intralesional injection.[3] There is some suggestion that preparations vary in their activity against the tumour and that it is not chorionic gonadotrophin itself, but some impurity (perhaps a ribonuclease[4] or the degradation product of the β-subunit[5]), that is the active principle.[3,6,7] Some contaminants may have a stimulant effect on the neoplasm, which might also contribute to the variable results.[5]

7. von Overbeck J, *et al.* Human chorionic gonadotropin for AIDS-related Kaposi's sarcoma. *Lancet* 1995; **346:** 642–3.

Obesity. A meta-analysis[1] involving 24 studies concluded that there was no evidence that chorionic gonadotrophin was effective in the treatment of obesity (p.2149).

1. Lijesen GKS, *et al.* The effect of human chorionic gonadotropin (HCG) in the treatment of obesity by means of the Simeons therapy: a criteria-based meta-analysis. *Br J Clin Pharmacol* 1995; **40:** 237–43.

Testicular function. Chorionic gonadotrophin is used in the assessment of testicular function in suspected primary hypogonadism and incomplete masculinisation. The *BNFC* states that for children 1 month to 18 years of age a dose of 1500 to 2000 units may be given once daily for 3 days (short stimulation test) or twice weekly for 3 weeks (prolonged test).

Clomifene Citrate *(BANM, rINNM)* ⊗

Chloramiphene Citrate; Citrato de clomifeno; Clomifène, citrate de; Clomifeni citras; Clomiphene Citrate *(USAN)*; Klomifeenisitraatti; Klomifen Sitrat; Klomifencitrat; Klomifén-citrát; Klomifen-citrát; Klomifeno citratas; MER-41; MRL-41; NSC-35770. A mixture of the *E* and *Z* isomers of 2-[4-(2-chloro-1,2-diphenylvinyl)phenoxy]triethylamine dihydrogen citrate.

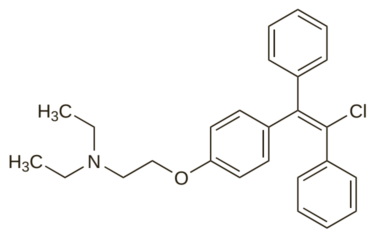
Кломифена Цитрат

$C_{26}H_{28}ClNO,C_6H_8O_7 = 598.1.$

CAS — 911-45-5 (clomifene); 15690-57-0 ((E)-clomifene); 15690-55-8 ((Z)-clomifene); 50-41-9 (clomifene citrate); 7599-79-3 ((E)-clomifene citrate); 7619-53-6 ((Z)-clomifene citrate).

ATC — G03GB02.

ATC Vet — QG03GB02.



(clomifene)

NOTE. Clomifene may be separated into its *Z*- and *E*-isomers, zuclomifene and enclomifene.

Pharmacopoeias. In *Chin., Eur.* (see p.vii), *Int., Jpn,* and *US.*

Ph. Eur. 6.2 (Clomifene Citrate). A white or pale yellow, crystalline powder. It contains 30 to 50% of the *Z* isomer. Slightly soluble in water; sparingly soluble in alcohol. Protect from light.

USP 31 (Clomiphene Citrate). A white to pale yellow, essentially odourless powder. It contains 30 to 50% of the *Z* isomer. Slightly soluble in water and in chloroform; sparingly soluble in alcohol; insoluble in ether; freely soluble in methyl alcohol.

Adverse Effects

The incidence and severity of adverse effects of clomifene citrate tend to be related to the dose used. The most commonly reported adverse effects are reversible ovarian enlargement and cyst formation, vasomotor flushes resembling menopausal symptoms, and abdominal or pelvic discomfort or pain, sometimes with nausea or vomiting. Ovarian hyperstimulation syndrome has occurred. Breast tenderness, abnormal uterine bleeding, weight gain, headache, and endometriosis have also been reported. Transient visual disturbances such as spots or flashes, after-images, and blurring of vision may occur, and there have been rare reports of cataracts and optic neuritis. Skin reactions such as allergic rashes and urticaria have occasionally been reported and reversible hair loss has been reported rarely. CNS disturbances have included convulsions, dizziness, lightheadedness, nervous tension, fatigue, vertigo, insomnia, and depression. Abnormalities in liver function tests and jaundice have sometimes been reported.

There is an increased risk of multiple births with clomifene therapy, but rarely more than twins. There is also an increased risk of ectopic pregnancy. Although there have been reports of congenital disorders such as neural tube defects or Down's syndrome in infants born to women treated with clomifene, the role of the drug in the causation of these defects has not been established and the incidence is reported to be similar to that for the general population.

Carcinogenicity. There have been a number of reports suggesting an association between drug therapy to treat infertility by stimulating ovulation and the subsequent development of ovarian cancer.[1-5] Concern has focused in particular on the use of clomifene citrate and gonadotrophins, and a study has reported an increased risk of ovarian cancer in women who had prolonged clomifene therapy (for one year or more) although not in those who received the drug for a shorter period.[6] No association between gonadotrophin therapy and ovarian cancer was noted in this study. The conclusions of this study were only tentative, since the numbers who developed ovarian cancer were small; it has been pointed out that a successfully achieved pregnancy may reduce the risk of some other cancers, and that the risks and benefits of the procedure are not easy to balance.[7] A review[8] of epidemiological and cohort studies concluded that clomifene was not associated with any increase in the risk of ovarian cancer when used for less than 12 cycles, but noted conflicting results, limitations of the data, and the need to control for infertility and nulliparity as risk factors for ovarian cancer. Further cohort[9,10] and case-control[11] studies, and pooled analyses,[12,13] have also found no association between use of clomifene and ovarian cancer.
